Iteration 7: Sum of abs. weighted deviations = 68229.532
Iteration 8: Sum of abs. weighted deviations = 68229.514
Iteration 9: Sum of abs. weighted deviations = 68229.508
Iteration 10: Sum of abs. weighted deviations = 68229.506
Iteration 11: Sum of abs. weighted deviations = 68229.505

Median regression Number of obs = 100,000
Raw sum of deviations 73861.64 (about 2.9443724)
Min sum of deviations 68229.51 Pseudo R2 = 0.0763
```

| y     | Coefficient | Std. err. | t      | P> t  | [95% conf. interval] |          |
|-------|-------------|-----------|--------|-------|----------------------|----------|
| x     | 1.266062    | .0117759  | 107.51 | 0.000 | 1.242981             | 1.289143 |
| _cons | .8083315    | .0222972  | 36.25  | 0.000 | .7646291             | .8520338 |

In the `qreg` output, the results for `x` correspond to the estimate of  $\beta_1$ , and the results for `_cons` correspond to the estimate of  $\beta_0$ . The reported estimates are close to their true values of 1.248832 and 0.8325546, which are given in [table 1](#).

The intuition in this example comes from the ability of `qreg` to recover the true parameters of our specified DGP. As we increase the number of observations in our sample size, the `qreg` estimates will get closer to the true values.

## ▷ Example 8

In the example below, we estimate the parameters of the conditional quantile function for the 0.25 quantile and compare them with the true values.

```
. qreg y x, quantile(.25)
Iteration 1: WLS sum of weighted deviations = 65395.359
Iteration 1: Sum of abs. weighted deviations = 65397.892
Iteration 2: Sum of abs. weighted deviations = 52640.481
Iteration 3: Sum of abs. weighted deviations = 50706.508
Iteration 4: Sum of abs. weighted deviations = 49767.356
Iteration 5: Sum of abs. weighted deviations = 49766.98
Iteration 6: Sum of abs. weighted deviations = 49765.818
Iteration 7: Sum of abs. weighted deviations = 49765.589
Iteration 8: Sum of abs. weighted deviations = 49765.549
Iteration 9: Sum of abs. weighted deviations = 49765.533
Iteration 10: Sum of abs. weighted deviations = 49765.528
Iteration 11: Sum of abs. weighted deviations = 49765.527
Iteration 12: Sum of abs. weighted deviations = 49765.527
Iteration 13: Sum of abs. weighted deviations = 49765.527

.25 Quantile regression Number of obs = 100,000
Raw sum of deviations 51945.91 (about 1.8560913)
Min sum of deviations 49765.53 Pseudo R2 = 0.0420
```

| y     | Coefficient | Std. err. | t     | P> t  | [95% conf. interval] |          |
|-------|-------------|-----------|-------|-------|----------------------|----------|
| x     | .8207143    | .0106425  | 77.12 | 0.000 | .799855              | .8415735 |
| _cons | .5075988    | .0201512  | 25.19 | 0.000 | .4681026             | .547095  |

Same as above, qreg reports the estimates of  $\beta_1$  and  $\beta_0$  in the output table for x and \_cons, respectively. The reported estimates are close to their true values of 0.80454 and 0.53636, which are given in [table 1](#). As expected, the estimates are close to their true values. Also as expected, the estimates for the 0.25 quantile are smaller than the estimates for the 0.5 quantile.

## ► Example 9

We finish this section by estimating the parameters of the conditional quantile function for the 0.8 quantile and comparing them with the true values.

```
. qreg y x, quantile(.8)
Iteration 1: WLS sum of weighted deviations = 66126.751
Iteration 1: Sum of abs. weighted deviations = 66130.001
Iteration 2: Sum of abs. weighted deviations = 55084.287
Iteration 3: Sum of abs. weighted deviations = 52914.276
Iteration 4: Sum of abs. weighted deviations = 52101.59
Iteration 5: Sum of abs. weighted deviations = 51899.426
Iteration 6: Sum of abs. weighted deviations = 51898.269
Iteration 7: Sum of abs. weighted deviations = 51898.268
Iteration 8: Sum of abs. weighted deviations = 51898.267

.8 Quantile regression Number of obs = 100,000
Raw sum of deviations 60129.76 (about 4.7060381)
Min sum of deviations 51898.27 Pseudo R2 = 0.1369
```

|  | y     | Coefficient | Std. err. | t      | P> t  | [95% conf. interval] |          |
|--|-------|-------------|-----------|--------|-------|----------------------|----------|
|  | x     | 1.911771    | .014834   | 128.88 | 0.000 | 1.882697             | 1.940846 |
|  | _cons | 1.254583    | .0280877  | 44.67  | 0.000 | 1.199531             | 1.309634 |

Same as above, qreg reports the estimates of  $\beta_1$  and  $\beta_0$  in the output table for x and \_cons, respectively. The reported estimates are close to their true values of 1.902954 and 1.268636, which are given in [table 1](#). As expected, the estimates are close to their true values. Also as expected, the estimates for the 0.8 quantile are larger than the estimates for the 0.5 quantile.

◀

## Stored results

qreg stores the following in `e()`:

### Scalars

|                          |                                                               |
|--------------------------|---------------------------------------------------------------|
| <code>e(N)</code>        | number of observations                                        |
| <code>e(df_m)</code>     | model degrees of freedom                                      |
| <code>e(df_r)</code>     | residual degrees of freedom                                   |
| <code>e(q)</code>        | quantile requested                                            |
| <code>e(q_v)</code>      | value of the quantile                                         |
| <code>e(r2_p)</code>     | pseudo- $R^2$                                                 |
| <code>e(sum_adev)</code> | sum of absolute deviations                                    |
| <code>e(sum_rdev)</code> | sum of raw deviations                                         |
| <code>e(sum_w)</code>    | sum of weights                                                |
| <code>e(f_r)</code>      | density estimate                                              |
| <code>e(sparsity)</code> | sparsity estimate                                             |
| <code>e(bwidth)</code>   | bandwidth                                                     |
| <code>e(kbwidth)</code>  | kernel bandwidth                                              |
| <code>e(rank)</code>     | rank of <code>e(V)</code>                                     |
| <code>e(convcode)</code> | 0 if converged; otherwise, return code for why nonconvergence |

| Matrices |                                                                                                                            |
| r(table) | matrix containing the coefficients with their standard errors, test statistics, <i>p</i> -values, and confidence intervals |

Note that results stored in `r()` are updated when the command is replayed and will be replaced when any `r`-class command is run after the estimation command.

## Methods and formulas

Methods and formulas are presented under the following headings:

*Introduction*

*Linear programming formulation of quantile regression*

*Standard errors when residuals are i.i.d.*

*Pseudo- $R^2$*

## Introduction

According to [Stuart and Ord \(1991, 1084\)](#), the method of minimum absolute deviations was first proposed by [Boscovich in 1757](#) and was later developed by [Laplace](#); [Stigler \(1986, 39–55\)](#) and [Hald \(1998, 97–103, 112–116\)](#) provide historical details. According to [Bloomfield and Steiger \(1980\)](#), [Harris \(1950\)](#) later observed that the problem of minimum absolute deviations could be turned into the linear programming problem that was first implemented by [Wagner \(1959\)](#). Interest has grown in this method because robust methods and extreme value modeling have become more popular. Statistical and computational properties of minimum absolute deviation estimators are surveyed by [Narula and Wellington \(1982\)](#). [Cameron and Trivedi \(2005\)](#), [Hao and Naiman \(2007\)](#), and [Wooldridge \(2010\)](#) provide excellent introductions to quantile regression methods, while [Koenker \(2005\)](#) gives an in-depth review of the topic.

## Linear programming formulation of quantile regression

Define  $\tau$  as the quantile to be estimated; the median is  $\tau = 0.5$ . For each observation  $i$ , let  $\varepsilon_i$  be the residual

$$\varepsilon_i = y_i - \mathbf{x}'_i \widehat{\boldsymbol{\beta}}_\tau$$

The objective function to be minimized is

$$\begin{aligned} c_\tau(\varepsilon_i) &= (\tau \mathbf{1}\{\varepsilon_i \geq 0\} + (1 - \tau) \mathbf{1}\{\varepsilon_i < 0\}) |\varepsilon_i| \\ &= (\tau \mathbf{1}\{\varepsilon_i \geq 0\} - (1 - \tau) \mathbf{1}\{\varepsilon_i < 0\}) \varepsilon_i \\ &= (\tau - \mathbf{1}\{\varepsilon_i < 0\}) \varepsilon_i \end{aligned} \tag{2}$$

where  $\mathbf{1}\{\cdot\}$  is the indicator function. This function is sometimes referred to as the check function because it resembles a check mark (Wooldridge 2010, 450); the slope of  $c_\tau(\varepsilon_i)$  is  $\tau$  when  $\varepsilon_i > 0$  and is  $\tau - 1$  when  $\varepsilon_i < 0$ , but is undefined for  $\varepsilon_i = 0$ . Choosing the  $\widehat{\boldsymbol{\beta}}_\tau$  that minimize  $c_\tau(\varepsilon_i)$  is equivalent to finding the  $\widehat{\boldsymbol{\beta}}_\tau$  that make  $\mathbf{x}\widehat{\boldsymbol{\beta}}_\tau$  best fit the quantiles of the distribution of  $y$  conditional on  $\mathbf{x}$ .

This minimization problem is set up as a linear programming problem and is solved with linear programming techniques, as suggested by Armstrong, Frome, and Kung (1979) and described in detail by Koenker (2005). Here  $2n$  slack variables,  $\mathbf{u}_{n \times 1}$  and  $\mathbf{v}_{n \times 1}$ , are introduced, where  $u_i \geq 0$ ,  $v_i \geq 0$ , and  $u_i \times v_i = 0$ , reformulating the problem as

$$\min_{\boldsymbol{\beta}_\tau, \mathbf{u}, \mathbf{v}} \{ \tau \mathbf{1}'_n \mathbf{u} + (1 - \tau) \mathbf{1}'_n \mathbf{v} \mid \mathbf{y} - \mathbf{X} \boldsymbol{\beta}_\tau = \mathbf{u} - \mathbf{v} \}$$

where  $\mathbf{1}_n$  is a vector of 1s. This is a linear objective function on a polyhedral constraint set with  $\binom{n}{k}$  vertices, and our goal is to find the vertex that minimizes (2). Each step in the search is described by a set of  $k$  observations through which the regression plane passes, called the *basis*. A step is taken by replacing a point in the basis if the linear objective function can be improved. If this occurs, a line is printed in the iteration log. The definition of convergence is exact in the sense that no amount of added iterations could improve the objective function.

A series of weighted least-squares (WLS) regressions is used to identify a set of observations as a starting basis. The WLS algorithm for  $\tau = 0.5$  is taken from Schlossmacher (1973) with a generalization for  $0 < \tau < 1$  implied from Hunter and Lange (2000).

## Standard errors when residuals are i.i.d.

The estimator for the VCE implemented in qreg assumes that the errors of the model are independent and identically distributed (i.i.d.). When the errors are i.i.d., the large-sample VCE is

$$\text{cov}(\boldsymbol{\beta}_\tau) = \frac{\tau(1 - \tau)}{f_Y^2(\xi_\tau)} \{E(\mathbf{x}_i \mathbf{x}'_i)\}^{-1} \tag{3}$$

where  $\xi_\tau = F_Y^{-1}(\tau)$  and  $F_Y(y)$  is the distribution function of  $Y$  with density  $f_Y(y)$ . See Koenker (2005, 73) for this result. From (3), we see that the regression precision depends on the inverse of the density function, termed the sparsity function,  $s_\tau = 1/f_Y(\xi_\tau)$ .

While  $1/n \sum_{i=1}^n \mathbf{x}_i \mathbf{x}'_i$  estimates  $E(\mathbf{x}_i \mathbf{x}'_i)$ , estimating the sparsity function is more difficult. qreg provides several methods to estimate the sparsity function. The different estimators are specified through the suboptions of `vce(iid, denmethod bwidth)`. The suboption `denmethod` specifies the functional form for the sparsity estimator. The default is `fitted`.

Here we outline the logic underlying the fitted estimator. Because  $F_Y(y)$  is the distribution function for  $Y$ , we have  $f_Y(y) = \{dF_Y(y)\}/dy$ ,  $\tau = F_Y(\xi_\tau)$ , and  $\xi_\tau = F_Y^{-1}(\tau)$ . When differentiating the identity  $F_Y\{F_Y^{-1}(\tau)\} = \tau$ , the sparsity function can be written as  $s_\tau = \{F_Y^{-1}(\tau)\}/dt$ . Numerically, we can approximate the derivative using the centered difference,

$$\frac{F_Y^{-1}(\tau)}{dt} \approx \frac{F_Y^{-1}(\tau+h) - F_Y^{-1}(\tau-h)}{2h} = \frac{\xi_{\tau+h} - \xi_{\tau-h}}{2h} = \hat{s}_\tau \quad (4)$$

where  $h$  is the bandwidth.

The empirical quantile function is computed by first estimating  $\beta_{\tau+h}$  and  $\beta_{\tau-h}$ , and then computing  $\hat{F}_Y^{-1}(\tau+h) = \bar{\mathbf{x}}'\hat{\beta}_{\tau+h}$  and  $\hat{F}_Y^{-1}(\tau-h) = \bar{\mathbf{x}}'\hat{\beta}_{\tau-h}$ , where  $\bar{\mathbf{x}}$  is the sample mean of the independent variables  $\mathbf{x}$ . These quantities are then substituted into (4).

Alternatively, as the option suggests, `vce(iid, residual)` specifies that `qreg` use the empirical quantile function of the residuals to estimate the sparsity. Here we substitute  $F_\epsilon$ , the distribution of the residuals, for  $F_Y$ , which only differ by their first moments.

The  $k$  residuals associated with the linear programming basis will be zero, where  $k$  is the number of regression coefficients. These zero residuals are removed before computing the  $\tau+h$  and  $\tau-h$  quantiles,  $\varepsilon_{(\tau+h)} = \hat{F}_\epsilon^{-1}(\tau+h)$  and  $\varepsilon_{(\tau-h)} = \hat{F}_\epsilon^{-1}(\tau-h)$ . The  $\hat{F}_\epsilon^{-1}$  estimates are then substituted for  $F_Y^{-1}$  in (4).

Each of the estimators for the sparsity function depends on a bandwidth. The `vce()` suboption `bandwidth` specifies the bandwidth method to use. The three bandwidth options and their citations are `hsheather` (Hall and Sheather 1988), `bofinger` (Bofinger 1975), and `chamberlain` (Chamberlain 1994).

Their formulas are

$$h_s = n^{-1/3} \Phi^{-1} \left( 1 - \frac{\alpha}{2} \right)^{2/3} \left[ \frac{3}{2} \times \frac{\phi\{\Phi^{-1}(\tau)\}^2}{2\Phi^{-1}(\tau)^2 + 1} \right]^{1/3}$$

$$h_b = n^{-1/5} \left[ \frac{\frac{9}{2}\phi\{\Phi^{-1}(\tau)\}^4}{\{2\Phi^{-1}(\tau)^2 + 1\}^2} \right]^{1/5}$$

$$h_c = \Phi^{-1} \left( 1 - \frac{\alpha}{2} \right) \sqrt{\frac{\tau(1-\tau)}{n}}$$

where  $h_s$  is the Hall–Sheather bandwidth,  $h_b$  is the Bofinger bandwidth,  $h_c$  is the Chamberlain bandwidth,  $\Phi()$  and  $\phi()$  are the standard normal distribution and density functions,  $n$  is the sample size, and  $100(1-\alpha)$  is the confidence level set by the `level()` option. Koehler (2005) discusses the derivation of the Hall–Sheather and the Bofinger bandwidth formulas. You should avoid modifying the confidence level when replaying estimates that use the Hall–Sheather or Chamberlain bandwidths because these methods use the confidence level to estimate the coefficient standard errors.

Finally, the `vce()` suboption `kernel(kernel)` specifies that `qreg` use one of several kernel density estimators to estimate the sparsity function. `kernel` allows you to choose which kernel function to use, where the default is the Epanechnikov kernel. See [R] `kdensity` for the functional form of the eight kernels.

The kernel bandwidth is computed using an adaptive estimate of scale

$$h_k = \min \left( \hat{\sigma}, \frac{r_q}{1.34} \right) \times \{ \Phi^{-1}(\tau+h) - \Phi^{-1}(\tau-h) \}$$

where  $h$  is one of  $h_s$ ,  $h_b$ , or  $h_c$ ;  $r_q$  is the interquartile range; and  $\hat{\sigma}$  is the standard deviation of  $\mathbf{y}$ ; see Silverman (1986, 47) and Koenker (2005, 81) for discussions. Let  $\hat{f}_\epsilon(\epsilon_i)$  be the kernel density estimate for the  $i$ th residual, and then the kernel estimator for the sparsity function is

$$\hat{s}_\tau = \frac{nh_k}{\sum_{i=1}^n \hat{f}_\epsilon(\epsilon_i)}$$

Finally, substituting your choice of sparsity estimate into (3) results in the i.i.d. variance–covariance matrix

$$\mathbf{V}_n = \hat{s}_\tau^2 \tau(1-\tau) \left( \sum_{i=1}^n \mathbf{x}_i \mathbf{x}_i' \right)^{-1}$$

## Pseudo- $R^2$

The pseudo- $R^2$  is calculated as

$$1 - \frac{\text{sum of weighted deviations about estimated quantile}}{\text{sum of weighted deviations about raw quantile}}$$

This is based on the likelihood for a double-exponential distribution  $e^{v_i|\epsilon_i|}$ , where  $v_i$  are multipliers

$$v_i = \begin{cases} \tau & \text{if } \epsilon_i > 0 \\ (1-\tau) & \text{otherwise} \end{cases}$$

Minimizing the objective function (2) with respect to  $\beta_\tau$  also minimizes  $\sum_i |\epsilon_i|v_i$ , the sum of weighted least absolute deviations. For example, for the 50th percentile  $v_i = 1$ , for all  $i$ , and we have median regression. If we want to estimate the 75th percentile, we weight the negative residuals by 0.25 and the positive residuals by 0.75. It can be shown that the criterion is minimized when 75% of the residuals are negative.

## Postestimation commands

The following postestimation command is of special interest after sqreg:

| Command                     | Description                                                             |
|-----------------------------|-------------------------------------------------------------------------|
| <code>estat coefplot</code> | plot coefficients and their confidence intervals at different quantiles |

The following postestimation commands are available after qreg, iqreg, bsqreg, and sqreg:

| Command                            | Description                                                                                       |
|------------------------------------|---------------------------------------------------------------------------------------------------|
| <code>contrast</code>              | contrasts and ANOVA-style joint tests of parameters                                               |
| <code>estat summarize</code>       | summary statistics for the estimation sample                                                      |
| <code>estat vce</code>             | variance-covariance matrix of the estimators (VCE)                                                |
| <code>estimates</code>             | cataloging estimation results                                                                     |
| <code>etable</code>                | table of estimation results                                                                       |
| <sup>†</sup> <code>forecast</code> | dynamic forecasts and simulations                                                                 |
| * <code>hausman</code>             | Hausman's specification test                                                                      |
| <code>lincom</code>                | point estimates, standard errors, testing, and inference for linear combinations of parameters    |
| <code>linktest</code>              | link test for model specification                                                                 |
| <code>margins</code>               | marginal means, predictive margins, marginal effects, and average marginal effects                |
| <code>marginsplot</code>           | graph the results from margins (profile plots, interaction plots, etc.)                           |
| <code>nlcom</code>                 | point estimates, standard errors, testing, and inference for nonlinear combinations of parameters |
| <code>predict</code>               | predictions and their SEs, residuals, etc.                                                        |
| <code>predictnl</code>             | point estimates, standard errors, testing, and inference for generalized predictions              |
| <code>pwcompare</code>             | pairwise comparisons of parameters                                                                |
| <code>test</code>                  | Wald tests of simple and composite linear hypotheses                                              |
| <code>testnl</code>                | Wald tests of nonlinear hypotheses                                                                |

\*`hausman` is not appropriate after `bsqreg`, `isqreg`, or `sqreg`.

<sup>†</sup>`forecast` is not appropriate with `mi` estimation results.

## predict

### Description for predict

`predict` creates a new variable containing predictions such as linear predictions, standard errors, and residuals.

### Menu for predict

Statistics > Postestimation

### Syntax for predict

For *qreg*, *iqreg*, and *bsqreg*

```
predict [type] newvar [if] [in] [, [xb|stdp|residuals]]
```

For *sqreg*

```
predict [type] newvar [if] [in] [, equation(eqno[,eqno]) statistic]
```

| <i>statistic</i>       | Description                                            |
|------------------------|--------------------------------------------------------|
| Main                   |                                                        |
| <code>xb</code>        | linear prediction; the default                         |
| <code>stdp</code>      | standard error of the linear prediction                |
| <code>stddp</code>     | standard error of the difference in linear predictions |
| <code>residuals</code> | residuals                                              |

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

### Options for predict

Main

`xb`, the default, calculates the linear prediction.

`stdp` calculates the standard error of the linear prediction.

`stddp` is allowed only after you have fit a model using *sqreg*. The standard error of the difference in linear predictions ( $\mathbf{x}_{1j}\mathbf{b} - \mathbf{x}_{2j}\mathbf{b}$ ) between equations 1 and 2 is calculated.

`residuals` calculates the residuals, that is,  $y_j - \mathbf{x}_j\mathbf{b}$ .

`equation(eqno[,eqno])` specifies the equation to which you are making the calculation.

`equation()` is filled in with one *eqno* for the `xb`, `stdp`, and `residuals` options. `equation(#1)` would mean that the calculation is to be made for the first equation, `equation(#2)` would mean the second, and so on. You could also refer to the equations by their names. `equation(income)` would refer to the equation named `income` and `equation(hours)` to the equation named `hours`.

If you do not specify `equation()`, results are the same as if you had specified `equation(#1)`.

To use `stddp`, you must specify two equations. You might specify `equation(#1, #2)` or `equation(q80, q20)` to indicate the 80th and 20th quantiles.

## margins

### Description for margins

`margins` estimates margins of response for linear predictions.

### Menu for margins

Statistics > Postestimation

### Syntax for margins

```
margins [marginlist] [, options]
```

```
margins [marginlist] , predict(statistic ...) [options]
```

| <i>statistic</i>              | Description                           |
|-------------------------------|---------------------------------------|
| <code>xb</code>               | linear prediction; the default        |
| <code>stdp</code>             | not allowed with <code>margins</code> |
| <code>stddp</code>            | not allowed with <code>margins</code> |
| <u><code>residuals</code></u> | not allowed with <code>margins</code> |

Statistics not allowed with `margins` are functions of stochastic quantities other than  $e(b)$ .

For the full syntax, see [R] [margins](#).

## estat

### Description for estat

`estat coefplot` plots the estimated coefficients and their confidence intervals (CIs) after `sqreg`.

### Menu for estat

Statistics > Postestimation

### Syntax for estat

```
estat coefplot [varname] [, options]
```

*varname* is one of the variables specified when fitting `sqreg`; the default is the first endogenous variable.

| <i>options</i>                                 | Description                                                                        |
|------------------------------------------------|------------------------------------------------------------------------------------|
| <code>noci</code>                              | do not plot the CIs                                                                |
| <code>nools</code>                             | do not plot the ordinary least-squares (OLS) estimates                             |
| Plot                                           |                                                                                    |
| <i>connect_options</i>                         | change look of lines or connecting method                                          |
| <i>marker_options</i>                          | change look of markers (color, size, etc.)                                         |
| CI plot                                        |                                                                                    |
| <code>ciopts</code> ( <i>area_options</i> )    | affect rendition of the pointwise CIs                                              |
| Line options                                   |                                                                                    |
| <code>lineopts</code> ( <i>cline_options</i> ) | affect rendition of reference line identifying the OLS estimates                   |
| Y axis, X axis, Titles, Legend, Overall        |                                                                                    |
| <i>twoway_options</i>                          | any options other than <code>by()</code> documented in [G-3] <i>twoway_options</i> |

### Options for estat

`noci` removes plots of the pointwise CIs. The default is to plot the CIs.

`nools` removes the plot of the OLS estimates. The default is to plot the OLS reference line.

#### Plot

*connect\_options* specify how points on a graph are to be connected; [G-3] *connect\_options*.

*marker\_options* affect the rendition of markers drawn at the plotted points, including their shape, size, color, and outline; see [G-3] *marker\_options*.

#### CI plot

`ciopts` (*area\_options*) affects rendition of the pointwise CIs; see [G-3] *area\_options*.

## Line options

`lineopts(cline_options)` affects rendition of reference line identifying the OLS estimates; see [G-3] *cline\_options*.

## Y axis, X axis, Titles, Legend, Overall

*twoway\_options* are any of the options documented in [G-3] *twoway\_options*, excluding `by()`. These include options for titling the graph (see [G-3] *title\_options*) and for saving the graph to disk (see [G-3] *saving\_option*).

## Remarks and examples

### ► Example 1: Predictions after qreg and iqreg

In [example 4](#) of [R] `qreg`, we fit regressions for the lower and the upper quartile of the `price` variable. The `predict` command can be used to obtain the linear prediction after each regression.

```
. use https://www.stata-press.com/data/r19/auto
(1978 automobile data)
. qreg price weight length foreign, quantile(.25)
(output omitted)
. predict q25
(option xb assumed; fitted values)
. qreg price weight length foreign, quantile(.75)
(output omitted)
. predict q75
(option xb assumed; fitted values)
```

We can use the variables generated by `predict` to compute the predicted interquartile range, that is,

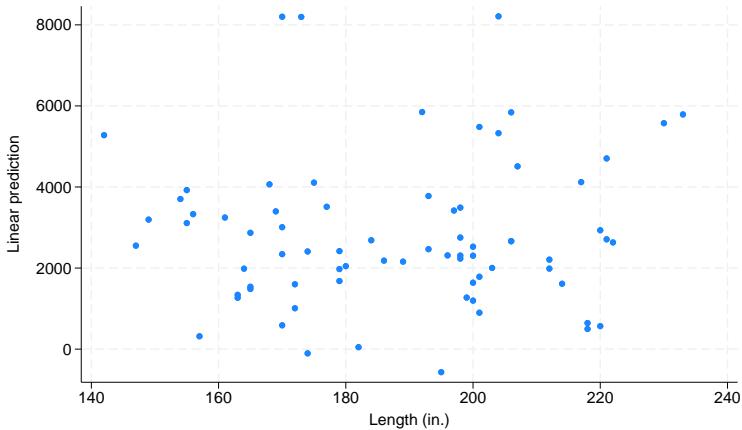

```
. generate iqr1 = q75 - q25
```

If we directly perform the interquartile range regression with the `iqreg` command, we can predict the interquartile range and also the standard error for the prediction.

```
. iqreg price weight length foreign, quantile(.25 .75)
(output omitted)
. predict iqr2
(option xb assumed; fitted values)
. predict stdp, stdp
```

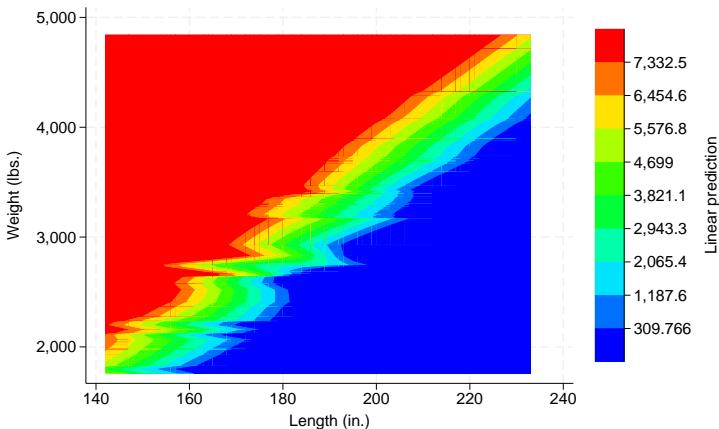

We now plot the predicted interquartile range versus variable length:

```
. scatter iqr2 length
```

As stated in [example 5](#) of [\[R\] qreg](#), the negative coefficient for the length variable means that increases in length imply decreases in the interquartile range and therefore in price dispersion. Consequently, we could have expected a downward trend in the plot, but there is not. This is because the regression output indicates that when we hold the rest of the variables constant, an increase in length leads to a decrease in iqr2. However, there is a high correlation between weight and length, which could be masking the effect of length on iqr2. We can achieve a better visualization by using a contour plot.

```
. twoway contour iqr2 weight length, level(10)
```

We can see the effect by setting a fixed value of length on the vertical axis, say, 3,000 lbs. When we move from left to right on the horizontal axis, we see that for small values of length, iqr2 values are shown in red, meaning high values, and when we move toward the right, the graph indicates transition into increasingly smaller values.

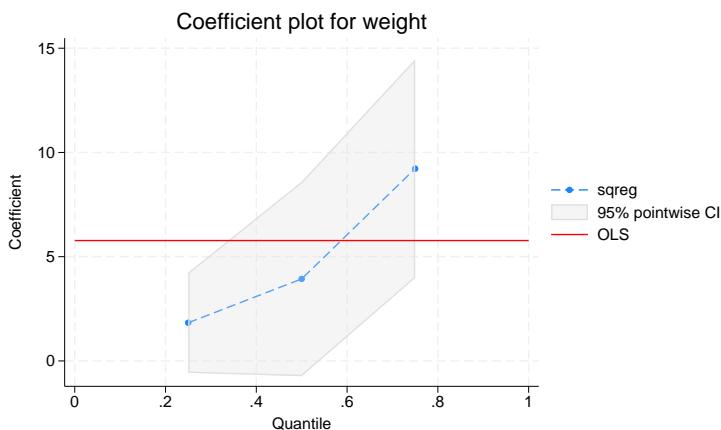

## ► Example 2: Coefficients plot after sqreg

In [example 5](#) of [\[R\] qreg](#), we simultaneously estimated the quantile regressions at different quantile indexes.

```
. use https://www.stata-press.com/data/r19/auto, clear
(1978 automobile data)
. set seed 1001
. sqreg price weight length foreign, q(.25 .5 .75) reps(100)
(output omitted)
```

We can now use `estat coefplot` to visualize the coefficients at different quantiles. For example, we can type `estat coefplot weight` to see the trend of the effects of weight on price across quantiles.

```
. estat coefplot weight
```

The resulting graph shows that there is an upward trend in the effects. For reference, the red line shows the OLS estimates.

[Description](#)[Syntax](#)[Remarks and examples](#)[Also see](#)

## Description

query displays the settings of various Stata parameters.

## Syntax

```
query [memory | output | interface | graphics | network | update |
 trace | mata | java | lapack | putdocx | putpdf | python | rng |
 sort | unicode | other]
```

## Remarks and examples

query provides more system information than you will ever want to know. You do not need to understand every line of output that query produces if all you need is one piece of information. Here is what happens when you type query:

```
. query
```

```

---

The output is broken into several divisions: memory, output, interface, graphics, network, update, trace, Mata, Java, LAPACK, putdocx, putpdf, Python, RNG, sort, Unicode, and other settings. We will discuss each one in turn.

We generated the output above using Stata/MP for Windows. Here is what happens when we type query and we are running Stata/SE for Mac:

```
. query
```

---

```

Memory settings
set maxvar 5000 2048-32767; max. vars allowed
set niceness 5 0-10
set min_memory 0 0-1600g
set max_memory . 32m-1600g or .
set segmentsize 32m 1m-32g
set adosize 1000 kilobytes

```

---

```

Output settings
set more off
set rmsg off
set dp period may be period or comma
set linesize 80 characters
set pagesize 23 lines

```

---

```
set iterlog on
```

---

```

set level 95 percent confidence intervals
set clevel 95 percent credible intervals

```

---

```

set showbaselevels may be empty, off, on, or all
set showemptycells may be empty, off, or on
set showomitted may be empty, off, or on
set fvlabel on
set fvwrap 1
set fvwrapon word may be word or width

```

---

```
set lstretch may be empty, off, or on
```

---

## Memory settings

Memory settings indicate how memory is allocated, the maximum number of variables, and the maximum size of a matrix.

For more information, see

|                 |                     |
|-----------------|---------------------|
| maxvar          | [D] <b>memory</b>   |
| niceness        | [D] <b>memory</b>   |
| min_memory      | [D] <b>memory</b>   |
| max_memory      | [D] <b>memory</b>   |
| segmentsize     | [D] <b>memory</b>   |
| adosize         | [P] <b>sysdir</b>   |
| max_preservemem | [P] <b>preserve</b> |

## Output settings

Output settings show how Stata displays output on the screen and in log files.

For more information, see

|                |          |                           |

| maxdb         | [R] | <b>db</b>  |

## Graphics settings

Graphics settings indicate how Stata's graphics are displayed.

For more information, see

|               |       |                       |
|---------------|-------|-----------------------|
| graphics      | [G-2] | <b>set graphics</b>   |
| autotabgraphs | [R]   | <b>set</b>            |
| scheme        | [G-2] | <b>set scheme</b>     |
| printcolor    | [G-2] | <b>set printcolor</b> |
| copycolor     | [G-2] | <b>set printcolor</b> |
| maxbezierpath | [R]   | <b>set</b>            |

## Network settings

Network settings determine how Stata interacts with the internet.

For more information, see [R] **netio**.

## Update settings

Update settings determine how Stata performs updates.

For more information, see [R] **update**.

## Trace settings

Trace settings adjust Stata's behavior and are particularly useful in debugging code.

For more information, see [P] **trace**.

## Mata settings

Mata settings affect Mata's system parameters.

For more information, see [\[M-3\] mata set](#).

## Java settings

Java settings control the Java Runtime Environment.

For more information, see [\[P\] Java utilities](#).

## LAPACK settings

LAPACK settings control the LAPACK and BLAS routines.

For more information, see [\[M-1\] LAPACK](#).

## putdocx settings

putdocx settings control how spacing is handled in blocks of text and the number of tables allowed.

For more information, see [\[RPT\] set docx](#) and [\[RPT\] putdocx table](#).

## putpdf settings

putpdf settings control the number of tables allowed.

For more information, see [\[RPT\] putpdf table](#).

## Python settings

Python settings control the version and search paths of Python.

For more information, see [\[P\] PyStata integration](#).

## RNG settings

The RNG settings set Stata's random-number generators.

For more information, see [\[R\] set rng](#), [\[R\] set seed](#) (set rngstate), and [\[R\] set rngstream](#).

## sort settings

The sort settings affect `sort`, `gsort`, and other commands that use sorting as part of their computation.

For more information, see [\[P\] set sortmethod](#) and [\[P\] set sortrngstate](#).

## Unicode settings

Unicode settings affect Stata's localization package for the user interface.

For more information, see [\[P\] set locale\\_ui](#) and [\[P\] set locale\\_functions](#).

## Other settings

The other settings are a miscellaneous collection.

For more information, see

|                |          |                           |

[Description](#)[Options for ranksum](#)[Methods and formulas](#)[Quick start](#)[Options for median](#)[References](#)[Menu](#)[Remarks and examples](#)[Also see](#)[Syntax](#)[Stored results](#)

## Description

`ranksum` tests the hypothesis that two independent samples (that is, *unmatched* data) are from populations with the same distribution by using the Wilcoxon rank-sum test, which is also known as the Mann–Whitney two-sample statistic (Wilcoxon 1945; Mann and Whitney 1947).

`median` performs a nonparametric  $k$ -sample test on the equality of medians. It tests the null hypothesis that the  $k$  samples were drawn from populations with the same median. For two samples, the  $\chi^2$  test statistic is computed both with and without a continuity correction.

`ranksum` and `median` are for use with *unmatched* data. For equality tests on matched data, see [\[R\] signrank](#).

## Quick start

*Wilcoxon rank-sum test*

Test for equality of distributions of  $v$  over two groups defined by the levels of `catvar1`

```
ranksum v, by(catvar1)
```

Compute an exact  $p$ -value for the Wilcoxon rank-sum test

```
ranksum v, by(catvar1) exact
```

Estimate the probability that a case from the first level of `catvar1` has a greater value of  $v$  than a case from the second level of `catvar1`

```
ranksum v, by(catvar1) porder
```

*Nonparametric equality-of-medians test*

Equality of medians test for  $v$  over two or more groups defined by the levels of `catvar2`

```
median v, by(catvar2)
```

Also report Fisher's exact test

```
median v, by(catvar2) exact
```

Same as above, but split cases at the median evenly between the above and below groups

```
median v, by(catvar2) exact medianties(split)
```

## Menu

### **ranksum**

Statistics > Nonparametric analysis > Tests of hypotheses > Wilcoxon rank-sum test

### **median**

Statistics > Nonparametric analysis > Tests of hypotheses > K-sample equality-of-medians test

## Syntax

Wilcoxon rank-sum test

```
ranksum varname [if] [in] , by(groupvar) [exact porder]
```

Nonparametric equality-of-medians test

```
median varname [if] [in] [weight] , by(groupvar) [median_options]
```

| <i>ranksum_options</i>  | Description                                                                                                                     |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------|
| Main                    |                                                                                                                                 |
| * by( <i>groupvar</i> ) | grouping variable                                                                                                               |
| exact                   | report exact <i>p</i> -value for rank-sum test; by default, exact <i>p</i> -value is computed when total sample size $\leq 200$ |
| <i>porder</i>           | probability that variable for first group is larger than variable for second group                                              |

| <i>median_options</i>     | Description                                                     |
|---------------------------|-----------------------------------------------------------------|
| Main                      |                                                                 |
| * by( <i>groupvar</i> )   | grouping variable                                               |
| exact                     | report <i>p</i> -value from Fisher's exact test                 |
| <u>medianties</u> (below) | assign values equal to the median to below group                |
| <u>medianties</u> (above) | assign values equal to the median to above group                |
| <u>medianties</u> (drop)  | drop values equal to the median from the analysis               |
| <u>medianties</u> (split) | split values equal to the median equally between the two groups |

\*by(*groupvar*) is required.

by and collect are allowed with ranksum and median; see [U] 11.1.10 Prefix commands.

fweights are allowed with median; see [U] 11.1.6 weight.

## Options for ranksum

Main

by(*groupvar*) is required. It specifies the name of the grouping variable.

exact specifies that the exact *p*-value be computed in addition to the approximate *p*-value. The exact *p*-value is based on the actual randomization distribution of the test statistic. The approximate *p*-value is based on a normal approximation to the randomization distribution. By default, the exact *p*-value is computed for sample sizes  $n = n_1 + n_2 \leq 200$  because the normal approximation may not be precise in small samples. The exact computation can be suppressed by specifying noexact. For sample sizes larger than 200, you must specify exact to compute the exact *p*-value. The exact computation is available for sample sizes  $n \leq 1000$ . As the sample size approaches 1,000, the computation takes significantly longer.

*porder* displays an estimate of the probability that a random draw from the first population is larger than a random draw from the second population.

## Options for median

Main

`by(groupvar)` is required. It specifies the name of the grouping variable.

`exact` displays the  $p$ -value calculated by Fisher's exact test. For two samples, both one- and two-sided  $p$ -values are displayed.

`medianties(below | above | drop | split)` specifies how values equal to the overall median are to be handled. The median test computes the median for *varname* by using all observations and then divides the observations into those falling above the median and those falling below the median. When values for an observation are equal to the sample median, they can be dropped from the analysis by specifying `medianties(drop)`; added to the group above or below the median by specifying `medianties(above)` or `medianties(below)`, respectively; or if there is more than 1 observation with values equal to the median, they can be equally divided into the two groups by specifying `medianties(split)`. If this option is not specified, `medianties(below)` is assumed.

## Remarks and examples

### ▷ Example 1

We are testing the effectiveness of a new fuel additive. We run an experiment with 24 cars: 12 cars with the fuel treatment and 12 cars without. We input these data by creating a dataset with 24 observations. `mpg` records the mileage rating, and `treat` records 0 if the mileage corresponds to untreated fuel and 1 if it corresponds to treated fuel.

```
. use https://www.stata-press.com/data/r19/fuel2
. ranksum mpg, by(treat)
Two-sample Wilcoxon rank-sum (Mann-Whitney) test
```

| treat     | Obs | Rank sum | Expected |
|-----------|-----|----------|----------|
| Untreated | 12  | 128      | 150      |
| Treated   | 12  | 172      | 150      |
| Combined  | 24  | 300      | 300      |

```
Unadjusted variance 300.00
Adjustment for ties -4.04
Adjusted variance 295.96
HO: mpg(treat==Untreated) = mpg(treat==Treated)
 z = -1.279
Prob > |z| = 0.2010
Exact prob = 0.2117
```

Because the total sample is only 24 cars, the exact  $p$ -value is computed by default. If the sample size were greater than 200, we would have to specify the `exact` option if we wanted the exact  $p$ -value computed.

Despite the small sample size, the  $p$ -value computed using a normal approximation, 0.2010, is similar to the exact  $p$ -value, 0.2117. These results indicate that the distributions are not statistically different at a 0.05 significance level.

Similarly, the median test,

```
. median mpg, by(treat) exact
Median test
```

| Greater than the median | Whether car received fuel additive |         | Total |
|-------------------------|------------------------------------|---------|-------|
|                         | Untreated                          | Treated |       |
| no                      | 7                                  | 5       | 12    |
| yes                     | 5                                  | 7       | 12    |
| Total                   | 12                                 | 12      | 24    |

```

Pearson chi2(1) = 0.6667 Pr = 0.414
Fisher's exact = 0.684
1-sided Fisher's exact = 0.342
Continuity corrected:
Pearson chi2(1) = 0.1667 Pr = 0.683
```

fails to reject the null hypothesis that there is no difference between the fuel with the additive and the fuel without the additive.

Compare these results from these two tests with those obtained from the `signrank` and `signtest` where we found significant differences; see [R] [signrank](#). An experiment run on 24 different cars is not as powerful as a before-and-after comparison using the same 12 cars.

◀

## Stored results

`ranksum` stores the following in `r()`:

Scalars

```

r(N) sample size
r(N_1) sample size of first group
r(N_2) sample size of second group
r(z) z statistic
r(Var_a) adjusted variance
r(group1) value of variable for first group
r(sum_obs) observed sum of ranks for first group
r(sum_exp) expected sum of ranks for first group
r(p) two-sided p-value from normal approximation
r(p_1) lower one-sided p-value from normal approximation
r(p_u) upper one-sided p-value from normal approximation
r(p_exact) two-sided exact p-value
r(p_1_exact) lower one-sided exact p-value
r(p_u_exact) upper one-sided exact p-value
r(porder) probability that draw from first population is larger than draw from second population
```

`median` stores the following in `r()`:

Scalars

```

r(N) sample size
r(chi2) Pearson's χ^2
r(chi2_cc) continuity-corrected Pearson's χ^2
r(groups) number of groups compared
r(p) p-value for Pearson's χ^2 test
r(p_cc) continuity-corrected p-value
r(p_exact) Fisher's exact p-value
r(p1_exact) one-sided Fisher's exact p-value
```

## Methods and formulas

For a practical introduction to these techniques with an emphasis on examples rather than theory, see [Acock \(2023\)](#), [Bland \(2015\)](#), or [Sprent and Smeeton \(2007\)](#). For a summary of these tests, see [Snedecor and Cochran \(1989\)](#).

Methods and formulas are presented under the following headings:

*ranksum*  
*median*

### ranksum

For the Wilcoxon rank-sum test, there are two independent random variables,  $X_1$  and  $X_2$ , and we test the null hypothesis that  $X_1 \sim X_2$ . We have a sample of size  $n_1$  from  $X_1$  and another of size  $n_2$  from  $X_2$ .

The data are then ranked without regard to the sample to which they belong. If the data are tied, averaged ranks are used. Wilcoxon's test statistic (1945) is the sum of the ranks for the observations in the first sample:

$$T = \sum_{i=1}^{n_1} R_{1i}$$

Mann and Whitney's  $U$  statistic (1947) is the number of pairs  $(X_{1i}, X_{2j})$  such that  $X_{1i} > X_{2j}$ . These statistics differ only by a constant:

$$U = T - \frac{n_1(n_1 + 1)}{2}$$

Fisher's principle of randomization provides a method for calculating the distribution of the test statistic. The randomization distribution consists of all the possible values of  $T$  resulting from the  $\binom{n}{n_1}$  ways to choose  $n_1$  ranks from the set of all  $n = n_1 + n_2$  observed ranks (untied or tied) and assign them to the first sample. When the exact option is specified (or implied for  $n \leq 200$ ), this distribution is computed using a recursive algorithm whose computational time is proportional to  $n^4$ . (See [Fisher \[1935\]](#) for the principle of randomization; [Wilcoxon, Katti, and Wilcox \[1970\]](#) for the computation with untied ranks; and [Hill and Peto \[1971\]](#) for the general recursive algorithm.)

$p$ -values can also be computed using a normal approximation to the randomization distribution. It is a straightforward exercise to verify that

$$E(T) = \frac{n_1(n+1)}{2} \quad \text{and} \quad \text{Var}(T) = \frac{n_1 n_2 s^2}{n}$$

where  $s$  is the standard deviation of the combined ranks,  $r_i$ , for both groups:

$$s^2 = \frac{1}{n-1} \sum_{i=1}^n (r_i - \bar{r})^2$$

This formula for the variance is exact and holds both when there are no ties and when there are ties and we use averaged ranks. (Indeed, the variance formula holds for the randomization distribution of choosing  $n_1$  numbers from any set of  $n$  numbers.)

For the normal approximation, we calculate

$$z = \frac{T - E(T)}{\sqrt{\text{Var}(T)}}$$

When the porder option is specified, the probability

$$p = \frac{U}{n_1 n_2}$$

is computed.

#### □ Technical note

We follow the great majority of the literature in naming these tests for Wilcoxon, Mann, and Whitney. However, they were independently developed by several other researchers in the late 1940s and early 1950s. In addition to Wilcoxon, Mann, and Whitney, credit is due to [Festinger \(1946\)](#), [Whitfield \(1947\)](#), [Haldane and Smith \(1947\)](#), and [Van der Reyden \(1952\)](#). Leon Festinger (1919–1989), John Burdon Sanderson Haldane (1892–1964), and Cedric Austen Bardell Smith (1917–2002) are well known for other work, but little seems to be known about Whitfield or van der Reyden. For a detailed study, including information on these researchers, see [Berry, Mielke, and Johnston \(2012\)](#).

□

## median

The median test examines whether it is likely that two or more samples came from populations with the same median. The null hypothesis is that the samples were drawn from populations with the same median. The alternative hypothesis is that at least one sample was drawn from a population with a different median. The test should be used only with ordinal or interval data.

Assume that there are score values for  $k$  independent samples to be compared. The median test is performed by first computing the median score for all observations combined, regardless of the sample group. Each score is compared with this computed grand median and is classified as being above the grand median, below the grand median, or equal to the grand median. Observations with scores equal to the grand median can be dropped, added to the “above” group, added to the “below” group, or split between the two groups.

Once all observations are classified, the data are cast into a  $2 \times k$  contingency table, and a Pearson’s  $\chi^2$  test or Fisher’s exact test is performed.

Henry Berthold Mann (1905–2000) was born in Vienna, Austria, where he completed a doctorate in algebraic number theory. He moved to the United States in 1938 and for several years made his livelihood by tutoring in New York. During this time, he proved a celebrated conjecture in number theory and studied statistics at Columbia with Abraham Wald, with whom he wrote three papers. After the war, he taught at Ohio State and the Universities of Wisconsin and Arizona. In addition to his work in number theory and statistics, he made major contributions to algebra and combinatorics.

Donald Ransom Whitney (1915–2007) studied at Oberlin, Princeton, and Ohio State Universities and worked at the latter throughout his career. His PhD thesis under Henry Mann was on nonparametric statistics. It was this work that produced the test that bears their names.

## Description

`ratio` produces estimates of ratios, along with standard errors.

## Quick start

Estimate, standard error, and 95% confidence interval for the ratio of `v1` to `v2`

```
ratio v1/v2
```

With bootstrap standard errors

```
ratio v1/v2, vce(bootstrap)
```

Ratios of `v1` to `v2` and `v3` to `v2`

```
ratio (v1/v2) (v3/v2)
```

Same as above, but name the ratios `ratio1` and `ratio2`

```
ratio (ratio1: v1/v2) (ratio2: v3/v2)
```

Test that `ratio1` is equal to `ratio2`

```
test ratio1 = ratio2
```

Ratio of `v1` to `v2` over strata defined by levels of `svar`

```
ratio v1/v2, over(svar)
```

Direct standardization across categories `cvar`, weighting by standardization weight `wvar`

```
ratio v1/v2, stdize(cvar) stdweight(wvar)
```

## Menu

| <code>coeflegend</code>                | display legend instead of statistics                                                                              |

bayesboot, bootstrap, collect, jackknife, mi estimate, rolling, statsby, and svy are allowed; see [U] 11.1.10 Prefix commands.

vce(bootstrap) and vce(jackknife) are not allowed with the mi estimate prefix; see [MI] mi estimate.

Weights are not allowed with the bootstrap prefix; see [R] bootstrap.

vce() and weights are not allowed with the svy prefix; see [SVY] svy.

fweights, iweights, and pweights are allowed; see [U] 11.1.6 weight.

coeflegend does not appear in the dialog box.

See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

## Options

### Model

`stdize(varname)` specifies that the point estimates be adjusted by direct standardization across the strata identified by *varname*. This option requires the `stdweight()` option.

`stdweight(varname)` specifies the weight variable associated with the standard strata identified in the `stdize()` option. The standardization weights must be constant within the standard strata.

`nostdrescale` prevents the standardization weights from being rescaled within the `over()` groups. This option requires `stdize()` but is ignored if the `over()` option is not specified.

### if/in/over

`over(varlist)` specifies that estimates be computed for multiple subpopulations, which are identified by the different values of the variables in *varlist*. Only numeric, nonnegative, integer-valued variables are allowed in `over(varlist)`.

### SE/Cluster

`vce(vcetype)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory (`linearized`), that allow for intragroup correlation (`cluster clustvar`), and that use bootstrap or jackknife methods (`bootstrap`, `jackknife`); see [R] [vce\\_option](#).

`vce(linearized)`, the default, uses the linearized or sandwich estimator of variance.

### Reporting

`level(#)`; see [R] [Estimation options](#).

`noheader` prevents the table header from being displayed. This option implies `nolegend`.

`nolegend` prevents the table legend identifying the ratios from being displayed.

*display\_options*: `vsquish`, `noemptycells`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, and `no1stretch`; see [R] [Estimation options](#).

The following option is available with `ratio` but is not shown in the dialog box:

`coeflegend`; see [R] [Estimation options](#).

## Remarks and examples

### ▷ Example 1

Using the fuel data from [example 3](#) of [R] `ttest`, we estimate the ratio of mileage for the cars without the fuel treatment (`mpg1`) to those with the fuel treatment (`mpg2`).

```
. use https://www.stata-press.com/data/r19/fuel
. ratio myratio: mpg1/mpg2
Ratio estimation Number of obs = 12
 myratio: mpg1/mpg2
```

|         | Ratio    | Linearized<br>std. err. | [95% conf. interval] |          |
|---------|----------|-------------------------|----------------------|----------|
| myratio | .9230769 | .032493                 | .8515603             | .9945936 |

Using these results, we can test to see if this ratio is significantly different from one.

```
. test myratio = 1
(1) myratio = 1
 F(1, 11) = 5.60
 Prob > F = 0.0373
```

We find that the ratio is different from one at the 5% significance level but not at the 1% significance level.

### ▷ Example 2

Using state-level census data, we want to test whether the marriage rate is equal to the deathrate.

```
. use https://www.stata-press.com/data/r19/census2
(1980 Census data by state)
. ratio (deathrate: death/pop) (marrate: marriage/pop)
Ratio estimation Number of obs = 50
 deathrate: death/pop
 marrate: marriage/pop
```

|           | Ratio    | Linearized<br>std. err. | [95% conf. interval] |          |
|-----------|----------|-------------------------|----------------------|----------|
| deathrate | .0087368 | .0002052                | .0083244             | .0091492 |
| marrate   | .0105577 | .0006184                | .009315              | .0118005 |

```
. test deathrate = marrate
(1) deathrate - marrate = 0
 F(1, 49) = 6.93
 Prob > F = 0.0113
```

## Stored results

ratio stores the following in `e()`:

### Scalars

|                          |                                          |
|--------------------------|------------------------------------------|

|-----------------------|----------------------------------------------------------------------------------------------------------------------------|

Note that results stored in `r()` are updated when the command is replayed and will be replaced when any *r*-class command is run after the estimation command.

## Methods and formulas

Methods and formulas are presented under the following headings:

*The ratio estimator*  
*Survey data*  
*The survey ratio estimator*  
*The standardized ratio estimator*  
*The poststratified ratio estimator*  
*The standardized poststratified ratio estimator*  
*Subpopulation estimation*

## The ratio estimator

Let  $R = Y/X$  be the ratio to be estimated, where  $Y$  and  $X$  are totals; see [R] **total**. The estimate for  $R$  is  $\widehat{R} = \widehat{Y}/\widehat{X}$  (the ratio of the sample totals). From the delta method (that is, a first-order Taylor expansion), the approximate variance of the sampling distribution of the linearized  $\widehat{R}$  is

$$V(\widehat{R}) \approx \frac{1}{\widehat{X}^2} \{V(\widehat{Y}) - 2R\widehat{\text{Cov}}(\widehat{Y}, \widehat{X}) + R^2V(\widehat{X})\}$$

Direct substitution of  $\widehat{X}$ ,  $\widehat{R}$ , and the estimated variances and covariance of  $\widehat{X}$  and  $\widehat{Y}$  leads to the following variance estimator:

$$\widehat{V}(\widehat{R}) = \frac{1}{\widehat{X}^2} \{\widehat{V}(\widehat{Y}) - 2\widehat{R}\widehat{\text{Cov}}(\widehat{Y}, \widehat{X}) + \widehat{R}^2\widehat{V}(\widehat{X})\} \quad (1)$$

## Survey data

See [SVY] **Variance estimation**, [SVY] **Direct standardization**, and [SVY] **Poststratification** for discussions that provide background information for the following formulas.

## The survey ratio estimator

Let  $Y_j$  and  $X_j$  be survey items for the  $j$ th individual in the population, where  $j = 1, \dots, M$  and  $M$  is the size of the population. The associated population ratio for the items of interest is  $R = Y/X$  where

$$Y = \sum_{j=1}^M Y_j \quad \text{and} \quad X = \sum_{j=1}^M X_j$$

Let  $y_j$  and  $x_j$  be the corresponding survey items for the  $j$ th sampled individual from the population, where  $j = 1, \dots, m$  and  $m$  is the number of observations in the sample.

The estimator  $\widehat{R}$  for the population ratio  $R$  is  $\widehat{R} = \widehat{Y}/\widehat{X}$ , where

$$\widehat{Y} = \sum_{j=1}^m w_j y_j \quad \text{and} \quad \widehat{X} = \sum_{j=1}^m w_j x_j$$

and  $w_j$  is a sampling weight. The score variable for the ratio estimator is

$$z_j(\widehat{R}) = \frac{y_j - \widehat{R}x_j}{\widehat{X}} = \frac{\widehat{X}y_j - \widehat{Y}x_j}{\widehat{X}^2}$$

## The standardized ratio estimator

Let  $D_g$  denote the set of sampled observations that belong to the  $g$ th standard stratum and define  $I_{D_g}(j)$  to indicate if the  $j$ th observation is a member of the  $g$ th standard stratum; where  $g = 1, \dots, L_D$  and  $L_D$  is the number of standard strata. Also, let  $\pi_g$  denote the fraction of the population that belongs to the  $g$ th standard stratum, thus  $\pi_1 + \dots + \pi_{L_D} = 1$ . Note that  $\pi_g$  is derived from the `stdweight()` option.

The estimator for the standardized ratio is

$$\widehat{R}^D = \sum_{g=1}^{L_D} \pi_g \frac{\widehat{Y}_g}{\widehat{X}_g}$$

where

$$\widehat{Y}_g = \sum_{j=1}^m I_{D_g}(j) w_j y_j$$

and  $\widehat{X}_g$  is similarly defined. The score variable for the standardized ratio is

$$z_j(\widehat{R}^D) = \sum_{g=1}^{L_D} \pi_g I_{D_g}(j) \frac{\widehat{X}_g y_j - \widehat{Y}_g x_j}{\widehat{X}_g^2}$$

## The poststratified ratio estimator

Let  $P_k$  denote the set of sampled observations that belong to poststratum  $k$ , and define  $I_{P_k}(j)$  to indicate if the  $j$ th observation is a member of poststratum  $k$ , where  $k = 1, \dots, L_P$  and  $L_P$  is the number of poststrata. Also, let  $M_k$  denote the population size for poststratum  $k$ .  $P_k$  and  $M_k$  are identified by specifying the `poststrata()` and `postweight()` options on `svyset`; see [SVY] `svyset`.

The estimator for the poststratified ratio is

$$\widehat{R}^P = \frac{\widehat{Y}^P}{\widehat{X}^P}$$

where

$$\widehat{Y}^P = \sum_{k=1}^{L_P} \frac{M_k}{\widehat{M}_k} \widehat{Y}_k = \sum_{k=1}^{L_P} \frac{M_k}{\widehat{M}_k} \sum_{j=1}^m I_{P_k}(j) w_j y_j$$

and  $\widehat{X}^P$  is similarly defined. The score variable for the poststratified ratio is

$$z_j(\widehat{R}^P) = \frac{z_j(\widehat{Y}^P) - \widehat{R}^P z_j(\widehat{X}^P)}{\widehat{X}^P} = \frac{\widehat{X}^P z_j(\widehat{Y}^P) - \widehat{Y}^P z_j(\widehat{X}^P)}{(\widehat{X}^P)^2}$$

where

$$z_j(\widehat{Y}^P) = \sum_{k=1}^{L_P} I_{P_k}(j) \frac{M_k}{\widehat{M}_k} \left( y_j - \frac{\widehat{Y}_k}{\widehat{M}_k} \right)$$

and  $z_j(\widehat{X}^P)$  is similarly defined.

## The standardized poststratified ratio estimator

The estimator for the standardized poststratified ratio is

$$\widehat{R}^{DP} = \sum_{g=1}^{L_D} \pi_g \frac{\widehat{Y}_g^P}{\widehat{X}_g^P}$$

where

$$\widehat{Y}_g^P = \sum_{k=1}^{L_p} \frac{M_k}{\widehat{M}_k} \widehat{Y}_{g,k} = \sum_{k=1}^{L_p} \frac{M_k}{\widehat{M}_k} \sum_{j=1}^m I_{D_g}(j) I_{P_k}(j) w_j y_j$$

and  $\widehat{X}_g^P$  is similarly defined. The score variable for the standardized poststratified ratio is

$$z_j(\widehat{R}^{DP}) = \sum_{g=1}^{L_D} \pi_g \frac{\widehat{X}_g^P z_j(\widehat{Y}_g^P) - \widehat{Y}_g^P z_j(\widehat{X}_g^P)}{(\widehat{X}_g^P)^2}$$

where

$$z_j(\widehat{Y}_g^P) = \sum_{k=1}^{L_p} I_{P_k}(j) \frac{M_k}{\widehat{M}_k} \left\{ I_{D_g}(j) y_j - \frac{\widehat{Y}_{g,k}}{\widehat{M}_k} \right\}$$

and  $z_j(\widehat{X}_g^P)$  is similarly defined.

## Subpopulation estimation

Let  $S$  denote the set of sampled observations that belong to the subpopulation of interest, and define  $I_S(j)$  to indicate if the  $j$ th observation falls within the subpopulation.

The estimator for the subpopulation ratio is  $\widehat{R}^S = \widehat{Y}^S / \widehat{X}^S$ , where

$$\widehat{Y}^S = \sum_{j=1}^m I_S(j) w_j y_j \quad \text{and} \quad \widehat{X}^S = \sum_{j=1}^m I_S(j) w_j x_j$$

Its score variable is

$$z_j(\widehat{R}^S) = I_S(j) \frac{y_j - \widehat{R}^S x_j}{\widehat{X}^S} = I_S(j) \frac{\widehat{X}^S y_j - \widehat{Y}^S x_j}{(\widehat{X}^S)^2}$$

The estimator for the standardized subpopulation ratio is

$$\widehat{R}^{DS} = \sum_{g=1}^{L_D} \pi_g \frac{\widehat{Y}_g^S}{\widehat{X}_g^S}$$

where

$$\widehat{Y}_g^S = \sum_{j=1}^m I_{D_g}(j) I_S(j) w_j y_j$$

and  $\widehat{X}_g^S$  is similarly defined. Its score variable is

$$z_j(\widehat{R}^{DS}) = \sum_{g=1}^{L_D} \pi_g I_{D_g}(j) I_S(j) \frac{\widehat{X}_g^S y_j - \widehat{Y}_g^S x_j}{(\widehat{X}_g^S)^2}$$

The estimator for the poststratified subpopulation ratio is

$$\widehat{R}^{PS} = \frac{\widehat{Y}^{PS}}{\widehat{X}^{PS}}$$

where

$$\widehat{Y}^{PS} = \sum_{k=1}^{L_P} \frac{M_k}{\widehat{M}_k} \widehat{Y}_k^S = \sum_{k=1}^{L_P} \frac{M_k}{\widehat{M}_k} \sum_{j=1}^m I_{P_k}(j) I_S(j) w_j y_j$$

and  $\widehat{X}^{PS}$  is similarly defined. Its score variable is

$$z_j(\widehat{R}^{PS}) = \frac{\widehat{X}^{PS} z_j(\widehat{Y}^{PS}) - \widehat{Y}^{PS} z_j(\widehat{X}^{PS})}{(\widehat{X}^{PS})^2}$$

where

$$z_j(\widehat{Y}^{PS}) = \sum_{k=1}^{L_P} I_{P_k}(j) \frac{M_k}{\widehat{M}_k} \left\{ I_S(j) y_j - \frac{\widehat{Y}_k^S}{\widehat{M}_k} \right\}$$

and  $z_j(\widehat{X}^{PS})$  is similarly defined.

The estimator for the standardized poststratified subpopulation ratio is

$$\widehat{R}^{DPS} = \sum_{g=1}^{L_D} \pi_g \frac{\widehat{Y}_g^{PS}}{\widehat{X}_g^{PS}}$$

where

$$\widehat{Y}_g^{PS} = \sum_{k=1}^{L_P} \frac{M_k}{\widehat{M}_k} \widehat{Y}_{g,k}^S = \sum_{k=1}^{L_P} \frac{M_k}{\widehat{M}_k} \sum_{j=1}^m I_{D_g}(j) I_{P_k}(j) I_S(j) w_j y_j$$

and  $\widehat{X}_g^{PS}$  is similarly defined. Its score variable is

$$z_j(\widehat{R}^{DPS}) = \sum_{g=1}^{L_D} \pi_g \frac{\widehat{X}_g^{PS} z_j(\widehat{Y}_g^{PS}) - \widehat{Y}_g^{PS} z_j(\widehat{X}_g^{PS})}{(\widehat{X}_g^{PS})^2}$$

where

$$z_j(\widehat{Y}_g^{PS}) = \sum_{k=1}^{L_P} I_{P_k}(j) \frac{M_k}{\widehat{M}_k} \left\{ I_{D_g}(j) I_S(j) y_j - \frac{\widehat{Y}_{g,k}^S}{\widehat{M}_k} \right\}$$

and  $z_j(\widehat{X}_g^{PS})$  is similarly defined.

## Description

`reg3` estimates a system of structural equations, where some equations contain endogenous variables among the explanatory variables. Estimation is via three-stage least squares (3SLS); see [Zellner and Theil \(1962\)](#). Typically, the endogenous explanatory variables are dependent variables from other equations in the system. `reg3` supports iterated GLS estimation and linear constraints.

`reg3` can also estimate systems of equations by seemingly unrelated regression estimation (SURE), multivariate regression (MVREG), and equation-by-equation ordinary least squares (OLS) or two-stage least squares (2SLS).

## Nomenclature

Under 3SLS or 2SLS estimation, a *structural equation* is defined as one of the equations specified in the system. A *dependent variable* will have its usual interpretation as the left-hand-side variable in an equation with an associated disturbance term. All dependent variables are explicitly taken to be *endogenous* to the system and are treated as correlated with the disturbances in the system's equations. Unless specified in an `endog()` option, all other variables in the system are treated as *exogenous* to the system and uncorrelated with the disturbances. The exogenous variables are taken to be *instruments* for the endogenous variables.

## Quick start

System of equations regressing  $y_1$  on  $x_1$ ,  $x_2$ , and  $y_2$  and  $y_2$  on  $x_1$ ,  $x_3$ , and  $y_1$

```
reg3 (y1 x1 x2 y2) (y2 x1 x3 y1)
```

Same as above, but name equations `eq1` and `eq2`

```
reg3 (eq1: y1 x1 x2 y2) (eq2: y2 x1 x3 y1)
```

Same as above, but specify that  $x_1$  is endogenous and add instrumental variable  $v_1$

```
reg3 (eq1: y1 x1 x2 y2) (eq2: y2 x1 x3 y1), endog(x1) exog(v1)
```

Same as above, but with iterated estimation

```
reg3 (eq1: y1 x1 x2 y2) (eq2: y2 x1 x3 y1), endog(x1) exog(v1) ireg3
```

## Menu

Statistics > Endogenous covariates > Three-stage least squares

## Syntax

### Basic syntax

```
reg3 (depvar1 varlist1) (depvar2 varlist2) ... (depvarN varlistN) [if] [in] [weight]
```

### Full syntax

```
reg3 ([eqname1:]depvar1a [depvar1b ... =]varlist1 [, noconstant])
 ([eqname2:]depvar2a [depvar2b ... =]varlist2 [, noconstant])
 ...
 ([eqnameN:]depvarNa [depvarNb ... =]varlistN [, noconstant])
 [if] [in] [weight] [, options]
```

| <i>options</i>                             | Description                                                                                                                                      |

| <code>coeflegend</code>     | display legend instead of statistics          |

*varlist*<sub>1</sub>, ..., *varlist*<sub>N</sub> and the `exog()` and the `inst()` *varlist* may contain factor variables; see [U] 11.4.3 **Factor variables**. You must have the same levels of factor variables in all equations that have factor variables.

*devar* and *varlist* may contain time-series operators; see [U] 11.4.4 **Time-series varlists**.

`bootstrap`, `by`, `collect`, `fp`, `jackknife`, `rolling`, and `statsby` are allowed; see [U] 11.1.10 **Prefix commands**.

Weights are not allowed with the `bootstrap` prefix; see [R] **bootstrap**.

`aweight`s are not allowed with the `jackknife` prefix; see [R] **jackknife**.

`aweight`s and `fweight`s are allowed; see [U] 11.1.6 **weight**.

`noheader`, `notable`, `nofooter`, and `coeflegend` do not appear in the dialog box.

See [U] 20 **Estimation and postestimation commands** for more capabilities of estimation commands.

Explicit equation naming (*eqname*;) cannot be combined with multiple dependent variables in an equation specification.

## Options

### Model

`ireg3` causes `reg3` to iterate over the estimated disturbance covariance matrix and parameter estimates until the parameter estimates converge. Although the iteration is usually successful, there is no guarantee that it will converge to a stable point. Under SURE, this iteration converges to the maximum likelihood estimates.

`3s1s` specifies the full 3SLS estimation of the system and is the default for `reg3`.

`2s1s` causes `reg3` to perform equation-by-equation 2SLS on the full system of equations. This option implies `dfk`, `small`, and `corr(independent)`.

Cross-equation testing should not be performed after estimation with this option. With `2s1s`, no covariance is estimated between the parameters of the equations. For cross-equation testing, use `3s1s`.

`ols` causes `reg3` to perform equation-by-equation OLS on the system—even if dependent variables appear as regressors or the regressors differ for each equation; see [MV] **mvreg**. `ols` implies `allexog`, `dfk`, `small`, and `corr(independent)`; `nodfk` and `nosmall` may be specified to override `dfk` and `small`.

The covariance of the coefficients between equations is not estimated under this option, and cross-equation tests should not be performed after estimation with `ols`. For cross-equation testing, use `sure` or `3s1s` (the default).

`sure` causes `reg3` to perform a SURE of the system—even if dependent variables from some equations appear as regressors in other equations; see [R] **sureg**. `sure` is a synonym for `allexog`.

`mvreg` is identical to `sure`, except that the disturbance covariance matrix is estimated with an OLS degrees-of-freedom adjustment—the `dfk` option. If the regressors are identical for all equations, the parameter point estimates will be the standard MVREG results. If any of the regressors differ, the point estimates are those for SURE with an OLS degrees-of-freedom adjustment in computing the covariance matrix. `nodfk` and `nosmall` may be specified to override `dfk` and `small`.

`corr` (*correlation*) specifies the assumed form of the correlation structure of the equation disturbances and is rarely requested explicitly. For the family of models fit by `reg3`, the only two allowable correlation structures are `unstructured` and `independent`. The default is `unstructured`.

This option is used almost exclusively to estimate a system of equations by 2SLS or to perform OLS regression with `reg3` on multiple equations. In these cases, the correlation is set to `independent`, forcing `reg3` to treat the covariance matrix of equation disturbances as diagonal in estimating model parameters. Thus, a set of two-stage coefficient estimates can be obtained if the system contains endogenous right-hand-side variables, or OLS regression can be imposed, even if the regressors differ across equations. Without imposing independent disturbances, `reg3` would estimate the former by 3SLS and the latter by SURE.

Any tests performed after estimation with the `independent` option will treat coefficients in different equations as having no covariance; cross-equation tests should not be used after specifying `corr(independent)`.

`exog` (*varlist*) specifies additional exogenous variables that are included in none of the system equations. This can occur when the system contains identities that are not estimated. If implicitly exogenous variables from the equations are listed here, `reg3` will just ignore the additional information. Specified variables will be added to the exogenous variables in the system and used in the first stage as instruments for the endogenous variables. By specifying dependent variables from the structural equations, you can use `exog()` to override their endogeneity.

`endog` (*varlist*) identifies variables in the system that are not dependent variables but are endogenous to the system. These variables must appear in the variable list of at least one equation in the system. Again, the need for this identification often occurs when the system contains identities. For example, a variable that is the sum of an exogenous variable and a dependent variable may appear as an explanatory variable in some equations.

`inst` (*varlist*) specifies a full list of all exogenous variables and may not be used with the `endog()` or `exog()` options. It must contain a full list of variables to be used as instruments for the endogenous regressors. Like `exog()`, the list may contain variables not specified in the system of equations. This option can be used to achieve the same results as the `endog()` and `exog()` options, and the choice is a matter of convenience. Any variable not specified in the *varlist* of the `inst()` option is assumed to be endogenous to the system. As with `exog()`, including the dependent variables from the structural equations will override their endogeneity.

`allexog` indicates that all right-hand-side variables are to be treated as exogenous—even if they appear as the dependent variable of another equation in the system. This option can be used to enforce a SURE or MVREG estimation even when some dependent variables appear as regressors.

`noconstant`, `constraints` (*constraints*); see [R] [Estimation options](#).

SE/Robust

`vce` (*vcetype*) specifies the type of standard error reported, which includes types that are derived from asymptotic theory (`unadjusted`), that are robust to some kinds of misspecification (`robust`), and that allow for intragroup correlation (`cluster clustvar`); see [R] [vce\\_option](#).

`vce(unadjusted)`, the default, specifies that an unadjusted (nonrobust) VCE matrix be used; this results in efficient estimates when assuming homoskedasticity.

## df adj.

`small` specifies that small-sample statistics be computed. It shifts the test statistics from  $\chi^2$  and  $z$  statistics to  $F$  statistics and  $t$  statistics. This option is intended primarily to support MVREG. Although the standard errors from each equation are computed using the degrees of freedom for the equation, the degrees of freedom for the  $t$  statistics are all taken to be those for the first equation. This approach poses no problem under MVREG because the regressors are the same across equations.

`dfk` specifies the use of an alternative divisor in computing the covariance matrix for the equation residuals. As an asymptotically justified estimator, `reg3` by default uses the number of sample observations  $n$  as a divisor. When the `dfk` option is set, a small-sample adjustment is made, and the divisor is taken to be  $\sqrt{(n - k_i)(n - k_j)}$ , where  $k_i$  and  $k_j$  are the number of parameters in equations  $i$  and  $j$ , respectively.

`dfk2` specifies the use of an alternative divisor in computing the covariance matrix for the equation errors. When the `dfk2` option is set, the divisor is taken to be the mean of the residual degrees of freedom from the individual equations.

## Reporting

`level(#)`; see [R] [Estimation options](#).

`first` requests that the first-stage regression results be displayed during estimation.

`nocnsreport`; see [R] [Estimation options](#).

`display_options`: `nocl`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `nolstretch`; see [R] [Estimation options](#).

## Optimization

`optimization_options` control the iterative process that minimizes the sum of squared errors when `ireg3` is specified. These options are seldom used.

`iterate(#)` specifies the maximum number of iterations. When the number of iterations equals  $\#$ , the optimizer stops and presents the current results, even if the convergence tolerance has not been reached. The default is the number set using `set maxiter`, which is 300 by default.

`trace` adds to the iteration log a display of the current parameter vector.

`log` and `nolog` specify whether to display the iteration log. The iteration log is displayed by default unless you used `set iterlog off` to suppress it; see `set iterlog` in [R] [set iter](#).

`tolerance(#)` specifies the tolerance for the coefficient vector. When the relative change in the coefficient vector from one iteration to the next is less than or equal to  $\#$ , the optimization process is stopped. `tolerance(1e-6)` is the default.

The following options are available with `reg3` but are not shown in the dialog box:

`noheader` suppresses display of the header reporting the estimation method and the table of equation summary statistics.

`notable` suppresses display of the coefficient table.

`nofooter` suppresses display of the footer reporting the list of endogenous and exogenous variables in the model.

`coeflegend`; see [R] [Estimation options](#).

## Remarks and examples

`reg3` estimates systems of structural equations where some equations contain endogenous variables among the explanatory variables. Generally, these endogenous variables are the dependent variables of other equations in the system, though not always. The disturbance is correlated with the endogenous variables—violating the assumptions of OLS. Further, because some of the explanatory variables are the dependent variables of other equations in the system, the error terms among the equations are expected to be correlated. `reg3` uses an instrumental-variables approach to produce consistent estimates and generalized least squares (GLS) to account for the correlation structure in the disturbances across the equations. Good general references on three-stage estimation include [Davidson and MacKinnon \(1993, 651–661\)](#) and [Greene \(2018, 363–365\)](#).

Three-stage least squares can be thought of as producing estimates from a three-step process.

**Step 1.** Develop instrumented values for all endogenous variables. These instrumented values can simply be considered as the predicted values resulting from a regression of each endogenous variable on all exogenous variables in the system. This stage is identical to the first step in 2SLS and is critical for the consistency of the parameter estimates.

**Step 2.** Obtain a consistent estimate for the covariance matrix of the equation disturbances. These estimates are based on the residuals from a 2SLS estimation of each structural equation.

**Step 3.** Perform a GLS-type estimation using the covariance matrix estimated in the second stage and with the instrumented values in place of the right-hand-side endogenous variables.

### □ Technical note

The estimation and use of the covariance matrix of disturbances in three-stage estimation is almost identical to the SURE method—`sureg`. As with SURE, using this covariance matrix improves the efficiency of the three-stage estimator. Even without the covariance matrix, the estimates would be consistent. (They would be 2SLS estimates.) This improvement in efficiency comes with a caveat. All the parameter estimates now depend on the consistency of the covariance matrix estimates. If one equation in the system is misspecified, the disturbance covariance estimates will be inconsistent, and the resulting coefficients will be biased and inconsistent. Alternatively, if each equation is estimated separately by 2SLS ([\[R\] regress](#)), only the coefficients in the misspecified equation are affected.

□

### □ Technical note

If an equation is just identified, the 3SLS point estimates for that equation are identical to the 2SLS estimates. However, as with `sureg`, even if all equations are just identified, fitting the model via `reg3` has at least one advantage over fitting each equation separately via `ivregress`; by using `reg3`, tests involving coefficients in different equations can be performed easily using `test` or `testnl`.

□

## ▷ Example 1

A simple macroeconomic model relates consumption (`consump`) to private and government wages paid (`wagepriv` and `wagegovt`). Simultaneously, private wages depend on consumption, total government expenditures (`govt`), and the lagged stock of capital in the economy (`capital1`). Although this is not a plausible model, it does meet the criterion of being simple. This model could be written as

$$\begin{aligned}\text{consump} &= \beta_0 + \beta_1 \text{wagepriv} + \beta_2 \text{wagegovt} + \epsilon_1 \\ \text{wagepriv} &= \beta_3 + \beta_4 \text{consump} + \beta_5 \text{govt} + \beta_6 \text{capital1} + \epsilon_2\end{aligned}$$

If we assume that this is the full system, `consump` and `wagepriv` will be endogenous variables, with `wagegovt`, `govt`, and `capital1` exogenous. Data for the US economy on these variables are taken from Klein (1950). This model can be fit with `reg3` by typing

```
. use https://www.stata-press.com/data/r19/klein
. reg3 (consump wagepriv wagegovt) (wagepriv consump govt capital1)
```

Three-stage least-squares regression

| consump  | .4026076    | .2567312  | 1.57  | 0.117 | -.1005764 .9057916   |
| govt     | 1.177792    | .5421253  | 2.17  | 0.030 | .1152461 2.240338    |
| capital1 | -.0281145   | .0572111  | -0.49 | 0.623 | -.1402462 .0840173   |
| _cons    | 14.63026    | 10.26693  | 1.42  | 0.154 | -5.492552 34.75306   |

```
Endogenous: consump wagepriv
Exogenous: wagegovt govt capital1
```

Without showing the 2SLS results, we note that the consumption function in this system falls under the conditions noted earlier. That is, the 2SLS and 3SLS coefficients for the equation are identical.

## ▶ Example 2

Some of the most common simultaneous systems encountered are supply-and-demand models. A simple system could be specified as

$$q\text{Demand} = \beta_0 + \beta_1 \text{price} + \beta_2 \text{pcompete} + \beta_3 \text{income} + \epsilon_1$$

$$q\text{Supply} = \beta_4 + \beta_5 \text{price} + \beta_6 \text{praw} + \epsilon_2$$

$$\text{Equilibrium condition: quantity} = q\text{Demand} = q\text{Supply}$$

where

quantity is the quantity of a product produced and sold,

price is the price of the product,

pcompete is the price of a competing product,

income is the average income level of consumers, and

praw is the price of raw materials used to produce the product.

In this system, price is assumed to be determined simultaneously with demand. The important statistical implications are that price is not a predetermined variable and that it is correlated with the disturbances of both equations. The system is somewhat unusual: quantity is associated with two disturbances. This fact really poses no problem because the disturbances are specified on the behavioral demand and supply equations—two separate entities. Often one of the two equations is rewritten to place price on the left-hand side, making this endogeneity explicit in the specification.

To provide a concrete illustration of the effects of simultaneous equations, we can simulate data for the above system by using known coefficients and disturbance properties. Specifically, we will simulate the data as

$$q\text{Demand} = 40 - 1.0\text{price} + 0.25\text{pcompete} + 0.5\text{income} + \epsilon_1$$

$$q\text{Supply} = 0.5\text{price} - 0.75\text{praw} + \epsilon_2$$

where

$$\epsilon_1 \sim N(0, 3.8)$$

$$\epsilon_2 \sim N(0, 2.4)$$

For comparison, we can estimate the supply and demand equations separately by OLS. The estimates for the demand equation are

```
. use https://www.stata-press.com/data/r19/supDem
. regress quantity price pcompete income
```

Examining the coefficients from these regressions, we note that they are not close to the known parameters used to generate the simulated data. In particular, the positive coefficient on price in the demand equation stands out. We constructed our simulated data to be consistent with economic theory—people demand less of a product if its price rises and more if their personal income rises. Although the price coefficient is statistically insignificant, the positive value contrasts starkly with what is predicted from economic price theory and the  $-1.0$  value that we used in the simulation. Likewise, we are disappointed with the insignificance and level of the coefficient on average income. The supply equation has correct signs on the two main parameters, but their levels are different from the known values. In fact, the coefficient on price (0.724675) is different from the simulated parameter (0.5) at the 5% level of significance.

All of these problems are to be expected. We explicitly constructed a simultaneous system of equations that violated one of the assumptions of least squares. Specifically, the disturbances were correlated with one of the regressors—price.

Two-stage least squares can be used to address the correlation between regressors and disturbances. Using instruments for the endogenous variable, price, 2SLS will produce consistent estimates of the parameters in the system. Let's use `ivregress` (see [R] [ivregress](#)) to see how our simulated system behaves when fit using 2SLS.

```

We are now much happier with the estimation results. All the coefficients from both equations are close to the true parameter values for the system. In particular, the coefficients are all well within 95% confidence intervals for the parameters. The missing  $R^2$  in the demand equation seems unusual; we will discuss that more later.

Finally, this system could be estimated using 3SLS. To demonstrate how large systems might be handled and to avoid multiline commands, we will use global macros (see [P] macro) to hold the specifications for our equations.

```
. global demand "(qDemand: quantity price pcompete income)"
. global supply "(qSupply: quantity price praw)"
. reg3 $demand $supply, endog(price)
```

We must specify price as endogenous because it does not appear as a dependent variable in either equation. Without this option, reg3 would assume that there are no endogenous variables in the system and produce seemingly unrelated regression (sureg) estimates. The reg3 output from our series of commands is

Three-stage least-squares regression

| Equation | Obs | Params | RMSE     | "R-squared" | chi2  | P>chi2 |

The use of 3SLS over 2SLS is essentially an efficiency issue. The coefficients of the demand equation from 3SLS are close to the coefficients from two-stage least squares, and those of the supply equation are identical. The latter case was mentioned earlier for systems with some exactly identified equations. However, even for the demand equation, we do not expect the coefficients to change systematically. What we do expect from three-stage least squares are more precise estimates of the parameters given the validity of our specification and `reg3`'s use of the covariances among the disturbances.

Let's summarize the results. With OLS, we got obviously biased estimates of the parameters. No amount of data would have improved the OLS estimates—they are inconsistent in the face of the violated OLS assumptions. With 2SLS, we obtained consistent estimates of the parameters, and these would have improved with more data. With 3SLS, we obtained consistent estimates of the parameters that are more efficient than those obtained by 2SLS.

### □ Technical note

We noted earlier that the  $R^2$  was missing from the two-stage estimates of the demand equation. Now we see that the  $R^2$  is negative for the three-stage estimates of the same equation. How can we have a negative  $R^2$ ?

In most estimators, other than least squares, the  $R^2$  is no more than a summary measure of the overall in-sample predictive power of the estimator. The computational formula for  $R^2$  is  $R^2 = 1 - \text{RSS}/\text{TSS}$ , where RSS is the residual sum of squares (sum of squared residuals) and TSS is the total sum of squared deviations about the mean of the dependent variable. In a standard linear model with a constant, the model from which the TSS is computed is nested within the full model from which RSS is computed—they both have a constant term based on the same data. Thus, it must be that  $\text{TSS} \geq \text{RSS}$  and  $R^2$  is constrained between 0 and 1.

For 2SLS and 3SLS, some of the regressors enter the model as instruments when the parameters are estimated. However, because our goal is to fit the structural model, the actual values, not the instruments for the endogenous right-hand-side variables, are used to determine  $R^2$ . The model residuals are computed over a different set of regressors from those used to fit the model. The two- or three-stage estimates are no longer nested within a constant-only model of the dependent variable, and the residual sum of squares is no longer constrained to be smaller than the total sum of squares.

A negative  $R^2$  in 3SLS should be taken for exactly what it is—an indication that the structural model predicts the dependent variable worse than a constant-only model. Is this a problem? It depends on the application. Three-stage least squares applied to our contrived supply-and-demand example produced good estimates of the known true parameters. Still, the demand equation produced an  $R^2$  of  $-0.854$ . How do we feel about our parameter estimates? This should be determined by the estimates themselves, their associated standard errors, and the overall model significance. On this basis, negative  $R^2$  and all, we feel pretty good about all the parameter estimates for both the supply and demand equations. Would we want to make predictions about equilibrium quantity by using the demand equation alone? Probably not. Would we want to make these quantity predictions by using the supply equation? Possibly, because based on in-sample predictions, they seem better than those from the demand equations. However, both the supply and demand estimates are based on limited information. If we are interested in predicting quantity, a reduced-form equation containing all our independent variables would usually be preferred.

## □ Technical note

As a matter of syntax, we could have specified the supply-and-demand model on one line without using global macros.

```
. reg3 (quantity price pcompete income) (quantity price praw), endog(price)
```

Endogenous: quantity price

Exogenous: pcompete income praw

However, here `reg3` has been forced to create a unique equation name for the supply equation—`2quantity`. Both the supply and demand equations could not be designated as `quantity`, so a number was prefixed to the name for the supply equation.

We could have specified

```
. reg3 (qDemand: quantity price pcompete income) (qSupply: quantity price praw),
> endog(price)
```

and obtained the same results and equation labeling as when we used global macros to hold the equation specifications.

Without explicit equation names, `reg3` always assumes that the dependent variable should be used to name equations. When each equation has a different dependent variable, this rule causes no problems and produces easily interpreted result tables. If the same dependent variable appears in more than one equation, however, `reg3` will create a unique equation name based on the dependent variable name. Because equation names must be used for cross-equation tests, you have more control in this situation if explicit names are placed on the equations.

□

▷ Example 3: Using the full syntax of reg3

Klein's (1950) model of the US economy is often used to demonstrate system estimators. It contains several common features that will serve to demonstrate the full syntax of reg3. The Klein model is defined by the following seven relationships:

$$c = \beta_0 + \beta_1 p + \beta_2 L.p + \beta_3 w + \epsilon_1 \quad (1)$$

$$i = \beta_4 + \beta_5 p + \beta_6 L.p + \beta_7 L.k + \epsilon_2 \quad (2)$$

$$wp = \beta_8 + \beta_9 y + \beta_{10} L.y + \beta_{11} yr + \epsilon_3 \quad (3)$$

$$y = c + i + g \quad (4)$$

$$p = y - t - wp \quad (5)$$

$$k = L.k + i \quad (6)$$

$$w = wg + wp \quad (7)$$

Here we have used Stata's lag operator `L.` to represent variables that appear with a one-period lag in our model; see [U] 13.10 Time-series operators.

The variables in the model are listed below. Two sets of variable names are shown. The concise first name uses traditional economics mnemonics, whereas the second name provides more guidance for everyone else. The concise names serve to keep the specification of the model small (and quite understandable to economists).

| Short name      | Long name             | Variable definition               | Type       |
|-----------------|-----------------------|-----------------------------------|------------|
| <code>c</code>  | <code>consump</code>  | Consumption                       | endogenous |
| <code>p</code>  | <code>profits</code>  | Private industry profits          | endogenous |
| <code>wp</code> | <code>wagepriv</code> | Private wage bill                 | endogenous |
| <code>wg</code> | <code>wagegovt</code> | Government wage bill              | exogenous  |
| <code>w</code>  | <code>wagetot</code>  | Total wage bill                   | endogenous |
| <code>i</code>  | <code>invest</code>   | Investment                        | endogenous |
| <code>k</code>  | <code>capital</code>  | Capital stock                     | endogenous |
| <code>y</code>  | <code>totinc</code>   | Total income/demand               | endogenous |
| <code>g</code>  | <code>govt</code>     | Government spending               | exogenous  |
| <code>t</code>  | <code>taxnetx</code>  | Indirect bus. taxes + net exports | exogenous  |
| <code>yr</code> | <code>year</code>     | Year—1931                         | exogenous  |

Equations (1)–(3) are behavioral and contain explicit disturbances ( $\epsilon_1$ ,  $\epsilon_2$ , and  $\epsilon_3$ ). The remaining equations are identities that specify additional variables in the system and their accounting relationships with the variables in the behavioral equations. Some variables are explicitly endogenous by appearing as dependent variables in (1)–(3). Others are implicitly endogenous as linear combinations that contain other endogenous variables (for example, `w` and `p`). Still other variables are implicitly exogenous by appearing in the identities but not in the behavioral equations (for example, `wg` and `g`).

Using the concise names, we can fit Klein’s model with the following command:

```
. use https://www.stata-press.com/data/r19/klein2
. reg3 (c p L.p w) (i p L.p L.k) (wp y L.y yr), endog(w p y) exog(t wg g)
Three-stage least-squares regression
```

Endogenous: c i wp w p y  
 Exogenous: L.p L.k L.y yr t wg g

We used the `exog()` option to identify `t`, `wg`, and `g` as exogenous variables in the system. These variables must be identified because they are part of the system but appear directly in none of the behavioral equations. Without this option, `reg3` would not know they were part of the system and could be used as instrumental variables. The `endog()` option specifying `w`, `p`, and `y` is also required. Without this information, `reg3` would be unaware that these variables are linear combinations that include endogenous variables. We did not include `k` in the `endog()` option because only its lagged value appears in the behavioral equations.

## □ Technical note

Rather than listing additional endogenous and exogenous variables, we could specify the full list of exogenous variables in an `inst()` option,

```
. reg3 (c p L.p w) (i p L.p L.k) (wp y L.y yr), inst(g t wg yr L.p L.k L.y)
```

or equivalently,

```
. global conseqn "(c p L.p w)"
. global inveqn "(i p L.p L.k)"
. global wageqn "(wp y L.y yr)"
. global inlist "g t wg yr L.p L.k L.y"
. reg3 $conseqn $inveqn $wageqn, inst($inlist)
```

Macros and explicit equations can also be mixed in the specification

```
. reg3 $conseqn (i p L.p L.k) $wageqn, endog(w p y) exog(t wg g)
```

or

```
. reg3 (c p L.p w) $inveqn (wp y L.y yr), endog(w p y) exog(t wg g)
```

Placing the equation-binding parentheses in the global macros was also arbitrary. We could have used

```
. global consump "c p L.p w"
. global invest "i p L.p L.k"
. global wagepriv "wp y L.y yr"
. reg3 ($consump) ($invest) ($wagepriv), endog(w p y) exog(t wg g)
```

`reg3` is tolerant of all combinations, and these commands will produce identical output.

□

Switching to the full variable names, we can fit Klein’s model with the commands below. We will use global macros to store the lists of endogenous and exogenous variables. Again, this is not necessary: these lists could have been typed directly on the command line. However, assigning the lists to local macros makes additional processing easier if alternative models are to be fit. We will also use the ireg3 option to produce the iterated estimates.

```
. use https://www.stata-press.com/data/r19/kleinfull
. global conseqn "(consump profits L.profits wagetot)"
. global inveqn "(invest profits L.profits L.capital)"
. global wageqn "(wagepriv totinc L.totinc year)"
. global enlist "wagetot profits totinc"
. global exlist "taxnetx wagegovt govt"
. reg3 $conseqn $inveqn $wageqn, endog($enlist) exog($exlist) ireg3

## ▷ Example 4: Constraints with reg3

As a simple example of constraints, (1) above may be rewritten with both wages explicitly appearing (rather than as a variable containing the sum). Using the longer variable names, we have

$$\text{consump} = \beta_0 + \beta_1 \text{profits} + \beta_2 \text{L.profits} + \beta_3 \text{wagepriv} + \beta_{12} \text{wagegovt} + \epsilon_1$$

To retain the effect of the identity in (7), we need  $\beta_3 = \beta_{12}$  as a constraint on the system. We obtain this result by defining the constraint in the usual way and then specifying its use in `reg3`. Because `reg3` is a system estimator, we will need to use the full equation syntax of `constraint`. The assumption that the following commands are entered after the model above has been estimated. We are simply changing the definition of the consumption equation (`consump`) and adding a constraint on two of its parameters. The rest of the model definition is carried forward.

```
. global conseqn "(consump profits L.profits wagepriv wagegovt)"
. constraint define 1 [consump]wagepriv = [consump]wagegovt
. reg3 $conseqn $inveqn $wageqn, endog($enlist) exog($exlist) constr(1) ireg3
note: additional endogenous variables not in the system have no effect and are
 ignored (wagetot).
Iteration 1: Tolerance = .3712547
Iteration 2: Tolerance = .189471
Iteration 3: Tolerance = .10764
 (output omitted)
Iteration 24: Tolerance = 7.049e-07
```

Endogenous: consump invest wagepriv wagetot profits totinc

Exogenous: L.profits wagegovt L.capital L.totinc year taxnetx govt

As expected, none of the parameter or standard error estimates has changed from the previous estimates (before the seventh significant digit). We have simply decomposed the total wage variable into its two parts and constrained the coefficients on these parts. The warning about additional endogenous variables was just reg3's way of letting us know that we had specified some information that was irrelevant to the estimation of the system. We had left the wagetot variable in our endog macro. It does not mean anything to the system to specify wagetot as endogenous because it is no longer in the system. That's fine with reg3 and fine for our current purposes.

We can also impose constraints across the equations. For example, the admittedly meaningless constraint of requiring profits to have the same effect in both the consumption and investment equations could be imposed. Retaining the constraint on the wage coefficients, we would estimate this constrained system.

```
. constraint define 2 [consump]profits = [invest]profits
. reg3 $conseqn $inveqn $wageqn, endog($enlist) exog($exlist) constr(1 2) ireg3
note: additional endogenous variables not in the system have no effect and are
 ignored (wagetot).
```

## □ Technical note

Identification in a system of simultaneous equations involves the notion that there is enough information to estimate the parameters of the model given the specified functional form. Under-identification usually manifests itself as one matrix in the 3SLS computations. The most commonly violated order condition for 2SLS or 3SLS involves the number of endogenous and exogenous variables. There must be at least as many noncollinear exogenous variables in the remaining system as there are endogenous right-hand-side variables in an equation. This condition must hold for each structural equation in the system.

Put as a set of rules the following:

1. Count the number of right-hand-side endogenous variables in an equation and call this  $m_i$ .
2. Count the number of exogenous variables in the same equation and call this  $k_i$ .
3. Count the total number of exogenous variables in all the structural equations plus any additional variables specified in an `exog()` or `inst()` option and call this  $K$ .
4. If  $m_i > (K - k_i)$  for any structural equation ( $i$ ), then the system is underidentified and cannot be estimated by 3SLS.

We are also possibly in trouble if any of the exogenous variables are linearly dependent. We must have  $m_i$  linearly independent variables among the exogenous variables represented by  $(K - k_i)$ .

The complete conditions for identification involve rank-order conditions on several matrices. For a full treatment, see [Theil \(1971\)](#) or [Greene \(2018, 363–365\)](#).

□

Henri Theil (1924–2000) was born in Amsterdam and awarded a PhD in 1951 by the University of Amsterdam. He researched and taught econometric theory, statistics, microeconomics, macroeconomic modeling, and economic forecasting, and policy at (now) Erasmus University Rotterdam, the University of Chicago, and the University of Florida. Theil's many specific contributions include work on 2SLS and 3SLS, inequality and concentration, and consumer demand.

## Stored results

reg3 stores the following in `e()`:

### Scalars

|                          |                                                        |
|--------------------------|--------------------------------------------------------|
| <code>e(N)</code>        | number of observations                                 |
| <code>e(k)</code>        | number of parameters                                   |
| <code>e(k_eq)</code>     | number of equations in <code>e(b)</code>               |

In addition to the above, the following is stored in `r()`:

Matrices

`r(table)`

matrix containing the coefficients with their standard errors, test statistics, *p*-values, and confidence intervals

Note that results stored in `r()` are updated when the command is replayed and will be replaced when any *r*-class command is run after the estimation command.

## Methods and formulas

The most concise way to represent a system of equations for 3SLS requires thinking of the individual equations and their associated data as being stacked. `reg3` does not expect the data in this format, but it is a convenient shorthand. The system could then be formulated as

$$\begin{bmatrix} \mathbf{y}_1 \\ \mathbf{y}_2 \\ \vdots \\ \mathbf{y}_M \end{bmatrix} = \begin{bmatrix} \mathbf{Z}_1 & 0 & \dots & 0 \\ 0 & \mathbf{Z}_2 & \dots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \dots & \mathbf{Z}_M \end{bmatrix} \begin{bmatrix} \beta_1 \\ \beta_2 \\ \vdots \\ \beta_M \end{bmatrix} + \begin{bmatrix} \epsilon_1 \\ \epsilon_2 \\ \vdots \\ \epsilon_M \end{bmatrix}$$

In full matrix notation, this is just

$$\mathbf{y} = \mathbf{Z}\mathbf{B} + \boldsymbol{\epsilon}$$

The **Z** elements in these matrices represent both the endogenous and the exogenous right-hand-side variables in the equations.

Also assume that there will be correlation between the disturbances of the equations so that

$$E(\boldsymbol{\epsilon}\boldsymbol{\epsilon}') = \boldsymbol{\Sigma}$$

where the disturbances are further assumed to have an expected value of 0;  $E(\boldsymbol{\epsilon}) = 0$ .

The first stage of 3SLS regression requires developing instrumented values for the endogenous variables in the system. These values can be derived as the predictions from a linear regression of each endogenous regressor on all exogenous variables in the system or, more succinctly, as the projection of each regressor through the projection matrix of all exogenous variables onto the regressors. Designating the set of all exogenous variables as **X** results in

$$\hat{\mathbf{z}}_i = \mathbf{X}(\mathbf{X}'\mathbf{X})^{-1}\mathbf{X}'\mathbf{z}_i \quad \text{for each } i$$

Taken collectively, these  $\hat{\mathbf{Z}}$  contain the instrumented values for all the regressors. They take on the actual values for the exogenous variables and first-stage predictions for the endogenous variables. Given these instrumented variables, a generalized least squares (GLS) or **Aitken (1935)** estimator can be formed for the parameters of the system

$$\hat{\mathbf{B}} = \left\{ \widehat{\mathbf{Z}}'(\boldsymbol{\Sigma}^{-1} \otimes \mathbf{I})\widehat{\mathbf{Z}} \right\}^{-1} \widehat{\mathbf{Z}}'(\boldsymbol{\Sigma}^{-1} \otimes \mathbf{I})\mathbf{y}$$

All that remains is to obtain a consistent estimator for  $\boldsymbol{\Sigma}$ . This estimate can be formed from the residuals of 2SLS estimates of each equation in the system. Alternately, and identically, the residuals can be computed from the estimates formed by taking  $\boldsymbol{\Sigma}$  to be an identity matrix. This maintains the full system of coefficients and allows constraints to be applied when the residuals are computed.

If we take  $\mathbf{E}$  to be the matrix of residuals from these estimates, a consistent estimate of  $\Sigma$  is

$$\widehat{\Sigma} = \frac{\mathbf{E}'\mathbf{E}}{n}$$

where  $n$  is the number of observations in the sample. An alternative divisor for this estimate can be obtained with the `dfk` option as outlined under options.

With the estimate of  $\widehat{\Sigma}$  placed into the GLS estimating equation,

$$\widehat{\mathbf{B}} = \left\{ \widehat{\mathbf{Z}}'(\widehat{\Sigma}^{-1} \otimes \mathbf{I})\widehat{\mathbf{Z}} \right\}^{-1} \widehat{\mathbf{Z}}'(\widehat{\Sigma}^{-1} \otimes \mathbf{I})\mathbf{y}$$

is the 3SLS estimates of the system parameters.

The asymptotic variance–covariance matrix of the estimator is just the standard formulation for a GLS estimator

$$\mathbf{V}_{\widehat{\mathbf{B}}} = \left\{ \widehat{\mathbf{Z}}'(\widehat{\Sigma}^{-1} \otimes \mathbf{I})\widehat{\mathbf{Z}} \right\}^{-1}$$

Iterated 3SLS estimates can be obtained by computing the residuals from the three-stage parameter estimates, using these to formulate a new  $\widehat{\Sigma}$ , and recomputing the parameter estimates. This process is repeated until the estimates  $\widehat{\mathbf{B}}$  converge—if they converge. Convergence is not guaranteed. When estimating a system by SURE, these iterated estimates will be the maximum likelihood estimates for the system. The iterated solution can also be used to produce estimates that are invariant to choice of system and restriction parameterization for many linear systems under full 3SLS.

The exposition above follows the parallel developments in [Greene \(2018\)](#) and [Davidson and MacKinnon \(1993\)](#).

This command supports the Huber/White/sandwich estimator of the variance and its clustered version using `vce(robust)` and `vce(cluster clustvar)`, respectively. See [\[P\] \\_robust](#), particularly [Introduction](#) and [Methods and formulas](#).

Alexander Craig Aitken (1895–1967) was born in Dunedin, New Zealand. He attended the University of Otago on a full scholarship but left the university to enlist in the New Zealand Expeditionary Force during World War I. He would later reflect on the time he spent in active service and publish two war memoirs.

After returning from the war, he completed his studies at the University of Otago and then worked on his PhD at the University of Edinburgh under E. T. Whittaker. Although he suffered weeks of illness during the course of his postgraduate studies, he managed to write an impressive thesis on data smoothing. He then became a professor of mathematics, and later the Chair of Pure Mathematics, a post he would hold until his retirement in 1965.

Among his many accolades, he was elected a Fellow of the Royal Society of Edinburgh and a Fellow of the Royal Society of Literature, following the publication of his second war memoir. He published many papers on numerical analysis and statistics as well as a couple of books on matrices. Aitken is credited with deriving the generalized least squares estimator, which has been referred to as Aitken's generalized least squares. Aside from his many academic contributions, he had mental calculating abilities like no other. He is known to have multiplied two 9-digit numbers in less than a minute and could recite up to 707 digits of  $\pi$ .

## Postestimation commands

The following postestimation commands are available after `reg3`:

| Command                      | Description                                                                                                                             |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <code>contrast</code>        | contrasts and ANOVA-style joint tests of parameters                                                                                     |
| * <code>estat ic</code>      | Akaike's, consistent Akaike's, corrected Akaike's, and Schwarz's Bayesian information criteria (AIC, CAIC, AICc, and BIC, respectively) |
| <code>estat summarize</code> | summary statistics for the estimation sample                                                                                            |
| <code>estat vce</code>       | variance–covariance matrix of the estimators (VCE)                                                                                      |
| <code>estimates</code>       | cataloging estimation results                                                                                                           |
| <code>etable</code>          | table of estimation results                                                                                                             |
| <code>forecast</code>        | dynamic forecasts and simulations                                                                                                       |
| <code>hausman</code>         | Hausman's specification test                                                                                                            |
| <code>lincom</code>          | point estimates, standard errors, testing, and inference for linear combinations of parameters                                          |
| <code>margins</code>         | marginal means, predictive margins, marginal effects, and average marginal effects                                                      |
| <code>marginsplot</code>     | graph the results from margins (profile plots, interaction plots, etc.)                                                                 |
| <code>nlcom</code>           | point estimates, standard errors, testing, and inference for nonlinear combinations of parameters                                       |
| <code>predict</code>         | predictions and their SEs, residuals, etc.                                                                                              |
| <code>predictnl</code>       | point estimates, standard errors, testing, and inference for generalized predictions                                                    |
| <code>pwcompare</code>       | pairwise comparisons of parameters                                                                                                      |
| <code>test</code>            | Wald tests of simple and composite linear hypotheses                                                                                    |
| <code>testnl</code>          | Wald tests of nonlinear hypotheses                                                                                                      |

\*`estat ic` is not appropriate after `reg3`, `2sls`.

# predict

## Description for predict

`predict` creates a new variable containing predictions such as linear predictions, standard errors, residuals, and differences between the linear predictions of two equations.

## Menu for predict

Statistics > Postestimation

## Syntax for predict

```
predict [type] newvar [if] [in] [, equation(eqno[, eqno]) statistic]
statistic Description
```

| Main                    |                                                            |
|-------------------------|------------------------------------------------------------|
| <code>xb</code>         | linear prediction; the default                             |
| <code>stdp</code>       | standard error of the linear prediction                    |
| <code>residuals</code>  | residuals                                                  |
| <code>difference</code> | difference between the linear predictions of two equations |
| <code>stddp</code>      | standard error of the difference in linear predictions     |

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

## Options for predict

Main

`equation(eqno[, eqno])` specifies to which equation you are referring.

`equation()` is filled in with one *eqno* for the `xb`, `stdp`, and `residuals` options. `equation(#1)` would mean the calculation is to be made for the first equation, `equation(#2)` would mean the second, and so on. You could also refer to the equations by their names. `equation(income)` would refer to the equation named `income` and `equation(hours)` to the equation named `hours`.

If you do not specify `equation()`, results are the same as if you specified `equation(#1)`.

`difference` and `stddp` refer to between-equation concepts. To use these options, you must specify two equations, for example, `equation(#1, #2)` or `equation(income, hours)`. When two equations must be specified, `equation()` is required.

`xb`, the default, calculates the linear prediction (fitted values)—the prediction of  $\mathbf{x}_j\mathbf{b}$  for the specified equation.

`stdp` calculates the standard error of the prediction for the specified equation. It can be thought of as the standard error of the predicted expected value or mean for the observation's covariate pattern. The standard error of the prediction is also referred to as the standard error of the fitted value.

`residuals` calculates the residuals.

`difference` calculates the difference between the linear predictions of two equations in the system. With `equation(#1,#2)`, `difference` computes the prediction of `equation(#1)` minus the prediction of `equation(#2)`.

`stdp` is allowed only after you have previously fit a multiple-equation model. The standard error of the difference in linear predictions ( $\mathbf{x}_{1j}\mathbf{b} - \mathbf{x}_{2j}\mathbf{b}$ ) between equations 1 and 2 is calculated.

For more information on using `predict` after multiple-equation estimation commands, see [R] [predict](#).

## margins

### Description for margins

`margins` estimates margins of response for linear predictions and differences between the linear predictions of two equations.

### Menu for margins

Statistics > Postestimation

### Syntax for margins

```
margins [marginlist] [, options]
```

```
margins [marginlist] , predict(statistic ...) [predict(statistic ...) ...] [options]
```

| <i>statistic</i>        | Description                                                |
|-------------------------|------------------------------------------------------------|
| <code>default</code>    | linear predictions for each equation                       |
| <code>xb</code>         | linear prediction for a specified equation                 |
| <code>difference</code> | difference between the linear predictions of two equations |
| <code>stdp</code>       | not allowed with <code>margins</code>                      |
| <code>residuals</code>  | not allowed with <code>margins</code>                      |
| <code>stddp</code>      | not allowed with <code>margins</code>                      |

`xb` defaults to the first equation.

Statistics not allowed with `margins` are functions of stochastic quantities other than  $e(b)$ .

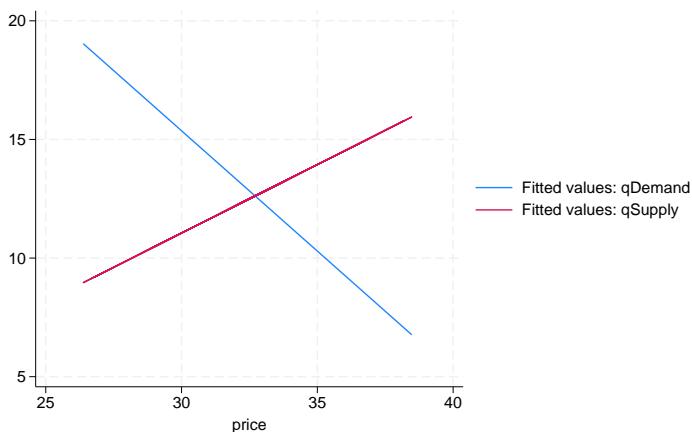

For the full syntax, see [R] [margins](#).

## Remarks and examples

### ▷ Example 1: Using predict

In [example 2](#) of [\[R\] reg3](#), we fit a simple supply-and-demand model. Here we obtain the fitted supply and demand curves assuming that the exogenous regressors equal their sample means. We first replace each of the three exogenous regressors with their sample means, then we call `predict` to obtain the predictions.

```
. use https://www.stata-press.com/data/r19/supDem
. global demand "(qDemand: quantity price pcompete income)"
. global supply "(qSupply: quantity price praw)"
. reg3 $demand $supply, endog(price)
 (output omitted)
. summarize pcompete, meanonly
. replace pcompete = r(mean)
(49 real changes made)
. summarize income, meanonly
. replace income = r(mean)
(49 real changes made)
. summarize praw, meanonly
. replace praw = r(mean)
(49 real changes made)
. predict demand, equation(qDemand)
(option xb assumed; fitted values)
. predict supply, equation(qSupply)
(option xb assumed; fitted values)
. graph twoway line demand price, sort || line supply price, ytitle(" ")
> legend(label(1 "Fitted values: qDemand") label(2 "Fitted values: qSupply"))
```

As we would expect based on economic theory, the demand curve slopes downward while the supply curve slopes upward. With the exogenous variables at their mean levels, the equilibrium price and quantity are slightly less than 33 and 13, respectively.

## ► Example 2: Obtaining forecasts

In [example 3](#) of [R] [reg3](#), we fit Klein's (1950) model of the US economy. That model includes three stochastic equations we fit using `reg3` as well as four identities. Here we briefly illustrate how the `forecast` command can be used to obtain forecasts for all the endogenous variables in the model. For a more detailed discussion of how to forecast with this model, see [TS] [forecast](#).

In Stata, we type

```
. use https://www.stata-press.com/data/r19/klein2, clear
. reg3 (c p L.p w) (i p L.p L.k) (wp y L.y yr), endog(w p y) exog(t wg g)
 (output omitted)
. estimates store kleineqs
. forecast create kleinmodel
 Forecast model kleinmodel started.
. forecast estimates kleineqs
 Added estimation results from reg3.
 Forecast model kleinmodel now contains 3 endogenous variables.
. forecast identity y = c + i + g
 Forecast model kleinmodel now contains 4 endogenous variables.
. forecast identity p = y - t - wp
 Forecast model kleinmodel now contains 5 endogenous variables.
. forecast identity k = L.k + i
 Forecast model kleinmodel now contains 6 endogenous variables.
. forecast identity w = wg + wp
 Forecast model kleinmodel now contains 7 endogenous variables.
. forecast solve, begin(1937)
Computing dynamic forecasts for model kleinmodel.
```

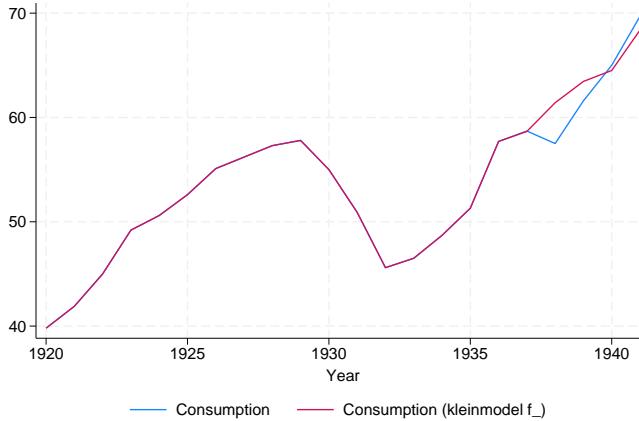

---

```
Starting period: 1937
Ending period: 1941
Forecast prefix: f_
1937:
1938:
1939:
1940:
1941:
Forecast 7 variables spanning 5 periods.
```

---

Here we have obtained dynamic forecasts for our 7 endogenous variables beginning in 1937. By default, the variables containing the forecasts begin with the prefix `f_`. Next we plot the forecast and actual values of consumption:

```
. tsline c f_c
```

For more information about producing forecasts, see [\[TS\] forecast](#).

## Methods and formulas

The computational formulas for the statistics produced by `predict` can be found in [\[R\] predict](#) and [\[R\] regress postestimation](#).

## Description

`regress` performs ordinary least-squares linear regression. `regress` can also perform weighted estimation, compute robust and cluster-robust standard errors, and adjust results for complex survey designs.

## Quick start

Simple linear regression of  $y$  on  $x_1$

```
regress y x1
```

Regression of  $y$  on  $x_1$ ,  $x_2$ , and indicators for categorical variable  $a$

```
regress y x1 x2 i.a
```

Add the interaction between continuous variable  $x_2$  and  $a$

```
regress y x1 c.x2##i.a
```

Fit model for observations where  $v_1$  is greater than zero

```
regress y x1 x2 i.a if v1>0
```

With cluster-robust standard errors for clustering by levels of  $cvar$

```
regress y x1 x2 i.a, vce(cluster cvar)
```

With cluster-robust standard errors for clustering by levels of  $cvar_1$  and  $cvar_2$

```
regress y x1 x2 i.a, vce(cluster cvar1 cvar2)
```

With bootstrap standard errors

```
regress y x1 x2 i.a, vce(bootstrap)
```

Report standardized coefficients

```
regress y x1 x2 i.a, beta
```

Adjust for complex survey design using `svyset` data

```
svy: regress y x1 x2 i.a
```

Use sampling weight  $wvar$

```
regress y x1 x2 i.a [pweight=wvar]
```

## Menu

Statistics > Linear models and related > Linear regression

## Syntax

```
regress deprvar [indepvars] [if] [in] [weight] [, options]
```

| <i>options</i>                       | Description                                                                                                                                                                                                           |

| <code>eform(<i>string</i>)</code>    | report exponentiated coefficients and label as <i>string</i>                                                                                                                                                          |
| <code>depname(<i>varname</i>)</code> | substitute dependent variable name; programmer's option                                                                                                                                                               |
| <code>clustertable</code>            | display table of multiway cluster combinations                                                                                                                                                                        |
| <code>display_options</code>         | control columns and column formats, row spacing, line width, display of omitted variables and base and empty cells, and factor-variable labeling                                                                      |
| <code>noheader</code>                | suppress output header                                                                                                                                                                                                |
| <code>notable</code>                 | suppress coefficient table                                                                                                                                                                                            |
| <code>plus</code>                    | make table extendable                                                                                                                                                                                                 |
| <code>mse1</code>                    | force mean squared error to 1                                                                                                                                                                                         |
| <code>coeflegend</code>              | display legend instead of statistics                                                                                                                                                                                  |

*indepvars* may contain factor variables; see [U] 11.4.3 **Factor variables**.

*deprvar* and *indepvars* may contain time-series operators; see [U] 11.4.4 **Time-series varlists**.

`bayes`, `bayesboot`, `bootstrap`, `by`, `collect`, `fmm`, `fp`, `jackknife`, `mfp`, `mi estimate`, `nestreg`, `rolling`, `statsby`, `stepwise`, and `svy` are allowed; see [U] 11.1.10 **Prefix commands**. For more details, see [BAYES] **bayes: regress** and [FMM] **fmm: regress**.

`vce(bootstrap)` and `vce(jackknife)` are not allowed with the `mi estimate` prefix; see [MI] **mi estimate**.

Weights are not allowed with the `bootstrap` prefix; see [R] **bootstrap**.

`aweight`s are not allowed with the `jackknife` prefix; see [R] **jackknife**.

`hascons`, `tsscons`, `vce()`, `beta`, `noheader`, `notable`, `plus`, `depname()`, `mse1`, and `weight`s are not allowed with the `svy` prefix; see [SVY] **svy**.

`aweight`s, `fweight`s, `iweight`s, and `pweight`s are allowed; see [U] 11.1.6 **weight**.

`noheader`, `notable`, `plus`, `mse1`, and `coeflegend` do not appear in the dialog box.

See [U] 20 **Estimation and postestimation commands** for more capabilities of estimation commands.

## Options

### Model

`noconstant`; see [R] [Estimation options](#).

`hascons` indicates that a user-defined constant or its equivalent is specified among the independent variables in *indepvars*. Some caution is recommended when specifying this option, as resulting estimates may not be as accurate as they otherwise would be. Use of this option requires “sweeping” the constant last, so the moment matrix must be accumulated in absolute rather than deviation form. This option may be safely specified when the means of the dependent and independent variables are all reasonable and there is not much collinearity between the independent variables. The best procedure is to view `hascons` as a reporting option—estimate with and without `hascons` and verify that the coefficients and standard errors of the variables not affected by the identity of the constant are unchanged.

`tsscons` forces the total sum of squares to be computed as though the model has a constant, that is, as deviations from the mean of the dependent variable. This is a rarely used option that has an effect only when specified with `noconstant`. It affects the total sum of squares and all results derived from the total sum of squares.

### SE/Robust

`vce(vctype)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory (`ols`), that are robust to some kinds of misspecification (`robust`), that allow for intragroup correlation (`cluster clustvarlist`), and that use bootstrap or jackknife methods (`bootstrap`, `jackknife`); see [R] [vce\\_option](#).

`vce(ols)`, the default, uses the standard variance estimator for ordinary least-squares regression.

`vce(cluster clustvarlist)` specifies that standard errors allow for intragroup correlation within groups defined by one or more variables in *clustvarlist*, relaxing the usual requirement that the observations be independent. For example, `vce(cluster clustvar1)` produces cluster-robust standard errors that allow for observations that are independent across groups defined by `clustvar1` but not necessarily independent within groups. You could also type `vce(cluster clustvar1 clustvar2 ... clusterp)` to account for correlation within groups formed by *p* variables (multiway clustering).

`regress` also allows the following:

`vce(hc2 [clustvar] [ , dfadjust ])` and `vce(hc3)` specify alternative bias corrections for the robust variance calculation. `vce(hc2)` and `vce(hc3)` may not be specified with the `svy` prefix. In the unclustered case, `vce(robust)` uses  $\hat{\sigma}_j^2 = \{n/(n - k)\}u_j^2$  as an estimate of the variance of the *j*th observation, where *n* is the number of observations, *k* is the number of regressors, *u<sub>j</sub>* is the calculated residual, and  $n/(n - k)$  is included to improve the overall estimate’s small-sample properties.

`vce(hc2)` instead uses  $u_j^2/(1 - h_{jj})$  as the observation's variance estimate, where  $h_{jj}$  is the diagonal element of the hat (projection) matrix. This estimate is unbiased if the model really is homoskedastic. `vce(hc2)` tends to produce slightly more conservative confidence intervals. `vce(hc2 clustvar)` produces estimates that allow for intragroup correlation within groups defined by `clustvar`. `dfadjust` computes the [Bell and McCaffrey \(2002\)](#) adjusted degrees of freedom based on `clustvar`. Note that `dfadjust` does not affect multiple-imputation results when the command is used with `mi estimate`. See [Methods and formulas](#) for a description of the computation when `clustvar` is specified.

`vce(hc3)` uses  $u_j^2/(1 - h_{jj})^2$  as suggested by [Davidson and MacKinnon \(1993\)](#), who report that this method tends to produce better results when the model really is heteroskedastic. `vce(hc3)` produces confidence intervals that tend to be even more conservative.

See [Davidson and MacKinnon \(1993, 554–556\)](#) and [Angrist and Pischke \(2009, 294–308\)](#) for more discussion on these two bias corrections.

---

Reporting

---

`level(#)`; see [\[R\] Estimation options](#).

`beta` asks that standardized beta coefficients be reported instead of confidence intervals. The beta coefficients are the regression coefficients obtained by first standardizing all variables to have a mean of 0 and a standard deviation of 1. `beta` may not be specified with `vce(cluster clustvarlist)` or the `svy` prefix.

`eform(string)` is used only in programs and ado-files that use `regress` to fit models other than linear regression. `eform()` specifies that the coefficient table be displayed in exponentiated form as defined in [\[R\] Maximize](#) and that `string` be used to label the exponentiated coefficients in the table.

`depname(varname)` is used only in programs and ado-files that use `regress` to fit models other than linear regression. `depname()` may be specified only at estimation time. `varname` is recorded as the identity of the dependent variable, even though the estimates are calculated using `depvar`. This method affects the labeling of the output—not the results calculated—but could affect subsequent calculations made by `predict`, where the residual would be calculated as deviations from `varname` rather than `depvar`. `depname()` is most typically used when `depvar` is a temporary variable (see [\[P\] macro](#)) used as a proxy for `varname`.

`depname()` is not allowed with the `svy` prefix.

`clustertable` displays a table reporting cluster combinations and the number of clusters per combination. This option is available only when `vce(cluster clustvarlist)` is specified with more than one variable in `clustvarlist` to compute multiway cluster–robust standard errors.

`display_options`: `nocl`, `nopvalues`, `dfci`, `dfpvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `no!stretch`; see [\[R\] Estimation options](#).

`dfci` specifies that parameter degrees of freedom and confidence intervals be reported in the coefficient table.

`dfpvalues` specifies that parameter degrees of freedom and *p*-values be reported in the coefficient table.

The following options are available with `regress` but are not shown in the dialog box:

`noheader` suppresses the display of the ANOVA table and summary statistics at the top of the output; only the coefficient table is displayed. This option is often used in programs and ado-files.

`notable` suppresses display of the coefficient table.

`plus` specifies that the output table be made extendable. This option is often used in programs and ado-files.

`mse1` is used only in programs and ado-files that use `regress` to fit models other than linear regression and is not allowed with the `svy` prefix. `mse1` sets the mean squared error to 1, forcing the variance–covariance matrix of the estimators to be  $(\mathbf{X}'\mathbf{X})^{-1}$  (see *Methods and formulas* below) and affecting calculated standard errors. Degrees of freedom for  $t$  statistics is calculated as  $n$  rather than  $n - k$ .

`coeflegend`; see [R] [Estimation options](#).

## Remarks and examples

Remarks are presented under the following headings:

- [Ordinary least squares](#)
- [Treatment of the constant](#)
- [Robust standard errors](#)
- [Weighted regression](#)
- [Video examples](#)

`regress` performs linear regression, including ordinary least squares and weighted least squares. See [\[U\] 27 Overview of Stata estimation commands](#) for a list of other regression commands that may be of interest. For a general discussion of linear regression, see [Kutner et al. \(2005\)](#).

See [Stock and Watson \(2019\)](#) and [Wooldridge \(2020\)](#) for an excellent treatment of estimation, inference, interpretation, and specification testing in linear regression models. See [Wooldridge \(2010, chap. 4\)](#) for a more advanced discussion along the same lines.

See [Hamilton \(2013, chap. 7\)](#) and [Cameron and Trivedi \(2022, chap. 3\)](#) for an introduction to linear regression using Stata. [Dohoo, Martin, and Stryhn \(2012, 2010\)](#) discuss linear regression using examples from epidemiology, and Stata datasets and do-files used in the text are available. [Cameron and Trivedi \(2022\)](#) discuss linear regression using econometric examples with Stata. [Mitchell \(2021\)](#) shows how to use graphics and postestimation commands to understand a fitted regression model.

[Chatterjee and Hadi \(2012\)](#) explain regression analysis by using examples containing typical problems that you might encounter when performing exploratory data analysis. We also recommend [Weisberg \(2014\)](#), who emphasizes the importance of the assumptions of linear regression and problems resulting from these assumptions. [Beckett \(2020\)](#) discusses regression analysis with an emphasis on time-series data. [Angrist and Pischke \(2009\)](#) approach regression as a tool for exploring relationships, estimating treatment effects, and providing answers to public policy questions. For a mathematically rigorous treatment, see [Peracchi \(2001, chap. 6\)](#). Finally, see [Plackett \(1972\)](#) if you are interested in the history of regression. Least squares, which dates back to the 1790s, was discovered independently by Legendre and Gauss.

## Ordinary least squares

### ▷ Example 1: Basic linear regression

Suppose that we have data on the mileage rating and weight of 74 automobiles. The variables in our data are `mpg`, `weight`, and `foreign`. The last variable assumes the value 1 for foreign and 0 for domestic automobiles. We wish to fit the model

$$\text{mpg} = \beta_0 + \beta_1 \text{weight} + \beta_2 \text{foreign} + \epsilon$$

This model can be fit with `regress` by typing

```
. use https://www.stata-press.com/data/r19/auto
(1978 automobile data)
. regress mpg weight foreign
```

| Source   | SS         | df | MS         | Number of obs | = | 74     |
|----------|------------|----|------------|---------------|---|--------|
| Model    | 1619.2877  | 2  | 809.643849 | F(2, 71)      | = | 69.75  |
| Residual | 824.171761 | 71 | 11.608053  | Prob > F      | = | 0.0000 |
|          |            |    |            | R-squared     | = | 0.6627 |
|          |            |    |            | Adj R-squared | = | 0.6532 |
| Total    | 2443.45946 | 73 | 33.4720474 | Root MSE      | = | 3.4071 |

| mpg     | Coefficient | Std. err. | t      | P> t  | [95% conf. interval] |           |
|---------|-------------|-----------|--------|-------|----------------------|-----------|
| weight  | -.0065879   | .0006371  | -10.34 | 0.000 | -.0078583            | -.0053175 |
| foreign | -1.650029   | 1.075994  | -1.53  | 0.130 | -3.7955              | .4954422  |
| _cons   | 41.6797     | 2.165547  | 19.25  | 0.000 | 37.36172             | 45.99768  |

`regress` produces a variety of summary statistics along with the table of regression coefficients. At the upper left, `regress` reports an analysis-of-variance (ANOVA) table. The column headings SS, df, and MS stand for “sum of squares”, “degrees of freedom”, and “mean square”, respectively. In this example, the total sum of squares is 2,443.5: 1,619.3 accounted for by the model and 824.2 left unexplained. Because the regression included a constant, the total sum reflects the sum after removal of means, as does the sum of squares due to the model. The table also reveals that there are 73 total degrees of freedom (counted as 74 observations less 1 for the mean removal), of which 2 are consumed by the model, leaving 71 for the residual.

To the right of the ANOVA table are presented other summary statistics. The  $F$  statistic associated with the ANOVA table is 69.75. The statistic has 2 numerator and 71 denominator degrees of freedom. The  $F$  statistic tests the hypothesis that all coefficients excluding the constant are zero. The chance of observing an  $F$  statistic that large or larger is reported as 0.0000, which is Stata’s way of indicating a number smaller than 0.00005. The  $R^2$  for the regression is 0.6627, and the  $R^2$  adjusted for degrees of freedom ( $R_a^2$ ) is 0.6532. The root mean squared error, labeled Root MSE, is 3.4071. It is the square root of the mean squared error reported for the residual in the ANOVA table.

Finally, Stata produces a table of the estimated coefficients. The first line of the table indicates that the left-hand-side variable is `mpg`. Thereafter follow the estimated coefficients. Our fitted model is

$$\text{mpg\_hat} = 41.68 - 0.0066 \text{weight} - 1.65 \text{foreign}$$

Reported to the right of the coefficients in the output are the standard errors. For instance, the standard error for the coefficient on `weight` is 0.0006371. The corresponding  $t$  statistic is  $-10.34$ , which has a two-sided significance level of 0.000. This number indicates that the significance is less than 0.0005. The 95% confidence interval for the coefficient is  $[-0.0079, -0.0053]$ .

### ▷ Example 2: Transforming the dependent variable

If we had a graph comparing mpg with weight, we would notice that the relationship is distinctly nonlinear. This is to be expected because energy usage per distance should increase linearly with weight, but mpg is measuring distance per energy used. We could obtain a better model by generating a new variable measuring the number of gallons used per 100 miles (gp100m) and then using this new variable in our model:

$$\text{gp100m} = \beta_0 + \beta_1 \text{weight} + \beta_2 \text{foreign} + \epsilon$$

We can now fit this model:

```
. generate gp100m = 100/mpg
. regress gp100m weight foreign
```

| Source   | SS         | df | MS         | Number of obs | = | 74     |
|----------|------------|----|------------|---------------|---|--------|
| Model    | 91.1761694 | 2  | 45.5880847 | F(2, 71)      | = | 113.97 |
| Residual | 28.4000913 | 71 | .400001287 | Prob > F      | = | 0.0000 |
|          |            |    |            | R-squared     | = | 0.7625 |
|          |            |    |            | Adj R-squared | = | 0.7558 |
| Total    | 119.576261 | 73 | 1.63803097 | Root MSE      | = | .63246 |

| gp100m  | Coefficient | Std. err. | t     | P> t  | [95% conf. interval] |          |
|---------|-------------|-----------|-------|-------|----------------------|----------|
| weight  | .0016254    | .0001183  | 13.74 | 0.000 | .0013896             | .0018612 |
| foreign | .6220535    | .1997381  | 3.11  | 0.003 | .2237871             | 1.02032  |
| _cons   | -.0734839   | .4019932  | -0.18 | 0.855 | -.8750354            | .7280677 |

Fitting the physically reasonable model increases our  $R^2$  to 0.7625.

◀

### ▷ Example 3: Obtaining beta coefficients

regress shares the features of all estimation commands. Among other things, this means that after running a regression, we can use test to test hypotheses about the coefficients, estat vce to examine the covariance matrix of the estimators, and predict to obtain predicted values, residuals, and influence statistics. See [U] 20 Estimation and postestimation commands. Options that affect how estimates are displayed, such as beta or level(), can be used when replaying results.

Suppose that we meant to specify the beta option to obtain beta coefficients (regression coefficients normalized by the ratio of the standard deviation of the regressor to the standard deviation of the dependent variable). Even though we forgot, we can specify the option now:

```
. regress, beta
```

| Source   | SS         | df | MS         | Number of obs | = | 74     |
|----------|------------|----|------------|---------------|---|--------|
| Model    | 91.1761694 | 2  | 45.5880847 | F(2, 71)      | = | 113.97 |
| Residual | 28.4000913 | 71 | .400001287 | Prob > F      | = | 0.0000 |
|          |            |    |            | R-squared     | = | 0.7625 |
|          |            |    |            | Adj R-squared | = | 0.7558 |
| Total    | 119.576261 | 73 | 1.63803097 | Root MSE      | = | .63246 |

| gp100m  | Coefficient | Std. err. | t     | P> t  | Beta     |
|---------|-------------|-----------|-------|-------|----------|
| weight  | .0016254    | .0001183  | 13.74 | 0.000 | .9870255 |
| foreign | .6220535    | .1997381  | 3.11  | 0.003 | .2236673 |
| _cons   | -.0734839   | .4019932  | -0.18 | 0.855 | .        |

◀

## Treatment of the constant

By default, `regress` includes an intercept (constant) term in the model. The `noconstant` option suppresses it, and the `hascons` option tells `regress` that the model already has one.

### ▷ Example 4: Suppressing the constant term

We wish to fit a regression of the weight of an automobile against its length, and we wish to impose the constraint that the weight is zero when the length is zero.

If we simply type `regress weight length`, we are fitting the model

$$\text{weight} = \beta_0 + \beta_1 \text{length} + \epsilon$$

Here a length of zero corresponds to a weight of  $\beta_0$ . We want to force  $\beta_0$  to be zero or, equivalently, estimate an equation that does not include an intercept:

$$\text{weight} = \beta_1 \text{length} + \epsilon$$

We do this by specifying the `noconstant` option:

```
. regress weight length, noconstant
```

| Source   | SS         | df | MS         | Number of obs | = | 74      |
|----------|------------|----|------------|---------------|---|---------|
| Model    | 703869302  | 1  | 703869302  | F(1, 73)      | = | 3450.13 |
| Residual | 14892897.8 | 73 | 204012.299 | Prob > F      | = | 0.0000  |
|          |            |    |            | R-squared     | = | 0.9793  |
|          |            |    |            | Adj R-squared | = | 0.9790  |
| Total    | 718762200  | 74 | 9713002.7  | Root MSE      | = | 451.68  |

| weight | Coefficient | Std. err. | t     | P> t  | [95% conf. interval] |         |
|--------|-------------|-----------|-------|-------|----------------------|---------|
| length | 16.29829    | .2774752  | 58.74 | 0.000 | 15.74528             | 16.8513 |

In our data, `length` is measured in inches and `weight` in pounds. We discover that each inch of length adds 16 pounds to the weight.

Sometimes there is no need for Stata to include a constant term in the model. Most commonly, this occurs when the model contains a set of mutually exclusive indicator variables. `hascons` is a variation of the `noconstant` option—it tells Stata not to add a constant to the regression because the regression specification already has one, either directly or indirectly.

For instance, we now refit our model of `weight` as a function of `length` and include separate constants for foreign and domestic cars by specifying `bn.foreign`. `bn.foreign` is factor-variable notation for “no base for foreign” or “include all levels of variable `foreign` in the model”; see [U] 11.4.3 **Factor variables**.

```
. regress weight length bn.foreign, hascons
```

| Source   | SS         | df | MS         | Number of obs | = | 74     |
|----------|------------|----|------------|---------------|---|--------|
| Model    | 39647744.7 | 2  | 19823872.3 | F(2, 71)      | = | 316.54 |
| Residual | 4446433.7  | 71 | 62625.8268 | Prob > F      | = | 0.0000 |
|          |            |    |            | R-squared     | = | 0.8992 |
|          |            |    |            | Adj R-squared | = | 0.8963 |
| Total    | 44094178.4 | 73 | 604029.841 | Root MSE      | = | 250.25 |

| weight   | Coefficient | Std. err. | t      | P> t  | [95% conf. interval] |           |
|----------|-------------|-----------|--------|-------|----------------------|-----------|
| length   | 31.44455    | 1.601234  | 19.64  | 0.000 | 28.25178             | 34.63732  |
| foreign  |             |           |        |       |                      |           |
| Domestic | -2850.25    | 315.9691  | -9.02  | 0.000 | -3480.274            | -2220.225 |
| Foreign  | -2983.927   | 275.1041  | -10.85 | 0.000 | -3532.469            | -2435.385 |

## □ Technical note

There is a subtle distinction between the `hascons` and `noconstant` options. We can most easily reveal it by refitting the last regression, specifying `noconstant` rather than `hascons`:

```
. regress weight length bn.foreign, noconstant
```

| Source   | SS        | df | MS         | Number of obs | = | 74      |
|----------|-----------|----|------------|---------------|---|---------|
| Model    | 714315766 | 3  | 238105255  | F(3, 71)      | = | 3802.03 |
| Residual | 4446433.7 | 71 | 62625.8268 | Prob > F      | = | 0.0000  |
|          |           |    |            | R-squared     | = | 0.9938  |
|          |           |    |            | Adj R-squared | = | 0.9936  |
| Total    | 718762200 | 74 | 9713002.7  | Root MSE      | = | 250.25  |

| weight   | Coefficient | Std. err. | t      | P> t  | [95% conf. interval] |           |
|----------|-------------|-----------|--------|-------|----------------------|-----------|
| length   | 31.44455    | 1.601234  | 19.64  | 0.000 | 28.25178             | 34.63732  |
| foreign  |             |           |        |       |                      |           |
| Domestic | -2850.25    | 315.9691  | -9.02  | 0.000 | -3480.274            | -2220.225 |
| Foreign  | -2983.927   | 275.1041  | -10.85 | 0.000 | -3532.469            | -2435.385 |

Comparing this output with that produced by the [previous `regress` command](#), we see that they are almost, but not quite, identical. The parameter estimates and their associated statistics—the second half of the output—are identical. The overall summary statistics and the ANOVA table—the first half of the output—are different, however.

In the first case, the  $R^2$  is shown as 0.8992; here it is shown as 0.9938. In the first case, the  $F$  statistic is 316.54; now it is 3,802.03. The numerator degrees of freedom is different as well. In the first case, the numerator degrees of freedom is 2; now the degrees of freedom is 3. Which is correct?

Both are. Specifying the `hascons` option causes `regress` to adjust the ANOVA table and its associated statistics for the explanatory power of the constant. The regression in effect has a constant; it is just written in such a way that a separate constant is unnecessary. No such adjustment is made with the `noconstant` option.

□

### □ Technical note

When the `hascons` option is specified, `regress` checks to make sure that the model does in fact have a constant term. If `regress` cannot find a constant term, it automatically adds one. Fitting a model of weight on length and specifying the `hascons` option, we obtain

```
. regress weight length, hascons
note: option hascons false.
```

| Source   | SS         | df | MS         | Number of obs | = | 74     |

| length | 33.01988    | 1.333364  | 24.76  | 0.000 | 30.36187             | 35.67789  |
| _cons  | -3186.047   | 252.3113  | -12.63 | 0.000 | -3689.02             | -2683.073 |

Even though we specified `hascons`, `regress` included a constant, anyway. It also added a note to our output: “note: option `hascons` false”.

□

### □ Technical note

Even if the model specification effectively includes a constant term, we need not specify the `hascons` option. `regress` is always on the lookout for collinear variables and omits them from the model. For instance,

```
. regress weight length bn.foreign
note: 1.foreign omitted because of collinearity.
```

| Source   | SS         | df | MS         | Number of obs | = | 74     |

## Robust standard errors

`regress` with the `vce(robust)` option substitutes a robust variance matrix calculation for the conventional calculation, or if `vce(cluster clustvarlist)` is specified, allows relaxing the assumption of independence within groups. How this method works is explained in [\[U\] 20.22 Obtaining robust variance estimates](#). Below, we show how well this approach works.

### ▷ Example 5: Heteroskedasticity and robust standard errors

Specifying the `vce(robust)` option is equivalent to requesting White-corrected standard errors in the presence of heteroskedasticity. We use the automobile data and, in the process of looking at the energy efficiency of cars, analyze a variable with considerable heteroskedasticity.

We will examine the amount of energy—measured in gallons of gasoline—that the cars in the data need to move 1,000 pounds of their weight 100 miles. We are going to examine the relative efficiency of foreign and domestic cars.

```
. generate gpmw = ((1/mpg)/weight)*100*1000
. summarize gpmw
```

| Variable | Obs | Mean     | Std. dev. | Min     | Max     |
|----------|-----|----------|-----------|---------|---------|
| gpmw     | 74  | 1.682184 | .2426311  | 1.09553 | 2.30521 |

In these data, the engines consume between 1.10 and 2.31 gallons of gas to move 1,000 pounds of the car's weight 100 miles. If we ran a regression with conventional standard errors of `gpmw` on `foreign`, we would obtain

```
. regress gpmw foreign
```

| Source   | SS         | df | MS         | Number of obs | = | 74     |
|----------|------------|----|------------|---------------|---|--------|
| Model    | .936705572 | 1  | .936705572 | F(1, 72)      | = | 20.07  |
| Residual | 3.36079459 | 72 | .046677703 | Prob > F      | = | 0.0000 |
| Total    | 4.29750017 | 73 | .058869865 | R-squared     | = | 0.2180 |
|          |            |    |            | Adj R-squared | = | 0.2071 |
|          |            |    |            | Root MSE      | = | .21605 |

| gpmw    | Coefficient | Std. err. | t     | P> t  | [95% conf. interval] |
|---------|-------------|-----------|-------|-------|----------------------|
| foreign | .2461526    | .0549487  | 4.48  | 0.000 | .1366143 .3556909    |
| _cons   | 1.609004    | .0299608  | 53.70 | 0.000 | 1.549278 1.66873     |

`regress` with the `vce(robust)` option, on the other hand, reports

```
. regress gpmw foreign, vce(robust)
```

```
Linear regression Number of obs = 74
 F(1, 72) = 13.13
 Prob > F = 0.0005
 R-squared = 0.2180
 Root MSE = .21605
```

| gpmw    | Coefficient | Robust std. err. | t     | P> t  | [95% conf. interval] |
|---------|-------------|------------------|-------|-------|----------------------|
| foreign | .2461526    | .0679238         | 3.62  | 0.001 | .1107489 .3815563    |
| _cons   | 1.609004    | .0234535         | 68.60 | 0.000 | 1.56225 1.655758     |

The point estimates are the same (foreign cars need one-quarter gallon more gas), but the standard errors differ by roughly 20%. Conventional regression reports the 95% confidence interval as  $[0.14, 0.36]$ , whereas the robust standard errors make the interval  $[0.11, 0.38]$ .

Which is right? Notice that `gpmw` is a variable with considerable heteroskedasticity:

```
. tabulate foreign, summarize(gpmw)
```

| Car origin | Summary of gpmw |           | Freq. |
|------------|-----------------|-----------|-------|
|            | Mean            | Std. dev. |       |
| Domestic   | 1.6090039       | .16845182 | 52    |
| Foreign    | 1.8551565       | .30186861 | 22    |
| Total      | 1.6821844       | .24263113 | 74    |

Thus, here we favor the robust standard errors. In [U] 20.22 **Obtaining robust variance estimates**, we show another example using linear regression where it makes little difference whether we specify `vce(robust)`. The linear-regression assumptions were true, and we obtained nearly linear-regression results. The advantage of the robust estimate is that in neither case did we have to check assumptions.

◀

## □ Technical note

`regress` purposefully suppresses displaying the ANOVA table when `vce(robust)` is specified. This is done because the sums of squares are no longer appropriate for use in the usual hypothesis tests, even though computationally the sums of squares remain the same. In the nonrobust setting, the  $F$  statistic reported by `regress` is defined in terms of the sums of squares, as in ANOVA. When `vce(robust)` is specified, the ANOVA test is not valid, and the  $F$  statistic corresponds to a Wald test based on the robustly estimated variance matrix.

Some references give formulas for the  $F$  statistic in terms of either  $R^2$  or the root MSE. It is not appropriate to use those formulas for the  $F$  statistic with robust standard errors because the  $R^2$  and root MSE are calculated from the sums of squares. Moreover, the root MSE can no longer be used as an estimate for  $\sigma$  because there is no longer a single  $\sigma$  to estimate—the variance of the residual varies observation by observation. However, `regress` continues to report the  $R^2$  and the root MSE in the robust setting because those statistics are still usable in other settings. In particular,  $R^2$  remains valid as a goodness-of-fit statistic.

□

## ▷ Example 6: Alternative robust standard errors

The `vce(hc2)` and `vce(hc3)` options modify the robust variance calculation. In the context of linear regression without clustering, the idea behind the robust calculation is somehow to measure  $\sigma_j^2$ , the variance of the residual associated with the  $j$ th observation, and then to use that estimate to improve the estimated variance of  $\hat{\beta}$ . Because residuals have (theoretically and practically) mean 0, one estimate of  $\sigma_j^2$  is the observation's squared residual itself— $u_j^2$ . A finite-sample correction could improve that by multiplying  $u_j^2$  by  $n/(n-k)$ , and, as a matter of fact, `vce(robust)` uses  $\{n/(n-k)\}u_j^2$  as its estimate of the residual's variance.

vce(hc2) and vce(hc3) use alternative estimators of the observation-specific variances. For instance, if the residuals are homoskedastic, we can show that the expected value of  $u_j^2$  is  $\sigma^2(1 - h_{jj})$ , where  $h_{jj}$  is the  $j$ th diagonal element of the projection (hat) matrix.  $h_{jj}$  has average value  $k/n$ , so  $1 - h_{jj}$  has average value  $1 - k/n = (n - k)/n$ . Thus, the default robust estimator  $\hat{\sigma}_j = \{n/(n - k)\}u_j^2$  amounts to dividing  $u_j^2$  by the average of the expectation.

vce(hc2) divides  $u_j^2$  by  $1 - h_{jj}$  itself, so it should yield better estimates if the residuals really are homoskedastic. vce(hc3) divides  $u_j^2$  by  $(1 - h_{jj})^2$  and has no such clean interpretation. Davidson and MacKinnon (1993) show that  $u_j^2/(1 - h_{jj})^2$  approximates a more complicated estimator that they obtain by jackknifing (MacKinnon and White 1985). Angrist and Pischke (2009) also illustrate the relative merits of these adjustments.

Here are the results of refitting our efficiency model using vce(hc2) and vce(hc3):

```
. regress gpmw foreign, vce(hc2)
```

```
Linear regression Number of obs = 74
 F(1, 72) = 12.93
 Prob > F = 0.0006
 R-squared = 0.2180
 Root MSE = .21605
```

| gpmw    | Robust HC2  |           | t     | P> t  | [95% conf. interval] |          |
|---------|-------------|-----------|-------|-------|----------------------|----------|
|         | Coefficient | std. err. |       |       |                      |          |
| foreign | .2461526    | .0684669  | 3.60  | 0.001 | .1096662             | .3826389 |
| _cons   | 1.609004    | .0233601  | 68.88 | 0.000 | 1.562437             | 1.655571 |

```
. regress gpmw foreign, vce(hc3)
```

```
Linear regression Number of obs = 74
 F(1, 72) = 12.38
 Prob > F = 0.0008
 R-squared = 0.2180
 Root MSE = .21605
```

| gpmw    | Robust HC3  |           | t     | P> t  | [95% conf. interval] |          |

| foreign | .2461526    | .069969   | 3.52  | 0.001 | .1066719             | .3856332 |
| _cons   | 1.609004    | .023588   | 68.21 | 0.000 | 1.561982             | 1.656026 |

► Example 7: Standard errors for clustered data

The `vce(cluster clustvarlist)` and `vce(hc2 clustvar)` options relax the assumption of independence. Below, we have 28,534 observations on 4,711 women aged 14–46 years. Data were collected on these women between 1968 and 1988. We are going to fit a classic earnings model, and we begin by ignoring that the majority of the women in the dataset have multiple observations.

```
. use https://www.stata-press.com/data/r19/regsmpl, clear
(NLS women 14-26 in 1968)
. regress ln_wage age c.age#c.age tenure
```

| Source   | SS         | df     | MS         | Number of obs | = | 28,101  |
|----------|------------|--------|------------|---------------|---|---------|
| Model    | 1054.52501 | 3      | 351.508335 | F(3, 28097)   | = | 1842.45 |
| Residual | 5360.43962 | 28,097 | .190783344 | Prob > F      | = | 0.0000  |
|          |            |        |            | R-squared     | = | 0.1644  |
|          |            |        |            | Adj R-squared | = | 0.1643  |
| Total    | 6414.96462 | 28,100 | .228290556 | Root MSE      | = | .43679  |

| ln_wage     | Coefficient | Std. err. | t      | P> t  | [95% conf. interval] |           |
|-------------|-------------|-----------|--------|-------|----------------------|-----------|
| age         | .0752172    | .0034736  | 21.65  | 0.000 | .0684088             | .0820257  |
| c.age#c.age | -.0010851   | .0000575  | -18.86 | 0.000 | -.0011979            | -.0009724 |
| tenure      | .0390877    | .0007743  | 50.48  | 0.000 | .0375699             | .0406054  |
| _cons       | .3339821    | .0504413  | 6.62   | 0.000 | .2351148             | .4328495  |

The number of observations in our model is 28,101 because Stata drops observations that have a missing value for one or more of the variables in the model. We can be reasonably certain that the standard errors reported above are meaningless. Without a doubt, a woman with higher-than-average wages in one year typically has higher-than-average wages in other years, and so the residuals are not independent. One way to deal with this is to use cluster-robust standard errors. We do this by specifying `vce(cluster id)` or `vce(hc2 id)`, which treat only observations with different person *ids* as truly independent:

```
. regress ln_wage age c.age#c.age tenure, vce(cluster id)
```

Linear regression

|               |   |        |
|---------------|---|--------|
| Number of obs | = | 28,101 |
| F(3, 4698)    | = | 748.82 |
| Prob > F      | = | 0.0000 |
| R-squared     | = | 0.1644 |
| Root MSE      | = | .43679 |

(Std. err. adjusted for 4,699 clusters in *idcode*)

| ln_wage     | Coefficient | Robust std. err. | t      | P> t  | [95% conf. interval] |           |
|-------------|-------------|------------------|--------|-------|----------------------|-----------|
| age         | .0752172    | .0045711         | 16.45  | 0.000 | .0662557             | .0841788  |
| c.age#c.age | -.0010851   | .0000778         | -13.94 | 0.000 | -.0012377            | -.0009325 |
| tenure      | .0390877    | .0014425         | 27.10  | 0.000 | .0362596             | .0419157  |
| _cons       | .3339821    | .0641918         | 5.20   | 0.000 | .208136              | .4598282  |

For comparison, we focus on the tenure coefficient, which in economics jargon can be interpreted as the rate of return for keeping your job. The 95% confidence interval we previously estimated—an interval we do not believe—is [0.038, 0.041]. The robust interval is twice as wide, being [0.036, 0.042]. For this example, `vce(hc2 id)` gives standard errors similar to `vce(cluster id)`.

Another possible way to account for the lack of independence is to fit a random-effects model. Here is the random-effects result:

```
. xtreg ln_wage age c.age#c.age tenure, re
Random-effects GLS regression Number of obs = 28,101
Group variable: idcode Number of groups = 4,699
R-squared: Obs per group:
 Within = 0.1370 min = 1
 Between = 0.2154 avg = 6.0
 Overall = 0.1608 max = 15
 Wald chi2(3) = 4717.05
 Prob > chi2 = 0.0000
```

| ln_wage     | Coefficient                                 | Std. err. | z      | P> z  | [95% conf. interval] |          |
|-------------|---------------------------------------------|-----------|--------|-------|----------------------|----------|
| age         | .0568296                                    | .0026958  | 21.08  | 0.000 | .0515459             | .0621132 |
| c.age#c.age | -.0007566                                   | .0000447  | -16.93 | 0.000 | -.0008441            | -.000669 |
| tenure      | .0260135                                    | .0007477  | 34.79  | 0.000 | .0245481             | .0274789 |
| _cons       | .6136792                                    | .0394611  | 15.55  | 0.000 | .5363368             | .6910216 |
| sigma_u     | .33542449                                   |           |        |       |                      |          |
| sigma_e     | .29674679                                   |           |        |       |                      |          |
| rho         | .56095413 (fraction of variance due to u_i) |           |        |       |                      |          |

Robust regression estimated the 95% interval [0.036,0.042], and xtreg (see [XT] xtreg) estimates [0.025, 0.027]. Which is better? The random-effects regression estimator assumes a lot. We can check some of these assumptions by performing a Hausman test. Using estimates (see [R] estimates store), we store the random-effects estimation results, and then we run the required fixed-effects regression to perform the test.

```
. estimates store random
. xtreg ln_wage age c.age#c.age tenure, fe
Fixed-effects (within) regression Number of obs = 28,101
Group variable: idcode Number of groups = 4,699
R-squared: Obs per group:
 Within = 0.1375 min = 1
 Between = 0.2066 avg = 6.0
 Overall = 0.1568 max = 15
 F(3, 23399) = 1243.00
 Prob > F = 0.0000
```

| ln_wage     | Coefficient                                | Std. err. | t      | P> t  | [95% conf. interval] |           |
|-------------|--------------------------------------------|-----------|--------|-------|----------------------|-----------|
| age         | .0522751                                   | .002783   | 18.78  | 0.000 | .0468202             | .05773    |

$$= 336.62$$

$$\text{Prob} > \text{chi2} = 0.0000$$

The Hausman test casts grave suspicions on the random-effects model we just fit, so we should be careful in interpreting those results.

Meanwhile, our robust regression results still stand, as long as we are careful about the interpretation. The correct interpretation is that, if the data collection were repeated (on women sampled the same way as in the original sample), and if we were to refit the model, 95% of the time we would expect the estimated coefficient on tenure to be in the range [0.036, 0.042].

Even with robust regression, we must be careful about going beyond that statement. Here the Hausman test is probably picking up something that differs within and between person, which would cast doubt on our robust regression model in terms of interpreting [0.036, 0.042] to contain the rate of return for keeping a job, economywide, for all women, without exception.

Let's take this example a bit further by also recognizing workers with the same education level, grade, may be more alike than those with different education levels. Here we will use multiway clustering (Cameron, Gelbach, and Miller 2008) to account for correlations within individuals over years and within education levels, assuming observations from different people and different education level are independent.

```
. regress ln_wage age c.age#c.age tenure, vce(cluster idcode grade) clustertable
Linear regression Number of obs = 28,099
Clusters per comb.: Cluster comb. = 3
 min = 19 F(3, 18) = 247.23
 avg = 3,138 Prob > F = 0.0000
 max = 4,697 R-squared = 0.1644
 Adj R-squared = 0.1644
 Root MSE = 0.4368
```

| Cluster combination | Clusters per comb. |

| _cons       | .334631     | .2769961         | 1.21  | 0.243 | -.2473162            | .9165782  |

Cluster combinations formed by **idcode** and **grade**.

With the `clustertable` option, the output includes a table that describes the cluster combinations and reports the number of levels for each cluster combination. We clustered on two variables, so there are three cluster combinations, and, in general, for  $p$  cluster variables, there are  $p^2 - 1$  cluster combinations. The  $t$ -statistic degrees of freedom is chosen from the cluster combination that has the smallest number of levels. In this case, we have  $19 - 1 = 18$  degrees of freedom, and the Wald test  $F$  statistic, computed from the cluster-robust VCE, has a denominator degrees of freedom of 18. The 95% confidence interval for `tenure` increases slightly to  $[0.035, 0.043]$ . Yet the confidence intervals here are not strictly comparable; this model is fit to two fewer observations because of missing values in the cluster variable `grade`, and we conjecture that observations are correlated within `grade`.

## Weighted regression

regress can perform weighted and unweighted regression. We indicate the weight by specifying the `[weight]` qualifier.

### ▷ Example 8: Using means as regression variables

We have census data recording the deathrate (`drate`) and median age (`medage`) for each state. The data also record the region of the country in which each state is located and the overall population of the state:

```
. use https://www.stata-press.com/data/r19/census9
(1980 Census data by state)
. describe
Contains data from https://www.stata-press.com/data/r19/census9.dta
Observations: 50 1980 Census data by state
Variables: 6 2 Dec 2024 15:22
```

| Variable name | Storage type | Display format | Value label | Variable label                |
|---------------|--------------|----------------|-------------|-------------------------------|
| state         | str13        | %-13s          |             | State                         |
| state2        | str2         | %-2s           |             | Two-letter state abbreviation |
| drate         | int          | %9.0g          |             | Deathrate                     |
| pop           | long         | %12.0gc        |             | Population                    |
| medage        | float        | %9.2f          |             | Median age                    |
| region        | byte         | %-8.0g         | cenreg      | Census region                 |

Sorted by:

We can use factor variables to include dummy variables for region. Because the variables in the regression reflect means rather than individual observations, the appropriate method of estimation is analytically weighted least squares (Davidson and MacKinnon 2004, 261–262), where the weight is total population:

```
. regress drate medage i.region [aweight=pop]
(sum of wgt is 225,907,472)
```

| Source   | SS         | df | MS         | Number of obs | = | 50     |
|----------|------------|----|------------|---------------|---|--------|

| _cons   | -39.14727   | 17.23613  | -2.27 | 0.028 | -73.86262            | -4.431915 |

To weight the regression by population, we added the qualifier `[aweight=pop]` to the end of the `regress` command. Stata informed us that the sum of the weight is  $2.2591 \times 10^8$ ; there were approximately 226 million people residing in the United States according to our 1980 data.

In the weighted regression, we see that the coefficient on West is statistically significant but that the coefficients on N Cntrl and South are not. We use `testparm` to test the joint significance of the `region` variable. Because we fit a weighted regression, `testparm` uses the appropriately weighted variance–covariance matrix.

```
. testparm i.region
(1) 2.region = 0
(2) 3.region = 0
(3) 4.region = 0
 F(3, 45) = 9.84
 Prob > F = 0.0000
```

The results indicate that the region variables are jointly significant. Note that we could have performed this same test by typing `contrast region`. You may prefer to use the `contrast` command because, in addition to the joint test, you can perform other tests such as comparisons of each region’s mean to the grand mean; see [R] [contrast](#) for more information. ◀

`regress` also accepts frequency weights (`fweights`). Frequency weights are appropriate when the data do not reflect cell means but instead represent replicated observations. Specifying `aweight` or `fweight` will not change the parameter estimates, but it will change the corresponding significance levels.

For instance, if we specified [`fweight=pop`] in the weighted regression [example](#) above—which would be statistically incorrect—Stata would treat the data as if the data represented 226 million independent observations on death rates and median age. The data most certainly do not represent that—they represent 50 observations on state averages.

With `aweight`, Stata treats the number of observations on the process as the number of observations in the data. When we specify `fweights`, Stata treats the number of observations as if it were equal to the sum of the weights; see [Methods and formulas](#) below.

## □ Technical note

A frequent inquiry sent to StataCorp Technical Services is to describe the effect of specifying [`aweight=exp`] with `regress` in terms of transformation of the dependent and independent variables. The mechanical answer is that typing

```
. regress y x1 x2 [aweight=n]
```

is equivalent to fitting the model

$$y_j \sqrt{n_j} = \beta_0 \sqrt{n_j} + \beta_1 x_{1j} \sqrt{n_j} + \beta_2 x_{2j} \sqrt{n_j} + u_j \sqrt{n_j}$$

This regression will reproduce the coefficients and covariance matrix produced by the `aweight`d regression. The mean squared errors (estimates of the variance of the residuals) will, however, be different. The transformed regression reports  $s_t^2$ , an estimate of  $\text{Var}(u_j \sqrt{n_j})$ . The `aweight`d regression reports  $s_a^2$ , an estimate of  $\text{Var}(u_j \sqrt{n_j} \sqrt{N / \sum_k n_k})$ , where  $N$  is the number of observations. Thus,

$$s_a^2 = \frac{N}{\sum_k n_k} s_t^2 = \frac{s_t^2}{\bar{n}} \quad (1)$$

The logic for this adjustment is as follows: Consider the model

$$y = \beta_0 + \beta_1 x_1 + \beta_2 x_2 + u$$

Assume that, were this model fit on individuals,  $\text{Var}(u) = \sigma_u^2$ , a constant. Assume that individual data are not available; what is available are averages  $(\bar{y}_j, \bar{x}_{1j}, \bar{x}_{2j})$  for  $j = 1, \dots, N$ , and each average is calculated over  $n_j$  observations. Then it is still true that

$$\bar{y}_j = \beta_0 + \beta_1 \bar{x}_{1j} + \beta_2 \bar{x}_{2j} + \bar{u}_j$$

where  $\bar{u}_j$  is the average of  $n_j$  mean 0, variance  $\sigma_u^2$  deviates and has variance  $\sigma_u^2/n_j$ . Thus, multiplying through by  $\sqrt{n_j}$  produces

$$\bar{y}_j \sqrt{n_j} = \beta_0 \sqrt{n_j} + \beta_1 \bar{x}_{1j} \sqrt{n_j} + \beta_2 \bar{x}_{2j} \sqrt{n_j} + \bar{u}_j \sqrt{n_j}$$

and  $\text{Var}(\bar{u}_j \sqrt{n_j}) = \sigma_u^2$ . The mean squared error,  $s_t^2$ , reported by fitting this transformed regression is an estimate of  $\sigma_u^2$ . The coefficients and covariance matrix could also be obtained by `aweighted regress`. The only difference would be in the reported mean squared error, which from (1) is  $\sigma_u^2/\bar{n}$ . On average, each observation in the data reflects the averages calculated over  $\bar{n} = \sum_k n_k/N$  individuals, and thus this reported mean squared error is the average variance of an observation in the dataset. We can retrieve the estimate of  $\sigma_u^2$  by multiplying the reported mean squared error by  $\bar{n}$ .

More generally, `aweights` are used to solve general heteroskedasticity problems. In these cases, we have the model

$$y_j = \beta_0 + \beta_1 x_{1j} + \beta_2 x_{2j} + u_j$$

and the variance of  $u_j$  is thought to be proportional to  $a_j$ . If the variance is proportional to  $a_j$ , it is also proportional to  $\alpha a_j$ , where  $\alpha$  is any positive constant. Not quite arbitrarily, but with no loss of generality, we could choose  $\alpha = \sum_k (1/a_k)/N$ , the average value of the inverse of  $a_j$ . We can then write  $\text{Var}(u_j) = k\alpha a_j \sigma^2$ , where  $k$  is the constant of proportionality that is no longer a function of the scale of the weights.

Dividing this regression through by the  $\sqrt{a_j}$ ,

$$y_j/\sqrt{a_j} = \beta_0/\sqrt{a_j} + \beta_1 x_{1j}/\sqrt{a_j} + \beta_2 x_{2j}/\sqrt{a_j} + u_j/\sqrt{a_j}$$

produces a model with  $\text{Var}(u_j/\sqrt{a_j}) = k\alpha\sigma^2$ , which is the constant part of  $\text{Var}(u_j)$ . This variance is a function of  $\alpha$ , the average of the reciprocal weights; if the weights are scaled arbitrarily, then so is this variance.

We can also fit this model by typing

```
. regress y x1 x2 [aweight=1/a]
```

This input will produce the same estimates of the coefficients and covariance matrix; the reported mean squared error is, from (1),  $\{N/\sum_k (1/a_k)\}k\alpha\sigma^2 = k\sigma^2$ . This variance is independent of the scale of  $a_j$ .

Note that results stored in `r()` are updated when the command is replayed and will be replaced when any `r-class` command is run after the estimation command.

## Methods and formulas

Methods and formulas are presented under the following headings:

*Coefficient estimation and ANOVA table*  
*Weighted regression*  
*A general notation for the robust variance calculation*  
*Robust calculation for regress*

### Coefficient estimation and ANOVA table

Variables printed in lowercase and not boldfaced (for example,  $x$ ) are scalars. Variables printed in lowercase and boldfaced (for example,  $\mathbf{x}$ ) are column vectors. Variables printed in uppercase and boldfaced (for example,  $\mathbf{X}$ ) are matrices.

Let  $\mathbf{X}$  denote the matrix of observations on the right-hand-side variables,  $\mathbf{y}$  the vector of observations on the left-hand-side variables. Define  $\mathbf{A}$  as  $\mathbf{X}'\mathbf{X}$  and  $\mathbf{a}$  as  $\mathbf{X}'\mathbf{y}$ . The coefficient vector  $\mathbf{b}$  is defined as  $\mathbf{A}^{-1}\mathbf{a}$ . Although not shown in the notation, unless `hascons` is specified,  $\mathbf{A}$  and  $\mathbf{a}$  are accumulated in deviation form and the constant is calculated separately. This comment applies to all statistics listed below.

The total sum of squares, TSS, equals  $\mathbf{y}'\mathbf{y}$  if there is no intercept and  $\mathbf{y}'\mathbf{y} - \{(\mathbf{1}'\mathbf{y})^2/n\}$  otherwise. The degrees of freedom is  $n - c$ , where  $n$  is the number of observations and  $c = 1$  if there is a constant in the regression and 0 otherwise.

The residual sum of squares, RSS, is defined as  $(\mathbf{y} - \mathbf{X}\mathbf{b})'(\mathbf{y} - \mathbf{X}\mathbf{b})$ . The degrees of freedom is  $n - k$ , where  $n$  is the number of observations and  $k$  is the number of right-hand-side variables (including the constant).

The model sum of squares, MSS, equals  $\text{TSS} - \text{RSS}$ . The degrees of freedom is  $k - c$ .

The mean squared error,  $s^2$ , is defined as  $\text{RSS}/(n - k)$ . The root mean squared error is  $s$ , its square root.

The  $F$  statistic with  $k - c$  and  $n - k$  degrees of freedom is defined as

$$F = \frac{\text{MSS}}{(k - c)s^2}$$

The  $R^2$  is defined as  $R^2 = 1 - \text{RSS}/\text{TSS}$ .

The adjusted  $R^2$  is defined as  $R_a^2 = 1 - (1 - R^2)(n - c)/(n - k)$ .

The conventional estimate of variance is  $s^2\mathbf{A}^{-1}$ . The calculation of variance estimates when robust variance estimates are specified is described below.

### Weighted regression

Let  $\mathbf{v}$  be a column vector of weights specified by the user. Let  $\mathbf{w}$  be a column vector of normalized weights,  $\mathbf{w} = \{\mathbf{v}/(\mathbf{1}'\mathbf{v})\}(\mathbf{1}'\mathbf{1})$ . For `fweights`,  $\mathbf{w} = \mathbf{v}$ . For historical reasons, `iweights` are treated like `fweights` when robust standard errors are not specified. Instead, when `vce(robust)`, `vce(cluster clustvarlist)`, `vce(hc2)`, or `vce(hc3)` is specified, `iweights` are treated like `aweights`.

If the user specifies weights, the number of observations,  $n$ , in the above formulas is defined as  $\mathbf{1}'\mathbf{w}$ . For `iweights`, this is truncated to an integer. The sum of the weights is  $\mathbf{1}'\mathbf{v}$ .  $\mathbf{X}'\mathbf{X}$ ,  $\mathbf{X}'\mathbf{y}$ , and  $\mathbf{y}'\mathbf{y}$  are replaced in the above formulas by  $\mathbf{X}'\mathbf{D}\mathbf{X}$ ,  $\mathbf{X}'\mathbf{D}\mathbf{y}$ , and  $\mathbf{y}'\mathbf{D}\mathbf{y}$ , respectively, where  $\mathbf{D}$  is a diagonal matrix whose diagonal elements are the elements of  $\mathbf{w}$ .

## A general notation for the robust variance calculation

Put aside all context of linear regression and the notation that goes with it—we will return to it. First, we are going to establish a notation for describing robust variance calculations.

The calculation formula for the robust variance calculation is

$$\widehat{\mathbf{v}} = q_c \widehat{\mathbf{V}} \left( \sum_{k=1}^M \mathbf{u}_k^{(G)'} \mathbf{u}_k^{(G)} \right) \widehat{\mathbf{V}}$$

where

$$\mathbf{u}_k^{(G)} = \sum_{j \in G_k} w_j \mathbf{u}_j$$

$G_1, G_2, \dots, G_M$  are the clusters specified by `vce(cluster clustvarlist)` when `clustvarlist` contains only one variable, and  $w_j$  are the user-specified weights, normalized if `aweights` or `pweights` are specified and equal to 1 if no weights are specified.

For `fweights` without clusters, the variance formula is

$$\widehat{\mathbf{v}} = q_c \widehat{\mathbf{V}} \left( \sum_{j=1}^N w_j \mathbf{u}_j' \mathbf{u}_j \right) \widehat{\mathbf{V}}$$

which is the same as expanding the dataset and making the calculation on the unweighted data.

If `vce(cluster clustvarlist)` is not specified,  $M = N$ , and each cluster contains 1 observation. The inputs into this calculation are

- $\widehat{\mathbf{V}}$ , which is typically a conventionally calculated variance matrix;
- $\mathbf{u}_j$ ,  $j = 1, \dots, N$ , a row vector of scores; and
- $q_c$ , a constant finite-sample adjustment.

Thus, we can now describe how estimators apply the robust calculation formula by defining  $\widehat{\mathbf{V}}$ ,  $\mathbf{u}_j$ , and  $q_c$ .

Two definitions are popular enough for  $q_c$  to deserve a name. The regression-like formula for  $q_c$  (Fuller et al. 1986) is

$$q_c = \frac{N-1}{N-k} \frac{M}{M-1}$$

where  $M$  is the number of clusters and  $N$  is the number of observations. For weights,  $N$  refers to the sum of the weights if weights are frequency weights and the number of observations in the dataset (ignoring weights) in all other cases. Also note that, weighted or not,  $M = N$  when `vce(cluster clustvarlist)` is not specified, and then  $q_c = N/(N-k)$ .

The asymptotic-like formula for  $q_c$  is

$$q_c = \frac{M}{M-1}$$

where  $M = N$  if `vce(cluster clustvarlist)` is not specified.

See [U] 20.22 **Obtaining robust variance estimates** and [P] **\_robust** for a discussion of the robust variance estimator and a development of these formulas.

## Robust calculation for regress

For `regress`,  $\widehat{\mathbf{V}} = \mathbf{A}^{-1}$ . The other terms are `vce(robust)`, but not `vce(hc2)` or `vce(hc3)`,

$$\mathbf{u}_j = (y_j - \mathbf{x}_j \mathbf{b}) \mathbf{x}_j$$

and  $q_c$  is given by its regression-like definition. `vce(hc2)`,

$$\mathbf{u}_j = \frac{1}{\sqrt{1 - h_{jj}}} (y_j - \mathbf{x}_j \mathbf{b}) \mathbf{x}_j$$

where  $q_c = 1$  and  $h_{jj} = \mathbf{x}_j (\mathbf{X}' \mathbf{X})^{-1} \mathbf{x}_j'$ . `vce(hc3)`,

$$\mathbf{u}_j = \frac{1}{1 - h_{jj}} (y_j - \mathbf{x}_j \mathbf{b}) \mathbf{x}_j$$

where  $q_c = 1$  and  $h_{jj} = \mathbf{x}_j (\mathbf{X}' \mathbf{X})^{-1} \mathbf{x}_j'$ . `vce(hc2 clustvar)`,

$$\mathbf{u}_j = (\mathbf{y}_j - \mathbf{X}_j \mathbf{b})' (\mathbf{I}_{G_j} - \mathbf{H}_{jj})^{-\frac{1}{2}} \mathbf{X}_j$$

where  $q_c = 1$ ,  $\mathbf{H}_{jj} = \mathbf{X}_j (\mathbf{X}' \mathbf{X})^{-1} \mathbf{X}_j'$  for cluster  $j$  of size  $G_j$ ,  $G_j \times k$  data matrix  $\mathbf{X}_j$ , and  $G_j \times 1$  vector  $\mathbf{y}_j$ .  $(\mathbf{I}_{G_j} - \mathbf{H}_{jj})^{-\frac{1}{2}}$  is the inverse of the symmetric square root of  $(\mathbf{I}_{G_j} - \mathbf{H}_{jj})$  (Bell and McCaffrey 2002).

`vce(hc2 [clustvar], dfadjust)` directs `regress` to compute the adjusted degrees of freedom described by Imbens and Kolesár (2016). Define the  $N \times M$  matrix  $\mathbf{G}$  such that the  $j$ th column is

$$(\mathbf{I}_N - \mathbf{H})_j' (\mathbf{I}_{G_j} - \mathbf{H}_{jj})^{-\frac{1}{2}} \mathbf{X}_j (\mathbf{X}' \mathbf{X})^{-1} \mathbf{e}_l$$

where  $j = 1, \dots, M$ ,  $\mathbf{e}_l$  is a unary vector for the  $l$ th regressor,  $l = 1, \dots, k$ , and  $(\mathbf{I}_N - \mathbf{H})_j$  is the  $G_j \times N$  subset of the  $N \times N$  matrix  $(\mathbf{I}_N - \mathbf{H})$  for cluster  $j$ . The Bell and McCaffrey (2002) adjusted degrees of freedom for the  $l$ th regressor is

$$\begin{aligned} K_l &= \frac{\text{tr}(\mathbf{G}' \mathbf{G})^2}{\text{tr}((\mathbf{G}' \mathbf{G})^2)} \\ &= \frac{(\sum_{i=1}^M \lambda_i)^2}{\sum_{i=1}^M \lambda_i^2} \end{aligned}$$

where  $\text{tr}(\cdot)$  is the trace function and  $\lambda_i$  are the eigenvalues of  $\mathbf{G}' \mathbf{G}$ .

When  $M$  is large, or when there are no clusters and  $M = N$ , computing the eigenvalues can be time consuming. We define

$$\begin{aligned} \mathbf{a}_j &= (\mathbf{I}_{G_j} - \mathbf{H}_{jj})^{-\frac{1}{2}} \mathbf{X}_j (\mathbf{X}'\mathbf{X})^{-1} \mathbf{e}_{L,k} \\ \mathbf{b}_j &= \mathbf{H}_j \mathbf{a}_j \\ \mathbf{A} &= (\mathbf{a}'_1 \mathbf{a}_1, \dots, \mathbf{a}'_M \mathbf{a}_M)' = (A_1, A_2, \dots, A_M)' \\ \mathbf{B} &= (\mathbf{b}_1, \dots, \mathbf{b}_M) = \begin{pmatrix} B_{1,1} & B_{1,2} & \cdots & B_{1,M} \\ \vdots & \vdots & \ddots & \vdots \\ B_{N,1} & B_{N,2} & \cdots & B_{N,M} \end{pmatrix} \end{aligned}$$

for  $j = 1, \dots, M$  and  $\mathbf{H}_j = \mathbf{X} (\mathbf{X}'\mathbf{X})^{-1} \mathbf{X}'_j$ . Then  $\mathbf{G}'\mathbf{G} = \text{diag}(\mathbf{A}) - \mathbf{B}'\mathbf{B}$  (Kolesár 2023).

We now express the adjusted degrees of freedom as

$$K_l = \frac{\left( \sum_{j=1}^M A_j - \sum_{i=1}^N \sum_{j=1}^M B_{ij}^2 \right)^2}{\sum_{j=1}^M A_j^2 - 2 \sum_{j=1}^M A_j \sum_{i=1}^N B_{ij}^2 + \sum_{j_1=1}^M \sum_{j_2=1}^M (\mathbf{b}'_{j_1} \mathbf{b}_{j_2})^2}$$

which can be computed efficiently in Mata and using QR decomposition. For example, by decomposing  $\mathbf{X} = \mathbf{QR}$ , where  $\mathbf{Q}$  is  $n \times k$  and orthonormal and  $\mathbf{R}$  is  $k \times k$  and upper triangular, we can rewrite the matrix  $\mathbf{B}$  so that it has dimension  $k \times M$  instead of  $N \times M$ .

When weights are specified, we use the weighted covariate matrix  $\tilde{\mathbf{X}} = \text{diag}(\mathbf{w})^{\frac{1}{2}} \mathbf{X}$  and its corresponding projection matrix  $\tilde{\mathbf{H}}$ , as well as the cluster covariance matrices  $\tilde{\mathbf{X}}_j$ , their projection matrices  $\tilde{\mathbf{H}}_{jj}$ , and weighted residuals  $\tilde{\epsilon}_j = \text{diag}(\mathbf{w}_j)^{\frac{1}{2}} \hat{\epsilon}_j$ . When frequency weights are specified without clusters, we substitute  $1/\sqrt{1-h_{jj}}$  with  $1/\sqrt{w_j - \tilde{h}_{jj}}$ , where  $j = 1, \dots, N$ . Also, when there are no clusters, the weights are included in the degrees-of-freedom algebra

$$K_l = \frac{\left( \sum_{j=1}^N w_j A_j - \sum_{i=1}^k \sum_{j=1}^N B_{ij}^2 \right)^2}{\sum_{j=1}^N w_j A_j^2 - 2 \sum_{j=1}^N A_j \sum_{i=1}^k B_{ij}^2 + \sum_{j_1=1}^N \sum_{j_2=1}^N (\mathbf{b}'_{j_1} \mathbf{b}_{j_2})^2}$$

Here we substituted  $k$  for  $N$  in the row dimension of  $\mathbf{B}$  as it is when using QR decomposition to perform the computations.

With weights, the `vce(hc2 clustvar)` computation discussed above is modified to

$$\begin{aligned} \mathbf{u}_j &= \left( \text{diag}(\mathbf{w}_j)^{\frac{1}{2}} (\mathbf{y}_j - \mathbf{X}_j \mathbf{b}) \right)' (\mathbf{I}_{G_j} - \tilde{\mathbf{H}}_{jj})^{-\frac{1}{2}} \tilde{\mathbf{X}}_j \\ &= (\tilde{\mathbf{y}}_j - \tilde{\mathbf{X}}_j \mathbf{b})' (\mathbf{I}_{G_j} - \tilde{\mathbf{H}}_{jj})^{-\frac{1}{2}} \tilde{\mathbf{X}}_j \end{aligned}$$

## Multiway clustering

When you type `vce(cluster clustvarlist)` with more than one variable, the variance–covariance estimator uses multiway cluster–robust variance estimation. This is carried out by estimating the robust VCE for all combinations of the specified cluster variables and summing. For  $p$  cluster variables, there will be  $P = 2^p - 1$  cluster variable combinations. Let  $\mathbf{V}_i$  be the  $i$ th robust VCE,  $i = 1, \dots, P$ . Define  $S_j$ ,  $j = 1, \dots, p$ , as the set of indices  $i$  involving  $j$  cluster variables. The size, or cardinality, of  $S_j$  is  $|S_j| = \binom{p}{j}$  and  $\sum_{j=1}^p \binom{p}{j} = 2^p - 1$ . For example, for  $p = 4$ ,  $|S_1| = \binom{4}{1} = 4$ ,  $|S_2| = \binom{4}{2} = 6$ ,  $|S_3| = \binom{4}{3} = 4$ , and  $|S_4| = \binom{4}{4} = 1$ . The multiway cluster–robust VCE is then

$$\mathbf{V}_* = \sum_{j=1}^p (-1)^{j-1} \sum_{i \in S_j} \mathbf{V}_i$$

You are more likely to cluster on two or, maybe, three variables. In the case of two cluster variables, the computation would be

$$\mathbf{V}_* = V_1 + V_2 - V_{12}$$

where  $V_1$  corresponds to the variance–covariance computation clustering at the level of the first cluster,  $V_2$  corresponds to the second level, and  $V_{12}$  corresponds to the variance–covariance computation for the group formed by the intersection of both clustering levels.

An eigendecomposition on  $\mathbf{V}_*$  ensures the matrix to be positive semidefinite. Let the columns of matrix  $\mathbf{U}$  contain the eigenvectors of  $\mathbf{V}_*$  and the vector contain  $\mathbf{u}$ , its eigenvalues. If  $\mathbf{V}_*$  is not positive definite, some of the elements of  $\mathbf{u}$  will be less than 0. Let  $\mathbf{u}_+$  contain all the nonnegative elements of  $\mathbf{u}$  and zeros where  $u_i < 0$ . The matrix  $\mathbf{V}_+ = \mathbf{U} \cdot \text{diag}(\mathbf{u}_+) \cdot \mathbf{U}'$  will then be positive semidefinite.

## Acknowledgments

The robust estimate of variance was first implemented in Stata by Mead Over of the Center for Global Development, Dean Jolliffe of the World Bank, and Andrew Foster of the Department of Economics at Brown University (Over, Jolliffe, and Foster 1996).

The history of regression is long and complicated: the books by [Stigler \(1986\)](#) and [Hald \(1998\)](#) are devoted largely to the story. Legendre published first on least squares in 1805. Gauss published later in 1809, but he had the idea earlier. Gauss, and especially Laplace, tied least squares to a normal errors assumption. The idea of the normal distribution can itself be traced back to De Moivre in 1733. Laplace discussed a variety of other estimation methods and error assumptions over his long career, while linear models long predate either innovation. Most of this work was linked to problems in astronomy and geodesy.

A second wave of ideas started when Galton used graphical and descriptive methods on data bearing on heredity to develop what he called regression. His term reflects the common phenomenon that characteristics of offspring are positively correlated with those of parents but with regression slope such that offspring “regress toward the mean”. Galton’s work was rather intuitive: contributions from Pearson, Edgeworth, Yule, and others introduced more formal machinery, developed related ideas on correlation, and extended application into the biological and social sciences. So most of the elements of regression as we know it were in place by 1900.

Pierre-Simon Laplace (1749–1827) was born in Normandy and was early recognized as a remarkable mathematician. He weathered a changing political climate well enough to rise to Minister of the Interior under Napoleon in 1799 (although only for 6 weeks) and to be made a Marquis by Louis XVIII in 1817. He made many contributions to mathematics and physics, his two main interests being theoretical astronomy and probability theory (including statistics). Laplace transforms are named for him.

[Adrien-Marie Legendre \(1752–1833\)](#) was born in Paris (or possibly in Toulouse) and educated in mathematics and physics. He worked in number theory, geometry, differential equations, calculus, function theory, applied mathematics, and geodesy. The Legendre polynomials are named for him. His main contribution to statistics is as one of the discoverers of least squares. He died in poverty, having refused to bow to political pressures.

[Johann Carl Friedrich Gauss \(1777–1855\)](#) was born in Braunschweig (Brunswick), now in Germany. He studied there and at Göttingen. His doctoral dissertation at the University of Helmstedt was a discussion of the fundamental theorem of algebra. He made many fundamental contributions to geometry, number theory, algebra, real analysis, differential equations, numerical analysis, statistics, astronomy, optics, geodesy, mechanics, and magnetism. An outstanding genius, Gauss worked mostly in isolation in Göttingen.

[Francis Galton \(1822–1911\)](#) was born in Birmingham, England, into a well-to-do family with many connections: he and Charles Darwin were first cousins. After an unsuccessful foray into medicine, he became independently wealthy at the death of his father. Galton traveled widely in Europe, the Middle East, and Africa, and became celebrated as an explorer and geographer. His pioneering work on weather maps helped in the identification of anticyclones, which he named. From about 1865, most of his work was centered on quantitative problems in biology, anthropology, and psychology. In a sense, Galton (re)invented regression, and he certainly named it. Galton also promoted the normal distribution, correlation approaches, and the use of median and selected quantiles as descriptive statistics. He was knighted in 1909.

## Postestimation commands

The following postestimation commands are of special interest after `regress`:

| Command                     | Description                                                      |
|-----------------------------|------------------------------------------------------------------|
| <code>dfbeta</code>         | DFBETA influence statistics                                      |
| <code>estat hettest</code>  | tests for heteroskedasticity                                     |
| <code>estat imtest</code>   | information matrix test                                          |
| <code>estat ovtest</code>   | Ramsey regression specification-error test for omitted variables |
| <code>estat szroeter</code> | Szroeter's rank test for heteroskedasticity                      |
| <code>estat vif</code>      | variance inflation factors for the independent variables         |
| <code>estat esize</code>    | $\eta^2$ , $\varepsilon^2$ , and $\omega^2$ effect sizes         |
| <code>estat moran</code>    | Moran's test of residual correlation with nearby residuals       |
| <code>lassogof</code>       | calculate goodness-of-fit predictions                            |

These commands are not appropriate with `svy` estimation results.

The following standard postestimation commands are also available:

| Command                      | Description                                                                                                                             |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <code>contrast</code>        | contrasts and ANOVA-style joint tests of parameters                                                                                     |
| <code>estat ic</code>        | Akaike's, consistent Akaike's, corrected Akaike's, and Schwarz's Bayesian information criteria (AIC, CAIC, AICc, and BIC, respectively) |
| <code>estat summarize</code> | summary statistics for the estimation sample                                                                                            |
| <code>estat vce</code>       | variance–covariance matrix of the estimators (VCE)                                                                                      |
| <code>estat (svy)</code>     | postestimation statistics for survey data                                                                                               |
| <code>estimates</code>       | cataloging estimation results                                                                                                           |
| <code>etable</code>          | table of estimation results                                                                                                             |
| * <code>forecast</code>      | dynamic forecasts and simulations                                                                                                       |
| * <code>hausman</code>       | Hausman's specification test                                                                                                            |
| <code>lincom</code>          | point estimates, standard errors, testing, and inference for linear combinations of parameters                                          |
| <code>linktest</code>        | link test for model specification                                                                                                       |
| * <code>lrtest</code>        | likelihood-ratio test                                                                                                                   |
| <code>margins</code>         | marginal means, predictive margins, marginal effects, and average marginal effects                                                      |
| <code>marginsplot</code>     | graph the results from margins (profile plots, interaction plots, etc.)                                                                 |
| <code>nlcom</code>           | point estimates, standard errors, testing, and inference for nonlinear combinations of parameters                                       |
| <code>predict</code>         | predictions and their SEs, leverage statistics, distance statistics, etc.                                                               |
| <code>predictnl</code>       | point estimates, standard errors, testing, and inference for generalized predictions                                                    |
| <code>pwcompare</code>       | pairwise comparisons of parameters                                                                                                      |
| <code>suest</code>           | seemingly unrelated estimation                                                                                                          |
| <code>test</code>            | Wald tests of simple and composite linear hypotheses                                                                                    |
| <code>testnl</code>          | Wald tests of nonlinear hypotheses                                                                                                      |

\*`forecast`, `hausman`, and `lrtest` are not appropriate with `svy` estimation results. `forecast` is also not appropriate with `mi` estimation results.

## Predictions

### Description for predict

`predict` creates a new variable containing predictions such as linear predictions, residuals, standardized residuals, Studentized residuals, Cook's distance, leverage, probabilities, expected values, DFBETAS for *varname*, standard errors, COVRATIOS, DFITS, and Welsch distances.

### Menu for predict

Statistics > Postestimation

### Syntax for predict

```
predict [type] newvar [if] [in] [, statistic]
```

| <i>statistic</i>               | Description                                 |
|--------------------------------|---------------------------------------------|
| Main                           |                                             |
| <code>xb</code>                | linear prediction; the default              |
| <code>residuals</code>         | residuals                                   |
| <code>score</code>             | score; equivalent to <code>residuals</code> |
| <code>rstandard</code>         | standardized residuals                      |
| <code>rstudent</code>          | Studentized (jackknifed) residuals          |
| <code>cooksd</code>            | Cook's distance                             |
| <code>leverage   hat</code>    | leverage (diagonal elements of hat matrix)  |
| <code>pr(a,b)</code>           | $\Pr(y_j   a < y_j < b)$                    |
| <code>e(a,b)</code>            | $E(y_j   a < y_j < b)$                      |
| <code>ystar(a,b)</code>        | $E(y_j^*), y_j^* = \max\{a, \min(y_j, b)\}$ |
| * <code>dfbeta(varname)</code> | DFBETA for <i>varname</i>                   |
| <code>stdp</code>              | standard error of the linear prediction     |
| <code>stdf</code>              | standard error of the forecast              |
| <code>stdr</code>              | standard error of the residual              |
| * <code>covratio</code>        | COVRATIO                                    |
| * <code>dfits</code>           | DFITS                                       |
| * <code>welsch</code>          | Welsch distance                             |

Unstarred statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample. Starred statistics are calculated only for the estimation sample, even when `if e(sample)` is not specified.

`rstandard`, `rstudent`, `cooksd`, `leverage`, `dfbeta()`, `stdf`, `stdr`, `covratio`, `dfits`, and `welsch` are not available if any `vce()` other than `vce(ols)` was specified with `regress`.

`xb`, `residuals`, `score`, and `stdp` are the only options allowed with `svy` estimation results.

where *a* and *b* may be numbers or variables; *a* missing ( $a \geq .$ ) means  $-\infty$ , and *b* missing ( $b \geq .$ ) means  $+\infty$ ; see [U] 12.2.1 Missing values.

## Options for predict

Main

`xb`, the default, calculates the linear prediction.

`residuals` calculates the residuals.

`score` is equivalent to `residuals` in linear regression.

`rstandard` calculates the standardized residuals.

`rstudent` calculates the Studentized (jackknifed) residuals.

`cooksdiagnostics` calculates the Cook's  $D$  influence statistic (Cook 1977).

`leverage` or `hat` calculates the diagonal elements of the projection (“hat”) matrix.

`pr(a, b)` calculates  $\Pr(a < \mathbf{x}_j\mathbf{b} + u_j < b)$ , the probability that  $y_j|\mathbf{x}_j$  would be observed in the interval  $(a, b)$ .

$a$  and  $b$  may be specified as numbers or variable names;  $lb$  and  $ub$  are variable names;

`pr(20, 30)` calculates  $\Pr(20 < \mathbf{x}_j\mathbf{b} + u_j < 30)$ ;

`pr(lb, ub)` calculates  $\Pr(lb < \mathbf{x}_j\mathbf{b} + u_j < ub)$ ; and

`pr(20, ub)` calculates  $\Pr(20 < \mathbf{x}_j\mathbf{b} + u_j < ub)$ .

$a$  missing ( $a \geq .$ ) means  $-\infty$ ; `pr(., 30)` calculates  $\Pr(-\infty < \mathbf{x}_j\mathbf{b} + u_j < 30)$ ;

`pr(lb, 30)` calculates  $\Pr(-\infty < \mathbf{x}_j\mathbf{b} + u_j < 30)$  in observations for which  $lb \geq .$

and calculates  $\Pr(lb < \mathbf{x}_j\mathbf{b} + u_j < 30)$  elsewhere.

$b$  missing ( $b \geq .$ ) means  $+\infty$ ; `pr(20, .)` calculates  $\Pr(+\infty > \mathbf{x}_j\mathbf{b} + u_j > 20)$ ;

`pr(20, ub)` calculates  $\Pr(+\infty > \mathbf{x}_j\mathbf{b} + u_j > 20)$  in observations for which  $ub \geq .$

and calculates  $\Pr(20 < \mathbf{x}_j\mathbf{b} + u_j < ub)$  elsewhere.

`e(a, b)` calculates  $E(\mathbf{x}_j\mathbf{b} + u_j \mid a < \mathbf{x}_j\mathbf{b} + u_j < b)$ , the expected value of  $y_j|\mathbf{x}_j$  conditional on  $y_j|\mathbf{x}_j$  being in the interval  $(a, b)$ , meaning that  $y_j|\mathbf{x}_j$  is truncated.  $a$  and  $b$  are specified as they are for `pr()`.

`ystar(a, b)` calculates  $E(y_j^*)$ , where  $y_j^* = a$  if  $\mathbf{x}_j\mathbf{b} + u_j \leq a$ ,  $y_j^* = b$  if  $\mathbf{x}_j\mathbf{b} + u_j \geq b$ , and  $y_j^* = \mathbf{x}_j\mathbf{b} + u_j$  otherwise, meaning that  $y_j^*$  is censored.  $a$  and  $b$  are specified as they are for `pr()`.

`dfbeta(varname)` calculates the DFBETA for *varname*, the difference between the regression coefficient when the  $j$ th observation is included and excluded, said difference being scaled by the estimated standard error of the coefficient. *varname* must have been included among the regressors in the previously fitted model. The calculation is automatically restricted to the estimation subsample.

`stdp` calculates the standard error of the prediction, which can be thought of as the standard error of the predicted expected value or mean for the observation's covariate pattern. The standard error of the prediction is also referred to as the standard error of the fitted value.

`stdf` calculates the standard error of the forecast, which is the standard error of the point prediction for 1 observation. It is commonly referred to as the standard error of the future or forecast value. By construction, the standard errors produced by `stdf` are always larger than those produced by `stdp`; see *Methods and formulas*.

`stdr` calculates the standard error of the residuals.

`covratio` calculates COVRATIO (Belsley, Kuh, and Welsch 1980), a measure of the influence of the  $j$ th observation based on considering the effect on the variance–covariance matrix of the estimates. The calculation is automatically restricted to the estimation subsample.

`dfits` calculates DFITS (Welsch and Kuh 1977) and attempts to summarize the information in the leverage versus residual-squared plot into one statistic. The calculation is automatically restricted to the estimation subsample.

`welsch` calculates Welsch distance (Welsch 1982) and is a variation on `dfits`. The calculation is automatically restricted to the estimation subsample.

## Remarks and examples for predict

Remarks are presented under the following headings:

*Terminology*  
*Fitted values and residuals*  
*Prediction standard errors*  
*Prediction with weighted data*  
*Leverage statistics*  
*Standardized and Studentized residuals*  
*DFITS, Cook's Distance, and Welsch Distance*  
*COVRATIO*

## Terminology

Many of these commands concern identifying influential data in linear regression. This is, unfortunately, a field that is dominated by jargon, codified and partially begun by Belsley, Kuh, and Welsch (1980). In the words of Chatterjee and Hadi (1986, 416), “Belsley, Kuh, and Welsch’s book, *Regression Diagnostics*, was a very valuable contribution to the statistical literature, but it unleashed on an unsuspecting statistical community a computer speak (à la Orwell), the likes of which we have never seen.” Things have only gotten worse since then. Chatterjee and Hadi’s (1986, 1988) own attempts to clean up the jargon did not improve matters (see Hoaglin and Kempthorne [1986], Velleman [1986], and Welsch [1986]). We apologize for the jargon, and for our contribution to the jargon in the form of inelegant command names, we apologize most of all.

Model *sensitivity* refers to how estimates are affected by subsets of our data. Imagine data on  $y$  and  $x$ , and assume that the data are to be fit by the regression  $y_i = \alpha + \beta x_i + \epsilon_i$ . The regression estimates of  $\alpha$  and  $\beta$  are  $a$  and  $b$ , respectively. Now imagine that the estimated  $a$  and  $b$  would be different if a small portion of the dataset, perhaps even one observation, were deleted. As a data analyst, you would like to think that you are summarizing tendencies that apply to all the data, but you have just been told that the model you fit is unduly influenced by one point or just a few points and that, as a matter of fact, there is another model that applies to the rest of the data—a model that you have ignored. The search for subsets of the data that, if deleted, would change the results markedly is a predominant theme of this entry.

There are three key issues in identifying model sensitivity to individual observations, which go by the names *residuals*, *leverage*, and *influence*. In our  $y_i = a + bx_i + e_i$  regression, the residuals are, of course,  $e_i$ —they reveal how much our fitted value  $\hat{y}_i = a + bx_i$  differs from the observed  $y_i$ . A point  $(x_i, y_i)$  with a corresponding large residual is called an outlier. Say that you are interested in outliers because you somehow think that such points will exert undue influence on your estimates. Your feelings are generally right, but there are exceptions. A point might have a huge residual and yet not affect the estimated  $b$  at all. Nevertheless, studying observations with large residuals almost always pays off.

$(x_i, y_i)$  can be an outlier in another way—just as  $y_i$  can be far from  $\hat{y}_i$ ,  $x_i$  can be far from the center of mass of the other  $x$ ’s. Such an “outlier” should interest you just as much as the more traditional outliers. Picture a scatterplot of  $y$  against  $x$  with thousands of points in some sort of mass at the lower left of the graph and one point at the upper right of the graph. Now, run a regression line through the points—the

regression line will come close to the point at the upper right of the graph and may in fact, go through it. That is, this isolated point will not appear as an outlier as measured by residuals because its residual will be small. Yet this point might have a dramatic effect on our resulting estimates in the sense that, were you to delete the point, the estimates would change markedly. Such a point is said to have high leverage. Just as with traditional outliers, a high leverage point does not necessarily have an undue effect on regression estimates, but if it does not, it is more the exception than the rule.

Now, all of this is a most unsatisfactory state of affairs. Points with large residuals may, but need not, have a large effect on our results, and points with small residuals may still have a large effect. Points with high leverage may, but need not, have a large effect on our results, and points with low leverage may still have a large effect. Can you not identify the influential points and simply have the computer list them for you? You can, but you will have to define what you mean by “influential”.

“Influential” is defined with respect to some statistic. For instance, you might ask which points in your data have a large effect on your estimated  $a$ , which points have a large effect on your estimated  $b$ , which points have a large effect on your estimated standard error of  $b$ , and so on, but do not be surprised when the answers to these questions are different. In any case, obtaining such measures is not difficult—all you have to do is fit the regression excluding each observation one at a time and record the statistic of interest which, in the day of the modern computer, is not too onerous. Moreover, you can save considerable computer time by doing algebra ahead of time and working out formulas that will calculate the same answers as if you ran each of the regressions. (Ignore the question of pairs of observations that, together, exert undue influence, and triples, and so on, which remains largely unsolved and for which the brute force fit-every-possible-regression procedure is not a viable alternative.)

## Fitted values and residuals

Typing `predict newvar` with no options creates `newvar` containing the fitted values. Typing `predict newvar, resid` creates `newvar` containing the residuals.

### ▷ Example 1

Continuing with [example 1](#) from [\[R\] regress](#), we wish to fit the following model:

$$\text{mpg} = \beta_0 + \beta_1 \text{weight} + \beta_2 \text{foreign} + \epsilon$$

```
. use https://www.stata-press.com/data/r19/auto
(1978 automobile data)
. regress mpg weight foreign
```

|          |             |           |            |               |                      |           |
|----------|-------------|-----------|------------|---------------|----------------------|-----------|
| Source   | SS          | df        | MS         | Number of obs | =                    | 74        |
| Model    | 1619.2877   | 2         | 809.643849 | F(2, 71)      | =                    | 69.75     |
| Residual | 824.171761  | 71        | 11.608053  | Prob > F      | =                    | 0.0000    |
|          |             |           |            | R-squared     | =                    | 0.6627    |
|          |             |           |            | Adj R-squared | =                    | 0.6532    |
| Total    | 2443.45946  | 73        | 33.4720474 | Root MSE      | =                    | 3.4071    |
| mpg      | Coefficient | Std. err. | t          | P> t          | [95% conf. interval] |           |
| weight   | -.0065879   | .0006371  | -10.34     | 0.000         | -.0078583            | -.0053175 |
| foreign  | -1.650029   | 1.075994  | -1.53      | 0.130         | -3.7955              | .4954422  |
| _cons    | 41.6797     | 2.165547  | 19.25      | 0.000         | 37.36172             | 45.99768  |

That done, we can now obtain the predicted values from the regression. We will store them in a new variable called `pmpg` by typing `predict pmpg`. Because `predict` produces no output, we will follow that by summarizing our predicted and observed values.

```
. predict pmpg
(option xb assumed; fitted values)
. summarize pmpg mpg
```

| Variable | Obs | Mean    | Std. dev. | Min      | Max      |
|----------|-----|---------|-----------|----------|----------|
| pmpg     | 74  | 21.2973 | 4.709779  | 9.794333 | 29.82151 |
| mpg      | 74  | 21.2973 | 5.785503  | 12       | 41       |

◀

## ▶ Example 2: Out-of-sample predictions

We can just as easily obtain predicted values from the model by using a wholly different dataset from the one on which the model was fit. The only requirement is that the data have the necessary variables, which here are `weight` and `foreign`.

Using the data on two new cars (the Pontiac Sunbird and the Volvo 260) from `newautos.dta`, we can obtain out-of-sample predictions (or forecasts) by typing

```
. use https://www.stata-press.com/data/r19/newautos, clear
(New automobile models)
. predict pmpg
(option xb assumed; fitted values)
. list, divider
```

|    | make          | weight | foreign  | pmpg     |
|----|---------------|--------|----------|----------|
| 1. | Pont. Sunbird | 2690   | Domestic | 23.95829 |
| 2. | Volvo 260     | 3170   | Foreign  | 19.14607 |

The Pontiac Sunbird has a predicted mileage rating of 23.96 mpg, whereas the Volvo 260 has a predicted rating of 19.15 mpg. In comparison, the actual mileage ratings are 24 for the Pontiac and 17 for the Volvo.

◀

## Prediction standard errors

`predict` can calculate the standard error of the forecast (`stdf` option), the standard error of the prediction (`stdp` option), and the standard error of the residual (`stdr` option). It is easy to confuse `stdf` and `stdp` because both are often called the prediction error. Consider the prediction  $\hat{y}_j = \mathbf{x}_j \mathbf{b}$ , where  $\mathbf{b}$  is the estimated coefficient (column) vector and  $\mathbf{x}_j$  is a (row) vector of independent variables for which you want the prediction. First,  $\hat{y}_j$  has a variance due to the variance of the estimated coefficient vector  $\mathbf{b}$ ,

$$\text{Var}(\hat{y}_j) = \text{Var}(\mathbf{x}_j \mathbf{b}) = s^2 h_j$$

where  $h_j = \mathbf{x}_j (\mathbf{X}' \mathbf{X})^{-1} \mathbf{x}_j'$  and  $s^2$  is the mean squared error of the regression. Do not panic over the algebra—just remember that  $\text{Var}(\hat{y}_j) = s^2 h_j$ , whatever  $s^2$  and  $h_j$  are. `stdp` calculates this quantity. This is the error in the prediction due to the uncertainty about  $\mathbf{b}$ .

If you are about to hand this number out as your forecast, however, there is another error. According to your model, the true value of  $y_j$  is given by

$$y_j = \mathbf{x}_j \mathbf{b} + \epsilon_j = \hat{y}_j + \epsilon_j$$

and thus the  $\text{Var}(y_j) = \text{Var}(\hat{y}_j) + \text{Var}(\epsilon_j) = s^2 h_j + s^2$ , which is the square of `stdf`. `stdf`, then, is the sum of the error in the prediction plus the residual error.

`stdr` has to do with an analysis-of-variance decomposition of  $s^2$ , the estimated variance of  $y$ . The standard error of the prediction is  $s^2 h_j$ , and therefore  $s^2 h_j + s^2(1 - h_j) = s^2$  decomposes  $s^2$  into the prediction and residual variances.

### ▷ Example 3: Standard error of the forecast

Returning to our model of `mpg` on `weight` and `foreign`, we previously predicted the mileage rating for the Pontiac Sunbird and Volvo 260 as 23.96 and 19.15 mpg, respectively. We now want to put a standard error around our forecast. Remember, the data for these two cars were in `newautos.dta`:

```
. use https://www.stata-press.com/data/r19/newautos, clear
(New automobile models)
. predict pmpg
(option xb assumed; fitted values)
. predict se_pmpg, stdf
. list, divider
```

|    | make          | weight | foreign  | pmpg     | se_pmpg  |
|----|---------------|--------|----------|----------|----------|
| 1. | Pont. Sunbird | 2690   | Domestic | 23.95829 | 3.462791 |
| 2. | Volvo 260     | 3170   | Foreign  | 19.14607 | 3.525875 |

Thus, an approximate 95% confidence interval for the mileage rating of the Volvo 260 is  $19.15 \pm 2 \cdot 3.53 = [12.09, 26.21]$ .

◀

### Prediction with weighted data

`predict` can be used after frequency-weighted (`fweight`) estimation, just as it is used after unweighted estimation. The technical note below concerns the use of `predict` after analytically weighted (`aweight`) estimation.

### □ Technical note

After analytically weighted estimation, `predict` is willing to calculate only the prediction (no options), residual (`residual` option), standard error of the prediction (`stdp` option), and diagonal elements of the projection matrix (`hat` option). For analytically weighted estimation, the standard error of the forecast and residuals, the standardized and Studentized residuals, and Cook's  $D$  are not statistically well-defined concepts.

□

## Leverage statistics

In addition to providing fitted values and the associated standard errors, the `predict` command can also be used to generate various statistics used to detect the influence of individual observations. This section provides a brief introduction to leverage (`hat`) statistics, and some of the following subsections discuss other influence statistics produced by `predict`.

### ► Example 4: Diagonal elements of projection matrix

The diagonal elements of the projection matrix, obtained by the `hat` option, are a measure of distance in explanatory variable space. Leverage is a synonym for `hat`.

```
. use https://www.stata-press.com/data/r19/auto, clear
(1978 automobile data)
. regress mpg weight foreign
(output omitted)
. predict xdist, hat
. summarize xdist, detail
```

| Leverage |             |          |                    |
|----------|-------------|----------|--------------------|
|          | Percentiles | Smallest |                    |
| 1%       | .0192325    | .0192325 |                    |
| 5%       | .0192686    | .0192366 |                    |
| 10%      | .0193448    | .019241  | Obs 74             |
| 25%      | .0220291    | .0192686 | Sum of wgt. 74     |
| 50%      | .0383797    |          | Mean .0405405      |
|          |             | Largest  | Std. dev. .0207624 |
| 75%      | .0494002    | .0880814 |                    |
| 90%      | .0693432    | .099715  | Variance .0004311  |
| 95%      | .0880814    | .099715  | Skewness 1.159745  |
| 99%      | .1003283    | .1003283 | Kurtosis 4.083313  |

Some 5% of our sample has an `xdist` measure in excess of 0.08. Let's force them to reveal their identities:

```
. list foreign make mpg if xdist>.08, divider
```

|     | foreign  | make              | mpg |
|-----|----------|-------------------|-----|
| 24. | Domestic | Ford Fiesta       | 28  |
| 26. | Domestic | Linc. Continental | 12  |
| 27. | Domestic | Linc. Mark V      | 12  |
| 43. | Domestic | Plym. Champ       | 34  |
| 64. | Foreign  | Peugeot 604       | 14  |

To understand why these cars are on this list, we must remember that the explanatory variables in our model are `weight` and `foreign` and that `xdist` measures distance in this metric. The Ford Fiesta and the Plymouth Champ are the two lightest domestic cars in our data. The Lincolns are the two heaviest domestic cars, and the Peugeot is the heaviest foreign car.

◀

See `lvr2plot` in [R] [regress postestimation diagnostic plots](#) for information on a leverage-versus-squared-residual plot.

## Standardized and Studentized residuals

The terms standardized and Studentized residuals have meant different things to different authors. In Stata, `predict` defines the standardized residual as  $\hat{e}_{s_i} = e_i / (s\sqrt{1 - h_i})$  and the Studentized residual as  $r_i = e_i / (s_{(i)}\sqrt{1 - h_i})$ , where  $s_{(i)}$  is the root mean squared error of a regression with the  $i$ th observation removed. Stata's definition of the Studentized residual is the same as the one given in [Bollen and Jackman \(1990, 264\)](#) and is what [Chatterjee and Hadi \(1988, 74\)](#) call the “externally Studentized” residual. Stata's “standardized” residual is the same as what [Chatterjee and Hadi \(1988, 74\)](#) call the “internally Studentized” residual.

Standardized and Studentized residuals are attempts to adjust residuals for their standard errors. Although the  $\epsilon_i$  theoretical residuals are homoskedastic by assumption (that is, they all have the same variance), the calculated  $e_i$  are not. In fact,

$$\text{Var}(e_i) = \sigma^2(1 - h_i)$$

where  $h_i$  are the leverage measures obtained from the diagonal elements of hat matrix. Thus, observations with the greatest leverage have corresponding residuals with the smallest variance.

Standardized residuals use the root mean squared error of the regression for  $\sigma$ . Studentized residuals use the root mean squared error of a regression omitting the observation in question for  $\sigma$ . In general, Studentized residuals are preferable to standardized residuals for purposes of outlier identification. Studentized residuals can be interpreted as the  $t$  statistic for testing the significance of a dummy variable equal to 1 in the observation in question and 0 elsewhere ([Belsley, Kuh, and Welsch 1980](#)). Such a dummy variable would effectively absorb the observation and so remove its influence in determining the other coefficients in the model. Caution must be exercised here, however, because of the simultaneous testing problem. You cannot simply list the residuals that would be individually significant at the 5% level—their joint significance would be far less (their joint significance *level* would be far greater).

### ► Example 5: Standardized and Studentized residuals

In the [Terminology](#) section of *Remarks and examples for predict*, we distinguished residuals from leverage and speculated on the impact of an observation with a small residual but large leverage. If we adjust the residuals for their standard errors, however, the adjusted residual would be (relatively) larger and perhaps large enough so that we could simply examine the adjusted residuals. Taking our price on weight and foreign##c.mpg model from [example 1](#) of [\[R\] regress postestimation diagnostic plots](#), we can obtain the in-sample standardized and Studentized residuals by typing

```
. use https://www.stata-press.com/data/r19/auto, clear
(1978 automobile data)
. regress price weight foreign##c.mpg
(output omitted)
. predict esta if e(sample), rstandard
. predict estu if e(sample), rstudent
```

In the `lvr2plot` section of [R] [regress postestimation diagnostic plots](#), we discovered that the VW Diesel has the highest leverage in our data, but a corresponding small residual. The standardized and Studentized residuals for the VW Diesel are

```
. list make price esta estu if make=="VW Diesel"
```

|     | make      | price | esta     | estu     |
|-----|-----------|-------|----------|----------|
| 71. | VW Diesel | 5,397 | .6142691 | .6114758 |

The Studentized residual of 0.611 can be interpreted as the  $t$  statistic for including a dummy variable for VW Diesel in our regression. Such a variable would not be significant.

◀

### DFITS, Cook's Distance, and Welsch Distance

DFITS ([Welsch and Kuh 1977](#)), Cook's Distance ([Cook 1977](#)), and Welsch Distance ([Welsch 1982](#)) are three attempts to summarize the information in the leverage versus residual-squared plot into one statistic. That is, the goal is to create an index that is affected by the size of the residuals—outliers—and the size of  $h_i$ —leverage. Viewed mechanically, one way to write DFITS ([Bollen and Jackman 1990](#), 265) is

$$\text{DFITS}_i = r_i \sqrt{\frac{h_i}{1 - h_i}}$$

where  $r_i$  are the Studentized residuals. Thus, large residuals increase the value of DFITS, as do large values of  $h_i$ . Viewed more traditionally, DFITS is a scaled difference between predicted values for the  $i$ th case when the regression is fit with and without the  $i$ th observation, hence the name.

The mechanical relationship between DFITS and Cook's Distance,  $D_i$  ([Bollen and Jackman 1990](#), 266), is

$$D_i = \frac{1}{k} \frac{s_{(i)}^2}{s^2} \text{DFITS}_i^2$$

where  $k$  is the number of variables (including the constant) in the regression,  $s$  is the root mean squared error of the regression, and  $s_{(i)}$  is the root mean squared error when the  $i$ th observation is omitted. Viewed more traditionally,  $D_i$  is a scaled measure of the distance between the coefficient vectors when the  $i$ th observation is omitted.

The mechanical relationship between DFITS and Welsch's Distance,  $W_i$  ([Chatterjee and Hadi 1988](#), 123), is

$$W_i = \text{DFITS}_i \sqrt{\frac{n-1}{1-h_i}}$$

The interpretation of  $W_i$  is more difficult because it is based on the empirical influence curve. Although DFITS and Cook's distance are similar, the Welsch distance measure includes another normalization by leverage.

[Belsley, Kuh, and Welsch \(1980, 28\)](#) suggest that DFITS values greater than  $2\sqrt{k/n}$  deserve more investigation, and so values of Cook's distance greater than  $4/n$  should also be examined ([Bollen and Jackman 1990](#), 265–266). Through similar logic, the cutoff for Welsch distance is approximately  $3\sqrt{k}$  ([Chatterjee and Hadi 1988](#), 124).

## ▷ Example 6: DFITS influence measure

Continuing with our model of price on weight and foreign##c.mpg, we can obtain the DFITS influence measure:

```
. predict e if e(sample), resid
. predict dfits, dfits
```

We did not specify `if e(sample)` in computing the DFITS statistic. DFITS is available only over the estimation sample, so specifying `if e(sample)` would have been redundant. It would have done no harm, but it would not have changed the results.

Our model has  $k = 5$  independent variables ( $k$  includes the constant) and  $n = 74$  observations; following the  $2\sqrt{k/n}$  cutoff advice, we type

```
. list make price e dfits if abs(dfits) > 2*sqrt(5/74), divider
```

|     | make             | price  | e         | dfits     |
|-----|------------------|--------|-----------|-----------|
| 12. | Cad. Eldorado    | 14,500 | 7271.96   | .9564455  |
| 13. | Cad. Seville     | 15,906 | 5036.348  | 1.356619  |
| 24. | Ford Fiesta      | 4,389  | 3164.872  | .5724172  |
| 27. | Linc. Mark V     | 13,594 | 3109.193  | .5200413  |
| 28. | Linc. Versailles | 13,466 | 6560.912  | .8760136  |
| 42. | Plym. Arrow      | 4,647  | -3312.968 | -.9384231 |

We calculate Cook's distance and list the observations greater than the suggested  $4/n$  cutoff:

```
. predict cooks if e(sample), cooks
. list make price e cooks if cooks > 4/74, divider
```

|     | make             | price  | e         | cooks    |
|-----|------------------|--------|-----------|----------|
| 12. | Cad. Eldorado    | 14,500 | 7271.96   | .1492676 |
| 13. | Cad. Seville     | 15,906 | 5036.348  | .3328515 |
| 24. | Ford Fiesta      | 4,389  | 3164.872  | .0638815 |
| 28. | Linc. Versailles | 13,466 | 6560.912  | .1308004 |
| 42. | Plym. Arrow      | 4,647  | -3312.968 | .1700736 |

Here we used `if e(sample)` because Cook's distance is not restricted to the estimation sample by default. It is worth comparing this list with the preceding one.

Finally, we use Welsch distance and the suggested  $3\sqrt{k}$  cutoff:

```
. predict wd, welsch
. list make price e wd if abs(wd) > 3*sqrt(5), divider
```

|     | make             | price  | e         | wd        |
|-----|------------------|--------|-----------|-----------|
| 12. | Cad. Eldorado    | 14,500 | 7271.96   | 8.394372  |
| 13. | Cad. Seville     | 15,906 | 5036.348  | 12.81125  |
| 28. | Linc. Versailles | 13,466 | 6560.912  | 7.703005  |
| 42. | Plym. Arrow      | 4,647  | -3312.968 | -8.981481 |

Here we did not need to specify `if e(sample)` because `welsch` automatically restricts the prediction to the estimation sample.

◀

## COVRATIO

COVRATIO (Belsley, Kuh, and Welsch 1980) measures the influence of the  $i$ th observation by considering the effect on the variance–covariance matrix of the estimates. The measure is the ratio of the determinants of the covariances matrix, with and without the  $i$ th observation. The resulting formula is

$$\text{COVRATIO}_i = \frac{1}{1 - h_i} \left( \frac{n - k - \hat{e}_{s_i}^2}{n - k - 1} \right)^k$$

where  $\hat{e}_{s_i}$  is the standardized residual.

For noninfluential observations, the value of COVRATIO is approximately 1. Large values of the residuals or large values of leverage will cause deviations from 1, although if both are large, COVRATIO may tend back toward 1 and therefore not identify such observations (Chatterjee and Hadi 1988, 139).

Belsley, Kuh, and Welsch (1980) suggest that observations for which

$$|\text{COVRATIO}_i - 1| \geq \frac{3k}{n}$$

are worthy of further examination.

## ▷ Example 7: COVRATIO influence measure

Using our model of price on weight and foreign##c.mpg, we can obtain the COVRATIO measure and list the observations outside the suggested cutoff by typing

```
. predict covr, covratio
. list make price e covr if abs(covr-1) >= 3*5/74, divider
```

|     | make             | price  | e         | covr     |
|-----|------------------|--------|-----------|----------|
| 12. | Cad. Eldorado    | 14,500 | 7271.96   | .3814242 |
| 13. | Cad. Seville     | 15,906 | 5036.348  | .7386969 |
| 28. | Linc. Versailles | 13,466 | 6560.912  | .4761695 |
| 43. | Plym. Champ      | 4,425  | 1621.747  | 1.27782  |
| 53. | Audi 5000        | 9,690  | 591.2883  | 1.206842 |
| 57. | Datsun 210       | 4,589  | 19.81829  | 1.284801 |
| 64. | Peugeot 604      | 12,990 | 1037.184  | 1.348219 |
| 66. | Subaru           | 3,798  | -909.5894 | 1.264677 |
| 71. | VW Diesel        | 5,397  | 999.7209  | 1.630653 |
| 74. | Volvo 260        | 11,995 | 1327.668  | 1.211888 |

The covratio option automatically restricts the prediction to the estimation sample.

# margins

## Description for margins

`margins` estimates margins of response for linear predictions.

## Menu for margins

Statistics > Postestimation

## Syntax for margins

```
margins [marginlist] [, options]
margins [marginlist] , predict(statistic ...) [options]
```

| <i>statistic</i>                      | Description                    |
|---------------------------------------|--------------------------------|
| <code>xb</code>                       | linear prediction; the default |
| <code>pr(<i>a</i>,<i>b</i>)</code>    | not allowed with margins       |
| <code>e(<i>a</i>,<i>b</i>)</code>     | not allowed with margins       |
| <code>ystar(<i>a</i>,<i>b</i>)</code> | not allowed with margins       |
| <code>residuals</code>                | not allowed with margins       |
| <code>score</code>                    | not allowed with margins       |
| <code>rstandard</code>                | not allowed with margins       |
| <code>rstudent</code>                 | not allowed with margins       |
| <code>cooksd</code>                   | not allowed with margins       |
| <code>leverage   <u>hat</u></code>    | not allowed with margins       |
| <code>dfbeta(<i>varname</i>)</code>   | not allowed with margins       |
| <code>stdp</code>                     | not allowed with margins       |
| <code>stdf</code>                     | not allowed with margins       |
| <code>stdr</code>                     | not allowed with margins       |
| <code>covratio</code>                 | not allowed with margins       |
| <code>dfits</code>                    | not allowed with margins       |
| <code>welsch</code>                   | not allowed with margins       |

Statistics not allowed with margins are functions of stochastic quantities other than `e(b)`.

For the full syntax, see [R] [margins](#).

## DFBETA influence statistics

### Description for dfbeta

`dfbeta` will calculate one, more than one, or all the DFBETAs after `regress`. Although `predict` will also calculate DFBETAs, `predict` can do this for only one variable at a time. `dfbeta` is a convenience tool for those who want to calculate DFBETAs for multiple variables. The names for the new variables created are chosen automatically and begin with the letters `_dfbeta_`.

### Menu for dfbeta

Statistics > Linear models and related > Regression diagnostics > DFBETAs

### Syntax for dfbeta

```
dfbeta [indepvar [indepvar [...]]] [, stub(name)]
```

### Option for dfbeta

`stub(name)` specifies the leading characters `dfbeta` uses to name the new variables to be generated. The default is `stub(_dfbeta_)`.

### Remarks and examples for dfbeta

DFBETAs are perhaps the most direct influence measure of interest to model builders. DFBETAs focus on one coefficient and measure the difference between the regression coefficient when the  $i$ th observation is included and excluded, the difference being scaled by the estimated standard error of the coefficient. [Belsley, Kuh, and Welsch \(1980, 28\)](#) suggest observations with  $|DFBETA_i| > 2/\sqrt{n}$  as deserving special attention, but it is also common practice to use 1 ([Bollen and Jackman 1990, 267](#)), meaning that the observation shifted the estimate at least one standard error.

#### ▷ Example 8: DFBETAs influence measure; the `dfbeta()` option

Using our model of `price` on `weight` and `foreign##c.mpg`, let's first ask which observations have the greatest impact on the determination of the coefficient on `1.foreign`. We will use the suggested  $2/\sqrt{n}$  cutoff:

```
. use https://www.stata-press.com/data/r19/auto, clear
(1978 automobile data)
. regress price weight foreign##c.mpg
(output omitted)
```

```
. sort foreign make
. predict dfor, dfbeta(1.foreign)
. list make price foreign dfor if abs(dfor) > 2/sqrt(74), divider
```

|     | make             | price  | foreign  | dfor      |
|-----|------------------|--------|----------|-----------|
| 12. | Cad. Eldorado    | 14,500 | Domestic | -.5290519 |
| 13. | Cad. Seville     | 15,906 | Domestic | .8243419  |
| 28. | Linc. Versailles | 13,466 | Domestic | -.5283729 |
| 42. | Plym. Arrow      | 4,647  | Domestic | -.6622424 |
| 43. | Plym. Champ      | 4,425  | Domestic | .2371104  |
| 64. | Peugeot 604      | 12,990 | Foreign  | .2552032  |
| 69. | Toyota Corona    | 5,719  | Foreign  | -.256431  |

The Cadillac Seville shifted the coefficient on `1.foreign` 0.82 standard deviations!

Now let us ask which observations have the greatest effect on the mpg coefficient:

```
. predict dmpg, dfbeta(mpg)
. list make price mpg dmpg if abs(dmpg) > 2/sqrt(74), divider
```

|     | make             | price  | mpg | dmpg      |
|-----|------------------|--------|-----|-----------|
| 12. | Cad. Eldorado    | 14,500 | 14  | -.5970351 |
| 13. | Cad. Seville     | 15,906 | 21  | 1.134269  |
| 28. | Linc. Versailles | 13,466 | 14  | -.6069287 |
| 42. | Plym. Arrow      | 4,647  | 28  | -.8925859 |
| 43. | Plym. Champ      | 4,425  | 34  | .3186909  |

Once again, we see the Cadillac Seville heading the list, indicating that our regression results may be dominated by this one car.

◀

### ► Example 9: DFBETAs influence measure; the `dfbeta` command

We can use `predict, dfbeta()` or the `dfbeta` command to generate the DFBETAs. `dfbeta` makes up names for the new variables automatically and, without arguments, generates the DFBETAs for all the variables in the regression:

```
. dfbeta
Generating DFBETA variables ...
 _dfbeta_1: DFBETA weight
 _dfbeta_2: DFBETA 1.foreign
 _dfbeta_3: DFBETA mpg
 _dfbeta_4: DFBETA 1.foreign#c.mpg
```

`dfbeta` created four new variables in our dataset: `_dfbeta_1`, containing the DFBETAs for `weight`; `_dfbeta_2`, containing the DFBETAs for `mpg`; and so on. Had we wanted only the DFBETAs for `mpg` and `weight`, we might have typed

```
. dfbeta mpg weight
Generating DFBETA variables ...
 _dfbeta_5: DFBETA weight
 _dfbeta_6: DFBETA mpg
```

In the example above, we typed `dfbeta mpg weight` instead of `dfbeta`; if we had typed `dfbeta` followed by `dfbeta mpg weight`, here is what would have happened:

```
. dfbeta
Generating DFBETA variables ...
 _dfbeta_7: DFBETA weight
 _dfbeta_8: DFBETA 1.foreign
 _dfbeta_9: DFBETA mpg
 _dfbeta_10: DFBETA 1.foreign#c.mpg
. dfbeta mpg weight
Generating DFBETA variables ...
 _dfbeta_11: DFBETA weight
 _dfbeta_12: DFBETA mpg
```

`dfbeta` would have made up different names for the new variables. `dfbeta` never replaces existing variables—it instead makes up a different name, so we need to pay attention to `dfbeta`'s output.

◀

## Tests for violation of assumptions

### Description for `estat hettest`

`estat hettest` performs three versions of the Breusch–Pagan (1979) and Cook–Weisberg (1983) test for heteroskedasticity. All three versions of this test present evidence against the null hypothesis that  $\mathbf{t} = \mathbf{0}$  in  $\text{Var}(e) = \sigma^2 \exp(\mathbf{z}\mathbf{t})$ . In the normal version, performed by default, the null hypothesis also includes the assumption that the regression disturbances are independent-normal draws with variance  $\sigma^2$ . The normality assumption is dropped from the null hypothesis in the `iid` and `fstat` versions, which respectively produce the score and  $F$  tests discussed in *Methods and formulas*. If `varlist` is not specified, the fitted values are used for  $\mathbf{z}$ . If `varlist` or the `rhs` option is specified, the variables specified are used for  $\mathbf{z}$ .

### Menu for `estat`

Statistics > Postestimation

### Syntax for `estat hettest`

```
estat hettest [varlist] [, rhs [normal | iid | fstat] mtest [spec]]
```

`collect` is allowed with `estat hettest`; see [U] 11.1.10 Prefix commands.

### Options for `estat hettest`

`rhs` specifies that tests for heteroskedasticity be performed for the right-hand-side (explanatory) variables of the fitted regression model. The `rhs` option may be combined with a *varlist*.

`normal`, the default, causes `estat hettest` to compute the original Breusch–Pagan/Cook–Weisberg test, which assumes that the regression disturbances are normally distributed.

`iid` causes `estat hettest` to compute the  $N * R^2$  version of the score test that drops the normality assumption.

`fstat` causes `estat hettest` to compute the  $F$ -statistic version that drops the normality assumption.

`mtest [ (spec) ]` specifies that multiple testing be performed. The argument specifies how  $p$ -values are adjusted. The following specifications, *spec*, are supported:

|                         |                                            |
|-------------------------|--------------------------------------------|
| <code>bonferroni</code> | Bonferroni's multiple testing adjustment   |
| <code>holm</code>       | Holm's multiple testing adjustment         |
| <code>sidak</code>      | Šidák's multiple testing adjustment        |
| <code>noadjust</code>   | no adjustment is made for multiple testing |

`mtest` may be specified without an argument. This is equivalent to specifying `mtest(noadjust)`; that is, tests for the individual variables should be performed with unadjusted  $p$ -values. By default, `estat hettest` does not perform multiple testing. `mtest` may not be specified with `iid` or `fstat`.

## Description for estat imtest

`estat imtest` performs an information matrix test for the regression model and an orthogonal decomposition into tests for heteroskedasticity, skewness, and kurtosis due to [Cameron and Trivedi \(1990\)](#); White's test for homoskedasticity against unrestricted forms of heteroskedasticity ([1980](#)) is available as an option. White's test is usually similar to the first term of the Cameron–Trivedi decomposition.

## Menu for estat

Statistics > Postestimation

## Syntax for estat imtest

```
estat imtest [, preserve white]
```

`collect` is allowed with `estat imtest`; see [\[U\] 11.1.10 Prefix commands](#).

## Options for estat imtest

`preserve` specifies that the data in memory be preserved, all variables and cases that are not needed in the calculations be dropped, and at the conclusion the original data be restored. This option is costly for large datasets. However, because `estat imtest` has to perform an auxiliary regression on  $k(k+1)/2$  temporary variables, where  $k$  is the number of regressors, it may not be able to perform the test otherwise.

`white` specifies that White's original heteroskedasticity test also be performed.

## Description for estat ovtest

`estat ovtest` performs two versions of the Ramsey (1969) regression specification-error test (RESET) for omitted variables. This test amounts to fitting  $y = \mathbf{x}\mathbf{b} + \mathbf{z}\mathbf{t} + u$  and then testing  $\mathbf{t} = \mathbf{0}$ . If the `rhs` option is not specified, powers of the fitted values are used for  $\mathbf{z}$ . If `rhs` is specified, powers of the individual elements of  $\mathbf{x}$  are used.

## Menu for estat

Statistics > Postestimation

## Syntax for estat ovtest

```
estat ovtest [, rhs]
```

`collect` is allowed with `estat ovtest`; see [U] 11.1.10 Prefix commands.

## Option for estat ovtest

`rhs` specifies that powers of the right-hand-side (explanatory) variables be used in the test rather than powers of the fitted values.

## Description for estat szroeter

`estat szroeter` performs Szroeter's rank test for heteroskedasticity for each of the variables in *varlist* or for the explanatory variables of the regression if `rhs` is specified.

## Menu for estat

Statistics > Postestimation

## Syntax for estat szroeter

```
estat szroeter [varlist] [, rhs mtest(spec)]
```

Either *varlist* or `rhs` must be specified.

## Options for estat szroeter

`rhs` specifies that tests for heteroskedasticity be performed for the right-hand-side (explanatory) variables of the fitted regression model. The `rhs` option may be combined with a *varlist*.

`mtest(spec)` specifies that multiple testing be performed. The argument specifies how *p*-values are adjusted. The following specifications, *spec*, are supported:

|                   |                                            |
|-------------------|--------------------------------------------|
| <u>bonferroni</u> | Bonferroni's multiple testing adjustment   |
| <u>holm</u>       | Holm's multiple testing adjustment         |
| <u>sidak</u>      | Šidák's multiple testing adjustment        |
| <u>noadjust</u>   | no adjustment is made for multiple testing |

`estat szroeter` always performs multiple testing. By default, it does not adjust the *p*-values.

## Remarks and examples for estat hettest, estat imtest, estat ovtest, and estat szroeter

We introduce some regression diagnostic commands that are designed to test for certain violations that `rvfplot` (see [R] [regress postestimation diagnostic plots](#)) less formally attempts to detect. `estat ovtest` provides Ramsey’s test for omitted variables—a pattern in the residuals. `estat hettest` provides a test for heteroskedasticity—the increasing or decreasing variation in the residuals with fitted values, with respect to the explanatory variables, or with respect to yet other variables. The score test implemented in `estat hettest` (Breusch and Pagan 1979; Cook and Weisberg 1983) performs a score test of the null hypothesis that  $b = 0$  against the alternative hypothesis of multiplicative heteroskedasticity. `estat szroeter` provides a rank test for heteroskedasticity, which is an alternative to the score test computed by `estat hettest`. Finally, `estat imtest` computes an information matrix test, including an orthogonal decomposition into tests for heteroskedasticity, skewness, and kurtosis (Cameron and Trivedi 1990). The heteroskedasticity test computed by `estat imtest` is similar to the general test for heteroskedasticity that was proposed by White (1980). Cameron and Trivedi (2022, chap. 3) discuss most of these tests and provides more examples.

### ► Example 10: estat ovtest, estat hettest, estat szroeter, and estat imtest

We use our model of price on weight and foreign##c.mpg.

```
. use https://www.stata-press.com/data/r19/auto, clear
(1978 automobile data)

. regress price weight foreign##c.mpg
(output omitted)

. estat ovtest

Ramsey RESET test for omitted variables
Omitted: Powers of fitted values of price
H0: Model has no omitted variables
F(3, 66) = 7.77
Prob > F = 0.0002

. estat hettest

Breusch-Pagan/Cook-Weisberg test for heteroskedasticity
Assumption: Normal error terms
Variable: Fitted values of price
H0: Constant variance
 chi2(1) = 6.50
Prob > chi2 = 0.0108
```

Testing for heteroskedasticity in the right-hand-side variables is requested by specifying the rhs option. By specifying the mtest(bonferroni) option, we request that tests be conducted for each of the variables, with a Bonferroni adjustment for the  $p$ -values to accommodate our testing multiple hypotheses.

```
. estat hettest, rhs mtest(bonf)
Breusch-Pagan/Cook-Weisberg test for heteroskedasticity
Assumption: Normal error terms
HO: Constant variance
```

| Variable     | chi2  | df | p       |
|--------------|-------|----|---------|
| weight       | 15.24 | 1  | 0.0004* |
| foreign      |       |    |         |
| Foreign      | 6.15  | 1  | 0.0525* |
| mpg          | 9.04  | 1  | 0.0106* |
| foreign#     |       |    |         |
| c.mpg        |       |    |         |
| Foreign      | 6.02  | 1  | 0.0566* |
| Simultaneous | 15.60 | 4  | 0.0036  |

```
* Bonferroni-adjusted p-values
. estat szroeter, rhs mtest(holm)
Szroeter's test for homoskedasticity
HO: Variance constant
Ha: Variance monotonic in variables
```

| Variable | chi2  | df | p       |
|----------|-------|----|---------|
| weight   | 17.07 | 1  | 0.0001* |
| foreign  |       |    |         |
| Foreign  | 6.15  | 1  | 0.0260* |
| mpg      | 11.45 | 1  | 0.0021* |
| foreign# |       |    |         |
| c.mpg    |       |    |         |
| Foreign  | 6.17  | 1  | 0.0260* |

```
* Holm-adjusted p-values
```

Finally, we request the information matrix test, which is a conditional moments test with second-, third-, and fourth-order moment conditions.

```
. estat imtest
Cameron & Trivedi's decomposition of IM-test
```

| Source             | chi2  | df | p      |
|--------------------|-------|----|--------|
| Heteroskedasticity | 18.86 | 10 | 0.0420 |
| Skewness           | 11.69 | 4  | 0.0198 |
| Kurtosis           | 2.33  | 1  | 0.1273 |
| Total              | 32.87 | 15 | 0.0049 |

We find evidence for omitted variables, heteroskedasticity, and nonnormal skewness.

So, why bother with the various graphical commands when the tests seem so much easier to interpret? In part, it is a matter of taste: both are designed to uncover the same problem, and both are, in fact, going about it in similar ways. One is based on a formal calculation, whereas the other is based on personal judgment in evaluating a graph. On the other hand, the tests are seeking evidence of specific problems, whereas judgment is more general. The careful analyst will use both.

We performed the omitted-variable test first. Omitted variables are a more serious problem than heteroskedasticity or the violations of higher moment conditions tested by `estat imtest`. If this were not a manual, having found evidence of omitted variables, we would never have run the `estat hettest`, `estat szroeter`, and `estat imtest` commands, at least not until we solved the omitted-variable problem.

◀

## □ Technical note

`estat ovtest` and `estat hettest` both perform two flavors of their respective tests. By default, `estat ovtest` looks for evidence of omitted variables by fitting the original model augmented by  $\hat{y}^2$ ,  $\hat{y}^3$ , and  $\hat{y}^4$ , which are the fitted values from the original model. Under the assumption of no misspecification, the coefficients on the powers of the fitted values will be zero. With the `rhs` option, `estat ovtest` instead augments the original model with powers (second through fourth) of the explanatory variables (except for dummy variables).

`estat hettest`, by default, looks for heteroskedasticity by modeling the variance as a function of the fitted values. If, however, we specify a variable or variables, the variance will be modeled as a function of the specified variables. In our example, if we had, a priori, some reason to suspect heteroskedasticity and that the heteroskedasticity is a function of a car's weight, then using a test that focuses on weight would be more powerful than the more general tests such as White's test or the first term in the Cameron–Trivedi decomposition test.

`estat hettest`, by default, computes the original Breusch–Pagan/Cook–Weisberg test, which includes the assumption of normally distributed errors. [Koenker \(1981\)](#) derived an  $N * R^2$  version of this test that drops the normality assumption. [Wooldridge \(2020, 270\)](#) gives an  $F$ -statistic version that does not require the normality assumption.

□

## Stored results for `estat hettest`, `estat imtest`, and `estat ovtest`

`estat hettest` stores the following results for the (multivariate) score test in `r()`:

Scalars

|                      |                                                          |
|----------------------|----------------------------------------------------------|
| <code>r(chi2)</code> | $\chi^2$ test statistic                                  |
| <code>r(df)</code>   | #df for the asymptotic $\chi^2$ distribution under $H_0$ |
| <code>r(p)</code>    | $p$ -value                                               |

`estat hettest`, `fstat` stores results for the (multivariate) score test in `r()`:

Scalars

|                      |                                                           |
|----------------------|-----------------------------------------------------------|
| <code>r(F)</code>    | test statistic                                            |
| <code>r(df_m)</code> | #df of the test for the $F$ distribution under $H_0$      |
| <code>r(df_r)</code> | #df of the residuals for the $F$ distribution under $H_0$ |
| <code>r(p)</code>    | $p$ -value                                                |

`estat hettest` (if `mtest` is specified) and `estat szroeter` store the following in `r()`:

#### Matrices

|                         |                                                                                      |
|-------------------------|--------------------------------------------------------------------------------------|
| <code>r(mtest)</code>   | a matrix of test results, with rows corresponding to the univariate tests            |
| <code>mtest[.,1]</code> | $\chi^2$ test statistic                                                              |
| <code>mtest[.,2]</code> | #df                                                                                  |
| <code>mtest[.,3]</code> | unadjusted <i>p</i> -value                                                           |
| <code>mtest[.,4]</code> | adjusted <i>p</i> -value (if an <code>mtest()</code> adjustment method is specified) |

#### Macros

|                         |                                       |
|-------------------------|---------------------------------------|
| <code>r(mtmetho)</code> | adjustment method for <i>p</i> -value |
|-------------------------|---------------------------------------|

`estat imtest` stores the following in `r()`:

#### Scalars

|                        |                                                                                                                           |
|------------------------|---------------------------------------------------------------------------------------------------------------------------|
| <code>r(chi2_t)</code> | LM-test statistic (= <code>r(chi2_h)</code> + <code>r(chi2_s)</code> + <code>r(chi2_k)</code> )                           |
| <code>r(df_t)</code>   | df for limiting $\chi^2$ distribution under $H_0$ (= <code>r(df_h)</code> + <code>r(df_s)</code> + <code>r(df_k)</code> ) |
| <code>r(chi2_h)</code> | heteroskedasticity test statistic                                                                                         |
| <code>r(df_h)</code>   | df for limiting $\chi^2$ distribution under $H_0$                                                                         |
| <code>r(chi2_s)</code> | skewness test statistic                                                                                                   |

| <code>r(df_r)</code> | residual degrees of freedom |

## Variance inflation factors

### Description for `estat vif`

`estat vif` calculates the centered or uncentered variance inflation factors (VIFs) for the independent variables specified in a linear regression model.

### Menu for `estat`

Statistics > Postestimation

### Syntax for `estat vif`

```
estat vif [, uncentered]
```

### Option for `estat vif`

`uncentered` requests the computation of the uncentered variance inflation factors. The uncentered VIFs are often used to detect the collinearity of the regressors with the constant. `uncentered` must be specified if the regression model did not include a constant term because centered VIFs are not appropriate for these models.

## Remarks and examples for estat vif

Problems arise in regression when the predictors are highly correlated. In this situation, there may be a significant change in the regression coefficients if you add or delete an independent variable. The estimated standard errors of the fitted coefficients are inflated, or the estimated coefficients may not be statistically significant even though a statistical relation exists between the dependent and independent variables.

Data analysts rely on these facts to check informally for the presence of multicollinearity. `estat vif`, another command for use after `regress`, calculates the variance inflation factors and tolerances for each of the independent variables.

The output shows the variance inflation factors together with their reciprocals. Some analysts compare the reciprocals with a predetermined tolerance. In the comparison, if the reciprocal of the VIF is smaller than the tolerance, the associated predictor variable is removed from the regression model. However, most analysts rely on informal rules of thumb applied to the VIF; see [Chatterjee and Hadi \(2012\)](#). According to these rules, there is evidence of multicollinearity if

1. The largest VIF is greater than 10 (some choose a more conservative threshold value of 30).
2. The mean of all the VIFs is considerably larger than 1.

### ▷ Example 11: estat vif

We examine a regression model fit using the ubiquitous automobile dataset:

```
. use https://www.stata-press.com/data/r19/auto
(1978 automobile data)
. regress price mpg rep78 trunk headroom length turn displ gear_ratio
```

| Source   | SS        | df | MS         | Number of obs | = | 69     |
|----------|-----------|----|------------|---------------|---|--------|
| Model    | 264102049 | 8  | 33012756.2 | F(8, 60)      | = | 6.33   |
| Residual | 312694909 | 60 | 5211581.82 | Prob > F      | = | 0.0000 |
|          |           |    |            | R-squared     | = | 0.4579 |
|          |           |    |            | Adj R-squared | = | 0.3856 |
| Total    | 576796959 | 68 | 8482308.22 | Root MSE      | = | 2282.9 |

| price        | Coefficient | Std. err. | t     | P> t  | [95% conf. interval] |
|--------------|-------------|-----------|-------|-------|----------------------|
| mpg          | -144.84     | 82.12751  | -1.76 | 0.083 | -309.1195 19.43948   |
| rep78        | 727.5783    | 337.6107  | 2.16  | 0.035 | 52.25638 1402.9      |
| trunk        | 44.02061    | 108.141   | 0.41  | 0.685 | -172.2935 260.3347   |
| headroom     | -807.0996   | 435.5802  | -1.85 | 0.069 | -1678.39 64.19062    |
| length       | -8.688914   | 34.89848  | -0.25 | 0.804 | -78.49626 61.11843   |
| turn         | -177.9064   | 137.3455  | -1.30 | 0.200 | -452.6383 96.82551   |
| displacement | 30.73146    | 7.576952  | 4.06  | 0.000 | 15.5753 45.88762     |
| gear_ratio   | 1500.119    | 1110.959  | 1.35  | 0.182 | -722.1303 3722.368   |
| _cons        | 6691.976    | 7457.906  | 0.90  | 0.373 | -8226.058 21610.01   |

```
. estat vif
```

| Variable     | VIF  | 1/VIF    |
|--------------|------|----------|
| length       | 8.22 | 0.121614 |
| displacement | 6.50 | 0.153860 |
| turn         | 4.85 | 0.205997 |
| gear_ratio   | 3.45 | 0.290068 |
| mpg          | 3.03 | 0.330171 |
| trunk        | 2.88 | 0.347444 |
| headroom     | 1.80 | 0.554917 |
| rep78        | 1.46 | 0.686147 |
| Mean VIF     | 4.02 |          |

The results are mixed. Although we have no VIFs greater than 10, the mean VIF is greater than 1, though not considerably so. We could continue the investigation of collinearity, but given that other authors advise that collinearity is a problem only when VIFs exist that are greater than 30 (contradicting our rule above), we will not do so here.

◀

### ▷ Example 12: estat vif, with strong evidence of multicollinearity

This example comes from a dataset described in [Kutner, Nachtsheim, and Neter \(2004, 257\)](#) that examines body fat as modeled by caliper measurements on the triceps, midarm, and thigh.

```
. use https://www.stata-press.com/data/r19/bodyfat
(Body fat)
. regress bodyfat tricep thigh midarm
```

| Source   | SS         | df | MS         | Number of obs | = | 20     |
|----------|------------|----|------------|---------------|---|--------|
| Model    | 396.984607 | 3  | 132.328202 | F(3, 16)      | = | 21.52  |
| Residual | 98.4049068 | 16 | 6.15030667 | Prob > F      | = | 0.0000 |
|          |            |    |            | R-squared     | = | 0.8014 |
|          |            |    |            | Adj R-squared | = | 0.7641 |
| Total    | 495.389513 | 19 | 26.0731323 | Root MSE      | = | 2.48   |

| bodyfat | Coefficient | Std. err. | t     | P> t  | [95% conf. interval] |          |
|---------|-------------|-----------|-------|-------|----------------------|----------|
| triceps | 4.334085    | 3.015511  | 1.44  | 0.170 | -2.058512            | 10.72668 |
| thigh   | -2.856842   | 2.582015  | -1.11 | 0.285 | -8.330468            | 2.616785 |
| midarm  | -2.186056   | 1.595499  | -1.37 | 0.190 | -5.568362            | 1.19625  |
| _cons   | 117.0844    | 99.78238  | 1.17  | 0.258 | -94.44474            | 328.6136 |

```
. estat vif
```

| Variable | VIF    | 1/VIF    |
|----------|--------|----------|
| triceps  | 708.84 | 0.001411 |
| thigh    | 564.34 | 0.001772 |
| midarm   | 104.61 | 0.009560 |
| Mean VIF | 459.26 |          |

Here we see strong evidence of multicollinearity in our model. More investigation reveals that the measurements on the thigh and the triceps are highly correlated:

```
. correlate triceps thigh midarm
(obs=20)
```

|         | triceps | thigh  | midarm |
|---------|---------|--------|--------|
| triceps | 1.0000  |        |        |
| thigh   | 0.9238  | 1.0000 |        |
| midarm  | 0.4578  | 0.0847 | 1.0000 |

If we remove the predictor `tricep` from the model (because it had the highest VIF), we get

```
. regress bodyfat thigh midarm
```

| Source   | SS         | df | MS         | Number of obs | = | 20     |
|----------|------------|----|------------|---------------|---|--------|
| Model    | 384.279748 | 2  | 192.139874 | F(2, 17)      | = | 29.40  |
| Residual | 111.109765 | 17 | 6.53586854 | Prob > F      | = | 0.0000 |
|          |            |    |            | R-squared     | = | 0.7757 |
|          |            |    |            | Adj R-squared | = | 0.7493 |
| Total    | 495.389513 | 19 | 26.0731323 | Root MSE      | = | 2.5565 |

| bodyfat | Coefficient | Std. err. | t     | P> t  | [95% conf. interval] |          |
|---------|-------------|-----------|-------|-------|----------------------|----------|
| thigh   | .8508818    | .1124482  | 7.57  | 0.000 | .6136367             | 1.088127 |
| midarm  | .0960295    | .1613927  | 0.60  | 0.560 | -.2444792            | .4365383 |
| _cons   | -25.99696   | 6.99732   | -3.72 | 0.002 | -40.76001            | -11.2339 |

```
. estat vif
```

| Variable | VIF  | 1/VIF    |
|----------|------|----------|
| midarm   | 1.01 | 0.992831 |
| thigh    | 1.01 | 0.992831 |
| Mean VIF | 1.01 |          |

Note how the coefficients change and how the estimated standard errors for each of the regression coefficients become much smaller. The calculated value of  $R^2$  for the overall regression for the subset model does not appreciably decline when we remove the correlated predictor. Removing an independent variable from the model is one way to deal with multicollinearity. Other methods include ridge regression, weighted least squares, and restricting the use of the fitted model to data that follow the same pattern of multicollinearity. In economic studies, it is sometimes possible to estimate the regression coefficients from different subsets of the data by using cross-section and time series.

All examples above demonstrated the use of centered VIFs. As pointed out by [Belsley \(1991\)](#), the centered VIFs may fail to discover collinearity involving the constant term. One solution is to use the uncentered VIFs instead. According to the definition of the uncentered VIFs, the constant is viewed as a legitimate explanatory variable in a regression model, which allows one to obtain the VIF value for the constant term.

▷ Example 13: estat vif, with strong evidence of collinearity with the constant term

Consider the extreme example in which one of the regressors is highly correlated with the constant. We simulate the data and examine both centered and uncentered VIF diagnostics after fitted regression model as follows.

```
. use https://www.stata-press.com/data/r19/extreme_collin
. regress y one x z
```

| Source   | SS         | df | MS         | Number of obs | = | 100     |
|----------|------------|----|------------|---------------|---|---------|
| Model    | 223801.985 | 3  | 74600.6617 | F(3, 96)      | = | 2710.27 |
| Residual | 2642.42124 | 96 | 27.5252213 | Prob > F      | = | 0.0000  |
|          |            |    |            | R-squared     | = | 0.9883  |
|          |            |    |            | Adj R-squared | = | 0.9880  |
| Total    | 226444.406 | 99 | 2287.31723 | Root MSE      | = | 5.2464  |

| y     | Coefficient | Std. err. | t     | P> t  | [95% conf. interval] |          |
|-------|-------------|-----------|-------|-------|----------------------|----------|
| one   | -3.278582   | 10.5621   | -0.31 | 0.757 | -24.24419            | 17.68702 |
| x     | 2.038696    | .0242673  | 84.01 | 0.000 | 1.990526             | 2.086866 |
| z     | 4.863137    | .2681036  | 18.14 | 0.000 | 4.330956             | 5.395319 |
| _cons | 9.760075    | 10.50935  | 0.93  | 0.355 | -11.10082            | 30.62097 |

```
. estat vif
```

| Variable | VIF  | 1/VIF    |
|----------|------|----------|
| z        | 1.03 | 0.968488 |
| x        | 1.03 | 0.971307 |
| one      | 1.00 | 0.995425 |
| Mean VIF | 1.02 |          |

```
. estat vif, uncentered
```

| Variable | VIF    | 1/VIF    |
|----------|--------|----------|
| one      | 402.94 | 0.002482 |
| _cons    | 401.26 | 0.002492 |
| z        | 2.93   | 0.341609 |
| x        | 1.13   | 0.888705 |
| Mean VIF | 202.06 |          |

According to the values of the centered VIFs (1.03, 1.03, 1.00), no harmful collinearity is detected in the model. However, by the construction of these simulated data, we know that one is highly collinear with the constant term. As such, the large values of uncentered VIFs for one (402.94) and \_cons (401.26) reveal high collinearity of the variable one with the constant term.

## Measures of effect size

### Description for estat esize

`estat esize` calculates effect sizes for linear models after `regress` or `anova`. By default, `estat esize` reports  $\eta^2$  estimates (Kerlinger and Lee 2000), which are equivalent to  $R^2$  estimates. If the option `epsilon` is specified, `estat esize` reports  $\epsilon^2$  estimates (Grissom and Kim 2012). If the option `omega` is specified, `estat esize` reports  $\omega^2$  estimates (Grissom and Kim 2012). Both  $\epsilon^2$  and  $\omega^2$  are adjusted  $R^2$  estimates. Confidence intervals for  $\eta^2$  estimates are estimated by using the noncentral  $F$  distribution (Smithson 2001). See Kline (2013) or Thompson (2006) for further information.

### Menu for estat

Statistics > Postestimation

### Syntax for estat esize

```
estat esize [, epsilon omega level(#)]
```

`collect` is allowed with `estat esize`; see [U] 11.1.10 Prefix commands.

### Options for estat esize

`epsilon` specifies that the  $\epsilon^2$  estimates of effect size be reported. The default is  $\eta^2$  estimates.

`omega` specifies that the  $\omega^2$  estimates of effect size be reported. The default is  $\eta^2$  estimates.

`level(#)` specifies the confidence level, as a percentage, for confidence intervals. The default is `level(95)` or as set by `set level`; see [U] 20.8 Specifying the width of confidence intervals.

### Remarks and examples for estat esize

Whereas  $p$ -values are used to assess the statistical significance of a result, measures of effect size are used to assess the practical significance of a result. Effect sizes can be broadly categorized as “measures of group differences” (the  $d$  family) and “measures of association” (the  $r$  family); see Ellis (2010, table 1.1). The  $d$  family includes estimators such as Cohen’s  $D$ , Hedges’s  $G$ , and Glass’s  $\Delta$  (also see [R] `esize`). The  $r$  family includes estimators such as the point-biserial correlation coefficient,  $\eta^2$ ,  $\epsilon^2$ , and  $\omega^2$ . For an introduction to the concepts and calculation of effect sizes, see Kline (2013) or Thompson (2006). For a more detailed discussion, see Kirk (1996), Ellis (2010), Cumming (2012), Grissom and Kim (2012), and Kelley and Preacher (2012).

## ▷ Example 14: Calculating effect sizes for a linear regression model

Suppose we fit a linear regression model for low-birthweight infants.

```
. use https://www.stata-press.com/data/r19/lbw
(Hosmer & Lemeshow data)
. regress bwt smoke i.race
```

| Source   | SS         | df  | MS         | Number of obs | = | 189    |
|----------|------------|-----|------------|---------------|---|--------|
| Model    | 12346897.6 | 3   | 4115632.54 | F(3, 185)     | = | 8.69   |
| Residual | 87568400.9 | 185 | 473342.708 | Prob > F      | = | 0.0000 |
|          |            |     |            | R-squared     | = | 0.1236 |
|          |            |     |            | Adj R-squared | = | 0.1094 |
| Total    | 99915298.6 | 188 | 531464.354 | Root MSE      | = | 688    |

| bwt   | Coefficient | Std. err. | t     | P> t  | [95% conf. interval] |
|-------|-------------|-----------|-------|-------|----------------------|
| smoke | -428.0254   | 109.0033  | -3.93 | 0.000 | -643.0746 -212.9761  |
| race  |             |           |       |       |                      |
| Black | -450.54     | 153.066   | -2.94 | 0.004 | -752.5194 -148.5607  |
| Other | -454.1813   | 116.436   | -3.90 | 0.000 | -683.8944 -224.4683  |
| _cons | 3334.858    | 91.74301  | 36.35 | 0.000 | 3153.86 3515.855     |

We can use the `estat esize` command to calculate  $\eta^2$  for the entire model and a partial  $\eta^2$  for each term in the model.

```
. estat esize
Effect sizes for linear models
```

| Source | Eta-squared | df | [95% conf. interval] |
|--------|-------------|----|----------------------|
| Model  | .1235736    | 3  | .0399862 .2041365    |
| smoke  | .0769345    | 1  | .0193577 .1579213    |
| race   | .0908394    | 2  | .0233037 .1700334    |

Note: Eta-squared values for individual model terms are partial.

The overall model effect size is 0.124. This means that roughly 12.4% of the variation in `bwt` is explained by the model. The partial effect size for `smoke` is 0.077. This means that roughly 7.7% of the variation in `bwt` is explained by `smoke` after you remove the variation explained by all other terms.

The `omega` option causes `estat esize` to report  $\omega^2$  and partial  $\omega^2$ .

```
. estat esize, omega
Effect sizes for linear models
```

| Source | Omega-squared | df |
|--------|---------------|----|
| Model  | .1088457      | 3  |
| smoke  | .0715877      | 1  |
| race   | .0806144      | 2  |

Note: Omega-squared values for individual model terms are partial.

## ▷ Example 15: Calculating effect size for an ANOVA model

We can use `estat esize` after ANOVA models as well.

```
. anova bwt smoke race
```

|          | Number of obs = | 189     | R-squared =     | 0.1236 |        |
|----------|-----------------|---------|-----------------|--------|--------|
|          | Root MSE =      | 687.999 | Adj R-squared = | 0.1094 |        |
| Source   | Partial SS      | df      | MS              | F      | Prob>F |

. estat esize
```

Effect sizes for linear models

| Source | Eta-squared | df | [95% conf. interval] |          |
|--------|-------------|----|----------------------|----------|
| Model  | .1235736    | 3  | .0399862             | .2041365 |
| smoke  | .0769345    | 1  | .0193577             | .1579213 |
| race   | .0908394    | 2  | .0233037             | .1700334 |

Note: Eta-squared values for individual model terms are partial.

## □ Technical note

$\eta^2$  was developed in the context of analysis of variance. Thus, the published research on the calculation of confidence intervals focuses on cases where the numerator degrees of freedom are relatively small (for example,  $df < 20$ ).

Some combinations of the  $F$  statistic, numerator degrees of freedom, and denominator degrees of freedom yield confidence limits that do not contain the corresponding estimated value for an  $\eta^2$ . This problem is most commonly observed for larger numerator degrees of freedom.

Nothing in the literature suggests alternative methods for constructing confidence intervals in such cases; therefore, we recommend cautious interpretation of confidence intervals for  $\eta^2$  when the numerator degrees of freedom are greater than 20.

## Stored results for estat esize

estat esize stores the following results in `r()`:

### Scalars

`r(level)` confidence level

### Matrices

`r(esize)` a matrix of effect sizes, confidence intervals, degrees of freedom, and  $F$  statistics with rows corresponding to each term in the model

|                         |                                     |

## Methods and formulas

See [Hamilton \(2013, chap. 7\)](#), [Kohler and Kreuter \(2012, sec. 9.3\)](#), or [Baum \(2006, chap. 5\)](#) for an overview of using Stata to perform regression diagnostics. See [Peracchi \(2001, chap. 8\)](#) for a mathematically rigorous discussion of diagnostics.

Methods and formulas are presented under the following headings:

*predict*  
Special-interest postestimation commands

## predict

Assume that you have already fit the regression model

$$\mathbf{y} = \mathbf{X}\mathbf{b} + \mathbf{e}$$

where  $\mathbf{X}$  is  $n \times k$ .

Denote the previously estimated coefficient vector by  $\mathbf{b}$  and its estimated variance matrix by  $\mathbf{V}$ . `predict` works by recalling various aspects of the model, such as  $\mathbf{b}$ , and combining that information with the data currently in memory. Let  $\mathbf{x}_j$  be the  $j$ th observation currently in memory, and let  $s^2$  be the mean squared error of the regression.

If the user specified weights in `regress`, then  $\mathbf{X}'\mathbf{X}$  in the following formulas is replaced by  $\mathbf{X}'\mathbf{D}\mathbf{X}$ , where  $\mathbf{D}$  is defined in [Weighted regression](#) under *Methods and formulas* in [\[R\] regress](#).

Let  $\mathbf{V} = s^2(\mathbf{X}'\mathbf{X})^{-1}$ . Let  $k$  be the number of independent variables including the intercept, if any, and let  $y_j$  be the observed value of the dependent variable.

The *predicted value* (`xb` option) is defined as  $\hat{y}_j = \mathbf{x}_j\mathbf{b}$ .

Let  $\ell_j$  represent a lower bound for an observation  $j$  and  $u_j$  represent an upper bound. The probability that  $y_j|\mathbf{x}_j$  would be observed in the interval  $(\ell_j, u_j)$ —the `pr` ( $\ell$ ,  $u$ ) option—is

$$P(\ell_j, u_j) = \Pr(\ell_j < \mathbf{x}_j\mathbf{b} + e_j < u_j) = \Phi\left(\frac{u_j - \hat{y}_j}{s}\right) - \Phi\left(\frac{\ell_j - \hat{y}_j}{s}\right)$$

where for the `pr` ( $\ell$ ,  $u$ ), `e` ( $\ell$ ,  $u$ ), and `ystar` ( $\ell$ ,  $u$ ) options,  $\ell_j$  and  $u_j$  can be anywhere in the range  $(-\infty, +\infty)$ .

The option `e` ( $\ell$ ,  $u$ ) computes the expected value of  $y_j|\mathbf{x}_j$  conditional on  $y_j|\mathbf{x}_j$  being in the interval  $(\ell_j, u_j)$ , that is, when  $y_j|\mathbf{x}_j$  is truncated. It can be expressed as

$$E(\ell_j, u_j) = E(\mathbf{x}_j\mathbf{b} + e_j \mid \ell_j < \mathbf{x}_j\mathbf{b} + e_j < u_j) = \hat{y}_j - s \frac{\phi\left(\frac{u_j - \hat{y}_j}{s}\right) - \phi\left(\frac{\ell_j - \hat{y}_j}{s}\right)}{\Phi\left(\frac{u_j - \hat{y}_j}{s}\right) - \Phi\left(\frac{\ell_j - \hat{y}_j}{s}\right)}$$

where  $\phi$  is the normal density and  $\Phi$  is the cumulative normal.

You can also compute `ystar` ( $\ell$ ,  $u$ )—the expected value of  $y_j|\mathbf{x}_j$ , where  $y_j$  is assumed censored at  $\ell_j$  and  $u_j$ :

$$y_j^* = \begin{cases} \ell_j & \text{if } \mathbf{x}_j\mathbf{b} + e_j \leq \ell_j \\ \mathbf{x}_j\mathbf{b} + e_j & \text{if } \ell_j < \mathbf{x}_j\mathbf{b} + e_j < u_j \\ u_j & \text{if } \mathbf{x}_j\mathbf{b} + e_j \geq u_j \end{cases}$$

This computation can be expressed in several ways, but the most intuitive formulation involves a combination of the two statistics just defined:

$$y_j^* = P(-\infty, \ell_j)\ell_j + P(\ell_j, u_j)E(\ell_j, u_j) + P(u_j, +\infty)u_j$$

A diagonal element of the projection matrix (`hat`) or (`leverage`) is given by

$$h_j = \mathbf{x}_j(\mathbf{X}'\mathbf{X})^{-1}\mathbf{x}_j'$$

The *standard error of the prediction* (the `stdp` option) is defined as  $s_{p_j} = \sqrt{\mathbf{x}_j\mathbf{V}\mathbf{x}_j'}$

and can also be written as  $s_{p_j} = s\sqrt{h_j}$ .

The *standard error of the forecast* (`stdf`) is defined as  $s_{f_j} = s\sqrt{1 + h_j}$ .

The *standard error of the residual* (`stdr`) is defined as  $s_{r_j} = s\sqrt{1 - h_j}$ .

The *residuals* (`residuals`) are defined as  $\hat{e}_j = y_j - \hat{y}_j$ .

The *standardized residuals* (`rstandard`) are defined as  $\hat{e}_{s_j} = \hat{e}_j/s_{r_j}$ .

The *Studentized residuals* (`rstudent`) are defined as

$$r_j = \frac{\hat{e}_j}{s_{(j)}\sqrt{1-h_j}}$$

where  $s_{(j)}$  represents the root mean squared error with the  $j$ th observation removed, which is given by

$$s_{(j)}^2 = \frac{s^2(n-k)}{n-k-1} - \frac{\hat{e}_j^2}{(n-k-1)(1-h_j)}$$

where  $n$  is the number of observations and  $k$  is the number of right-hand-side variables (including the constant).

Cook's  $D$  (`cooksD`) is given by

$$D_j = \frac{\hat{e}_{s_j}^2 (s_{p_j}/s_{r_j})^2}{k} = \frac{h_j \hat{e}_j^2}{ks^2(1-h_j)^2}$$

DFITS (`dfits`) is given by

$$\text{DFITS}_j = r_j \sqrt{\frac{h_j}{1-h_j}}$$

Welsch distance (`welsch`) is given by

$$W_j = \frac{r_j \sqrt{h_j(n-1)}}{1-h_j}$$

COVRATIO (`covratio`) is given by

$$\text{COVRATIO}_j = \frac{1}{1-h_j} \left( \frac{n-k-\hat{e}_{s_j}^2}{n-k-1} \right)^k$$

The DFBETAS (`dfbeta`) for a particular regressor  $x_i$  are given by

$$\text{DFBETA}_{j,i} = \frac{r_j u_{j,i}}{\sqrt{U^2(1-h_j)}}$$

where  $u_j$  are the residuals obtained from a regression of  $x_i$  on the remaining  $x$ 's and  $U^2 = \sum_j u_j^2$ .

## Special-interest postestimation commands

The omitted-variable test (Ramsey 1969) reported by `estat ovtest` fits the regression  $y_i = \mathbf{x}_i \mathbf{b} + \mathbf{z}_i \mathbf{t} + u_i$  and then performs a standard  $F$  test of  $\mathbf{t} = \mathbf{0}$ . The default test uses  $\mathbf{z}_i = (\hat{y}_i^2, \hat{y}_i^3, \hat{y}_i^4)$ . If `rhs` is specified,  $\mathbf{z}_i = (x_{1i}^2, x_{1i}^3, x_{1i}^4, x_{2i}^2, \dots, x_{mi}^4)$ . In either case, the variables are normalized to have minimum 0 and maximum 1 before powers are calculated.

The test for heteroskedasticity (Breusch and Pagan 1979; Cook and Weisberg 1983) models  $\text{Var}(e_i) = \sigma^2 \exp(\mathbf{z} \mathbf{t})$ , where  $\mathbf{z}$  is a variable list specified by the user, the list of right-hand-side variables, or the fitted values  $\mathbf{x} \hat{\boldsymbol{\beta}}$ . The test is of  $\mathbf{t} = \mathbf{0}$ . Mechanically, `estat hettest` fits the augmented regression  $\hat{e}_i^2 / \hat{\sigma}^2 = a + \mathbf{z}_i \mathbf{t} + v_i$ .

The original Breusch–Pagan/Cook–Weisberg version of the test assumes that the  $e_i$  are normally distributed under the null hypothesis which implies that the score test statistic  $S$  is equal to the model sum of squares from the augmented regression divided by 2. Under the null hypothesis,  $S$  has the  $\chi^2$  distribution with  $m$  degrees of freedom, where  $m$  is the number of columns of  $\mathbf{z}$ .

Koenker (1981) derived a score test of the null hypothesis that  $\mathbf{t} = \mathbf{0}$  under the assumption that the  $e_i$  are independent and identically distributed (i.i.d.). Koenker showed that  $S = N * R^2$  has a large-sample  $\chi^2$  distribution with  $m$  degrees of freedom, where  $N$  is the number of observations and  $R^2$  is from the augmented regression and  $m$  is the number of columns of  $\mathbf{z}$ . `estat hettest, iid` produces this version of the test.

Wooldridge (2020, 270) showed that an  $F$  test of  $\mathbf{t} = \mathbf{0}$  in the augmented regression can also be used under the assumption that the  $e_i$  are i.i.d. `estat hettest, fstat` produces this version of the test.

Szroeter’s class of tests for homoskedasticity against the alternative that the residual variance increases in some variable  $x$  is defined in terms of

$$H = \frac{\sum_{i=1}^n h(x_i) e_i^2}{\sum_{i=1}^n e_i^2}$$

where  $h(x)$  is some weight function that increases in  $x$  (Szroeter 1978).  $H$  is a weighted average of the  $h(x)$ , with the squared residuals serving as weights. Under homoskedasticity,  $H$  should be approximately equal to the unweighted average of  $h(x)$ . Large values of  $H$  suggest that  $e_i^2$  tends to be large where  $h(x)$  is large; that is, the variance indeed increases in  $x$ , whereas small values of  $H$  suggest that the variance actually decreases in  $x$ . `estat szroeter` uses  $h(x_i) = \text{rank}(x_i \text{ in } x_1 \dots x_n)$ ; see Judge et al. [1985, 452] for details. `estat szroeter` displays a normalized version of  $H$ ,

$$Q = \sqrt{\frac{6n}{n^2 - 1}} H$$

which is approximately  $N(0, 1)$  distributed under the null (homoskedasticity).

`estat hettest` and `estat szroeter` provide adjustments of  $p$ -values for multiple testing. The supported methods are described in [R] [test](#).

`estat imtest` performs the information matrix test for the regression model, as well as an orthogonal decomposition into tests for heteroskedasticity  $\delta_1$ , nonnormal skewness  $\delta_2$ , and nonnormal kurtosis  $\delta_3$  (Cameron and Trivedi 1990; Long and Trivedi 1993). The decomposition is obtained via three auxiliary regressions. Let  $e$  be the regression residuals,  $\hat{\sigma}^2$  be the maximum likelihood estimate of  $\sigma^2$  in the regression,  $n$  be the number of observations,  $X$  be the set of  $k$  variables specified with `estat imtest`, and  $R_{\text{un}}^2$  be the uncentered  $R^2$  from a regression.  $\delta_1$  is obtained as  $nR_{\text{un}}^2$  from a regression of  $e^2 - \hat{\sigma}^2$  on the cross products of the variables in  $X$ .  $\delta_2$  is computed as  $nR_{\text{un}}^2$  from a regression of  $e^3 - 3\hat{\sigma}^2 e$  on  $X$ . Finally,  $\delta_3$  is obtained as  $nR_{\text{un}}^2$  from a regression of  $e^4 - 6\hat{\sigma}^2 e^2 - 3\hat{\sigma}^4$  on  $X$ .  $\delta_1$ ,  $\delta_2$ , and  $\delta_3$  are asymptotically  $\chi^2$  distributed with  $1/2k(k+1)$ ,  $K$ , and 1 degree of freedom. The information test statistic  $\delta = \delta_1 + \delta_2 + \delta_3$  is asymptotically  $\chi^2$  distributed with  $1/2k(k+3)$  degrees of freedom. White’s test for heteroskedasticity is computed as  $nR^2$  from a regression of  $\hat{u}^2$  on  $X$  and the cross products of the variables in  $X$ . This test statistic is usually close to  $\delta_1$ .

`estat vif` calculates the centered variance inflation factor ( $VIF_c$ ) (Chatterjee and Hadi 2012, 248–251) for  $x_j$ , given by

$$VIF_c(x_j) = \frac{1}{1 - \widehat{R}_j^2}$$

where  $\widehat{R}_j^2$  is the square of the centered multiple correlation coefficient that results when  $x_j$  is regressed against all other explanatory variables, including the constant.

The uncentered variance inflation factor ( $VIF_{uc}$ ) (Belsley 1991, 28–29) for  $x_j$  is given by

$$VIF_{uc}(x_j) = \frac{1}{1 - \widetilde{R}_j^2}$$

where  $\widetilde{R}_j^2$  is the square of the uncentered multiple correlation coefficient that results when  $x_j$  is regressed against all other explanatory variables and a constant of 1. If the original regression model was fit without a constant, the constant would also be omitted from the regression of  $x_j$ .

The methods and formulas for `estat esize` are described in *Methods and formulas* of [R] `esize`.

## Acknowledgments

`estat ovtest` and `estat htest` are based on programs originally written by Richard Goldstein. `estat imtest`, `estat szroeter`, and the current version of `estat htest` were written by Jeroen Weesie of the Department of Sociology at Utrecht University, The Netherlands. `estat imtest` is based in part on code written by J. Scott Long of the Department of Sociology at Indiana University, coauthor of the Stata Press book *Regression Models for Categorical and Limited Dependent Variables*, and author of the Stata Press book *The Workflow of Data Analysis Using Stata*.

## Description

The following postestimation commands are of special interest after `regress`:

| Command               | Description                            |
|-----------------------|----------------------------------------|
| <code>rvfplot</code>  | residual-versus-fitted plot            |
| <code>avplot</code>   | added-variable plot                    |
| <code>avplots</code>  | all added-variables plots in one image |
| <code>cprplot</code>  | component-plus-residual plot           |
| <code>acprplot</code> | augmented component-plus-residual plot |
| <code>rvpplot</code>  | residual-versus-predictor plot         |
| <code>lvr2plot</code> | leverage-versus-squared-residual plot  |

These commands are not appropriate with `svy` estimation results.

For a discussion of the terminology used in this entry, see the [Terminology](#) section of *Remarks and examples for predict* in [R] [regress postestimation](#).

## rvfplot

### Description for rfvplot

`rvfplot` graphs a residual-versus-fitted plot, a graph of the residuals against the fitted values.

### Menu for rfvplot

Statistics > Linear models and related > Regression diagnostics > Residual-versus-fitted plot

### Syntax for rfvplot

```
rvfplot [, rvfplot_options]
```

| <i>rvfplot_options</i>                  | Description                                                                                 |
|-----------------------------------------|---------------------------------------------------------------------------------------------|
| Plot                                    |                                                                                             |
| <a href="#">marker_options</a>          | change look of markers (color, size, etc.)                                                  |
| <a href="#">marker_label_options</a>    | add marker labels; change look or position                                                  |
| Add plots                               |                                                                                             |
| <code>addplot (<i>plot</i>)</code>      | add plots to the generated graph                                                            |
| Y axis, X axis, Titles, Legend, Overall |                                                                                             |
| <a href="#">twoway_options</a>          | any options other than <code>by()</code> documented in [G-3] <a href="#">twoway_options</a> |

## Options for rvfplot

## Plot

*marker\_options* affect the rendition of markers drawn at the plotted points, including their shape, size, color, and outline; see [G-3] *marker\_options*.

*marker\_label\_options* specify if and how the markers are to be labeled; see [G-3] *marker\_label\_options*.

## Add plots

`addplot (plot)` provides a way to add plots to the generated graph. See [G-3] *addplot\_option*.

## Y axis, X axis, Titles, Legend, Overall

*twoway\_options* are any of the options documented in [G-3] *twoway\_options*, excluding `by()`. These include options for titling the graph (see [G-3] *title\_options*) and for saving the graph to disk (see [G-3] *saving\_option*).

## Remarks and examples for rvfplot

`rvfplot` graphs the residuals against the fitted values.

## ▷ Example 1

Using `auto.dta` described in [U] 1.2.2 *Example datasets*, we will use `regress` to fit a model of price on weight, mpg, foreign, and the interaction of foreign with mpg. We specify `foreign#c.mpg` to obtain the interaction of foreign with mpg; see [U] 11.4.3 *Factor variables*.

```
. use https://www.stata-press.com/data/r19/auto
(1978 automobile data)
```

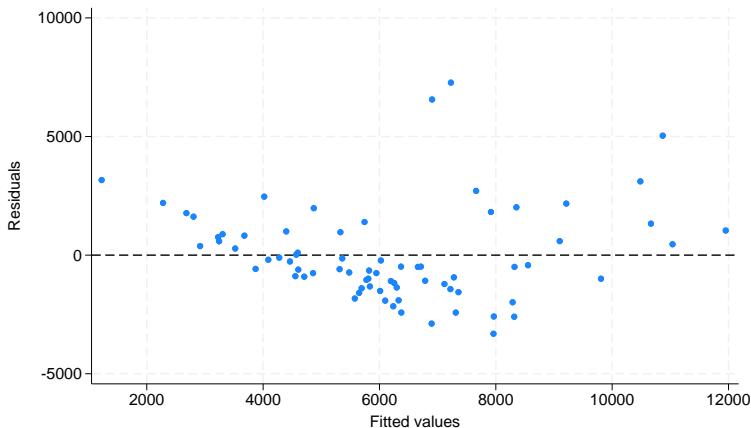

```
. regress price weight foreign#c.mpg
```

| Source   | SS        | df | MS         | Number of obs | = | 74     |
|----------|-----------|----|------------|---------------|---|--------|
| Model    | 350319665 | 4  | 87579916.3 | F(4, 69)      | = | 21.22  |
| Residual | 284745731 | 69 | 4126749.72 | Prob > F      | = | 0.0000 |
|          |           |    |            | R-squared     | = | 0.5516 |
|          |           |    |            | Adj R-squared | = | 0.5256 |
| Total    | 635065396 | 73 | 8699525.97 | Root MSE      | = | 2031.4 |

| price         | Coefficient | Std. err. | t     | P> t  | [95% conf. interval] |           |
|---------------|-------------|-----------|-------|-------|----------------------|-----------|
| weight        | 4.613589    | .7254961  | 6.36  | 0.000 | 3.166263             | 6.060914  |
| foreign       |             |           |       |       |                      |           |
| Foreign       | 11240.33    | 2751.681  | 4.08  | 0.000 | 5750.878             | 16729.78  |
| mpg           | 263.1875    | 110.7961  | 2.38  | 0.020 | 42.15527             | 484.2197  |
| foreign#c.mpg |             |           |       |       |                      |           |
| Foreign       | -307.2166   | 108.5307  | -2.83 | 0.006 | -523.7294            | -90.70368 |
| _cons         | -14449.58   | 4425.72   | -3.26 | 0.002 | -23278.65            | -5620.51  |

Once we have fit a model, we may use any of the regression diagnostics commands. `rvfplot` (read residual-versus-fitted plot) graphs the residuals against the fitted values:

```
. rvfplot, yline(0)
```

All the diagnostic plot commands allow the `graph twoway` and `graph twoway scatter` options; we specified a `yline(0)` to draw a line across the graph at  $y = 0$ ; see [G-2] [graph twoway scatter](#).

In a well-fitted model, there should be no pattern to the residuals plotted against the fitted values—something not true of our model. Ignoring the two outliers at the top center of the graph, we see curvature in the pattern of the residuals, suggesting a violation of the assumption that price is linear in our independent variables. We might also have seen increasing or decreasing variation in the residuals—heteroskedasticity. Any pattern whatsoever indicates a violation of the least-squares assumptions.

◀

## avplot

### Description for avplot

`avplot` graphs an added-variable plot (a.k.a. partial-regression leverage plot, partial regression plot, or adjusted partial residual plot) after `regress`. *indepvar* may be an independent variable (a.k.a. predictor, carrier, or covariate) that is currently in the model or not.

### Menu for avplot

Statistics > Linear models and related > Regression diagnostics > Added-variable plot

### Syntax for avplot

```
avplot indepvar [, avplot_options]
```

| <i>avplot_options</i>                     | Description                                                                        |
|-------------------------------------------|------------------------------------------------------------------------------------|
| Plot                                      |                                                                                    |
| <i>marker_options</i>                     | change look of markers (color, size, etc.)                                         |
| <i>marker_label_options</i>               | add marker labels; change look or position                                         |
| Reference line                            |                                                                                    |
| <code>rlopts(<i>cline_options</i>)</code> | affect rendition of the reference line                                             |
| Add plots                                 |                                                                                    |
| <code>addplot(<i>plot</i>)</code>         | add other plots to the generated graph                                             |
| Y axis, X axis, Titles, Legend, Overall   |                                                                                    |
| <i>twoway_options</i>                     | any options other than <code>by()</code> documented in [G-3] <i>twoway_options</i> |

### Options for avplot

Plot

*marker\_options* affects the rendition of markers drawn at the plotted points, including their shape, size, color, and outline; see [G-3] *marker\_options*.

*marker\_label\_options* specify if and how the markers are to be labeled; see [G-3] *marker\_label\_options*.

Reference line

`rlopts(cline_options)` affects the rendition of the reference line. See [G-3] *cline\_options*.

Add plots

`addplot(plot)` provides a way to add plots to the generated graph. See [G-3] *addplot\_option*.

Y axis, X axis, Titles, Legend, Overall

*twoway\_options* are any of the options documented in [G-3] *twoway\_options*, excluding `by()`. These include options for titling the graph (see [G-3] *title\_options*) and for saving the graph to disk (see [G-3] *saving\_option*).

## Remarks and examples for avplot

avplot graphs an added-variable plot, also known as the partial-regression leverage plot.

One of the wonderful features of one-regressor regressions (regressions of  $y$  on one  $x$ ) is that we can graph the data and the regression line. There is no easier way to understand the regression than to examine such a graph. Unfortunately, we cannot do this when we have more than one regressor. With two regressors, it is still theoretically possible—the graph must be drawn in three dimensions, but with three or more regressors no graph is possible.

The added-variable plot is an attempt to project multidimensional data back to the two-dimensional world for each of the original regressors. This is, of course, impossible without making some concessions. Call the coordinates on an added-variable plot  $y$  and  $x$ . The added-variable plot has the following properties:

- There is a one-to-one correspondence between  $(x_i, y_i)$  and the  $i$ th observation used in the original regression.
- A regression of  $y$  on  $x$  has the same coefficient and standard error (up to a degree-of-freedom adjustment) as the estimated coefficient and standard error for the regressor in the original regression.
- The “outlierness” of each observation in determining the slope is in some sense preserved.

It is equally important to note the properties that are not listed. The  $y$  and  $x$  coordinates of the added-variable plot cannot be used to identify functional form, or, at least, not well (see [Mallows \[1986\]](#)). In the construction of the added-variable plot, the relationship between  $y$  and  $x$  is forced to be linear.

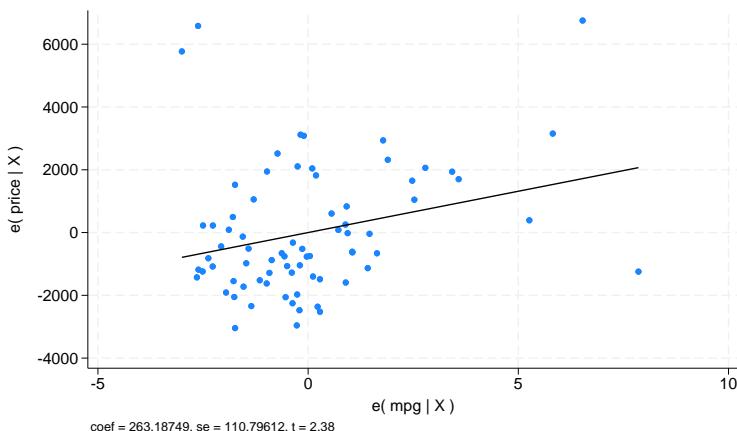

### ▷ Example 2

Let’s use the same model as we used in [example 1](#).

```
. use https://www.stata-press.com/data/r19/auto
(1978 automobile data)
. regress price weight foreign##c.mpg
(output omitted)
```

We can now examine the added-variable plot for mpg.

```
. avplot mpg
```

This graph suggests a problem in determining the coefficient on mpg. Were this a one-regressor regression, the two points at the top-left corner and the one at the top right would cause us concern, and so it does in our more complicated multiple-regressor case. To identify the problem points, we retyped our command, modifying it to read `avplot mpg, mlabel(make)`, and discovered that the two cars at the top left are the Cadillac Eldorado and the Lincoln Versailles; the point at the top right is the Cadillac Seville. These three cars account for 100% of the luxury cars in our data, suggesting that our model is misspecified. By the way, the point at the lower right of the graph, also cause for concern, is the Plymouth Arrow, our data entry error.

◀

## □ Technical note

Stata's `avplot` command can be used with regressors already in the model, as we just did, or with potential regressors not yet in the model. In either case, `avplot` will produce the correct graph. The name “added-variable plot” is unfortunate in the case when the variable is already among the list of regressors but is, we think, still preferable to the name “partial-regression leverage plot” assigned by [Belsley, Kuh, and Welsch \(1980, 30\)](#) and more in the spirit of the original use of such plots by [Mosteller and Tukey \(1977, 271–279\)](#). [Welsch \(1986, 403\)](#), however, disagrees: “I am sorry to see that [Chatterjee and Hadi \[1986\]](#) endorse the term ‘added-variable plot’ when  $X_j$  is part of the original model” and goes on to suggest the name “adjusted partial residual plot”.

□

## avplots

### Description for avplots

`avplots` graphs all the added-variable plots in one image.

### Menu for avplots

Statistics > Linear models and related > Regression diagnostics > Added-variable plot

### Syntax for avplots

```
avplots [, avplots_options]
```

| <i>avplots_options</i>                  | Description                                                            |
|-----------------------------------------|------------------------------------------------------------------------|
| Plot                                    |                                                                        |
| <i>marker_options</i>                   | change look of markers (color, size, etc.)                             |
| <i>marker_label_options</i>             | add marker labels; change look or position                             |
| <i>combine_options</i>                  | any of the options documented in [G-2] <b>graph combine</b>            |
| Reference line                          |                                                                        |
| <i>rlopts</i> ( <i>cline_options</i> )  | affect rendition of the reference line                                 |
| Y axis, X axis, Titles, Legend, Overall |                                                                        |
| <i>twoway_options</i>                   | any options other than by () documented in [G-3] <i>twoway_options</i> |

## Options for avplots

### Plot

*marker\_options* affects the rendition of markers drawn at the plotted points, including their shape, size, color, and outline; see [G-3] *marker\_options*.

*marker\_label\_options* specify if and how the markers are to be labeled; see [G-3] *marker\_label\_options*.

*combine\_options* are any of the options documented in [G-2] *graph combine*. These include options for titling the graph (see [G-3] *title\_options*) and for saving the graph to disk (see [G-3] *saving\_option*).

### Reference line

*r1opts* (*cline\_options*) affects the rendition of the reference line. See [G-3] *cline\_options*.

### Y axis, X axis, Titles, Legend, Overall

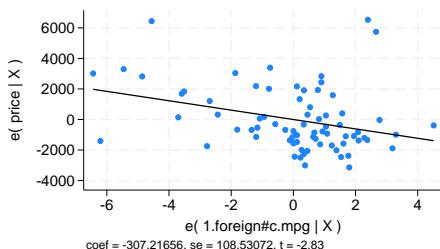

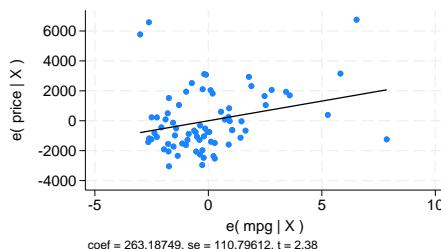

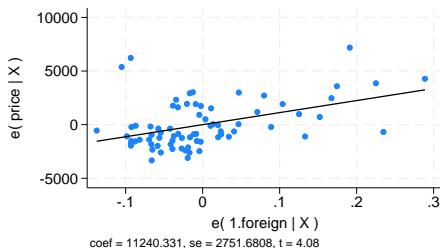

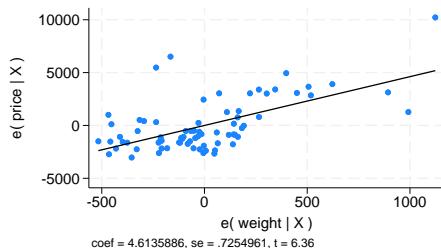

*twoway\_options* are any of the options documented in [G-3] *twoway\_options*, excluding *by()*. These include options for titling the graph (see [G-3] *title\_options*) and for saving the graph to disk (see [G-3] *saving\_option*).

## Remarks and examples for avplots

### ▷ Example 3

In [example 2](#), we used `avplot` to examine the added-variable plot for `mpg` in our regression of `price` on `weight` and `foreign##c.mpg`. Now, let's use `avplots` to graph an added-variable plot for every regressor in the data.

```
. avplots
```

## cprplot

### Description for cprplot

cprplot graphs a component-plus-residual plot (a.k.a. partial residual plot) after regress. *indepvar* must be an independent variable that is currently in the model.

### Menu for cprplot

Statistics > Linear models and related > Regression diagnostics > Component-plus-residual plot

### Syntax for cprplot

```
cprplot indepvar [, cprplot_options]
```

| <i>cprplot_options</i> | Description |
|------------------------|-------------|
|------------------------|-------------|

#### Plot

*marker\_options*

change look of markers (color, size, etc.)

*marker\_label\_options*

add marker labels; change look or position

#### Reference line

*rlopts* (*cline\_options*)

affect rendition of the reference line

#### Options

*lowess*

add a lowess smooth of the plotted points

*lsopts* (*lowess\_options*)

affect rendition of the lowess smooth

*mspline*

add median spline of the plotted points

*msopts* (*mspline\_options*)

affect rendition of the spline

#### Add plots

*addplot* (*plot*)

add other plots to the generated graph

#### Y axis, X axis, Titles, Legend, Overall

*twoway\_options*

any options other than by() documented in [G-3] *twoway\_options*

## Options for `cprplot`

### Plot

`marker_options` affects the rendition of markers drawn at the plotted points, including their shape, size, color, and outline; see [G-3] [marker\\_options](#).

`marker_label_options` specify if and how the markers are to be labeled; see [G-3] [marker\\_label\\_options](#).

### Reference line

`rlopts` (`cline_options`) affects the rendition of the reference line. See [G-3] [cline\\_options](#).

### Options

`lowess` adds a lowess smooth of the plotted points to assist in detecting nonlinearities.

`lsopts` (`lowess_options`) affects the rendition of the lowess smooth. For an explanation of these options, especially the `bwidth()` option, see [R] [lowess](#). Specifying `lsopts()` implies the `lowess` option.

`mspline` adds a median spline of the plotted points to assist in detecting nonlinearities.

`msopts` (`mspline_options`) affects the rendition of the spline. For an explanation of these options, especially the `bands()` option, see [G-2] [graph twoway mspline](#). Specifying `msopts()` implies the `mspline` option.

### Add plots

`addplot` (`plot`) provides a way to add other plots to the generated graph. See [G-3] [addplot\\_option](#).

### Y axis, X axis, Titles, Legend, Overall

`twoway_options` are any of the options documented in [G-3] [twoway\\_options](#), excluding `by()`. These include options for titling the graph (see [G-3] [title\\_options](#)) and for saving the graph to disk (see [G-3] [saving\\_option](#)).

## Remarks and examples for `cprplot`

Added-variable plots are successful at identifying outliers, but they cannot be used to identify functional form. The component-plus-residual plot (Ezekiel 1924; Larsen and McCleary 1972) is another attempt at projecting multidimensional data into a two-dimensional form, but with different properties. Although the added-variable plot can identify outliers, the component-plus-residual plot cannot. It can, however, be used to examine the functional form assumptions of the model. Both plots have the property that a regression line through the coordinates has a slope equal to the estimated coefficient in the regression model.

## ▷ Example 4

We illustrate component-plus-residual plots using a variation of `auto.dta`.

```
. use https://www.stata-press.com/data/r19/auto1
(Automobile models)
```

```
. regress price mpg weight
```

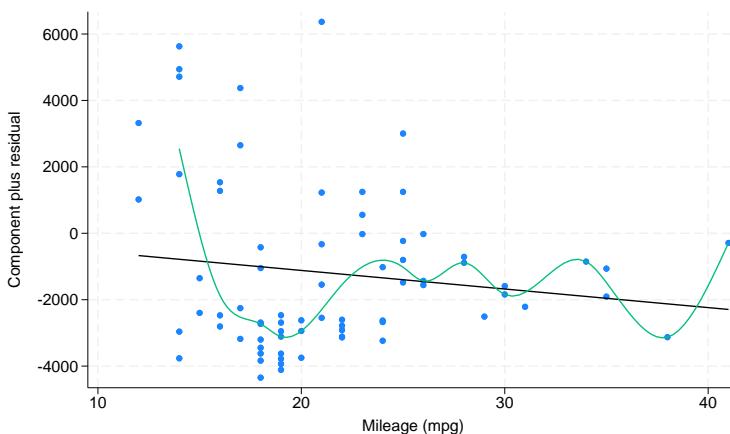

| Source   | SS        | df | MS         | Number of obs | = | 74     |
|----------|-----------|----|------------|---------------|---|--------|
| Model    | 187716578 | 2  | 93858289   | F(2, 71)      | = | 14.90  |
| Residual | 447348818 | 71 | 6300687.58 | Prob > F      | = | 0.0000 |
|          |           |    |            | R-squared     | = | 0.2956 |
|          |           |    |            | Adj R-squared | = | 0.2757 |
| Total    | 635065396 | 73 | 8699525.97 | Root MSE      | = | 2510.1 |

| price  | Coefficient | Std. err. | t     | P> t  | [95% conf. interval] |
|--------|-------------|-----------|-------|-------|----------------------|
| mpg    | -55.9393    | 75.24136  | -0.74 | 0.460 | -205.9663 94.08771   |
| weight | 1.710992    | .5861682  | 2.92  | 0.005 | .5422063 2.879779    |
| _cons  | 2197.9      | 3190.768  | 0.69  | 0.493 | -4164.311 8560.11    |

In fact, we know that the effects of `mpg` in this model are nonlinear—if we added `mpg squared` to the model, its coefficient would have a  $t$  statistic of 2.38, the  $t$  statistic on `mpg` would become  $-2.48$ , and `weight`'s effect would become about one-third of its current value and become statistically insignificant. Pretend that we do not know this.

The component-plus-residual plot for `mpg` is

```
. cprplot mpg, mspline msopts(bands(13))
```

We are supposed to examine the above graph for nonlinearities or, equivalently, ask if the regression line, which has slope equal to the estimated effect of `mpg` in the original model, fits the data adequately. To assist our eyes, we added a median spline. Perhaps some people may detect nonlinearity from this graph, but we assert that if we had not previously revealed the nonlinearity of `mpg` and if we had not added the median spline, the graph would not overly bother us.

## acprplot

### Description for acprplot

`acprplot` graphs an augmented component-plus-residual plot (a.k.a. augmented partial residual plot) as described by [Mallows \(1986\)](#). This seems to work better than the component-plus-residual plot for identifying nonlinearities in the data.

### Menu for acprplot

Statistics > Linear models and related > Regression diagnostics > Augmented component-plus-residual plot

### Syntax for acprplot

```
acprplot indepvar [, acprplot_options]
```

| <i>acprplot_options</i>                  | Description                                                            |
|------------------------------------------|------------------------------------------------------------------------|
| Plot                                     |                                                                        |
| <i>marker_options</i>                    | change look of markers (color, size, etc.)                             |
| <i>marker_label_options</i>              | add marker labels; change look or position                             |
| Reference line                           |                                                                        |
| <i>rlopts</i> ( <i>cline_options</i> )   | affect rendition of the reference line                                 |
| Options                                  |                                                                        |
| <i>lowess</i>                            | add a lowess smooth of the plotted points                              |
| <i>lsopts</i> ( <i>lowess_options</i> )  | affect rendition of the lowess smooth                                  |
| <i>mspline</i>                           | add median spline of the plotted points                                |
| <i>msopts</i> ( <i>mspline_options</i> ) | affect rendition of the spline                                         |
| Add plots                                |                                                                        |
| <i>addplot</i> ( <i>plot</i> )           | add other plots to the generated graph                                 |
| Y axis, X axis, Titles, Legend, Overall  |                                                                        |
| <i>twoway_options</i>                    | any options other than by () documented in [G-3] <i>twoway_options</i> |

### Options for acprplot

#### Plot

*marker\_options* affects the rendition of markers drawn at the plotted points, including their shape, size, color, and outline; see [G-3] *marker\_options*.

*marker\_label\_options* specify if and how the markers are to be labeled; see [G-3] *marker\_label\_options*.

#### Reference line

*rlopts*(*cline\_options*) affects the rendition of the reference line. See [G-3] *cline\_options*.

#### Options

*lowess* adds a lowess smooth of the plotted points to assist in detecting nonlinearities.

`lsopts` (*lowess\_options*) affects the rendition of the lowess smooth. For an explanation of these options, especially the `bwidth()` option, see [R] [lowess](#). Specifying `lsopts()` implies the `lowess` option.

`mspline` adds a median spline of the plotted points to assist in detecting nonlinearities.

`msopts` (*mspline\_options*) affects the rendition of the spline. For an explanation of these options, especially the `bands()` option, see [G-2] [graph twoway mspline](#). Specifying `msopts()` implies the `mspline` option.

#### Add plots

`addplot` (*plot*) provides a way to add other plots to the generated graph. See [G-3] [addplot\\_option](#).

#### Y axis, X axis, Titles, Legend, Overall

*twoway\_options* are any of the options documented in [G-3] [twoway\\_options](#), excluding `by()`. These include options for titling the graph (see [G-3] [title\\_options](#)) and for saving the graph to disk (see [G-3] [saving\\_option](#)).

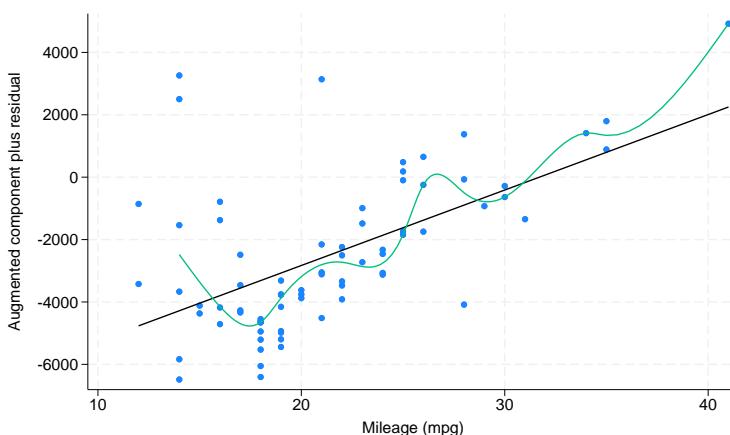

## Remarks and examples for `acrplot`

In the [cprplot](#) section above, we discussed the component-plus-residual plot. Mallows (1986) proposed an augmented component-plus-residual plot that is often more sensitive to detecting nonlinearity.

### ▶ Example 5

Let's compare the augmented component-plus-residual plot with the component-plus-residual plot of [example 4](#).

```
. use https://www.stata-press.com/data/r19/auto
(1978 automobile data)
. regress price weight foreign##c.mpg
(output omitted)
. acrplot mpg, mspline msopts(bands(13))
```

It does do somewhat better.

# rvpplot

## Description for rvpplot

`rvpplot` graphs a residual-versus-predictor plot (a.k.a. independent variable plot or carrier plot), a graph of the residuals against the specified predictor.

## Menu for rvpplot

Statistics > Linear models and related > Regression diagnostics > Residual-versus-predictor plot

## Syntax for rvpplot

```
rvpplot indepvar [, rvpplot_options]
```

| <i>rvpplot_options</i>                  | Description                                                                        |
|-----------------------------------------|------------------------------------------------------------------------------------|
| Plot                                    |                                                                                    |
| <i>marker_options</i>                   | change look of markers (color, size, etc.)                                         |
| <i>marker_label_options</i>             | add marker labels; change look or position                                         |
| Add plots                               |                                                                                    |
| <code>addplot(<i>plot</i>)</code>       | add plots to the generated graph                                                   |
| Y axis, X axis, Titles, Legend, Overall |                                                                                    |
| <i>twoway_options</i>                   | any options other than <code>by()</code> documented in [G-3] <i>twoway_options</i> |

## Options for rvpplot

### Plot

*marker\_options* affects the rendition of markers drawn at the plotted points, including their shape, size, color, and outline; see [G-3] *marker\_options*.

*marker\_label\_options* specify if and how the markers are to be labeled; see [G-3] *marker\_label\_options*.

### Add plots

`addplot(plot)` provides a way to add other plots to the generated graph; see [G-3] *addplot\_option*.

### Y axis, X axis, Titles, Legend, Overall

*twoway\_options* are any of the options documented in [G-3] *twoway\_options*, excluding `by()`. These include options for titling the graph (see [G-3] *title\_options*) and for saving the graph to disk (see [G-3] *saving\_option*).

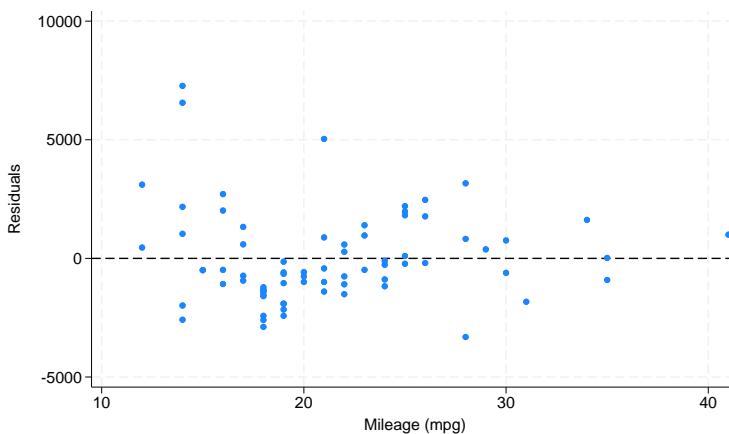

## Remarks and examples for rvpplot

The residual-versus-predictor plot is a simple way to look for violations of the regression assumptions. If the assumptions are correct, there should be no pattern on the graph.

### ▷ Example 6

Let's use our model of price on mpg and weight.

```
. use https://www.stata-press.com/data/r19/auto
(1978 automobile data)
. regress price weight foreign##c.mpg
(output omitted)
. rvpplot mpg, yline(0)
```

Remember, any pattern counts as a problem, and in this graph, we see that the variation in the residuals decreases as mpg increases.

# lvr2plot

## Description for lvr2plot

`lvr2plot` graphs a leverage-versus-squared-residual plot (a.k.a. L-R plot).

## Menu for lvr2plot

Statistics > Linear models and related > Regression diagnostics > Leverage-versus-squared-residual plot

## Syntax for lvr2plot

```
lvr2plot [, lvr2plot_options]
```

| <i>lvr2plot_options</i>                 | Description                                                                        |
|-----------------------------------------|------------------------------------------------------------------------------------|
| Plot                                    |                                                                                    |
| <i>marker_options</i>                   | change look of markers (color, size, etc.)                                         |
| <i>marker_label_options</i>             | add marker labels; change look or position                                         |
| Add plots                               |                                                                                    |
| <code>addplot(<i>plot</i>)</code>       | add other plots to the generated graph                                             |
| Y axis, X axis, Titles, Legend, Overall |                                                                                    |
| <i>twoway_options</i>                   | any options other than <code>by()</code> documented in [G-3] <i>twoway_options</i> |

## Options for lvr2plot

### Plot

*marker\_options* affects the rendition of markers drawn at the plotted points, including their shape, size, color, and outline; see [G-3] *marker\_options*.

*marker\_label\_options* specify if and how the markers are to be labeled; see [G-3] *marker\_label\_options*.

### Add plots

`addplot(plot)` provides a way to add other plots to the generated graph. See [G-3] *addplot\_option*.

### Y axis, X axis, Titles, Legend, Overall

*twoway\_options* are any of the options documented in [G-3] *twoway\_options*, excluding `by()`. These include options for titling the graph (see [G-3] *title\_options*) and for saving the graph to disk (see [G-3] *saving\_option*).

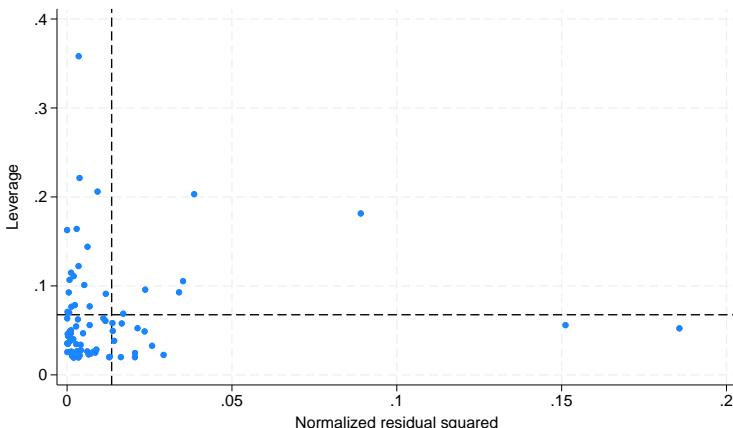

## Remarks and examples for lvr2plot

One of the most useful diagnostic graphs is provided by `lvr2plot` (leverage-versus-residual-squared plot), a graph of leverage against the (normalized) residuals squared.

### ▷ Example 7

We illustrate `lvr2plot` using our model in [example 1](#).

```
. use https://www.stata-press.com/data/r19/auto
(1978 automobile data)
. regress price weight foreign##c.mpg
(output omitted)
. lvr2plot
```

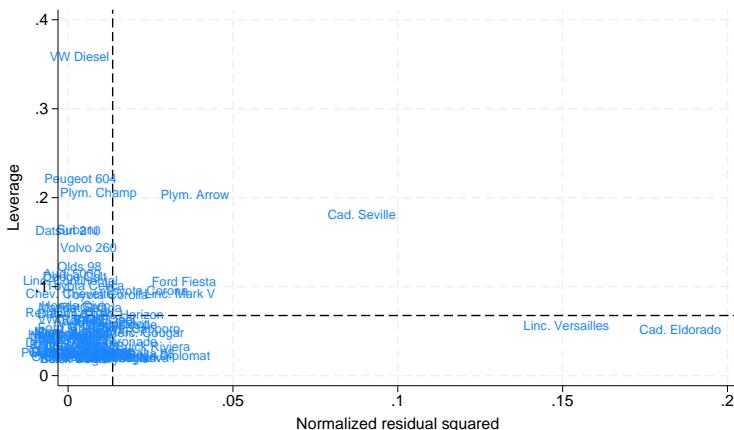

The lines on the chart show the average values of leverage and the (normalized) residuals squared. Points above the horizontal line have higher-than-average leverage; points to the right of the vertical line have larger-than-average residuals.

One point immediately catches our eye, and four more make us pause. The point at the top of the graph has high leverage and a smaller-than-average residual. The other points that bother us all have higher-than-average leverage, two with smaller-than-average residuals and two with larger-than-average residuals.

A less pretty but more useful version of the above graph specifies that make be used as the symbol (see [G-3] *marker\_label\_options*):

```
. lvr2plot, mlabel(make) mlabp(0) m(none) mlabsize(small)
```

The VW Diesel, Plymouth Champ, Plymouth Arrow, and Peugeot 604 are the points that cause us the most concern. When we further examine our data, we discover that the VW Diesel is the only diesel in our data and that the data for the Plymouth Arrow were entered incorrectly into the computer. No such simple explanations were found for the Plymouth Champ and Peugeot 604.

◀

## Methods and formulas

See [Hamilton \(2013, 209–214\)](#) and [Kohler and Kreuter \(2012, sec. 9.3\)](#) for a discussion of these diagnostic graphs.

The `lvr2plot` command plots leverage against the squares of the normalized residuals. The normalized residuals are defined as  $\hat{e}_{n_j} = \hat{e}_j / (\sum_i \hat{e}_i^2)^{1/2}$ .

## Postestimation commands

The following postestimation commands for time series are available for `regress`:

| Command                      | Description                                                            |
|------------------------------|------------------------------------------------------------------------|
| <code>estat archlm</code>    | test for ARCH effects in the residuals                                 |
| <code>estat bgodfrey</code>  | Breusch–Godfrey test for higher-order serial correlation               |
| <code>estat durbinalt</code> | Durbin’s alternative test for serial correlation                       |
| <code>estat dwatson</code>   | Durbin–Watson $d$ statistic to test for first-order serial correlation |
| <code>estat sbcusum</code>   | perform cumulative sum test for parameter stability                    |
| <code>estat sbknown</code>   | perform tests for a structural break with a known break date           |
| <code>estat sbsingle</code>  | perform tests for a structural break with an unknown break date        |

These commands provide regression diagnostic tools specific to time series. You must `tsset` your data before using these commands; see [\[TS\] `tsset`](#).

## estat archlm

### Description for estat archlm

`estat archlm` performs Engle’s Lagrange multiplier (LM) test for the presence of autoregressive conditional heteroskedasticity.

### Menu for estat

Statistics > Postestimation

### Syntax for estat archlm

```
estat archlm [, archlm_options]
```

| <i>archlm_options</i>             | Description                                                      |
|-----------------------------------|------------------------------------------------------------------|
| <code>lags(<i>numlist</i>)</code> | test <i>numlist</i> lag orders                                   |
| <code>force</code>                | allow test after <code>regress</code> , <code>vce(robust)</code> |

`collect` is allowed; see [\[U\] 11.1.10 Prefix commands](#).

## Options for estat archlm

`lags` (*numlist*) specifies a list of numbers, indicating the lag orders to be tested. The test will be performed separately for each order. The default is order one.

`force` allows the test to be run after `regress, vce(robust)`. The command will not work if the `vce(cluster clustvar)` option is specified with `regress`; see [R] [regress](#).

## estat bgodfrey

### Description for estat bgodfrey

`estat bgodfrey` performs the Breusch–Godfrey test for higher-order serial correlation in the disturbance. This test does not require that all the regressors be strictly exogenous.

### Menu for estat

Statistics > Postestimation

### Syntax for estat bgodfrey

```
estat bgodfrey [, bgodfrey_options]
```

| <i>bgodfrey_options</i>              | Description                                                         |
|--------------------------------------|---------------------------------------------------------------------|
| <code>lags</code> ( <i>numlist</i> ) | test <i>numlist</i> lag orders                                      |
| <code>nomiss0</code>                 | do not use Davidson and MacKinnon's approach                        |
| <code>small</code>                   | obtain <i>p</i> -values using the <i>F</i> or <i>t</i> distribution |

`collect` is allowed; see [U] [11.1.10 Prefix commands](#).

### Options for estat bgodfrey

`lags` (*numlist*) specifies a list of numbers, indicating the lag orders to be tested. The test will be performed separately for each order. The default is order one.

`nomiss0` specifies that Davidson and MacKinnon's approach (1993, 358), which replaces the missing values in the initial observations on the lagged residuals in the auxiliary regression with zeros, not be used.

`small` specifies that the *p*-values of the test statistics be obtained using the *F* or *t* distribution instead of the default  $\chi^2$  or normal distribution.

## estat durbinalt

### Description for estat durbinalt

`estat durbinalt` performs Durbin's alternative test for serial correlation in the disturbance. This test does not require that all the regressors be strictly exogenous.

### Menu for estat

| <code>small</code>                | obtain <i>p</i> -values using the <i>F</i> or <i>t</i> distribution                          |
| <code>force</code>                | allow test after <code>regress</code> , <code>vce(robust)</code> or after <code>newey</code> |

`collect` is allowed; see [U] 11.1.10 Prefix commands.

### Options for estat durbinalt

`lags(numlist)` specifies a list of numbers, indicating the lag orders to be tested. The test will be performed separately for each order. The default is order one.

`nomiss0` specifies that Davidson and MacKinnon's approach (1993, 358), which replaces the missing values in the initial observations on the lagged residuals in the auxiliary regression with zeros, not be used.

`robust` specifies that the Huber/White/sandwich robust estimator for the variance–covariance matrix be used in Durbin's alternative test.

`small` specifies that the *p*-values of the test statistics be obtained using the *F* or *t* distribution instead of the default  $\chi^2$  or normal distribution. This option may not be specified with `robust`, which always uses an *F* or a *t* distribution.

`force` allows the test to be run after `regress`, `vce(robust)` and after `newey` (see [R] `regress` and [TS] `newey`). The command will not work if the `vce(cluster clustvar)` option is specified with `regress`.

## estat dwatson

### Description for estat dwatson

`estat dwatson` computes the Durbin–Watson  $d$  statistic (Durbin and Watson 1950) to test for first-order serial correlation in the disturbance when all the regressors are strictly exogenous.

### Menu for estat

Statistics > Postestimation

### Syntax for estat dwatson

```
estat dwatson
```

`collect` is allowed; see [U] 11.1.10 Prefix commands.

### Remarks and examples

The Durbin–Watson test is used to determine whether the error term in a linear regression model follows an AR(1) process. For the linear model

$$y_t = \mathbf{x}_t\boldsymbol{\beta} + u_t$$

the AR(1) process can be written as

$$u_t = \rho u_{t-1} + \epsilon_t$$

In general, an AR(1) process requires only that  $\epsilon_t$  be independent and identically distributed (i.i.d.). The Durbin–Watson test, however, requires  $\epsilon_t$  to be distributed  $N(0, \sigma^2)$  for the statistic to have an exact distribution. Also, the Durbin–Watson test can be applied only when the regressors are strictly exogenous. A regressor  $x$  is strictly exogenous if  $\text{Corr}(x_s, u_t) = 0$  for all  $s$  and  $t$ , which precludes the use of the Durbin–Watson statistic with models where lagged values of the dependent variable are included as regressors.

The null hypothesis of the test is that there is no first-order autocorrelation. The Durbin–Watson  $d$  statistic can take on values between 0 and 4 and under the null  $d$  is equal to 2. Values of  $d$  less than 2 suggest positive autocorrelation ( $\rho > 0$ ), whereas values of  $d$  greater than 2 suggest negative autocorrelation ( $\rho < 0$ ). Calculating the exact distribution of the  $d$  statistic is difficult, but empirical upper and lower bounds have been established based on the sample size and the number of regressors. Extended tables for the  $d$  statistic have been published by Savin and White (1977). For example, suppose you have a model with 30 observations and three regressors (including the constant term). For a test of the null hypothesis of no autocorrelation versus the alternative of positive autocorrelation, the lower bound of the  $d$  statistic is 1.284, and the upper bound is 1.567 at the 5% significance level. You would reject the null if  $d < 1.284$ , and you would fail to reject if  $d > 1.567$ . A value falling within the range (1.284, 1.567) leads to no conclusion about whether or not to reject the null hypothesis.

When lagged dependent variables are included among the regressors, the past values of the error term are correlated with those lagged variables at time  $t$ , implying that they are not strictly exogenous regressors. The inclusion of covariates that are not strictly exogenous causes the  $d$  statistic to be biased toward the acceptance of the null hypothesis. Durbin (1970) suggested an alternative test for models with lagged dependent variables and extended that test to the more general  $AR(p)$  serial correlation process

$$u_t = \rho_1 u_{t-1} + \dots + \rho_p u_{t-p} + \epsilon_t$$

where  $\epsilon_t$  is i.i.d. with variance  $\sigma^2$  but is not assumed or required to be normal for the test.

The null hypothesis of Durbin’s alternative test is

$$H_0 : \rho_1 = 0, \dots, \rho_p = 0$$

and the alternative is that at least one of the  $\rho$ ’s is nonzero. Although the null hypothesis was originally derived for an  $AR(p)$  process, this test turns out to have power against  $MA(p)$  processes as well. Hence, the actual null of this test is that there is no serial correlation up to order  $p$  because the  $MA(p)$  and the  $AR(p)$  models are locally equivalent alternatives under the null. See Godfrey (1988, 113–115) for a discussion of this result.

Durbin’s alternative test is in fact a LM test, but it is most easily computed with a Wald test on the coefficients of the lagged residuals in an auxiliary OLS regression of the residuals on their lags and all the covariates in the original regression. Consider the linear regression model

$$y_t = \beta_1 x_{1t} + \dots + \beta_k x_{kt} + u_t \tag{1}$$

in which the covariates  $x_1$  through  $x_k$  are not assumed to be strictly exogenous and  $u_t$  is assumed to be i.i.d. and to have finite variance. The process is also assumed to be stationary. (See Wooldridge [2020, sec. 11.1] for a discussion of stationarity.) Estimating the parameters in (1) by OLS obtains the residuals  $\hat{u}_t$ . Next another OLS regression is performed of  $\hat{u}_t$  on  $\hat{u}_{t-1}, \dots, \hat{u}_{t-p}$  and the other regressors,

$$\hat{u}_t = \gamma_1 \hat{u}_{t-1} + \dots + \gamma_p \hat{u}_{t-p} + \beta_1 x_{1t} + \dots + \beta_k x_{kt} + \epsilon_t \tag{2}$$

where  $\epsilon_t$  stands for the random-error term in this auxiliary OLS regression. Durbin’s alternative test is then obtained by performing a Wald test that  $\gamma_1, \dots, \gamma_p$  are jointly zero. The test can be made robust to an unknown form of heteroskedasticity by using a robust VCE estimator when estimating the regression in (2). When there are only strictly exogenous regressors and  $p = 1$ , this test is asymptotically equivalent to the Durbin–Watson test.

The Breusch–Godfrey test is also an LM test of the null hypothesis of no autocorrelation versus the alternative that  $u_t$  follows an  $AR(p)$  or  $MA(p)$  process. Like Durbin’s alternative test, it is based on the auxiliary regression (2), and it is computed as  $NR^2$ , where  $N$  is the number of observations and  $R^2$  is the simple  $R^2$  from the regression. This test and Durbin’s alternative test are asymptotically equivalent. The test statistic  $NR^2$  has an asymptotic  $\chi^2$  distribution with  $p$  degrees of freedom. It is valid with or without the strict exogeneity assumption but is not robust to conditional heteroskedasticity, even if a robust VCE is used when fitting (2).

In fitting (2), the values of the lagged residuals will be missing in the initial periods. As noted by Davidson and MacKinnon (1993), the residuals will not be orthogonal to the other covariates in the model in this restricted sample, which implies that the  $R^2$  from the auxiliary regression will not be zero when the lagged residuals are left out. Hence, Breusch and Godfrey’s  $NR^2$  version of the test may overreject in small samples. To correct this problem, Davidson and MacKinnon (1993) recommend setting the

missing values of the lagged residuals to zero and running the auxiliary regression in (2) over the full sample used in (1). This small-sample correction has become conventional for both the Breusch–Godfrey and Durbin’s alternative test, and it is the default for both commands. Specifying the `nomiss0` option overrides this default behavior and treats the initial missing values generated by regressing on the lagged residuals as missing. Hence, `nomiss0` causes these initial observations to be dropped from the sample of the auxiliary regression.

Durbin’s alternative test and the Breusch–Godfrey test were originally derived for the case covered by `regress` without the `vce(robust)` option. However, after `regress`, `vce(robust)` and `newey`, Durbin’s alternative test is still valid and can be invoked if the `robust` and `force` options are specified.

### ▷ Example 1: tests for serial correlation

Using data from [Klein \(1950\)](#), we first fit an OLS regression of consumption on the government wage bill:

```
. use https://www.stata-press.com/data/r19/klein
. tsset yr
Time variable: yr, 1920 to 1941
 Delta: 1 unit
. regress consump wagegovt
```

| Source   | SS         | df | MS         | Number of obs | = | 22     |
|----------|------------|----|------------|---------------|---|--------|
| Model    | 532.567711 | 1  | 532.567711 | F(1, 20)      | = | 17.72  |
| Residual | 601.207167 | 20 | 30.0603584 | Prob > F      | = | 0.0004 |
|          |            |    |            | R-squared     | = | 0.4697 |
|          |            |    |            | Adj R-squared | = | 0.4432 |
| Total    | 1133.77488 | 21 | 53.9892799 | Root MSE      | = | 5.4827 |

| consump  | Coefficient | Std. err. | t     | P> t  | [95% conf. interval] |
|----------|-------------|-----------|-------|-------|----------------------|
| wagegovt | 2.50744     | .5957173  | 4.21  | 0.000 | 1.264796 3.750085    |
| _cons    | 40.84699    | 3.192183  | 12.80 | 0.000 | 34.18821 47.50577    |

If we assume that `wagegovt` is a strictly exogenous variable, we can use the Durbin–Watson test to check for first-order serial correlation in the errors.

```
. estat dwatson
Durbin-Watson d-statistic(2, 22) = .3217998
```

The Durbin–Watson  $d$  statistic, 0.32, is far from the center of its distribution ( $d = 2.0$ ). Given 22 observations and two regressors (including the constant term) in the model, the lower 5% bound is about 0.997, much greater than the computed  $d$  statistic. Assuming that `wagegovt` is strictly exogenous, we can reject the null of no first-order serial correlation. Rejecting the null hypothesis does not necessarily mean an AR process; other forms of misspecification may also lead to a significant test statistic. If we are willing to assume that the errors follow an AR(1) process and that `wagegovt` is strictly exogenous, we could refit the model using `arima` or `prais` and model the error process explicitly; see [\[TS\] arima](#) and [\[TS\] prais](#).

If we are not willing to assume that wagegov is strictly exogenous, we could instead use Durbin’s alternative test or the Breusch–Godfrey to test for first-order serial correlation. Because we have only 22 observations, we will use the small option.

```
. estat durbinalt, small
```

Durbin’s alternative test for autocorrelation

| lags(p) | F      | df        | Prob > F |
|---------|--------|-----------|----------|
| 1       | 35.035 | ( 1, 19 ) | 0.0000   |

H0: no serial correlation

```
. estat bgodfrey, small
```

Breusch–Godfrey LM test for autocorrelation

| lags(p) | F      | df        | Prob > F |
|---------|--------|-----------|----------|
| 1       | 14.264 | ( 1, 19 ) | 0.0013   |

H0: no serial correlation

Both tests strongly reject the null of no first-order serial correlation, so we decide to refit the model with two lags of consump included as regressors and then rerun estat durbinalt and estat bgodfrey. Because the revised model includes lagged values of the dependent variable, the Durbin–Watson test is not applicable.

```
. regress consump wagegovt L.consump L2.consump
```

| Source   | SS         | df | MS         | Number of obs | = | 20     |

|---------|-------|-----------|----------|
| 1       | 0.080 | ( 1, 15 ) | 0.7805   |
| 2       | 0.260 | ( 2, 14 ) | 0.7750   |

H0: no serial correlation

```
. estat bgodfrey, small lags(1/2)
Breusch-Godfrey LM test for autocorrelation
```

| lags(p) | F     | df        | Prob > F |
|---------|-------|-----------|----------|
| 1       | 0.107 | ( 1, 15 ) | 0.7484   |
| 2       | 0.358 | ( 2, 14 ) | 0.7056   |

H0: no serial correlation

Although `wagegov` and the constant term are no longer statistically different from zero at the 5% level, the output from `estat durbinalt` and `estat bgodfrey` indicates that including the two lags of `consump` has removed any serial correlation from the errors.

Engle (1982) suggests an LM test for checking for autoregressive conditional heteroskedasticity (ARCH) in the errors. The  $p$ th-order ARCH model can be written as

$$\begin{aligned} \sigma_t^2 &= E(u_t^2 | u_{t-1}, \dots, u_{t-p}) \\ &= \gamma_0 + \gamma_1 u_{t-1}^2 + \dots + \gamma_p u_{t-p}^2 \end{aligned}$$

To test the null hypothesis of no autoregressive conditional heteroskedasticity (that is,  $\gamma_1 = \dots = \gamma_p = 0$ ), we first fit the OLS model (1), obtain the residuals  $\hat{u}_t$ , and run another OLS regression on the lagged residuals:

$$\hat{u}_t^2 = \gamma_0 + \gamma_1 \hat{u}_{t-1}^2 + \dots + \gamma_p \hat{u}_{t-p}^2 + \epsilon \tag{3}$$

The test statistic is  $NR^2$ , where  $N$  is the number of observations in the sample and  $R^2$  is the  $R^2$  from the regression in (3). Under the null hypothesis, the test statistic follows a  $\chi_p^2$  distribution.

### ► Example 2: `estat archlm`

We refit the original model that does not include the two lags of `consump` and then use `estat archlm` to see if there is any evidence that the errors are autoregressive conditional heteroskedastic.

```
. regress consump wagegovt
```

| Source   | SS         | df | MS         | Number of obs | = | 22     |
|----------|------------|----|------------|---------------|---|--------|
| Model    | 532.567711 | 1  | 532.567711 | F(1, 20)      | = | 17.72  |
| Residual | 601.207167 | 20 | 30.0603584 | Prob > F      | = | 0.0004 |
|          |            |    |            | R-squared     | = | 0.4697 |
|          |            |    |            | Adj R-squared | = | 0.4432 |
| Total    | 1133.77488 | 21 | 53.9892799 | Root MSE      | = | 5.4827 |

| consump  | Coefficient | Std. err. | t     | P> t  | [95% conf. interval] |
|----------|-------------|-----------|-------|-------|----------------------|
| wagegovt | 2.50744     | .5957173  | 4.21  | 0.000 | 1.264796 3.750085    |
| _cons    | 40.84699    | 3.192183  | 12.80 | 0.000 | 34.18821 47.50577    |

```
. estat archlm, lags(1 2 3)
LM test for autoregressive conditional heteroskedasticity (ARCH)
```

| lags(p) | chi2  | df | Prob > chi2 |
|---------|-------|----|-------------|
| 1       | 5.543 | 1  | 0.0186      |
| 2       | 9.431 | 2  | 0.0090      |
| 3       | 9.039 | 3  | 0.0288      |

H0: no ARCH effects vs. H1: ARCH(p) disturbance

estat archlm shows the results for tests of ARCH(1), ARCH(2), and ARCH(3) effects, respectively. At the 5% significance level, all three tests reject the null hypothesis that the errors are not autoregressive conditional heteroskedastic. See [TS] arch for information on fitting ARCH models.

## Stored results

estat archlm stores the following in r():

Scalars

- r(N) number of observations
- r(k) number of regressors
- r(N\_gaps) number of gaps

Macros

- r(lags) lag order

Matrices

- r(arch) test statistic for each lag order
- r(df) degrees of freedom
- r(p) two-sided *p*-values

estat bgodfrey stores the following in r():

Scalars

- r(N) number of observations
- r(k) number of regressors
- r(N\_gaps) number of gaps

Macros

- r(lags) lag order

Matrices

- r(chi2)  $\chi^2$  statistic for each lag order
- r(F) *F* statistic for each lag order (small only)
- r(df\_r) residual degrees of freedom (small only)
- r(df) degrees of freedom
- r(p) two-sided *p*-values

`estat durbinalt` stores the following in `r()`:

Scalars

|                        |                        |

## Methods and formulas

Consider the regression

$$y_t = \beta_1 x_{1t} + \cdots + \beta_k x_{kt} + u_t \quad (4)$$

in which some of the covariates are not strictly exogenous. In particular, some of the  $x_{it}$  may be lags of the dependent variable. We are interested in whether the  $u_t$  are serially correlated.

The Durbin–Watson  $d$  statistic reported by `estat dwatson` is

$$d = \frac{\sum_{t=1}^{n-1} (\hat{u}_{t+1} - \hat{u}_t)^2}{\sum_{t=1}^n \hat{u}_t^2}$$

where  $\hat{u}_t$  represents the residual of the  $t$ th observation.

To compute Durbin’s alternative test and the Breusch–Godfrey test against the null hypothesis that there is no  $p$ th order serial correlation, we fit the regression in (4), compute the residuals, and then fit the following auxiliary regression of the residuals  $\hat{u}_t$  on  $p$  lags of  $\hat{u}_t$  and on all the covariates in the original regression in (4):

$$\hat{u}_t = \gamma_1 \hat{u}_{t-1} + \cdots + \gamma_p \hat{u}_{t-p} + \beta_1 x_{1t} + \cdots + \beta_k x_{kt} + \epsilon \quad (5)$$

Durbin’s alternative test is computed by performing a Wald test to determine whether the coefficients of  $\hat{u}_{t-1}, \dots, \hat{u}_{t-p}$  are jointly different from zero. By default, the statistic is assumed to be distributed  $\chi^2(p)$ . When `small` is specified, the statistic is assumed to follow an  $F(p, N - p - k)$  distribution. The reported  $p$ -value is a two-sided  $p$ -value. When `robust` is specified, the Wald test is performed using the Huber/White/sandwich estimator of the variance–covariance matrix, and the test is robust to an unspecified form of heteroskedasticity.

The Breusch–Godfrey test is computed as  $NR^2$ , where  $N$  is the number of observations in the auxiliary regression (5) and  $R^2$  is the  $R^2$  from the same regression (5). Like Durbin’s alternative test, the Breusch–Godfrey test is asymptotically distributed  $\chi^2(p)$ , but specifying `small` causes the  $p$ -value to be computed using an  $F(p, N - p - k)$ .

By default, the initial missing values of the lagged residuals are replaced with zeros, and the auxiliary regression is run over the full sample used in the original regression of (4). Specifying the `miss0` option causes these missing values to be treated as missing values, and the observations are dropped from the sample.

Engle’s LM test for ARCH( $p$ ) effects fits an OLS regression of  $\hat{u}_t^2$  on  $\hat{u}_{t-1}^2, \dots, \hat{u}_{t-p}^2$ :

$$\hat{u}_t^2 = \gamma_0 + \gamma_1 \hat{u}_{t-1}^2 + \dots + \gamma_p \hat{u}_{t-p}^2 + \epsilon$$

The test statistic is  $nR^2$  and is asymptotically distributed  $\chi^2(p)$ .

**James Durbin** (1923–2012) was a British statistician who was born in Wigan, near Manchester. He studied mathematics at Cambridge and after military service and various research posts joined the London School of Economics in 1950. Later in life, he was also affiliated with University College London. His many contributions to statistics centered on serial correlation, time series (including major contributions to structural or unobserved components models), sample survey methodology, goodness-of-fit tests, and sample distribution functions, with emphasis on applications in the social sciences. He served terms as president of the Royal Statistical Society and the International Statistical Institute.

**Geoffrey Stuart Watson** (1921–1998) was born in Victoria, Australia, and earned degrees at Melbourne University and North Carolina State University. After a visit to the University of Cambridge, he returned to Australia, working at Melbourne and then the Australian National University. Following periods at Toronto and Johns Hopkins, he settled at Princeton. Throughout his wide-ranging career, he made many notable accomplishments and important contributions, including the Durbin–Watson test for serial correlation, the Nadaraya–Watson estimator in nonparametric regression, and methods for analyzing directional data.

**Leslie G. Godfrey** (1946–) was born in London and earned degrees at the Universities of Exeter and London. He is now a professor of econometrics at the University of York. His interests center on implementation and interpretation of tests of econometric models, including nonnested models.

**Trevor Stanley Breusch** (1953–) was born in Queensland and earned degrees at the University of Queensland and Australian National University (ANU). After a post at the University of Southampton, he returned to work at ANU. His background is in econometric methods and his recent interests include political values and social attitudes, earnings and income, and measurement of underground economic activity.

## Description

`reri` reports three statistics that assess two-way interactions in an additive model of relative risk. The statistics are of interest for determining how two risk factors interact to produce a positive result for the outcome of interest. The estimates of the interactions themselves are reported as excess relative risks (ERRs). Statistics reported for the interaction are the relative excess risk due to interaction (RERI), attributable proportion (AP), and synergy index (SI); `reri` supports binomial generalized linear, Poisson, negative binomial, logistic, Cox, parametric survival, and interval-censored parametric and semiparametric survival models.

## Quick start

Report ERRs, RERI, AP, and SI for the interaction of exposures `exp1` and `exp2` from a binomial generalized linear model for `y` fit by `binreg`

```
reri binreg y exp1 exp2
```

Same as above, but use `poisson` to fit the model

```
reri poisson y exp1 exp2
```

Same as above, but report incidence-rate ratios for the interactions rather than ERRs

```
reri poisson y exp1 exp2, irr
```

Same as above, but include the covariate `x`, and specify `noisily` to view the full Poisson model

```
reri poisson y exp1 exp2 x, irr noisily
```

Same as above, but report ERRs for the interactions as well as incidence-rate ratios for the full model

```
reri poisson y exp1 exp2 x, irr err noisily
```

Fit a [Cox model](#) using `stset` data stratified by `svar`, and report ERRs, RERI, AP, and SI for the interactions of `exp1` and `exp2`

```
reri stcox exp1 exp2, strata(svar)
```

Same as above, but fit a [Weibull model](#)

```
reri streg exp1 exp2, strata(svar) distribution(weibull)
```

Fit a Weibull model with [interval-censored survival data](#), with variables `t1` and `t2` giving lower and upper endpoints for the censoring interval, and report ERRs, RERI, AP, and SI for the interactions

```
reri stintreg exp1 exp2, distribution(weibull) interval(t1 t2)
```

## Menu

Statistics > Epidemiology and related > Other > Relative excess risk due to interaction (RERI)

## Syntax

```
reri cmd depvar var1 var2 [control_vars] [if] [in] [weight]
 [, options cmd_options]
```

*cmd* defines the estimation command to be executed and may be one of the following:

`binreg`, `logistic`, `nbreg`, `poisson`, `stcox`, `stintcox`, `stintreg`, and `streg`

*depvar* is required for all except `stcox`, `stintcox`, `stintreg`, and `streg`, which do not allow *depvar*.

*var1* and *var2* are binary variables (integer valued and nonnegative) whose interactions are to be tested for additivity.

| <code>err</code>       | report interactions as ERR, the default                         |
| <code>coef_type</code> | report interactions as <i>coef_type</i> rather than ERR         |
| <code>level(#)</code>  | set confidence level; default is level(95)                      |
| <code>novlabel</code>  | display numeric values rather than <a href="#">value labels</a> |
| <code>nolegend</code>  | do not display the legend for the interactions                  |

*var1* and *var2* cannot be factor variables, but *control\_vars* may contain factor variables; see [\[U\] 11.4.3 Factor variables](#).

*cmd\_options* are any options allowed by *cmd*, except options `or`, `hr`, `rd`, and `vce(jackknife1)` are not allowed when *cmd* is `binreg`.

When *cmd* is `poisson`, `vce(robust)` is used by default when *depvar* is 0/1.

`bootstrap`, `by`, `collect`, `jackknife`, and `statsby` are allowed; see [\[U\] 11.1.10 Prefix commands](#).

Weights are allowed if *cmd* allows them; see [\[U\] 11.1.6 weight](#).

All postestimation commands behave as they would after *cmd*; see the postestimation manual entry for *cmd*.

## Options

### Model

`baselevel1(#)` and `baselevel2(#)` specify base levels for *var1* and *var2*, respectively, the two variables that give the interactions of interest.

If *var1* and *var2* are 0/1 variables, then by default, the RERI statistic is a test of whether the ERR of interaction 01 (01 meaning *var1* = 0 and *var2* = 1) plus the ERR of interaction 10 equals the ERR of interaction 11. In shorthand notation, we say we are testing  $01 + 10 = 11$  on the ERR scale.

Specifying `baselevel1(#)` or `baselevel2(#)` allows the base levels of the interactions to be changed. For example, with 0/1 variables, `baselevel1(1)` sets the base level for *var1* to 1, and RERI tests whether  $11 + 00 = 01$ .

If `baselevel1(#)` is not specified, the base level of `var1` is the default base level of the factor variable `i.var1`. The default base level is the smallest of the two values of `var1`, unless the default has been changed by `fvset`. This is similarly true for `baselevel2(#)` and `var2`. See [U] 11.4.3.2 Base levels and [R] `fvset`. Note that base levels cannot be set using factor-variable notation when specifying `var1` and `var2`.

#### Reporting

`noisily` displays all output from `cmd`.

`err` specifies that the coefficients of the interactions be displayed as ERRs. This is the default. ERR is equal to relative risk minus one. See [Remarks and examples](#) below.

`coef_type` specifies an alternative scale for the coefficients of the interactions instead of ERRs. Allowed `coef_type` depends on `cmd` and can be `rr`, `or`, `irr`, or `hr`, whichever is allowed by `cmd`. In addition, `coef_type` can be `coef`, which displays the interaction terms as unscaled coefficients.

For `binreg`, `coef_type rr` displays the interactions as relative-risk ratios. The other models fit by `binreg` using options `or`, `hr`, and `rd` are not available with `reri`. For `logistic`, `coef_type or` displays the interactions as odds ratios. For `poisson` and `nbreg`, `coef_type irr` displays the interactions as incidence-rate ratios. For `stcox`, `stintcox`, `stintreg`, and `streg`, `coef_type hr` displays the interactions as hazard ratios. For the survival-time commands, `nohr` may be used as a synonym for `coef`.

When `noisily` is specified, `err` and a `coef_type` may be specified simultaneously. In this case, the table of interactions displayed by `reri` reports ERRs, and the coefficient table produced by `cmd` displays coefficients on the `coef_type` scale.

`level(#)` specifies the confidence level, as a percentage, for confidence intervals. The default is `level(95)` or as set by `set level1`; see [R] [level](#).

`nofvlabel` specifies that numeric values rather than [value labels](#) be displayed in the legend and `cmd` output.

`nolegend` suppresses the display of the legend for the interactions.

## Remarks and examples

Remarks are presented under the following headings:

[Introduction](#)

[Additive versus multiplicative interactions](#)

[Incidence-rate ratios, hazard ratios, and odds ratios](#)

### Introduction

`reri` reports three statistics that assess additive interactions of relative risk: RERI, AP, and SI ([Lash et al. 2021](#)). These measures are typically of interest when working with epidemiologic data. When one assesses the effect of multiple exposures on an outcome, determining whether one exposure modifies the effect of another can be an important piece of the puzzle.

When there are two exposures that affect an outcome, we often want to model how the exposures interact. That is, for binary exposures *A* and *B*, we want to model the risk of a positive outcome for subjects having both *A* and *B* compared with subjects having only *A* and those having only *B*.

Typically, a multiplicative model for the interaction is fit to the data: the risk for those with  $A$  and  $B$  is hypothesized to equal the risk for only  $A$  times the risk for only  $B$ . If the risk for  $A$  and  $B$  equals the multiplicative risk, then we say there is no interaction of  $A$  and  $B$ . If the risk is greater than the multiplicative risk, we say there is a positive interaction of  $A$  and  $B$ . Multiplicative models are computationally convenient because they are simple to specify, and it is easy to test whether the interaction term is greater (or less) than multiplicative.

Inherent to this model is the hypothesis that the risk is multiplicative. For many biological processes, however, an additive model of risk may model the process better than a multiplicative one (see, for example, [Andersson et al. \[2005\]](#)). That is, the risk for subjects with  $A$  and  $B$  is hypothesized to equal the risk for only  $A$  plus the risk for only  $B$ . For this hypothesis, we want to look at how much the risk for  $A$  and  $B$  is greater (or less) than the additive risk.

The RERI statistic is this risk difference formulated using relative risks. A RERI statistic that is 0 means the risk is additive. One that is positive means the risk is superadditive, and one that is negative means the risk is subadditive. The test of statistical significance of the RERI statistic is straightforward, but it is not as simple as the test for the multiplicative model (see [Methods and formulas](#)).

Besides the RERI statistic, there are two other related statistics for additive models: AP and SI. The AP is the proportion of risk of  $A$  and  $B$  due to the superadditivity of exposures  $A$  and  $B$ . The SI recasts the RERI statistic as a ratio, rather than a difference.

Let's formally define these statistics. Let  $p_{A+B+}$  be the probability of having a positive outcome for subjects positive for binary exposure  $A$  and positive for binary exposure  $B$ . Define  $p_{A-B+}$ ,  $p_{A+B-}$ , and  $p_{A-B-}$  similarly. An additive model for the probabilities is

$$p_{A+B+} = p_{A-B-} + (p_{A-B+} - p_{A-B-}) + (p_{A+B-} - p_{A-B-})$$

Said in words, the probability of a positive outcome for  $A+B+$  equals the probability for the base category  $A-B-$  plus the amounts that probabilities for  $A-B+$  and  $A+B-$  exceed the probability for the base category.

If we divide this equation by  $p_{A-B-}$  and note that  $p_{A+B+}/p_{A-B-} = RR_{A+B+}$ , the relative risk for  $A+B+$  (and similarly for  $RR_{A-B+}$  and  $RR_{A+B-}$ ), we get

$$RR_{A+B+} = RR_{A-B+} + RR_{A+B-} - 1$$

ERR is defined as  $ERR = RR - 1$ . In terms of ERR, the additive model becomes

$$ERR_{A+B+} = ERR_{A-B+} + ERR_{A+B-}$$

The RERI statistic is defined as

$$RERI = ERR_{A+B+} - ERR_{A-B+} - ERR_{A+B-}$$

Hence, RERI is 0 for a perfectly additive model. If it is negative, the effect of the  $A+B+$  interaction is less than additive (subadditive). If positive, the effect is more than additive (superadditive).

The AP is simply RERI scaled by the relative risk (not ERR) of  $A+B+$ . That is,

$$AP = \frac{RERI}{RR_{A+B+}}$$

When AP is positive, it represents the proportion of risk of  $A+B+$  due to the superadditivity of exposures  $A$  and  $B$  (that is, the amount greater than additivity). Note that it is a proportion of risk, not relative risk, as one can see by multiplying both numerator and denominator by the reference probability  $p_{A-B-}$ .

The SI is a ratio measure:

$$SI = \frac{ERR_{A+B+}}{ERR_{A-B+} + ERR_{A+B-}}$$

The SI is 1, rather than 0, for a perfectly additive model. It is  $< 1$  for a subadditive model and  $> 1$  for a superadditive model. Note that because ERRs can be negative (they are always  $\geq -1$ ), the SI can be negative, making interpretation difficult. The SI is intended as a measure for cases in which all ERRs of the model are positive, but this will not always be the case. ERRs will be determined by the data and the specification of the model. See [Knol et al. \(2011\)](#) and [example 4](#) for discussions about negative ERRs.

## Additive versus multiplicative interactions

Typically, interactions are fit and tested by specifying main effects and interactions of the main effects ([Rothman, Greenland, and Walker 1980](#)). Suppose  $x_{A+}$  is a 0/1 variable that is 1 when exposure  $A$  is positive and 0 when it is negative. The variable  $x_{B+}$  is defined similarly for exposure  $B$ . Let  $x_{A+B+}$  be the 0/1 variable that is 1 when both  $A$  and  $B$  are positive and 0 otherwise.

When we specify a model and include terms

$$b_1x_{A+} + b_2x_{B+} + b_3x_{A+B+}$$

we call  $b_1x_{A+}$  and  $b_2x_{B+}$  main effects and  $b_3x_{A+B+}$  their interaction. The test of the interaction is the test of  $b_3 = 0$ .

It is a model of interaction that is additive in these terms. However, when the statistics of interest are risk ratios, odds ratios, or hazard ratios, the model is generally called multiplicative because it is multiplicative in these statistics. The risk ratios (or odds ratios or hazard ratios) are given by the exponentiated coefficients; that is,  $RR_{A+} = e^{b_1}$ ,  $RR_{B+} = e^{b_2}$ , etc. The risk ratio for  $A+B+$  is  $RR_{A+B+} = e^{b_1}e^{b_2}e^{b_3}$ . If the interaction is multiplicative,  $e^{b_3} = 1$  and

$$RR_{A+B+} = RR_{A+} \times RR_{B+}$$

As mentioned earlier, many biological processes more closely follow an additive model of risk than a multiplicative one. The additive model of ERR is

$$ERR_{A+B+} = ERR_{A-B+} + ERR_{A+B-}$$

Note that unlike the multiplicative model with main effects, the three states in the additive model,  $A-B+$ ,  $A+B-$ , and  $A+B+$ , are disjoint.

reri is called with the syntax

```
reri cmd depvar var1 var2 . . .
```

reri uses *var1* and *var2* to create the three terms for the additive model using [factor-variable notation](#). Suppose *var1* is *xa*, a 0/1 variable, indicating whether a subject has exposure  $A$ . Suppose *var2* is *xb* for exposure  $B$ . Then, the terms needed to test for additive ERR are, in factor-variable notation,

```
0.xa#1.xb 1.xa#0.xb 1.xa#1.xb
```

reri creates these terms and calls *cmd* to fit the model. Then, it uses [nlcom](#) to calculate the RERI, AP, and SI statistics and their standard errors. See [Methods and formulas](#).

## Incidence-rate ratios, hazard ratios, and odds ratios

Incidence rates and hazards are measures of risk. An incidence rate is a probability adjusted for time at risk. A hazard is a conditional probability when the distribution is discrete and an incremental conditional probability when the distribution is continuous (Kalbfleisch and Prentice 2002). Hence, incidence-rate ratios and hazard ratios are measures of relative risk. So using RERI, AP, and SI statistics with models that estimate incidence-rate ratios (`poisson` and `nbreg`) or hazard ratios (`stcox`, `stintcox`, `streg`, `stintreg`) presents no difficulties.

Odds ratios, however, are different. As is well known, the odds ratio approximates the risk ratio in the population when the prevalence of the outcome in the population is low (see, for example, Greenland and Thomas [1982]). So if your data are from a case-control study and the population prevalence of a positive outcome is low, then odds ratios from a logistic regression will approximate the risk ratios in the population, and the RERI, AP, and SI statistics are appropriate. On the other hand, if the population prevalence is high, the odds ratio is typically a poor approximation to the risk ratio (unless it is close to 1), and interpretation of the RERI, AP, and SI statistics may be problematic (see, for example, Skrondal [2003]).

If the study you are analyzing is a cohort study, observational study, or a randomized controlled trial with a binary outcome, you can estimate risk directly rather than fitting a logistic regression. A binomial model of risk or a Poisson model can be fit (using an appropriate variance estimator; see Cummings [2009] and example 2).

If time to outcome is measured, then a survival model may be fit, and there are no issues interpreting the RERI and SI statistics. Interpreting the AP statistic is a little trickier because it relates to the hazard at a point in time rather than risk in a population, so the proportion is the proportion of the hazard at a given time.

### ▷ Example 1: Binomial model of risk

We have simulated data on birth defects that mimic the results from Brender et al. (2013), an observational study of birth defects. Three binary outcomes are included in these data and are `tube`, `palate`, and `heart`, representing neural tube defects, palate defects, and heart defects, respectively. Predictors of birth defects are two measures of nitrate intake: `drug`, with values 0/1, indicating nitrosatable drug exposure; and `nitrate`, also with values 0/1, representing either low or high daily consumption of nitrates from drinking water.

We load the dataset and describe it.

```
. use https://www.stata-press.com/data/r19/nitrates
(Simulated prenatal nitrate intake and birth defects data)
. describe
Contains data from https://www.stata-press.com/data/r19/nitrates.dta
Observations: 1,367 Simulated prenatal nitrate
 intake and birth defects data
Variables: 6 4 Oct 2024 16:05
 (_dta has notes)
```

| Variable name | Storage type | Display format | Value label | Variable label             |
|---------------|--------------|----------------|-------------|----------------------------|
| id            | int          | %9.0g          |             | Identification number      |
| tube          | byte         | %9.0g          | case        | Neural tube defect         |
| heart         | byte         | %9.0g          | case        | Conotruncal heart defect   |
| palate        | byte         | %9.0g          | case        | Cleft palate               |
| drug          | byte         | %9.0g          | yesno       | Nitrosatable drug exposure |
| nitrate       | byte         | %9.0g          | nitrate     | Total nitrate intake       |

Sorted by: id

We first examine the outcome `tube`. We want to see whether the interactions of the two predictors `drug` and `nitrate` follow an additive model of risk. Because this is an observational study, a binomial model of risk is appropriate, and we can fit it using `binreg`.

The syntax of `rerī` is `rerī cmd depvar var1 var2`, where `var1` and `var2` are the binary predictors of interest. Note that `var1` and `var2` are specified without using factor-variable notation. `rerī` will create the interactions automatically. Here’s the result:

```
. rerī binreg tube drug nitrate
Fitting binreg ...
Interaction of drug and nitrate on an additive scale
Model: Binomial generalized linear Number of observations = 1,284
drug#nitrate
 - + No#High
 + - Yes#Low
 + + Yes#High
```

Note: P>|z| for synergy index (SI) is for test H0: SI = 1.

Note that the interactions created by `rerī` represent disjoint groups in the data. The `-+` interaction is for `drug = No` and `nitrate = High`. The `+ -` and `+ +` interactions are defined similarly as shown in the legend. The interaction `-` is, of course, the reference category.

By default, `reri` displays the model coefficients for the  $-+$ ,  $+ -$ , and  $++$  interactions as ERR, which is relative risk minus one. So ERR greater than 0 means that relative risk is greater than 1. If the model is additive, we would have

$$\text{ERR}_{++} = \text{ERR}_{-+} + \text{ERR}_{+-}$$

The RERI statistic is the difference between the two sides of this equation:

$$\text{RERI} = \text{ERR}_{++} - \text{ERR}_{-+} - \text{ERR}_{+-}$$

The estimates are  $\text{ERR}_{-+} = 0.116$  and  $\text{ERR}_{+-} = 0.239$ , so  $\text{ERR}_{-+} + \text{ERR}_{+-} = 0.355$ . The estimate of  $\text{ERR}_{++}$  is 0.777, which is greater than  $\text{ERR}_{-+} + \text{ERR}_{+-}$ . So the model is superadditive. The RERI statistic is 0.422, the difference between 0.777 and 0.355.

The  $p$ -value for RERI is a test of the null hypothesis  $\text{RERI} = 0$ . That is, a small  $p$ -value provides evidence to reject the additive model for the interactions. In this case,  $p = 0.352$ , so we do not have enough evidence to reject the additive model, despite the observed superadditivity.

The AP is

$$\text{AP} = \frac{\text{RERI}}{\text{RR}_{++}}$$

It is the proportion of risk for the  $++$  interaction that is due to the risk that is above additive. In this case, AP is 0.238 or 23.8%. Its  $p$ -value is a test of the null hypothesis  $\text{AP} = 0$ . This null hypothesis is equivalent to the null hypothesis  $\text{RERI} = 0$ , so  $p$ -values will be similar.

The SI is

$$\text{SI} = \frac{\text{ERR}_{++}}{\text{ERR}_{-+} + \text{ERR}_{+-}}$$

It is how many times larger (or smaller) is  $\text{ERR}_{++} = 0.777$  than  $\text{ERR}_{-+} + \text{ERR}_{+-} = 0.355$ . In this example, it is about twice as large, or more precisely, 2.19 times as large. The null hypothesis is  $\text{SI} = 1$ , rather than 0. The SI is a rather odd statistic because it is a test of an additive model using a multiplicative scale!

rer\_i can optionally display the interaction coefficients from binreg as relative risk (that is, risk ratios) rather than ERR. This is done by specifying the rr option. We do so and also specify the noisily option to see the output from binreg.

```
. rer_i binreg tube drug nitrate, rr noisily
Fitting binreg:

Note: P>|z| for synergy index (SI) is for test H0: SI = 1.

We see the output of binreg followed by the output of rer\_i. In this case, rer\_i displays the interaction coefficients as risk ratios, matching the output of binreg. Risk ratios are just ERRs plus one, so point estimates and confidence intervals for the interactions are just shifted by one from the previous results, and standard errors and p-values are unchanged. The RERI, AP, and SI statistics are all exactly the same as they were in the previous results.

For comparison, we can fit a binreg model specifying the interaction in the standard manner: main effects for drug and nitrate and a single interaction term for drug = Yes and nitrate = High.

```
. binreg tube drug##nitrate, rr
Iteration 1: Deviance = 1617.128
Iteration 2: Deviance = 1213.623
Iteration 3: Deviance = 1177.487

Note: `_cons` estimates baseline risk.

This model is not as easy to interpret as the previous ones and shows no evidence that drug, nitrate, or their interaction has any effect on neural tube defects. However, the previous model fit with disjoint interactions provided strong evidence that the relative risk of neural tube defects was greater for the ++ group when compared with the reference group; in that model, the risk ratio for the ++ group was greater than 1, and the *p*-value was 0.012.

Note that when running binreg directly, we must specify the rr model option. When rer1 calls binreg, it automatically fits an rr model. Specifying rr with rer1 is merely a display option; it reports relative risk rather than ERR.

□ Technical note

As mentioned earlier, when rerri is called with, say,

```
rerri cmd y x1 x2 ...
```

it creates disjoint interactions and runs

```
cmd y 0.x1#1.x2 1.x1#0.x2 1.x1#1.x2 ...
```

(assuming that x1 and x2 are 0/1 and that 0 is taken as the base category for both).

If rerri gives an error message and you cannot figure out the reason why, run

```
cmd y 0.x1#1.x2 1.x1#0.x2 1.x1#1.x2 $...$
```

and see whether this gives any problems such as dropped terms or dropped observations.

▷ Example 2: Poisson model

We continue with our previous [example](#). We again fit a model for the outcome tube, representing neural tube birth defects. Our predictors, as in the previous example, are drug (nitrosatable drug exposure) and nitrate (drinking water nitrate intake). The only difference is that we specify poisson rather than binreg.

```
. rerri poisson tube drug nitrate
Fitting poisson ...
Interaction of drug and nitrate on an additive scale
Model: Poisson Number of observations = 1,284
drug#nitrate
 - + No#High
 + - Yes#Low
 + + Yes#High
```

|              | ERR      | Robust<br>std. err. | z    | P> z  | [95% conf. interval] |          |
|--------------|----------|---------------------|------|-------|----------------------|----------|
| drug#nitrate |          |                     |      |       |                      |          |
| - +          | .1161419 | .1571636            | 0.78 | 0.435 | -.1530418            | .4708787 |
| + -          | .2385481 | .2393248            | 1.11 | 0.268 | -.1519233            | .8088004 |
| + +          | .7769424 | .4072075            | 2.51 | 0.012 | .133993              | 1.78443  |
| RERI         | .4222523 | .4534688            | 0.93 | 0.352 | -.4665302            | 1.311035 |
| Attr. prop.  | .2376286 | .2187937            | 1.09 | 0.277 | -.1911993            | .6664564 |
| Synergy ind. | 2.190483 | 2.035131            | 0.84 | 0.399 | .3545735             | 13.53235 |

Note: P>|z| for synergy index (SI) is for test H0: SI = 1.

We see that the reported point estimates for the interactions, RERI, AP, and SI are identical to the ones estimated when we used binreg. The standard errors are almost the same, differing only in the fourth significant digit.

When the outcome is 0/1, `rerI poisson` by default reports standard errors calculated using `vce(robust)`. This is because when the outcome is 0/1, the distribution is binomial (Bernoulli), not Poisson, and `vce(robust)` gives standard errors that are valid in this case. The other `vcetypes` allowed with `poisson` are available and can be selected by specifying the `vce()` option with `rerI`. See [R] [poisson](#) and [R] [vce\\_option](#).

`binreg` by default fits models using iterated, reweighted least-squares optimization and uses the expected information matrix for the variance estimator. `poisson` uses maximum likelihood optimization. Point estimates will theoretically be the same but will have numerical differences because of the different optimizers used. Different variance estimators are used, so slight differences, as we observed here, are to be expected.

One advantage of using `poisson` with `rerI` rather than `binreg` is that maximum likelihood optimization is more robust than iterated, reweighted least-squares optimization. There can be convergence problems with iterated, reweighted least squares when maximum likelihood will converge without any difficulty.

`binreg` does have an `ml` option for maximum likelihood optimization. We can also specify `vce(robust)` to reproduce the results given by `poisson`.

```
. rerI binreg tube drug nitrate, ml vce(robust)
Fitting binreg ...
Interaction of drug and nitrate on an additive scale
Model: Binomial generalized linear Number of observations = 1,284
drug#nitrate
 - + No#High
 + - Yes#Low
 + + Yes#High
```

|              | ERR      | Robust<br>std. err. | z    | P> z  | [95% conf. interval] |          |
|--------------|----------|---------------------|------|-------|----------------------|----------|
| drug#nitrate |          |                     |      |       |                      |          |
| - +          | .1161419 | .1571636            | 0.78 | 0.435 | -.1530418            | .4708787 |
| + -          | .2385481 | .2393248            | 1.11 | 0.268 | -.1519233            | .8088004 |
| + +          | .7769424 | .4072075            | 2.51 | 0.012 | .133993              | 1.78443  |
| RERI         | .4222523 | .4534688            | 0.93 | 0.352 | -.4665302            | 1.311035 |
| Attr. prop.  | .2376286 | .2187937            | 1.09 | 0.277 | -.1911993            | .6664564 |
| Synergy ind. | 2.190483 | 2.035131            | 0.84 | 0.399 | .3545735             | 13.53235 |

Note: P>|z| for synergy index (SI) is for test H0: SI = 1.

`rerI binreg` with `ml` and `vce(robust)` gives the same results as `rerI poisson`. But if we want maximum likelihood with the robust variance estimator, we might as well just use `rerI poisson`.

▷ Example 3: Logistic model

We continue with the previous [example](#). These data were simulated to mimic an observational study with full data from several sites over a set period of time. So risk ratios can be estimated directly. But let's pretend it was a case-control study. The outcomes, birth defects, have low prevalences, so odds ratios from a logistic regression should be good approximations to the risk ratios.

We specify logistic with rerl:

```
. rerl logistic tube drug nitrate
Fitting logistic ...
Interaction of drug and nitrate on an additive scale
Model: Logistic Number of observations = 1,284
drug#nitrate
 - + No#High
 + - Yes#Low
 + + Yes#High
```

|              | ERR      | Std. err. | z    | P> z  | [95% conf. interval] |          |
|--------------|----------|-----------|------|-------|----------------------|----------|
| drug#nitrate |          |           |      |       |                      |          |
| - +          | .141003  | .1933785  | 0.78 | 0.436 | -.1814898            | .5905577 |
| + -          | .2965734 | .3085999  | 1.09 | 0.275 | -.1867932            | 1.067251 |
| + +          | 1.080139 | .6495028  | 2.35 | 0.019 | .1280107             | 2.835939 |
| RERI         | .642563  | .691611   | 0.93 | 0.353 | -.7129695            | 1.998096 |
| Attr. prop.  | .3089038 | .2594074  | 1.19 | 0.234 | -.1995252            | .8173329 |
| Synergy ind. | 2.468459 | 2.456832  | 0.91 | 0.364 | .3509409             | 17.36273 |

Note: P>|z| for synergy index (SI) is for test H0: SI = 1.

The ERRs reported are the odds ratios minus one. Calculating ERR using odds ratios assumes that the odds ratios are approximations to the risk ratios.

Here we see that RERI = 0.643, AP = 0.309, and SI = 2.47. When we used poisson and binreg, we got RERI = 0.422, AP = 0.238, and SI = 2.19. Results are similar but not that close numerically.

If we have data from an observational study, a cohort, or a randomized controlled trial, we can estimate risk ratios directly, and we should do so using poisson or binreg. If it is a case-control study, we have no choice but to use logistic.

► Example 4: Negative ERRs

We present data from [example 2](#) in [ST] [stcox](#). The data represent 48 participants in a cancer drug trial. Some receive treatment (drug = 1) and some receive a placebo (drug = 0). The data contain the participants' age and time until death. It has already been `stset` and is ready to be analyzed using a survival model.

We load the dataset, describe it, and run `st` to see the survival-time settings.

```
. use https://www.stata-press.com/data/r19/drugtr
(Patient survival in drug trial)
. describe
Contains data from https://www.stata-press.com/data/r19/drugtr.dta
Observations: 48 Patient survival in drug trial
Variables: 8 3 Mar 2024 02:12

The RERI statistic requires two 0/1 predictors. These data have two predictors, drug and age, but age is not 0/1. Let's create a 0/1 variable from age. First, we summarize age:

```
. summarize age, detail
 Patient's age at start of exp.
```

| Percentiles |      | Smallest |             |          |
|-------------|------|----------|-------------|----------|
| 1%          | 47   | 47       |             |          |
| 5%          | 48   | 48       |             |          |
| 10%         | 49   | 48       | Obs         | 48       |
| 25%         | 50.5 | 49       | Sum of wgt. | 48       |
| 50%         | 56   |          | Mean        | 55.875   |
|             |      | Largest  | Std. dev.   | 5.659205 |
| 75%         | 60   | 65       |             |          |
| 90%         | 65   | 67       | Variance    | 32.0266  |
| 95%         | 67   | 67       | Skewness    | .3161066 |
| 99%         | 67   | 67       | Kurtosis    | 2.125197 |

The age of the participants ranges from 47 to 67 years. Median age is 56. Second, we create the variable `older` with `older = 1` representing those with ages  $> 56$  and `older = 0` those with ages  $\leq 56$ . We give it a `value label` as well.

```
. generate older = cond(age > 56, 1, 0)
. label define older_lbl 0 "age<=56" 1 "age>56"
. label values older older_lbl
```

Now, we run `rer1 stcox`:

```
. rer1 stcox drug older
Fitting stcox ...
Interaction of drug and older on an additive scale
Model: Cox proportional hazards Number of observations = 48
 drug#older
 - + 0#age>56
 + - 1#age<=56
 + + 1#age>56
```

|              | ERR       | Std. err. | z     | P> z  | [95% conf. interval] |           |
|--------------|-----------|-----------|-------|-------|----------------------|-----------|
| drug#older   |           |           |       |       |                      |           |
| - +          | .6268459  | .7688877  | 1.03  | 0.303 | -.3557603            | 3.108141  |
| + -          | -.9158604 | .0532904  | -3.91 | 0.000 | -.9756843            | -.7088514 |
| + +          | -.7313977 | .1392912  | -2.53 | 0.011 | -.9027935            | -.2577947 |
| RERI         | -.4423833 | .7436483  | -0.59 | 0.552 | -1.899907            | 1.015141  |
| Attr. prop.  | -1.646983 | 2.711232  | -0.61 | 0.544 | -6.960901            | 3.666935  |
| Synergy ind. | 2.530662  | 6.713001  | 0.35  | 0.726 | .0139727             | 458.3401  |

Notes: P>|z| for synergy index (SI) is for test H0: SI = 1.  
Some estimates of excess relative risk are not positive.

The ERR is negative for the +- (`drug = 1` and `older = 0`) and ++ (`drug = 1` and `older = 1`) interactions. This means the relative risk is less than one.

The RERI, AP, and SI statistics were designed for models in which the -, +-, and ++ interactions each have positive ERRs. That is, values of 1 for the predictors are hypothesized to be associated with increased risk. Clearly, this is not true here. `drug = 1` is hypothesized to be associated with decreased risk. We incorrectly specified the model for `rer1`. `drug = 0` should be the category hypothesized for a positive ERR.

We can correct this by specifying the option `baselevel1(1)`, which tells `reri` to use `drug = 1` as the base level for the first predictor.

```
. reri stcox drug older, baselevel1(1)
Fitting stcox ...
Interaction of drug and older on an additive scale
Model: Cox proportional hazards Number of observations = 48
drug#older
 - + 1#age>56
 + - 0#age<=56
 + + 0#age>56
```

|              | ERR      | Std. err. | z    | P> z  | [95% conf. interval] |          |
|--------------|----------|-----------|------|-------|----------------------|----------|
| drug#older   |          |           |      |       |                      |          |
| - +          | 2.192339 | 1.962714  | 1.89 | 0.059 | -.0433052            | 9.652331 |
| + -          | 10.885   | 7.527446  | 3.91 | 0.000 | 2.434672             | 40.12572 |
| + +          | 18.33507 | 12.94706  | 4.42 | 0.000 | 4.20437              | 70.83291 |
| RERI         | 5.257728 | 8.484262  | 0.62 | 0.535 | -11.37112            | 21.88658 |
| Attr. prop.  | .271927  | .3309285  | 0.82 | 0.411 | -.376681             | .920535  |
| Synergy ind. | 1.402049 | .677738   | 0.70 | 0.484 | .5436253             | 3.615984 |

Note: P>|z| for synergy index (SI) is for test H0: SI = 1.

The ERRs are now all positive, and the model is easy to interpret. The RERI statistic is 5.26, so the effects are superadditive. But the RERI statistic has a *p*-value of 0.535, so we cannot reject the additive model.

The message of this example is clear. If you have negative ERRs, first check that you correctly specified the hypothesized direction of effects. If the model is correctly specified and there are negative ERRs (not close to 0), then the RERI, AP, and SI statistics may not be useful descriptors for the observed effects.

## Stored results

`reri` stores the following in `r()`:

Scalars

- `r(N)`                    number of observations
- `r(reri)`                 RERI
- `r(ap)`                    AP
- `r(si)`                    SI
- `r(level)`                confidence level

Matrices

- `r(reri_table)`         table of results

The `e()` and `r()` stored results from *cmd* are returned as well.

## Methods and formulas

The RERI statistic is

$$\text{RERI} = \text{ERR}_{A+B+} - \text{ERR}_{A-B+} - \text{ERR}_{A+B-}$$

where  $\text{ERR} = \text{RR} - 1$  is the ERR and RR denotes relative risk. Here  $A+B+$  refers to subjects positive for exposure  $A$  and positive for exposure  $B$ , with  $A-B+$  and  $A+B-$  defined similarly.

The AP is

$$\text{AP} = \frac{\text{RERI}}{\text{RR}_{A+B+}}$$

The SI is

$$\text{SI} = \frac{\text{ERR}_{A+B+}}{\text{ERR}_{A-B+} + \text{ERR}_{A+B-}}$$

When incidence-rate ratios, odds ratios, or hazard ratios are estimated rather than risk ratios, they are used in the calculation in place of relative risk.

Standard errors are calculated by `nlcom` using the “delta method”. See [Methods and formulas in \[R\] nlcom](#) for details. The standard error for the SI is calculated by first calculating the standard error for the logarithm of SI and then transforming the result back to the SI scale.

## Acknowledgment

`reri` is based on the `ic` package written by Niels Henrik Bruun, Morten Fenger-Grøn, and Anders Prior, while all were at Aarhus University (2017).

## Description

The `#review` command displays the last few lines typed at the terminal.

## Syntax

```
#review [#1 [#2]]
```

## Remarks and examples

`#review` (pronounced *pound-review*) is a Stata preprocessor command. `#commands` do not generate a return code or generate ordinary Stata errors. The only error message associated with `#commands` is “unrecognized `#command`”.

The `#review` command displays the last few lines typed at the terminal. If no arguments follow `#review`, the last 20 lines typed at the terminal are displayed. The first argument specifies the number of lines to be reviewed, so `#review 10` displays the last 10 lines typed. The second argument specifies the number of lines to be displayed, so `#review 10 5` displays five lines, starting at the 10th previous line.

Stata reserves a buffer for `#review` lines and stores as many previous lines in the buffer as will fit, rolling out the oldest line to make room for the newest. Requests to `#review` lines no longer stored will be ignored. Only lines typed at the terminal are placed in the `#review` buffer. See [\[U\] 10.5 Editing previous lines in Stata](#).

### ▷ Example 1

Typing `#review` by itself will show the last 20 lines you typed at the terminal:

```
. #review
20 webuse auto
19 describe
18 notes
17 * comments go into the #review buffer, too
16 tabulate rep78
15 codebook foreign
14 regress mpg weight i.foreign
13 generate gp100m = 100/mpg
12 label variable gp100m "Gallons per 100 miles"
11 tabulate rep78, summarize(gp100m)
10 ttest gp100m, by(foreign)
9 regress gp100m weight i.foreign
8 regress, beta
7 margins foreign
6 generate gpmw = ((100/mpg)/weight)*1000
5 summarize gpmw
4 twoway scatter price gpmw
3 regress gpmw i.foreign
2 regress gpmw i.foreign, vce(robust)
1 #review
. _
```

Typing #review 15 2 shows the 15th and 14th previous lines:

```
. #review 15 2
15 regress mpg weight i.foreign
14 generate gp100m = 100/mpg
. _
```

## Description

ROC analysis quantifies the accuracy of diagnostic tests or other evaluation modalities used to discriminate between two states or conditions, which are here referred to as normal and abnormal or control and case. The discriminatory accuracy of a diagnostic test is measured by its ability to correctly classify known normal and abnormal subjects. For this reason, we often refer to the diagnostic test as a classifier. The analysis uses the ROC curve, a graph of the sensitivity versus  $1 - \text{specificity}$  of the diagnostic test. The sensitivity is the fraction of positive cases that are correctly classified by the diagnostic test, whereas the specificity is the fraction of negative cases that are correctly classified. Thus the sensitivity is the true-positive rate, and the specificity is the true-negative rate.

There are six ROC commands:

| Command                 | Entry                 | Description                                                 |
|-------------------------|-----------------------|-------------------------------------------------------------|
| <code>roccomp</code>    | [R] <b>roccomp</b>    | Tests of equality of ROC areas                              |
| <code>rocgold</code>    | [R] <b>roccomp</b>    | Tests of equality of ROC areas against a standard ROC curve |
| <code>rocfit</code>     | [R] <b>rocfit</b>     | Parametric ROC models                                       |
| <code>rocreg</code>     | [R] <b>rocreg</b>     | Nonparametric and parametric ROC regression models          |
| <code>rocregplot</code> | [R] <b>rocregplot</b> | Plot marginal and covariate-specific ROC curves             |
| <code>roctab</code>     | [R] <b>roctab</b>     | Nonparametric ROC analysis                                  |

Postestimation commands are available after `rocfit` and `rocreg`; see [R] [rocfit postestimation](#) and [R] [rocreg postestimation](#).

Both nonparametric and parametric (semiparametric) methods have been suggested for generating the ROC curve. The `roctab` command performs nonparametric ROC analysis for a single classifier. `roccomp` extends the nonparametric ROC analysis function of `roctab` to situations where we have multiple diagnostic tests of interest to be compared and tested. The `rocgold` command also provides ROC analysis for multiple classifiers. `rocgold` compares each classifier's ROC curve to a "gold standard" ROC curve and makes adjustments for multiple comparisons in the analysis. Both `rocgold` and `roccomp` also allow parametric estimation of the ROC curve through a binormal fit. In a binormal fit, both the control and the case populations are normal.

The `rocfit` command also estimates the ROC curve of a classifier through a binormal fit. Unlike `roctab`, `roccomp`, and `rocgold`, `rocfit` is an estimation command. In postestimation, graphs of the ROC curve and confidence bands can be produced. Additional tests on the parameters can also be conducted.

ROC analysis can be interpreted as a two-stage process. First, the control distribution of the classifier is estimated, assuming a normal model or using a distribution-free estimation technique. The classifier is standardized using the control distribution to  $1 - \text{percentile value}$ , the false-positive rate. Second, the ROC curve is estimated as the case distribution of the standardized classifier values.

Covariates may affect both stages of ROC analysis. The first stage may be affected, yielding a covariate-adjusted ROC curve. The second stage may also be affected, producing multiple covariate-specific ROC curves.

The `rocreg` command performs ROC analysis under both types of covariate effects. Both parametric (semiparametric) and nonparametric methods may be used by `rocreg`. Like `rocfit`, `rocreg` is an estimation command and provides many postestimation capabilities.

The global performance of a diagnostic test is commonly summarized by the area under the ROC curve (AUC). This area can be interpreted as the probability that the result of a diagnostic test of a randomly selected abnormal subject will be greater than the result of the same diagnostic test from a randomly selected normal subject. The greater the AUC, the better the global performance of the diagnostic test. Each of the ROC commands provides computation of the AUC.

Citing a lack of clinical relevance for the AUC, other ROC summary measures have been suggested. These include the partial area under the ROC curve for a given false-positive rate  $t$  [ $\text{pAUC}(t)$ ]. This is the area under the ROC curve from the false-positive rate of 0 to  $t$ . The ROC value at a particular false-positive rate and the false-positive rate for a particular ROC value are also useful summary measures for the ROC curve. These three measures are directly estimated by `rocreg` during the model fit or postestimation stages. Point estimates of ROC value are computed by the other ROC commands, but no standard errors are reported.

See [Pepe \(2003\)](#) for a discussion of ROC analysis. Pepe has posted Stata datasets and programs used to reproduce results presented in the book (<https://www.stata.com/bookstore/pepe.html>).

## Description

`roccomp` and `rocgold` are used to perform receiver operating characteristic (ROC) analyses with rating and discrete classification data.

The two variables *refvar* and *classvar* must be numeric. The reference variable indicates the true state of the observation, such as diseased and nondiseased or normal and abnormal, and must be coded as 0 and 1. The rating or outcome of the diagnostic test or test modality is recorded in *classvar*, which must be at least ordinal, with higher values indicating higher risk.

`roccomp` tests the equality of two or more ROC areas obtained from applying two or more test modalities to the same sample or to independent samples. `roccomp` expects the data to be in wide form when comparing areas estimated from the same sample and in long form for areas estimated from independent samples.

`rocgold` independently tests the equality of the ROC area of each of several test modalities, specified by *classvar*, against a “gold standard” ROC curve, *goldvar*. For each comparison, `rocgold` reports the raw and the Bonferroni-adjusted *p*-value. Optionally, Šidák’s adjustment for multiple comparisons can be obtained.

See [R] [rocfits](#) and [R] [roclogit](#) for commands that fit maximum-likelihood ROC models.

## Quick start

Equality of AUCs for rating *v1* of true state *true* between samples defined by *catvar*

```
roccomp true v1, by(catvar)
```

Equality of AUCs for ratings *v1* and *v2* for the same sample

```
roccomp true v1 v2
```

Same as above, but plot ROC curves without reporting summary statistics and test of equality

```
roccomp true v1 v2, graph
```

Same as above, but plot *v1* with a dashed line and *v2* with a solid line

```
roccomp true v1 v2, graph plot1opts(lpattern(dash)) ///
plot2opts(lpattern(solid))
```

Use contrast matrix *mymat* to compare ROC areas for *v1*, *v2*, *v3*, and *v4*

```
matrix mymat = (1,0,-1,0 \ 0,1,0,-1)
roccomp true v1 v2 v3 v4, test(mymat)
```

Test equality of ROC area for *v1* against a “gold standard” *gold*

```
rocgold true gold v1
```

## Menu

### roccomp

Statistics > Epidemiology and related > ROC analysis > Test equality of two or more ROC areas

### rocgold

Statistics > Epidemiology and related > ROC analysis > Test equality of ROC area against gold standard

## Syntax

Test equality of ROC areas

```
roccomp refvar classvar [classvars] [if] [in] [weight] [, roccomp_options]
```

Test equality of ROC area against a standard ROC curve

```
rocgold refvar goldvar classvar [classvars] [if] [in] [weight] [, rocgold_options]
```

| <i>roccomp_options</i>                       | Description                                                                        |
|----------------------------------------------|------------------------------------------------------------------------------------|
| Main                                         |                                                                                    |

`collect` is allowed with `roccomp` and `rocgold`; see [U] [11.1.10 Prefix commands](#).

`fweights` are allowed; see [U] [11.1.6 weight](#).

## Options

### Main

by(*varname*) (`roccomp` only) is required when comparing independent ROC areas. The `by()` variable identifies the groups to be compared.

`sidak` (`rocgold` only) requests that the  $p$ -value be adjusted for the effect of multiple comparisons by using Šidák's method. Bonferroni's adjustment is reported by default.

`test(matname)` specifies the contrast matrix to be used when comparing ROC areas. By default, the null hypothesis that all areas are equal is tested.

`graph` produces graphical output of the ROC curve.

`norefln` suppresses plotting the 45-degree reference line from the graphical output of the ROC curve.

`separate` is meaningful only with `roccomp` and specifies that each ROC curve be placed on its own graph rather than one curve on top of the other.

`summary` reports the area under the ROC curve, its standard error, and its confidence interval. This option is needed only when also specifying `graph`.

`binormal` specifies that the areas under the ROC curves to be compared should be estimated using the binormal distribution assumption. By default, areas to be compared are computed using the trapezoidal rule.

`line#opts(cline_options)` affect the rendition of the line representing the #th ROC curve drawn using the binormal distribution assumption; see [G-3] *cline\_options*. These lines are drawn only if the `binormal` option is specified.

`level(#)` specifies the confidence level, as a percentage, for the confidence intervals. The default is `level(95)` or as set by `set level1`; see [R] *level*.

#### Plot

`plot#opts(plot_options)` affect the rendition of the #th ROC curve—the curve’s plotted points connected by lines. The *plot\_options* can affect the size and color of markers, whether and how the markers are labeled, and whether and how the points are connected; see [G-3] *marker\_options*, [G-3] *marker\_label\_options*, and [G-3] *cline\_options*.

For `rocgold`, `plot1opts()` are applied to the ROC for the gold standard.

#### Reference line

`rlopts(cline_options)` affects the rendition of the reference line; see [G-3] *cline\_options*.

#### Y axis, X axis, Titles, Legend, Overall

*twoway\_options* are any of the options documented in [G-3] *twoway\_options*. These include options for titling the graph (see [G-3] *title\_options*), options for saving the graph to disk (see [G-3] *saving\_option*), and the `by()` option (see [G-3] *by\_option*).

## Remarks and examples

Remarks are presented under the following headings:

- Introduction*
- Comparing areas under the ROC curve*
- Correlated data*
- Independent data*
- Comparing areas with a gold standard*

## Introduction

`roccomp` provides comparison of the ROC curves of multiple classifiers. `rocgold` compares the ROC curves of multiple classifiers with a single “gold standard” classifier. Adjustment of inference for multiple comparisons is also provided by `rocgold`.

See [Pepe \(2003\)](#) for a discussion of ROC analysis. Pepe has posted Stata datasets and programs used to reproduce results presented in the book (<https://www.stata.com/bookstore/pepe.html>).

## Comparing areas under the ROC curve

The area under multiple ROC curves can be compared by using `roccomp`. The command syntax is slightly different if the ROC curves are correlated (that is, different diagnostic tests are applied to the same sample) or independent (that is, diagnostic tests are applied to different samples).

### Correlated data

#### ▷ Example 1

Hanley and McNeil (1983) presented data from an evaluation of two computer algorithms designed to reconstruct CT images from phantoms. We will call these two algorithms' modalities 1 and 2. A sample of 112 phantoms was selected; 58 phantoms were considered normal, and the remaining 54 were abnormal. Each of the two modalities was applied to each phantom, and the resulting images were rated by a reviewer using a six-point scale: 1 = definitely normal, 2 = probably normal, 3 = possibly normal, 4 = possibly abnormal, 5 = probably abnormal, and 6 = definitely abnormal. Because each modality was applied to the same sample of phantoms, the two sets of outcomes are correlated.

We list the first 7 observations:

```
. use https://www.stata-press.com/data/r19/ct
(Reconstruction of CT images)
. list in 1/7, sep(0)
```

|    | mod1 | mod2 | status |
|----|------|------|--------|
| 1. | 2    | 1    | 0      |
| 2. | 5    | 5    | 1      |
| 3. | 2    | 1    | 0      |
| 4. | 2    | 3    | 0      |
| 5. | 5    | 6    | 1      |
| 6. | 2    | 2    | 0      |
| 7. | 3    | 2    | 0      |

The data are in wide form, which is required when dealing with correlated data. Each observation corresponds to one phantom. The variable `mod1` identifies the rating assigned for the first modality, and `mod2` identifies the rating assigned for the second modality. The true status of the phantoms is given by `status=0` if they are normal and `status=1` if they are abnormal. The observations with at least one missing rating were dropped from the analysis.

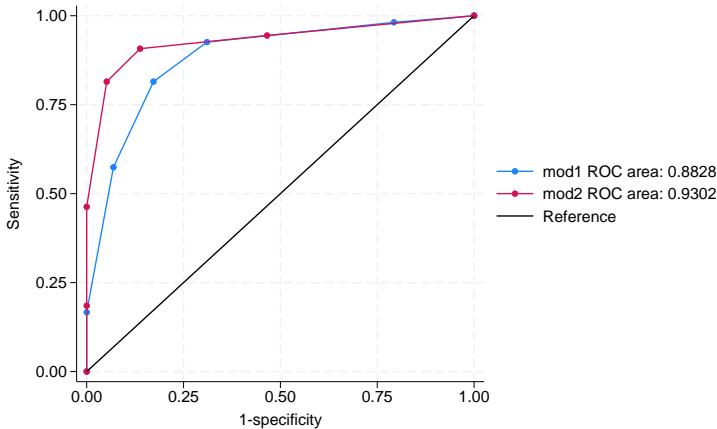

We plot the two ROC curves and compare their areas.

```
. roccomp status mod1 mod2, graph summary
```

|      | Obs | ROC<br>area | Std. err. | Asymptotic normal<br>[95% conf. interval] |         |
|------|-----|-------------|-----------|-------------------------------------------|---------|
| mod1 | 112 | 0.8828      | 0.0317    | 0.82067                                   | 0.94498 |
| mod2 | 112 | 0.9302      | 0.0256    | 0.88005                                   | 0.98042 |

```
H0: area(mod1) = area(mod2)
```

```
chi2(1) = 2.31 Prob>chi2 = 0.1282
```

By default, `roccomp`, with the `graph` option specified, plots the ROC curves on the same graph. Optionally, the curves can be plotted side by side, each on its own graph, by also specifying `separate`.

For each curve, `roccomp` reports summary statistics and provides a test for the equality of the area under the curves, using an algorithm suggested by [DeLong, DeLong, and Clarke-Pearson \(1988\)](#).

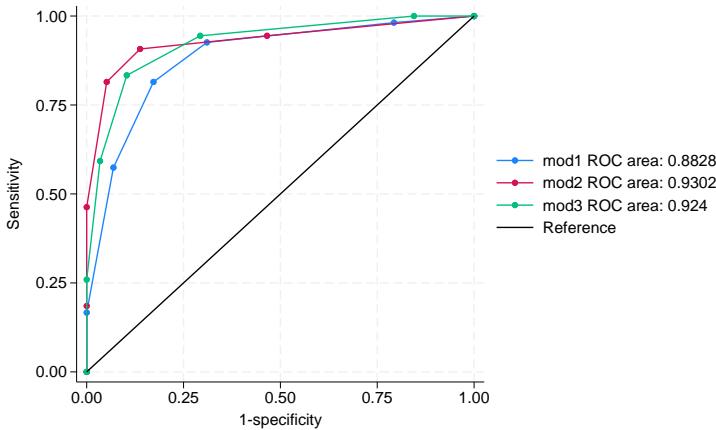

Although the area under the ROC curve for modality 2 is larger than that of modality 1, the  $\chi^2$  test yielded a  $p$ -value of 0.1282, suggesting that there is no significant difference between these two areas.

The `roccomp` command can also be used to compare more than two ROC areas. To illustrate this, we modified the previous dataset by including a fictitious third modality.

```
. use https://www.stata-press.com/data/r19/ct2
(Reconstruction of CT images)
. roccomp status mod1 mod2 mod3, graph summary
```

|      | Obs | ROC<br>area | Std. err. | Asymptotic normal<br>[95% conf. interval] |         |
|------|-----|-------------|-----------|-------------------------------------------|---------|
| mod1 | 112 | 0.8828      | 0.0317    | 0.82067                                   | 0.94498 |
| mod2 | 112 | 0.9302      | 0.0256    | 0.88005                                   | 0.98042 |
| mod3 | 112 | 0.9240      | 0.0241    | 0.87670                                   | 0.97132 |

```
H0: area(mod1) = area(mod2) = area(mod3)
chi2(2) = 6.54 Prob>chi2 = 0.0381
```

By default, `roccomp` tests whether the areas under the ROC curves are all equal. Other comparisons can be tested by creating a contrast matrix and specifying `test(matname)`, where `matname` is the name of the contrast matrix.

For example, assume that we are interested in testing whether the area under the ROC for `mod1` is equal to that of `mod3`. To do this, we can first create an appropriate contrast matrix and then specify its name with the `test()` option.

Of course, this is a trivial example because we could have just specified

```
. roccomp status mod1 mod3
```

without including `mod2` to obtain the same test results. However, for illustration, we will continue with this example.

The contrast matrix must have its number of columns equal to the number of *classvars* (that is, the total number of ROC curves) and a number of rows less than or equal to the number of *classvars*, and the elements of each row must add to zero.

```
. matrix C=(1,0,-1)
. roccomp status mod1 mod2 mod3, test(C)
```

|      | Obs | ROC<br>area | Std. err. | Asymptotic normal<br>[95% conf. interval] |         |
|------|-----|-------------|-----------|-------------------------------------------|---------|
| mod1 | 112 | 0.8828      | 0.0317    | 0.82067                                   | 0.94498 |
| mod2 | 112 | 0.9302      | 0.0256    | 0.88005                                   | 0.98042 |
| mod3 | 112 | 0.9240      | 0.0241    | 0.87670                                   | 0.97132 |

```
HO: Comparison as defined by contrast matrix: C
chi2(1) = 5.25 Prob>chi2 = 0.0220
```

Although all three areas are reported, the comparison is made using the specified contrast matrix.

Perhaps more interesting would be a comparison of the area from mod1 and the average area of mod2 and mod3.

```
. matrix C=(1,-.5,-.5)
. roccomp status mod1 mod2 mod3, test(C)
```

|      | Obs | ROC<br>area | Std. err. | Asymptotic normal<br>[95% conf. interval] |         |
|------|-----|-------------|-----------|-------------------------------------------|---------|
| mod1 | 112 | 0.8828      | 0.0317    | 0.82067                                   | 0.94498 |
| mod2 | 112 | 0.9302      | 0.0256    | 0.88005                                   | 0.98042 |
| mod3 | 112 | 0.9240      | 0.0241    | 0.87670                                   | 0.97132 |

```
HO: Comparison as defined by contrast matrix: C
chi2(1) = 3.43 Prob>chi2 = 0.0642
```

Other contrasts could be made. For example, we could test if mod3 is different from at least one of the other two by first creating the following contrast matrix:

```
. matrix C=(-1,0,1 \ 0,-1,1)
. mat list C
C[2,3]
 c1 c2 c3
r1 -1 0 1
r2 0 -1 1
```

## Independent data

### ▷ Example 2

In [example 1](#), we noted that because each test modality was applied to the same sample of phantoms, the classification outcomes were correlated. Now, assume that we have collected the same data presented by [Hanley and McNeil \(1983\)](#), except that we applied the first test modality to one sample of phantoms and the second test modality to a different sample of phantoms. The resulting measurements are now considered independent.

Here are a few of the observations.

```
. use https://www.stata-press.com/data/r19/ct3
(Reconstruction of CT images)
. list in 1/7, sep(0)
```

|    | pop | status | rating | mod |
|----|-----|--------|--------|-----|
| 1. | 12  | 0      | 1      | 1   |
| 2. | 31  | 0      | 1      | 2   |
| 3. | 1   | 1      | 1      | 1   |
| 4. | 3   | 1      | 1      | 2   |
| 5. | 28  | 0      | 2      | 1   |
| 6. | 19  | 0      | 2      | 2   |
| 7. | 3   | 1      | 2      | 1   |

The data are in long form, which is required when dealing with independent data. The data consist of 24 observations: 6 observations corresponding to abnormal phantoms and 6 to normal phantoms evaluated using the first modality, and similarly 6 observations corresponding to abnormal phantoms and 6 to normal phantoms evaluated using the second modality. The number of phantoms corresponding to each observation is given by the `pop` variable. Once again, we have frequency-weighted data. The variable `mod` identifies the modality, and `rating` is the assigned classification.

We can better view our data by using the `table` command.

```
. table (mod status) (rating) [fw=pop], totals(mod mod#status mod#rating)
```

|               |        | Rating |    |    |    |    |    | Total |
|---------------|--------|--------|----|----|----|----|----|-------|
|               |        | 1      | 2  | 3  | 4  | 5  | 6  |       |
| Modality<br>1 | Status |        |    |    |    |    |    |       |
|               | 0      | 12     | 28 | 8  | 6  | 4  |    | 58    |
|               | 1      | 1      | 3  | 6  | 13 | 22 | 9  | 54    |
|               | Total  | 13     | 31 | 14 | 19 | 26 | 9  | 112   |
| 2             | Status |        |    |    |    |    |    |       |
|               | 0      | 31     | 19 | 5  | 3  |    |    | 58    |
|               | 1      | 3      | 2  | 5  | 19 | 15 | 10 | 54    |
|               | Total  | 34     | 21 | 10 | 22 | 15 | 10 | 112   |

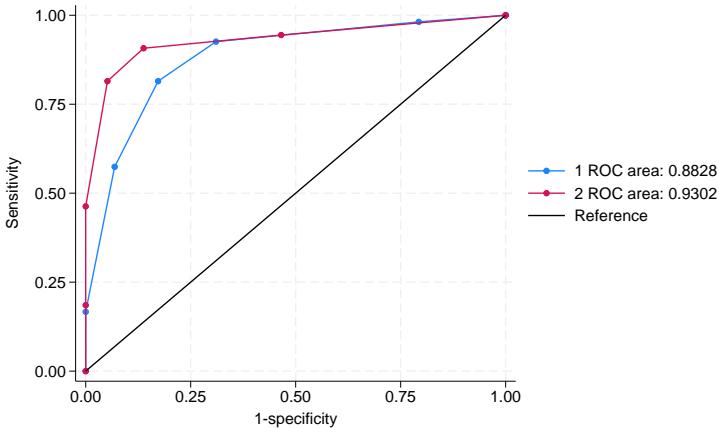

The `status` variable indicates the true status of the phantoms: `status = 0` if they are normal and `status = 1` if they are abnormal.

We now compare the areas under the two ROC curves.

```
. roccomp status rating [fw=pop], by(mod) graph summary
```

| mod | Obs | ROC area | Std. err. | Asymptotic normal<br>[95% conf. interval] |         |
|-----|-----|----------|-----------|-------------------------------------------|---------|
| 1   | 112 | 0.8828   | 0.0317    | 0.82067                                   | 0.94498 |
| 2   | 112 | 0.9302   | 0.0256    | 0.88005                                   | 0.98042 |

```
HO: area(1) = area(2)
chi2(1) = 1.35 Prob>chi2 = 0.2447
```

### Comparing areas with a gold standard

The area under multiple ROC curves can be compared with a gold standard using `rocgold`. The command syntax is similar to that of `roccomp`. The tests are corrected for the effect of multiple comparisons.

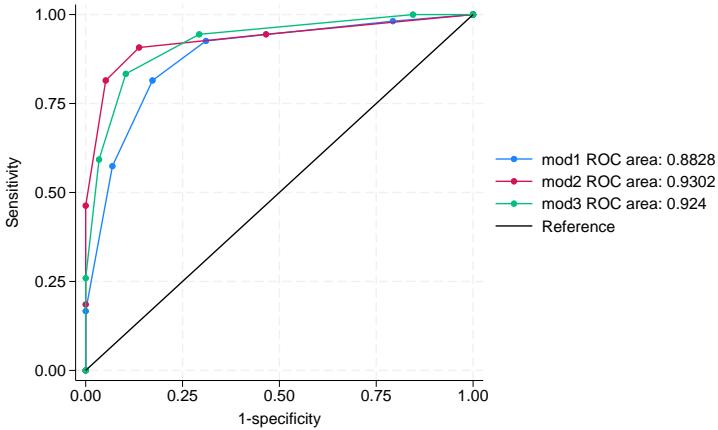

#### ➤ Example 3

We will use the same data (presented by [Hanley and McNeil \[1983\]](#)) as in the `roccomp` examples. Let's assume that the first modality is considered to be the standard against which both the second and third modalities are compared.

We want to plot and compare both the areas of the ROC curves of `mod2` and `mod3` with `mod1`. Because we consider `mod1` to be the gold standard, it is listed first after the reference variable in the `rocgold` command line.

```
. use https://www.stata-press.com/data/r19/ct2
(Reconstruction of CT images)
. rocgold status mod1 mod2 mod3, graph summary
```

|                 | ROC area | Std. err. | chi2   | df | Pr>chi2 | Bonferroni<br>Pr>chi2 |
|-----------------|----------|-----------|--------|----|---------|-----------------------|
| mod1 (standard) | 0.8828   | 0.0317    |        |    |         |                       |
| mod2            | 0.9302   | 0.0256    | 2.3146 | 1  | 0.1282  | 0.2563                |

## Methods and formulas

Assume that we applied a diagnostic test to each of  $N_n$  normal and  $N_a$  abnormal subjects. Further assume that the higher the outcome value of the diagnostic test, the higher the risk of the subject being abnormal. Let  $\hat{\theta}$  be the estimated area under the curve, and let  $X_i, i = 1, 2, \dots, N_n$  and  $Y_j, j = 1, 2, \dots, N_n$  be the values of the diagnostic test for the abnormal and normal subjects, respectively.

Areas under ROC curves are compared using an algorithm suggested by DeLong, DeLong, and Clarke-Pearson (1988). Let  $\hat{\theta} = (\hat{\theta}^1, \hat{\theta}^2, \dots, \hat{\theta}^k)$  be a vector representing the areas under  $k$  ROC curves. See *Methods and formulas* in [R] **roctab** for the definition of these area estimates.

For the  $r$ th area, define

$$V_{10}^r(X_i) = \frac{1}{N_n} \sum_{j=1}^{N_n} \psi(X_i^r, Y_j^r)$$

and for each normal subject,  $j$ , define

$$V_{01}^r(Y_j) = \frac{1}{N_a} \sum_{i=1}^{N_a} \psi(X_i^r, Y_j^r)$$

where

$$\psi(X^r, Y^r) = \begin{cases} 1 & Y^r < X^r \\ \frac{1}{2} & Y^r = X^r \\ 0 & Y^r > X^r \end{cases}$$

Define the  $k \times k$  matrix  $\mathbf{S}_{10}$  such that the  $(r, s)$ th element is

$$S_{10}^{r,s} = \frac{1}{N_a - 1} \sum_{i=1}^{N_a} \{V_{10}^r(X_i) - \hat{\theta}^r\} \{V_{10}^s(X_i) - \hat{\theta}^s\}$$

and  $\mathbf{S}_{01}$  such that the  $(r, s)$ th element is

$$S_{01}^{r,s} = \frac{1}{N_n - 1} \sum_{j=1}^{N_n} \{V_{01}^r(Y_j) - \hat{\theta}^r\} \{V_{01}^s(Y_j) - \hat{\theta}^s\}$$

Then, the covariance matrix is

$$S = \frac{1}{N_a} S_{10} + \frac{1}{N_n} S_{01}$$

Let  $\mathbf{L}$  be a contrast matrix defining the comparison, so that

$$(\hat{\theta} - \theta)' \mathbf{L}' (\mathbf{L} \mathbf{S} \mathbf{L}')^{-1} \mathbf{L} (\hat{\theta} - \theta)$$

has a  $\chi^2$  distribution with degrees of freedom equal to the rank of  $\mathbf{L} \mathbf{S} \mathbf{L}'$ .

## Description

`rocfit` fits maximum-likelihood ROC models assuming a binormal distribution of the latent variable.

The two variables *refvar* and *classvar* must be numeric. The reference variable indicates the true state of the observation, such as diseased and nondiseased or normal and abnormal, and must be coded as 0 and 1. The rating or outcome of the diagnostic test or test modality is recorded in *classvar*, which must be at least ordinal, with higher values indicating higher risk.

See [\[R\] roc](#) for other commands designed to perform receiver operating characteristic (ROC) analyses with rating and discrete classification data.

## Quick start

Binary true state, `true`, as a function of classification variable `class`

```
rocfit true class
```

Same as above, but with frequency weights `wvar`

```
rocfit true class [fweight = wvar]
```

Specify that `class` is continuous and generate `v1` containing classification groups

```
rocfit true class, continuous(3) generate(v1)
```

## Menu

Statistics > Epidemiology and related > ROC analysis > Parametric ROC analysis without covariates

## Syntax

```
rocfit refvar classvar [if] [in] [weight] [, rocfit_options]
```

## Options

### Model

`continuous(#)` specifies that the continuous *classvar* be divided into # groups of approximately equal length. This option is required when *classvar* takes on more than 20 distinct values.

`continuous(.)` may be specified to indicate that *classvar* be used as it is, even though it could have more than 20 distinct values.

`generate(newvar)` specifies the new variable that is to contain values indicating the groups produced by `continuous(#)`. `generate()` may be specified only with `continuous()`.

### SE

`vce(vcetype)` specifies the type of standard error reported. *vcetype* may be either oim or opg; see [R] [vce\\_option](#).

### Reporting

`level(#)`; see [R] [Estimation options](#).

### Maximization

`maximize_options`: `difficult`, `technique(algorithm_spec)`, `iterate(#)`, `[no]log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `ltolerance(#)`, `nrtolerance(#)`, `nonrtolerance`, and `from(init_specs)`; see [R] [Maximize](#). These options are seldom used.

Setting the optimization type to `technique(bhhh)` resets the default *vcetype* to `vce(opg)`.

## Remarks and examples

Dorfman and Alf (1969) developed a generalized approach for obtaining maximum likelihood estimates of the parameters for a smooth fitting ROC curve. The most commonly used method for ordinal data, and the one implemented here, is based upon the binormal model; see Pepe (2003), Pepe, Longton, and Janes (2009), and Janes, Longton, and Pepe (2009) for methods of ROC analysis for continuous data, including methods for adjusting for covariates.

The model assumes the existence of an unobserved, continuous, latent variable that is normally distributed (perhaps after a monotonic transformation) in both the normal and abnormal populations with means  $\mu_n$  and  $\mu_a$  and variances  $\sigma_n^2$  and  $\sigma_a^2$ , respectively. The model further assumes that the  $K$  categories of the rating variable result from partitioning the unobserved latent variable by  $K - 1$  fixed boundaries. The method fits a straight line to the empirical ROC points plotted using normal probability scales on both axes. Maximum likelihood estimates of the line's slope and intercept and the  $K - 1$  boundaries are obtained simultaneously. See *Methods and formulas* for details.

The intercept from the fitted line is a measurement of  $(\mu_a - \mu_n)/\sigma_a$ , and the slope measures  $\sigma_n/\sigma_a$ .

Thus, the intercept is the standardized difference between the two latent population means, and the slope is the ratio of the two standard deviations. The null hypothesis that there is no difference between the two population means is evaluated by testing that the intercept = 0, and the null hypothesis that the variances in the two populations are equal is evaluated by testing that the slope = 1.

### ▷ Example 1

We use Hanley and McNeil's (1982) dataset, described in [example 1](#) of [\[R\] roctab](#), to fit a smooth ROC curve assuming a binormal model.

```
. use https://www.stata-press.com/data/r19/hanley
(Tomographic images)
. rocfit disease rating

Fitting binormal model:
Iteration 0: Log likelihood = -123.68069
Iteration 1: Log likelihood = -123.64867
Iteration 2: Log likelihood = -123.64855
Iteration 3: Log likelihood = -123.64855

Binormal model of disease on rating Number of obs = 109
Goodness-of-fit chi2(2) = 0.21
Prob > chi2 = 0.9006
Log likelihood = -123.64855
```

(\*) z test for slope==1

rocfit outputs the MLE for the intercept and slope of the fitted regression line along with, here, four boundaries (because there are five ratings) labeled /cut1 through /cut4. Also rocfit computes and reports four indices based on the fitted ROC curve: the area under the curve (labeled ROC area),  $\delta(m)$  (labeled delta(m)),  $d_e$  (labeled d(e)), and  $d_a$  (labeled d(a)). More information about these indices can be found in *Methods and formulas* and in [Erdreich and Lee \(1981\)](#).

## Stored results

rocfit stores the following in e():

| e(vce)      | vcetype specified in vce()                                               |
| e(vcetype)  | title used to label Std. err.                                            |
| e(opt)      | type of optimization                                                     |
| e(which)    | max or min; whether optimizer is to perform maximization or minimization |

|               |                                              |
|---------------|----------------------------------------------|
| e(ml_method)  | type of ml method                            |
| e(user)       | name of likelihood-evaluator program         |
| e(technique)  | maximization technique                       |
| e(properties) | b V                                          |
| Matrices      |                                              |
| e(b)          | coefficient vector                           |
| e(iolog)      | iteration log (up to 20 iterations)          |
| e(gradient)   | gradient vector                              |
| e(V)          | variance–covariance matrix of the estimators |
| Functions     |                                              |
| e(sample)     | marks estimation sample                      |

In addition to the above, the following is stored in `r()`:

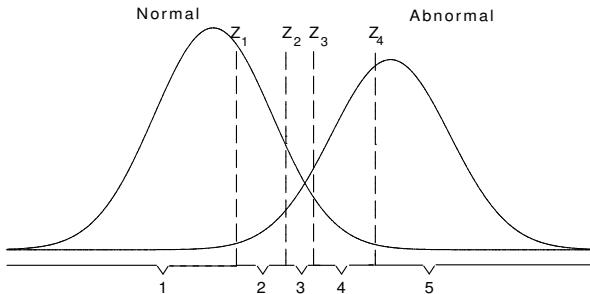

|          |                                                                                                                       |
|----------|-----------------------------------------------------------------------------------------------------------------------|
| Matrices |                                                                                                                       |
| r(table) | matrix containing the coefficients with their standard errors, test statistics, $p$ -values, and confidence intervals |

Note that results stored in `r()` are updated when the command is replayed and will be replaced when any `r-class` command is run after the estimation command.

## Methods and formulas

Dorfman and Alf (1969) developed a general procedure for obtaining maximum likelihood estimates of the parameters of a smooth-fitting ROC curve. The most common method, and the one implemented in Stata, is based upon the binormal model.

The model assumes that there is an unobserved continuous latent variable that is normally distributed in both the normal and abnormal populations. The idea is better explained with the following illustration:

The latent variable is assumed to be normally distributed for both the normal and abnormal subjects, perhaps after a monotonic transformation, with means  $\mu_n$  and  $\mu_a$  and variances  $\sigma_n^2$  and  $\sigma_a^2$ , respectively.

This latent variable is assumed to be partitioned into the  $k$  categories of the rating variable by  $k - 1$  fixed boundaries. In the above figure, the  $k = 5$  categories of the rating variable identified on the bottom result from the partition of the four boundaries  $Z_1$  through  $Z_4$ .

Let  $R_j$  for  $j = 1, 2, \dots, k$  indicate the categories of the rating variable, let  $i = 1$  if the subject belongs to the normal group, and let  $i = 2$  if the subject belongs to the abnormal group.

Then,

$$p(R_j|i = 1) = F(Z_j) - F(Z_{j-1})$$

where  $Z_k = (x_k - \mu_n)/\sigma_n$ ,  $F$  is the cumulative normal distribution,  $F(Z_0) = 0$ , and  $F(Z_k) = 1$ . Also,

$$p(R_j|i = 2) = F(bZ_j - a) - F(bZ_{j-1} - a)$$

where  $b = \sigma_n/\sigma_a$  and  $a = (\mu_a - \mu_n)/\sigma_a$ .

The parameters  $a$ ,  $b$  and the  $k - 1$  fixed boundaries  $Z_j$  are simultaneously estimated by maximizing the log-likelihood function

$$\log L = \sum_{i=1}^2 \sum_{j=1}^k r_{ij} \log\{p(R_j|i)\}$$

where  $r_{ij}$  is the number of  $R_j$ s in group  $i$ .

The area under the fitted ROC curve is computed as

$$\Phi\left(\frac{a}{\sqrt{1+b^2}}\right)$$

where  $\Phi$  is the standard normal cumulative distribution function.

Point estimates for the ROC curve indices are as follows:

$$\delta(m) = \frac{a}{b} \quad d_e = \frac{2a}{b+1} \quad d_a = \frac{a\sqrt{2}}{\sqrt{1+b^2}}$$

Variances for these indices are computed using the delta method.

The  $\delta(m)$  estimates  $(\mu_a - \mu_n)/\sigma_n$ ,  $d_e$  estimates  $2(\mu_a - \mu_n)/(\sigma_a - \sigma_n)$ , and  $d_a$  estimates  $\sqrt{2}(\mu_a - \mu_n)/(\sigma_a^2 - \sigma_n^2)^{1/2}$ .

Simultaneous confidence bands for the entire curve are obtained, as suggested by [Ma and Hall \(1993\)](#), by first obtaining [Working–Hotelling \(1929\)](#) confidence bands for the fitted straight line in normal probability coordinates and then transforming them back to ROC coordinates.

## Postestimation commands

The following command is of special interest after `rocfit`:

| Command              | Description                                                 |
|----------------------|-------------------------------------------------------------|
| <code>rocplot</code> | plot the fitted ROC curve and simultaneous confidence bands |

The following standard postestimation commands are also available:

| Command                      | Description                                                                                                                             |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <code>estat ic</code>        | Akaike's, consistent Akaike's, corrected Akaike's, and Schwarz's Bayesian information criteria (AIC, CAIC, AICC, and BIC, respectively) |
| <code>estat summarize</code> | summary statistics for the estimation sample                                                                                            |
| <code>estat vce</code>       | variance–covariance matrix of the estimators (VCE)                                                                                      |
| <code>estimates</code>       | cataloging estimation results                                                                                                           |
| <code>etable</code>          | table of estimation results                                                                                                             |
| * <code>lincom</code>        | point estimates, standard errors, testing, and inference for linear combinations of parameters                                          |
| * <code>test</code>          | Wald tests of simple and composite linear hypotheses                                                                                    |

\*See *Using `lincom` and `test`* below.

# rocplot

## Description for rocplot

rocplot plots the fitted ROC curve and simultaneous confidence bands.

## Menu for rocplot

Statistics > Epidemiology and related > ROC analysis > ROC curves after rocfit

## Syntax for rocplot

```
rocplot [, rocplot_options]
```

| <i>rocplot_options</i>                      | Description                                                                           |
|---------------------------------------------|---------------------------------------------------------------------------------------|
| Main                                        |                                                                                       |
| <code>confband</code>                       | display confidence bands                                                              |
| <code>norefline</code>                      | suppress plotting the reference line                                                  |
| <code>level(#)</code>                       | set confidence level; default is level(95)                                            |
| Plot                                        |                                                                                       |
| <code>plotopts(<i>plot_options</i>)</code>  | affect rendition of the ROC points                                                    |
| Fit line                                    |                                                                                       |

## Options for rocplot

### Main

`confband` specifies that simultaneous confidence bands be plotted around the ROC curve.

`norefline` suppresses plotting the 45-degree reference line from the graphical output of the ROC curve.

`level(#)` specifies the confidence level, as a percentage, for the confidence bands. The default is `level(95)` or as set by `set level`; see [R] [level](#).

### Plot

`plotopts` (*plot\_options*) affects the rendition of the plotted ROC points, including the size and color of markers, whether and how the markers are labeled, and whether and how the points are connected. For the full list of available *plot\_options*, see [G-3] [marker\\_options](#), [G-3] [marker\\_Label\\_options](#), and [G-3] [cline\\_options](#).

### Fit line

`lineopts` (*cline\_options*) affects the rendition of the fitted ROC line; see [G-3] [cline\\_options](#).

### CI plot

`ciopts` (*area\_options*) affects the rendition of the confidence bands; see [G-3] [area\\_options](#).

### Reference line

`rlopts` (*cline\_options*) affects the rendition of the reference line; see [G-3] [cline\\_options](#).

### Add plots

`addplot` (*plot*) provides a way to add other plots to the generated graph. See [G-3] [addplot\\_option](#).

### Y axis, X axis, Titles, Legend, Overall

*twoway\_options* are any of the options documented in [G-3] [twoway\\_options](#), excluding `by()`. These include options for titling the graph (see [G-3] [title\\_options](#)) and for saving the graph to disk (see [G-3] [saving\\_option](#)).

## Remarks and examples

Remarks are presented under the following headings:

[Using lincom and test](#)  
[Using rocplot](#)

## Using lincom and test

`intercept`, `slope`, and `/cut#`, shown in [example 1](#) of [\[R\] rocfit](#), are equation names and not variable names, so they need to be referenced as described in [Special syntaxes after multiple-equation estimation](#) of [\[R\] test](#). For example, instead of typing

```
. test intercept
intercept not found
r(111);
```

you should type

```
. test [intercept]_cons
(1) [intercept]_cons = 0
 chi2(1) = 28.48
 Prob > chi2 = 0.0000
```

## Using rocplot

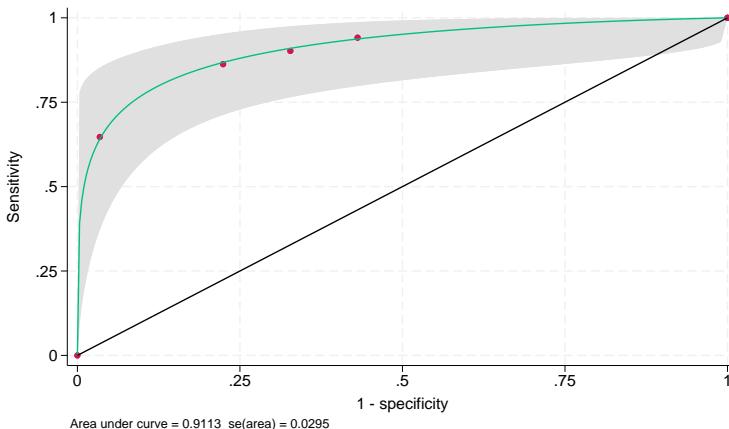

### ▷ Example 1

In [example 1](#) of [\[R\] rocfit](#), we fit a ROC curve by typing `rocfit disease rating`.

In the output table for our model, we are testing whether the variances of the two latent populations are equal by testing that the slope = 1.

We plot the fitted ROC curve.

```
. rocplot, confband
```

## Description

The `rocreg` command is used to perform receiver operating characteristic (ROC) analyses with rating and discrete classification data under the presence of covariates.

The two variables *refvar* and *classvar* must be numeric. The reference variable indicates the true state of the observation—such as diseased and nondiseased or normal and abnormal—and must be coded as 0 and 1. The *refvar* coded as 0 can also be called the control population, while the *refvar* coded as 1 comprises the case population. The rating or outcome of the diagnostic test or test modality is recorded in *classvar*, which must be ordinal, with higher values indicating higher risk.

`rocreg` can fit three models: a nonparametric model, a parametric probit model that uses the bootstrap for inference, and a parametric probit model fit using maximum likelihood.

## Quick start

*Nonparametric estimation with bootstrap resampling*

Area under the ROC curve for test classifier `v1` and true state `true` using seed 20547

```
rocreg true v1, bseed(20547)
```

Add `v2` as an additional classifier

```
rocreg true v1 v2, bseed(20547)
```

Same as above, but estimate ROC value for a false-positive rate of 0.7

```
rocreg true v1 v2, bseed(20547) roc(.7)
```

Covariate stratification of controls by categorical variable `a` using seed 121819

```
rocreg true v1 v2, bseed(121819) ctrlcov(a)
```

Linear control covariate adjustment with binary variable `b` and continuous variable `x`

```
rocreg true v1 v2, bseed(121819) ctrlcov(b x) ctrlmodel(linear)
```

*Parametric estimation*

Area under the ROC curve for test classifier v1 and true state true by estimating equations using seed 200512

```
rocreg true v1, probit bseed(200512)
```

And save results to myfile.dta for use by rocregplot

```
rocreg true v1, probit bseed(200512) bsave(myfile)
```

Add v2 as a classifier and x as a control covariate in a linear control covariate-adjustment model

```
rocreg true v1 v2, probit bseed(200512) ctrlcov(x) ctrlmodel(linear)
```

Also treat x as a ROC covariate

```
rocreg true v1 v2, probit bseed(200512) ctrlcov(x) ///
ctrlmodel(linear) roccov(x)
```

Estimate AUC by maximum likelihood instead of bootstrap resampling

```
rocreg true v1, probit ml
```

## Menu

Statistics > Epidemiology and related > ROC analysis > ROC regression models

## Syntax

Perform nonparametric analysis of ROC curve under covariates, using bootstrap

```
rocreg refvar classvar [classvars] [if] [in] [, np_options]
```

| <i>np_options</i>                       | Description                                                                                             |
|-----------------------------------------|---------------------------------------------------------------------------------------------------------|
| <b>Model</b>                            |                                                                                                         |
| <code>auc</code>                        | estimate total area under the ROC curve; the default                                                    |
| <code>roc(numlist)</code>               | estimate ROC for given false-positive rates                                                             |
| <code>invroc(numlist)</code>            | estimate false-positive rates for given ROC values                                                      |
| <code>pauc(numlist)</code>              | estimate partial area under the ROC curve (pAUC) up to each false-positive rate                         |
| <code>cluster(varname)</code>           | variable identifying resampling clusters                                                                |
| <code>ctrlcov(varlist)</code>           | adjust control distribution for covariates in <i>varlist</i>                                            |
| <code>ctrlmodel(strata   linear)</code> | stratify or regress on covariates; default is <code>ctrlmodel(strata)</code>                            |
| <code>pvc(empirical   normal)</code>    | use empirical or normal distribution percentile value estimates; default is <code>pvc(empirical)</code> |
| <code>tiecorrected</code>               | adjust for tied observations; not allowed with <code>pvc(normal)</code>                                 |
| <b>Bootstrap</b>                        |                                                                                                         |
| <code>nobootstrap</code>                | do not perform bootstrap, just output point estimates                                                   |
| <code>bseed(#)</code>                   | random-number seed for bootstrap                                                                        |
| <code>breps(#)</code>                   | number of bootstrap replications; default is <code>breps(1000)</code>                                   |
| <code>bootcc</code>                     | perform case–control (stratified on <i>refvar</i> ) sampling rather than cohort sampling in bootstrap   |
| <code>nobstrata</code>                  | ignore covariate stratification in bootstrap sampling                                                   |
| <code>nodots</code>                     | suppress bootstrap replication dots                                                                     |
| <b>Reporting</b>                        |                                                                                                         |
| <code>level(#)</code>                   | set confidence level; default is <code>level(95)</code>                                                 |

| <i>probit_options</i>                   | Description                                                                                             |

| <code>ctrlcov(varlist)</code>  | adjust control distribution for covariates in <i>varlist</i>         |
| Reporting                      |                                                                      |
| <code>level(#)</code>          | set confidence level; default is <code>level(95)</code>              |
| <code>display_options</code>   | control column formats, line width, and display of omitted variables |
| Maximization                   |                                                                      |
| <code>maximize_options</code>  | control the maximization process; seldom used                        |

\*probit and ml are required.

`fweights`, `iweights`, and `pweights` are allowed with maximum likelihood estimation; see [U] 11.1.6 [weight](#).

`collect` is allowed. `bayesboot` is allowed only with maximum likelihood estimation. See [U] 11.1.10 [Prefix commands](#).

See [U] 20 [Estimation and postestimation commands](#) for more capabilities of estimation commands.

## Options

Options are presented under the following headings:

*Options for nonparametric ROC estimation, using bootstrap*  
*Options for parametric ROC estimation, using bootstrap*  
*Options for parametric ROC estimation, using maximum likelihood*

### Options for nonparametric ROC estimation, using bootstrap

#### Model

`auc` estimates the total area under the ROC curve. This is the default summary statistic.

`roc(numlist)` estimates the ROC corresponding to each of the false-positive rates in *numlist*. The values of *numlist* must be in the range (0,1).

`invroc(numlist)` estimates the false-positive rates corresponding to each of the ROC values in *numlist*. The values of *numlist* must be in the range (0,1).

`pauc(numlist)` estimates the partial area under the ROC curve up to each false-positive rate in *numlist*. The values of *numlist* must in the range (0,1].

`cluster(varname)` specifies the variable identifying resampling clusters.

`ctrlcov(varlist)` specifies the covariates to be used to adjust the control population.

`ctrlmodel(strata | linear)` specifies how to model the control population of classifiers on `ctrlcov()`. When `ctrlmodel(linear)` is specified, linear regression is used. The default is `ctrlmodel(strata)`; that is, the control population of classifiers is stratified on the control variables.

`pvc(empirical | normal)` determines how the percentile values of the control population will be calculated. When `pvc(normal)` is specified, the standard normal cumulative distribution function (CDF) is used for calculation. Specifying `pvc(empirical)` will use the empirical CDFs of the control population classifiers for calculation. The default is `pvc(empirical)`.

`tiecorrected` adjusts the percentile values for ties. For each value of the classifier, one half the probability that the classifier equals that value under the control population is added to the percentile value. `tiecorrected` is not allowed with `pvc(normal)`.

#### Bootstrap

`nobootstrap` specifies that bootstrap standard errors not be calculated.

`bseed(#)` specifies the random-number seed to be used in the bootstrap.

`breps(#)` sets the number of bootstrap replications. The default is `breps(1000)`.

`bootcc` performs case–control (stratified on *refvar*) sampling rather than cohort bootstrap sampling.

`nobstrata` ignores covariate stratification in bootstrap sampling.

`nodots` suppresses bootstrap replication dots.

#### Reporting

`level(#)`; see [\[R\] Estimation options](#).

## Options for parametric ROC estimation, using bootstrap

## Model

- `probit` fits the probit model. This option is required and implies parametric estimation.
- `roccov(varlist)` specifies the covariates that will affect the ROC curve.
- `fprpts(#)` sets the number of false-positive rate points to use in modeling the ROC curve. These points form an equispaced grid on (0,1). The default is `fprpts(10)`.
- `ctrlfprall` models the ROC curve at each false-positive rate in the control population.
- `cluster(varname)` specifies the variable identifying resampling clusters.
- `ctrlcov(varlist)` specifies the covariates to be used to adjust the control population.
- `ctrlmodel(strata | linear)` specifies how to model the control population of classifiers on `ctrlcov()`. When `ctrlmodel(linear)` is specified, linear regression is used. The default is `ctrlmodel(strata)`; that is, the control population of classifiers is stratified on the control variables.
- `pvc(empirical | normal)` determines how the percentile values of the control population will be calculated. When `pvc(normal)` is specified, the standard normal CDF is used for calculation. Specifying `pvc(empirical)` will use the empirical CDFs of the control population classifiers for calculation. The default is `pvc(empirical)`.
- `tierecorrected` adjusts the percentile values for ties. For each value of the classifier, one half the probability that the classifier equals that value under the control population is added to the percentile value. `tierecorrected` is not allowed with `pvc(normal)`.

## Bootstrap

- `nobootstrap` specifies that bootstrap standard errors not be calculated.
- `bseed(#)` specifies the random-number seed to be used in the bootstrap.
- `breps(#)` sets the number of bootstrap replications. The default is `breps(1000)`.
- `bootcc` performs case–control (stratified on *refvar*) sampling rather than cohort bootstrap sampling.
- `nobstrata` ignores covariate stratification in bootstrap sampling.
- `nodots` suppresses bootstrap replication dots.
- `bsave(filename, ...)` saves bootstrap replicates from parametric estimation in the given *filename* with specified options (that is, `replace`). `bsave()` is only allowed with parametric analysis using bootstrap.
- `bfile(filename)` specifies to use the bootstrap replicates dataset for estimation replay. `bfile()` is only allowed with parametric analysis using bootstrap.

## Reporting

- `level(#)`; see [\[R\] Estimation options](#).

## Options for parametric ROC estimation, using maximum likelihood

### Model

`probit` fits the probit model. This option is required and implies parametric estimation.

`ml` fits the probit model by maximum likelihood estimation. This option is required and must be specified with `probit`.

`roccov`(*varlist*) specifies the covariates that will affect the ROC curve.

`cluster`(*varname*) specifies the variable used for clustering.

`ctrlcov`(*varlist*) specifies the covariates to be used to adjust the control population.

### Reporting

`level`(#); see [R] [Estimation options](#).

`display_options`: `noomitted`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `no!stretch`; see [R] [Estimation options](#).

### Maximization

`maximize_options`: `difficult`, `technique`(*algorithm\_spec*), `iterate`(#), `[no]log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance`(#), `ltolerance`(#), `nrtolerance`(#), `nonrntolerance`, and `from`(*init\_specs*); see [R] [Maximize](#). These options are seldom used. The `technique`(`bhhh`) option is not allowed.

[Parametric ROC curves: Maximum likelihood](#)

## Introduction

Receiver operating characteristic (ROC) analysis provides a quantitative measure of the accuracy of diagnostic tests to discriminate between two states or conditions. These conditions may be referred to as normal and abnormal, nondiseased and diseased, or control and case. We will use these terms interchangeably. The discriminatory accuracy of a diagnostic test is measured by its ability to correctly classify known control and case subjects.

The analysis uses the ROC curve, a graph of the sensitivity versus  $1 - \text{specificity}$  of the diagnostic test. The sensitivity is the fraction of positive cases that are correctly classified by the diagnostic test, whereas the specificity is the fraction of negative cases that are correctly classified. Thus, the sensitivity is the true-positive rate, and the specificity is the true-negative rate. We also call  $1 - \text{specificity}$  the false-positive rate.

These rates are functions of the possible outcomes of the diagnostic test. At each outcome, a decision will be made by the user of the diagnostic test to classify the tested subject as either normal or abnormal. The true-positive and false-positive rates measure the probability of correct classification or incorrect classification of the subject as abnormal. Given the classification role of the diagnostic test, we will refer to it as the classifier.

Using this basic definition of the ROC curve, [Pepe \(2000\)](#) and [Pepe \(2003\)](#) describe how ROC analysis can be performed as a two-stage process. In the first stage, the control distribution of the classifier is estimated. The specificity is then determined as the percentiles of the classifier values calculated based on the control population. The false-positive rates are calculated as  $1 - \text{specificity}$ . In the second stage, the ROC curve is estimated as the cumulative distribution of the case population's "false-positive" rates, also known as the survival function under the case population of the previously calculated percentiles. We use the terms ROC value and true-positive value interchangeably.

This formulation of ROC curve analysis provides simple, nonparametric estimates of several ROC curve summary parameters: area under the ROC curve, partial area under the ROC curve, ROC value for a given false-positive rate, and false-positive rate (also known as invROC) for a given ROC value. In the next section, we will show how to use `rocreg` to compute these estimates with bootstrap inference. There we will also show how `rocreg` complements the other nonparametric Stata ROC commands `roctab` and `roccomp`.

Other factors beyond condition status and the diagnostic test may affect both stages of ROC analysis. For example, a test center may affect the control distribution of the diagnostic test. Disease severity may affect the distribution of the standardized diagnostic test under the case population. Our analysis of the ROC curve in these situations will be more accurate if we take these covariates into account.

In a nonparametric ROC analysis, covariates may only affect the first stage of estimation; that is, they may be used to adjust the control distribution of the classifier. In a parametric ROC analysis, it is assumed that ROC follows a normal distribution, and thus covariates may enter the model at both stages; they may be used to adjust the control distribution and to model ROC as a function of these covariates and the false-positive rate. In parametric models, both sets of covariates need not be distinct but, in fact, they are often the same.

To model covariate effects on the first stage of ROC analysis, [Janes and Pepe \(2009\)](#) propose a covariate-adjusted ROC curve. We will demonstrate the covariate adjustment capabilities of `rocreg` in [Covariate-adjusted ROC curves](#).

To account for covariate effects at the second stage, we assume a parametric model. Particularly, the ROC curve is a generalized linear model of the covariates. We will thus have a separate ROC curve for each combination of the relevant covariates. In [Parametric ROC curves: Estimating equations](#), we show how to fit the model with estimating equations and bootstrap inference using `rocreg`. This method, documented as the "pdf" approach in [Alonzo and Pepe \(2002\)](#), works well with weak assumptions about the control distribution.

Also in [Parametric ROC curves: Estimating equations](#), we show how to fit a constant-only parametric model (involving no covariates) of the ROC curve with weak assumptions about the control distribution. The constant-only model capabilities of `rocreg` in this context will be compared with those of `rocf`. `roccomp` has the `binormal` option, which will allow it to compute area under the ROC curve according to a normal ROC curve, equivalent to that obtained by `rocf`. We will compare this functionality with that of `rocreg`.

In [Parametric ROC curves: Maximum likelihood](#), we demonstrate maximum likelihood estimation of the ROC curve model with `rocreg`. There we assume a normal linear model for the classifier on the covariates and case–control status. This method is documented in [Pepe \(2003\)](#). We will also demonstrate how to use this method with no covariates, and we will compare `rocreg` under the constant-only model with `rocf` and `roccomp`.

The `rocregplot` command is used repeatedly in this entry. This command provides graphical output for `rocreg` and is documented in [\[R\] rocregplot](#).

## ROC statistics

`roctab` computes the ROC curve by calculating the false-positive rate and true-positive rate empirically at every value of the input classifier. It makes no distributional assumptions about the case or control distributions. We can get identical behavior from `rocreg` by using the default option settings.

### ▷ Example 1: Nonparametric ROC, AUC

Hanley and McNeil (1982) presented data from a study in which a reviewer was asked to classify, using a five-point scale, a random sample of 109 tomographic images from patients with neurological problems. The rating scale was as follows: 1 is definitely normal, 2 is probably normal, 3 is questionable, 4 is probably abnormal, and 5 is definitely abnormal. The true disease status was normal for 58 of the patients and abnormal for the remaining 51 patients.

Here we list 9 of the 109 observations:

```
. use https://www.stata-press.com/data/r19/hanley
(Tomographic images)
. list disease rating in 1/9
```

|    | disease | rating |
|----|---------|--------|
| 1. | 1       | 5      |
| 2. | 0       | 1      |
| 3. | 1       | 5      |
| 4. | 0       | 4      |
| 5. | 0       | 1      |
| 6. | 0       | 3      |
| 7. | 1       | 5      |
| 8. | 0       | 5      |
| 9. | 0       | 1      |

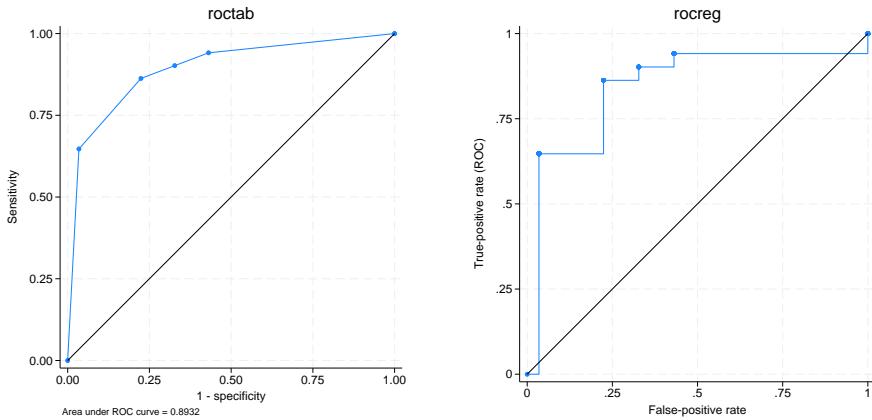

For each observation, `disease` identifies the true disease status of the subject (0 is normal, 1 is abnormal), and `rating` contains the classification value assigned by the reviewer.

We run `roctab` on these data, specifying the `graph` option so that the ROC curve is rendered. We then calculate the false-positive and true-positive rates of the ROC curve by using `rocreg`. We graph the rates with `rocregplot`. Because we focus on `rocreg` output later, for now we use the `quietly` prefix to omit the output of `rocreg`. Both graphs are combined using `graph combine` (see [G-2] [graph combine](#)) for comparison. To ease the comparison, we specify the `aspectratio(1)` option in `roctab`; this is the default aspect ratio in `rocregplot`.

```

. roctab disease rating, graph aspectratio(1) name(a) nodraw title("roctab")
. quietly rocreg disease rating
. rocregplot, name(b) nodraw legend(off) title("rocreg")
. graph combine a b

```

Both `roctab` and `rocreg` compute the same false-positive rate and ROC values. The stairstep line connection style of the graph on the right emphasizes the empirical nature of its estimates. The control distribution of the classifier is estimated using the empirical CDF estimate. Similarly, the ROC curve, the distribution of the resulting case observation false-positive rate values, is estimated using the empirical CDF. Note the footnote in the `roctab` plot. By default, `roctab` will estimate the area under the ROC curve (AUC) using a trapezoidal approximation to the estimated false-positive rate and true-positive rate points.

The AUC can be interpreted as the probability that a randomly selected member of the case population will have a larger classifier value than a randomly selected member of the control population. It can also be viewed as the average ROC value, averaged uniformly over the  $(0,1)$  false-positive rate domain (Pepe 2003).

The nonparametric estimator of the AUC (DeLong, DeLong, and Clarke-Pearson 1988; Hanley and Hajian-Tilaki 1997) used by `rocreg` is equivalent to the sample mean of the percentile values of the case observations. Thus to calculate the nonparametric AUC estimate, we only need to calculate the percentile values of the case observations with respect to the control distribution.

This estimate can differ from the trapezoidal approximation estimate. Under discrete classification data, like we have here, there may be ties between classifier values from case to control. The trapezoidal approximation uses linear interpolation between the classifier values to correct for ties. Correcting the nonparametric estimator involves adding a correction term to each observation's percentile value, which measures the probability that the classifier is equal to (instead of less than) the observation's classifier value.

The tie-corrected nonparametric estimate (trapezoidal approximation) is used when we think the true ROC curve is smooth. This means that the classifier we measure is a discretized approximation of a true latent and a continuous classifier.

We now recompute the ROC curve of `rating` for classifying disease and calculate the AUC. Specifying the `tiecorrected` option allows tie correction to be used in the `rocreg` calculation. Under nonparametric estimation, `rocreg` bootstraps to obtain standard errors and confidence intervals for re-

quested statistics. We use the default 1,000 bootstrap replications to obtain confidence intervals for our parameters. This is a reasonable lower bound to the number of replications (Mooney and Duval 1993) required for estimating percentile confidence intervals. By specifying the summary option in roctab, we will obtain output showing the trapezoidal approximation of the AUC estimate, along with standard error and confidence interval estimates for the trapezoidal approximation suggested by DeLong, DeLong, and Clarke-Pearson (1988).

The estimates of AUC match well. The standard error from roctab is close to the bootstrap standard error calculated by rocreg. The bootstrap standard error generalizes to the more complex models that we consider later, whereas the roctab standard-error calculation does not.

The AUC can be used to compare different classifiers. It is the most popular summary statistic for comparisons (Pepe, Longton, and Janes 2009). roccomp will compute the trapezoidal approximation of the AUC and graph the ROC curves of multiple classifiers. Using the DeLong, DeLong, and Clarke-Pearson (1988) covariance estimates for the AUC estimate, roccomp performs a Wald test of the null hypothesis that all classifier AUC values are equal. rocreg has similar capabilities.

## ► Example 2: Nonparametric ROC, AUC, multiple classifiers

Hanley and McNeil (1983) presented data from an evaluation of two computer algorithms designed to reconstruct CT images from phantoms. We will call these two algorithms modalities 1 and 2. A sample of 112 phantoms was selected; 58 phantoms were considered normal, and the remaining 54 were abnormal. Each of the two modalities was applied to each phantom, and the resulting images were rated by a reviewer using a six-point scale: 1 is definitely normal, 2 is probably normal, 3 is possibly normal, 4 is possibly abnormal, 5 is probably abnormal, and 6 is definitely abnormal. Because each modality was applied to the same sample of phantoms, the two sets of outcomes are correlated.

We list the first seven observations:

```
. use https://www.stata-press.com/data/r19/ct, clear
(Reconstruction of CT images)
. list in 1/7, sep(0)
```

|    | mod1 | mod2 | status |
|----|------|------|--------|
| 1. | 2    | 1    | 0      |
| 2. | 5    | 5    | 1      |
| 3. | 2    | 1    | 0      |
| 4. | 2    | 3    | 0      |
| 5. | 5    | 6    | 1      |
| 6. | 2    | 2    | 0      |
| 7. | 3    | 2    | 0      |

Each observation corresponds to one phantom. The mod1 variable identifies the rating assigned for the first modality, and the mod2 variable identifies the rating assigned for the second modality. The true status of the phantoms is given by `status==0` if they are normal and `status==1` if they are abnormal. The observations with at least one missing rating were dropped from the analysis.

A fictitious dataset was created from this true dataset, adding a third test modality. We will use `roccomp` to compute the AUC statistic for each modality in these data and compare the AUC of the three modalities. We obtain the same behavior from `rocreg`. As before, the `tiecorrected` option is specified so that the AUC is calculated with the trapezoidal approximation.

```
HO: All classifiers have equal AUC values
Ha: At least one classifier has a different AUC value
P-value: .0339546 Test based on bootstrap (N) assumptions.
```

We see that the AUC estimates are equivalent, and the standard errors are quite close as well. The  $p$ -value for the tests of equal AUC under `rocreg` leads to similar inference as the  $p$ -value from `roccomp`. The Wald test performed by `rocreg` uses the joint bootstrap estimate variance matrix of the three AUC estimators rather than the [DeLong, DeLong, and Clarke-Pearson \(1988\)](#) variance estimate used by `roccomp`.

`roccomp` is used here on potentially correlated classifiers that are recorded in wide-format data. It can also be used on long-format data to compare independent classifiers. Further details can be found in [\[R\] roccomp](#).

Citing the AUC's lack of clinical relevance, there is argument against using it as a key summary statistic of the ROC curve ([Pepe 2003](#); [Cook 2007](#)). [Pepe, Longton, and Janes \(2009\)](#) suggest using the estimate of the ROC curve itself at a particular point, or the estimate of the false-positive rate at a given ROC value, also known as `invROC`.

Recall from [example 1](#) how nonparametric `rocreg` graphs look, with the staircase pattern in the ROC curve. In an ideal world, the graph would be a smooth one-to-one function, and it would be trivial to map a false-positive rate to its corresponding true-positive rate and vice versa.

However, smooth ROC curves can only be obtained by assuming a parametric model that uses linear interpolation between observed false-positive rates and between observed true-positive rates, and `rocreg` is certainly capable of that; see [example 1](#) of [\[R\] rocregplot](#). However, under nonparametric estimation, the mapping between false-positive rates and true-positive rates is not one to one, and estimates tend to be less reliable the further you are from an observed data point. This is somewhat mitigated by using tie-corrected rates (the `tiecorrected` option).

When we examine continuous data, the difference between the tie-corrected estimates and the standard estimates becomes negligible, and the empirical estimate of the ROC curve becomes close to the smooth ROC curve obtained by linear interpolation. So the nonparametric ROC and `invROC` estimates work well.

Fixing one rate value of interest can be difficult and subjective ([Pepe 2003](#)). A compromise measure is the partial area under the ROC curve (`pAUC`) ([McClish 1989](#); [Thompson and Zucchini 1989](#)). This is the integral of the ROC curve from 0 and above to a given false-positive rate (perhaps the largest clinically acceptable value). Like the `AUC` estimate, the nonparametric estimate of the `pAUC` can be written as a sample average of the case observation percentiles, but with an adjustment based on the prescribed maximum false-positive rate ([Dodd and Pepe 2003](#)). A tie correction may also be applied so that it reflects the trapezoidal approximation.

We cannot compare `rocreg` with `roctab` or `roccomp` on the estimation of `pAUC`, because `pAUC` is not computed by the latter two.

### ► Example 3: Nonparametric ROC, other statistics

To see how `rocreg` estimates ROC, `invROC`, and `pAUC`, we will examine a new study. [Wieand et al. \(1989\)](#) examined a pancreatic cancer study with two continuous classifiers, here called `y1` (CA 19-9) and `y2` (CA 125). This study was also examined in [Pepe, Longton, and Janes \(2009\)](#). The indicator of cancer in a subject is recorded as `d`. The study was a case-control study, stratifying participants on disease status.

We list the first five observations:

```
. use https://research.fredhutch.org/content/dam/stripe/diagnostic-biomarkers-
> statistical-center/files/wiedat2b.dta, clear
(S. Wieand - Pancreatic cancer diagnostic marker data)

. list in 1/5
```

|    | y1   | y2   | d  |
|----|------|------|----|
| 1. | 28   | 13.3 | no |
| 2. | 15.5 | 11.1 | no |
| 3. | 8.2  | 16.7 | no |
| 4. | 3.4  | 12.6 | no |
| 5. | 17.3 | 7.4  | no |

We will estimate the ROC curves at a large value (0.7) and a small value (0.2) of the false-positive rate. These values are specified in `roc()`. The false-positive rate for ROC or sensitivity value of 0.6 will also be estimated by specifying `invroc()`. Percentile confidence intervals for these parameters are displayed in the graph obtained by `rocregplot` after `rocreg`. The `pAUC` statistic will be calculated for

the false-positive rate of 0.5, which is specified as an argument to the `pauc()` option. Following [Pepe, Longton, and Janes \(2009\)](#), we use a stratified bootstrap, sampling separately from the case and control populations by specifying the `bootcc` option. This reflects the case–control nature of the study.

All four statistics can be estimated simultaneously by `rocreg`. For clarity, however, we will estimate each statistic with a separate call to `rocreg`. `rocregplot` is used after estimation to graph the ROC and false-positive rate estimates. The display of the individual, observation-specific false-positive rate and ROC values will be omitted in the plot. This is accomplished by specifying `msymbol(i)` in our `plot1opts()` and `plot2opts()` options to `rocregplot`.

We also find significant evidence supporting the hypothesis that the pAUC for y1 up to a false-positive rate of 0.5 differs from the area of the same region under the ROC curve of y2.

### Covariate-adjusted ROC curves

When covariates affect the control distribution of the diagnostic test, thresholds for the test being classified as abnormal may be chosen that vary with the covariate values. These conditional thresholds will be more accurate than the marginal thresholds that would normally be used, because they take into account the specific distribution of the diagnostic test under the given covariate values as opposed to the marginal distribution over all covariate values.

By using these covariate-specific thresholds, we are essentially creating new classifiers for each covariate-value combination, and thus we are creating multiple ROC curves. As explained in [Pepe \(2003\)](#), when the case and control distributions of the covariates are the same, the marginal ROC curve will always be bound above by these covariate-specific ROC curves. So using conditional thresholds will never provide a less powerful test diagnostic in this case.

In the marginal ROC curve calculation, the classifiers are standardized to percentiles according to the control distribution, marginalized over the covariates. Thus, the ROC curve is the CDF of the standardized case observations. The covariate-adjusted ROC curve is the CDF of one minus the conditional control percentiles for the case observations, and the marginal ROC curve is the CDF of one minus the marginal control percentiles for the case observations ([Pepe and Cai 2004](#)). Thus, the standardization of classifier to false-positive rate value is conditioned on the specific covariate values under the covariate-adjusted ROC curve.

The covariate-adjusted ROC curve ([Janes and Pepe 2009](#)) at a given false-positive rate  $t$  is equivalent to the expected value of the covariate-specific ROC at  $t$  over all covariate combinations. When the covariates in question do not affect the case distribution of the classifier, the covariate-specific ROC will have the same value at each covariate combination. So here the covariate-adjusted ROC is equivalent to the covariate-specific ROC, regardless of covariate values.

When covariates do affect the case distribution of the classifier, users of the diagnostic test would likely want to model the covariate-specific ROC curves separately. Tools to do this can be found in the parametric modeling discussion in the following two sections. Regardless, the covariate-adjusted ROC curve can serve as a meaningful summary of covariate-adjusted accuracy.

Also note that the ROC summary statistics defined in the previous section have covariate-adjusted analogs. These analogs are estimated in a similar manner as under the marginal ROC curve (Janes, Longton, and Pepe 2009). The options for their calculation in `rocreg` are identical to those given in the previous section. Further details can be found in *Methods and formulas*.

#### ► Example 4: Nonparametric ROC, linear covariate adjustment

Norton et al. (2000) studied data from a neonatal audiology study on three tests to identify hearing impairment in newborns. These data were also studied in Janes, Longton, and Pepe (2009). Here we list 5 of the 5,058 observations.

```
. use https://www.stata-press.com/data/r19/nmhs, clear
(Norton - neonatal audiology data)
. list in 1/5
```

|    | id    | ear | male | currage | d | y1    | y2    | y3    |
|----|-------|-----|------|---------|---|-------|-------|-------|
| 1. | B0157 | R   | M    | 42.42   | 0 | -3.1  | -9    | -1.5  |
| 2. | B0157 | L   | M    | 42.42   | 0 | -4.5  | -8.7  | -2.71 |
| 3. | B0158 | R   | M    | 40.14   | 1 | -3.2  | -13.2 | -2.64 |
| 4. | B0161 | L   | F    | 38.14   | 0 | -22.1 | -7.8  | -2.59 |
| 5. | B0167 | R   | F    | 37      | 0 | -10.9 | -6.6  | -1.42 |

The classifiers `y1` (DPOAE 65 at 2 kHz), `y2` (TEOAE 80 at 2 kHz), and `y3` (ABR) and the hearing impairment indicator `d` are recorded along with some relevant covariates. The infant's age is recorded in months as `currage`, and the infant's gender is indicated by `male`. Over 90% of the newborns were tested in each ear (`ear`), so we will cluster on infant ID (`id`).

Following the strategy of Janes, Longton, and Pepe (2009), we will first perform ROC analysis for the classifiers while adjusting for the covariate effects of the infant's gender and age. This is done by specifying these variables in the `ctrlcov()` option. We adjust using a linear regression rule, by specifying `ctrlmodel(linear)`. This means that when a user of the diagnostic test chooses a threshold conditional on the age and gender covariates, they assume that the diagnostic test classifier has some linear dependence on age and gender and equal variance as their levels vary. Our cluster adjustment is made by specifying the `cluster()` option.

We will focus on the first classifier. The percentile, or specificity, values are calculated empirically by default, and thus so are the false-positive rates,  $(1 - \text{specificity})$ . Also by default, the ROC curve values are empirically defined by the false-positive rates. To draw the ROC curve, we again use `rocregplot`.

The AUC is calculated by default. For brevity, we specify the nobootstrap option so that bootstrap sampling is not performed. The AUC point estimate will be sufficient for our purposes.

```

. rocregplot
```

Our covariate control adjustment model shows that `currage` has a negative effect on `y1` (DPOAE 65 at 2 kHz) under the control population. At the 0.001 significance level, we reject that its contribution to `y1` is zero, and the point estimate has a negative sign. This result does not directly tell us about the effect of `currage` on the ROC curve of `y1` as a classifier of `d`. None of the case observations are used in the linear regression, so information on `currage` for abnormal cases is not used in the model. This result does show us how to calculate false-positive rates for tests that use thresholds conditional on a child's sex and current age. We will see how `currage` affects the ROC curve when `y1` is used as a classifier and conditional thresholds are used based on `male` and `currage` in the following section, *Parametric ROC curves: Estimating equations*.

#### □ Technical note

Under this nonparametric estimation, `rocreg` saved the false-positive rate for each observation's `y1` values in the utility variable `_fpr_y1`. The true-positive rates are stored in the utility variable `_roc_y1`. For other models, say with classifier `yname`, these variables would be named `_fpr_yname` and `_roc_yname`. They will also be overwritten with each call of `rocreg`. The variables `_roc_*` and `_fpr_*` are usually for internal `rocreg` use only and are overwritten with each call of `rocreg`. They are only created for nonparametric models or parametric models that do not involve ROC covariates. In these models, covariates may only affect the first stage of estimation, the control distribution, and not the ROC curve itself. In parametric models that allow ROC covariates, different covariate values would lead to different ROC curves.

□

To see how the covariate-adjusted ROC curve estimate differs from the standard marginal estimate, we will reestimate the ROC curve for classifier `y1` without covariate adjustment. We rename these variables before the new estimation and then draw an overlaid twoway line (see [G-2] **graph twoway line**) plot to compare the two.

```

. rename _fpr_y1 o_fpr_y1
. rename _roc_y1 o_roc_y1
. label variable o_roc_y1 "Covariate adjusted"

> connect(J) lpattern(dash) aspectratio(1) legend(cols(1))

```

Though they are close, particularly in AUC, there are clearly some points of difference between the estimates. So the covariate-adjusted ROC curve may be useful here.

In our examples thus far, we have used the empirical CDF estimator to estimate the control distribution. `rocreg` allows some flexibility here. The `pvc(normal)` option may be specified to calculate the percentile values according to a Gaussian distribution of the control.

Covariate adjustment in `rocreg` may also be performed with stratification instead of linear regression. Under the stratification method, the unique values of the stratified covariates each define separate parameters for the control distribution of the classifier. A user of the diagnostic test chooses a threshold based on the control distribution conditioned on the unique covariate value parameters.

We will demonstrate the use of normal percentile values and covariate stratification in our next example.

### ▷ Example 5: Nonparametric ROC, covariate stratification

The hearing test study of [Stover et al. \(1996\)](#) examined the effectiveness of negative signal-to-noise ratio, `nsnr`, as a classifier of hearing loss. The test was administered under nine different settings, corresponding to different frequency, `xf`, and intensity, `x1`, combinations. Here we list 10 of the 1,848 observations.

```
. use https://www.stata-press.com/data/r19/dp, clear
(Stover - DPOAE test data)
. list in 1/10
```

|     | id  | d | nsnr | xf    | x1  | xd  |
|-----|-----|---|------|-------|-----|-----|
| 1.  | 101 | 1 | 18   | 10.01 | 5.5 | 3.5 |
| 2.  | 101 | 1 | 19   | 20.02 | 5.5 | 3   |
| 3.  | 101 | 1 | 7.6  | 10.01 | 6   | 3.5 |
| 4.  | 101 | 1 | 15   | 20.02 | 6   | 3   |
| 5.  | 101 | 1 | 16   | 10.01 | 6.5 | 3.5 |
| 6.  | 101 | 1 | 5.8  | 20.02 | 6.5 | 3   |
| 7.  | 102 | 0 | -2.6 | 10.01 | 5.5 | .   |
| 8.  | 102 | 0 | -3   | 14.16 | 5.5 | .   |
| 9.  | 102 | 1 | 10   | 20.02 | 5.5 | 1   |
| 10. | 102 | 0 | -5.8 | 10.01 | 6   | .   |

Hearing loss is represented by `d`. The covariate `xd` is a measure of the degree of hearing loss. We will use this covariate in later analysis, because it only affects the case distribution of the classifier. Multiple measurements are taken for each individual, `id`, so we will cluster by individual.

We evaluate the effectiveness of `nsnr` using `xf` and `x1` as stratification covariates with `rocreg`; the default method of covariate adjustment.

As mentioned before, the default false-positive rate calculation method in `rocreg` estimates the conditional control distribution of the classifiers empirically. For comparison, we will also estimate a separate ROC curve using false-positive rates assuming the conditional control distribution is normal. This behavior is requested by specifying the `pvc(normal)` option. Using the `rocregplot` option `name()` to store the ROC plots and using the `graph combine` command, we are able to compare the Gaussian and empirical ROC curves side by side. As before, for brevity we specify the `nobootstrap` option to suppress bootstrap sampling.

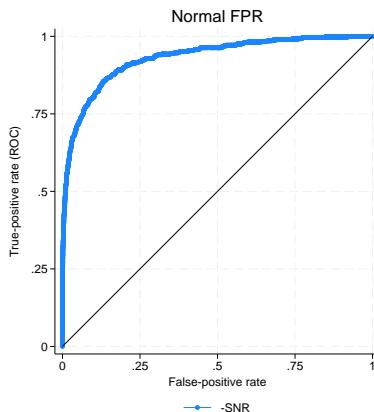

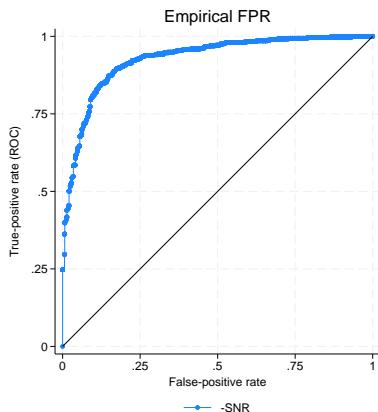

```
. rocreg d nsnr, ctrlcov(xf xl) cluster(id) nobootstrap

On cursory visual inspection, we see little difference between the two curves. The AUC values are close as well. So it is sensible to assume that we have Gaussian percentile values for control standardization. ◀

## Parametric ROC curves: Estimating equations

We now assume a parametric model for covariate effects on the second stage of ROC analysis. Particularly, the ROC curve is a probit model of the covariates. We will thus have a separate ROC curve for each combination of the relevant covariates.

Under weak assumptions about the control distribution of the classifier, we can fit this model by using estimating equations as described in [Alonzo and Pepe \(2002\)](#). This method can be also be used without covariate effects in the second stage, assuming a parametric model for the single (constant only) ROC curve. Covariates may still affect the first stage of estimation, so we parametrically model the single covariate-adjusted ROC curve (from the previous section). The marginal ROC curve, involving no covariates in either stage of estimation, can be fit parametrically as well.

In addition to the [Alonzo and Pepe \(2002\)](#) explanation, further details are given in [Pepe, Longton, and Janes \(2009\)](#); [Janes, Longton, and Pepe \(2009\)](#); [Pepe \(2003\)](#); and [Janes and Pepe \(2009\)](#).

The parametric models that we consider assume that the ROC curve is a cumulative distribution function  $g$  invoked with input of a linear polynomial in the corresponding quantile function invoked on the false-positive rate  $u$ . In this context, we assume that  $g$  corresponds to a standard normal cumulative distribution function,  $\Phi$ . So the corresponding quantile function is  $\Phi^{-1}$ . The constant intercept of the polynomial may depend on covariates, but the slope term  $\alpha$  (the quantile coefficient) may not.

$$\text{ROC}(u) = g\{\mathbf{x}'\beta + \alpha g^{-1}(u)\}$$

The first step of the algorithm involves the choice of false-positive rates to use in the parametric fit. These are typically a set of equispaced points spanning the interval (0,1). [Alonzo and Pepe \(2002\)](#) examined the effect of fitting large and small sets of points, finding that relatively small sets could be used with little loss of efficiency. Alternatively, the set can be formed by using the observed false-positive rates in the data ([Pepe 2003](#)). Further details on the algorithm are provided in [Methods and formulas](#).

Under parametric estimation, all the summary measures we defined earlier, except the AUC, are not calculated until postestimation. In models with covariates, each covariate combination would yield a different ROC curve and thus different summary parameters, so no summary parameters are initially estimated. In marginal parametric models (where there are no ROC covariates, but there are potentially control covariates), we will calculate the AUC and leave the other measures for postestimation; see [\[R\] rocreg postestimation](#). As with the other parameters, we bootstrap for standard errors and inference.

We will now demonstrate how `rocreg` performs the [Alonzo and Pepe \(2002\)](#) algorithm using the previous section's examples and others.

### ▶ Example 6: Parametric ROC, linear covariate adjustment

We return to the neonatal audiology study with gender and age covariates ([Norton et al. 2000](#)), which we discussed in [example 4](#). [Janes, Longton, and Pepe \(2009\)](#) suspected the current age of the infant would play a role in the case distribution of the classifier  $y_1$  (DPOAE 65 at 2 kHz). They postulated a probit link between the ROC curve and the covariate-adjusted false-positive rates. We follow their investigation and reach similar results.

In *example 4*, we saw the results of adjusting for the currage and male variables in the control population for classifier y1. Now, we see how currage affects the ROC curve when y1 is used with thresholds conditioned on male and currage.

We specify the covariates that should affect the ROC curve in the `roccov()` option. By default, `rocreg` will choose 10 equally spaced false-positive rates in the (0,1) interval as fitting points. The `fprpts()` option allows the user to specify more or fewer points. We specify the `bsave()` option with the `nnhs2y1` dataset so that we can use the bootstrap resamples in postestimation.

```
. use https://www.stata-press.com/data/r19/nnhs, clear
(Norton - neonatal audiology data)
. rocreg d y1, probit ctrlcov(currage male) ctrlmodel(linear) roccov(currage)
> cluster(id) bseed(56930) bsave(nnhs2y1) nodots
```

Bootstrap results Number of obs = 5,056  
Replications = 1,000

Note how the number of clusters—here infants—changes from the covariate control adjustment model fit to the ROC model. The control fit is limited to control cases and thus fewer infants. The ROC is fit on all the data, so the variance is adjusted for all clustering on all infants.

With a 0.05 level of statistical significance, we cannot reject the null hypothesis that currage has no effect on the ROC curve at a given false-positive rate. This is because each of our 95% bootstrap confidence intervals contains 0. This corresponds with the finding in [Janes, Longton, and Pepe \(2009\)](#) where the reported 95% intervals each contained 0. We cannot reject that the intercept parameter  $\beta_0$ , reported as `_cons` in the main table, is 0 at the 0.05 level either. The slope parameter  $\alpha$ , reported as `_cons` in the `probit` table, is close to 1 and cannot be rejected as being 1 at the 0.05 level. Under the assumption that the ROC coefficients except  $\alpha$  are 0 and that  $\alpha = 1$ , the ROC curve at false-positive rate  $u$  is equal to  $u$ . In other words, we cannot reject that the false-positive rate is equal to the true-positive rate, and so the test is noninformative. Further investigation of the results requires postestimation; see [\[R\] rocreg postestimation](#).

◀

The fitting point set can be formed by using the observed false-positive rates ([Pepe 2003](#)). Our next example will illustrate this.

### ▷ Example 7: Parametric ROC, covariate stratification

We return to the hearing test study of [Stover et al. \(1996\)](#), which we discussed in [example 5](#). [Pepe \(2003\)](#) suspected that intensity, `xd`, would play a role in the case distribution of the negative signal-to-noise ratio (`nsnr`) classifier. A ROC regression was fit with covariate adjustment for `xf` and `x1` with stratification, and for ROC covariates `xf`, `x1`, and `xd`. There is no prohibition against the same covariate being used in the first and second stages of ROC calculation. The false-positive rate fitting point set was composed of all observed false-positive rates in the control data.

We fit the model with `rocreg` here. Using observed false-positive rates as the fitting point set can make the dataset very large, so fitting the model is computationally intensive. We demonstrate the fitting algorithm without precise confidence intervals, focusing instead on the coefficient estimates and standard errors. We will thus perform only 50 bootstrap replications, a reasonable number to obtain accurate standard error estimates ([Mooney and Duval 1993](#)). The number of replications is specified in the `brep` option.

The ROC covariates are specified in `roccov()`. We specify that all observed false-positive rates in the control observations be used as fitting points with the `ctrlfprall` option. The `nobstrata` option specifies that the bootstrap is not stratified. The covariate stratification in the first stage of estimation does not affect the resampling. We will return to this example in postestimation, so we save the bootstrap results in the `nsnrf` dataset with the `bsave()` option.

We obtain results similar to those reported in [Pepe \(2003, 159\)](#). We find that the coefficients for `xl` and `xd` differ from 0 at the 0.05 level of significance. So over certain covariate combinations, we can have a variety of informative tests using `nsnr` as a classifier.

As mentioned before, when there are no covariates, `rocreg` can still fit a parametric model for the ROC curve of a classifier by using the [Alonzo and Pepe \(2002\)](#) method. `roccomp` and `rocfit` can fit marginal probit models as well. We will compare the behavior of `rocreg` with that of `roccomp` and `rocfit` for probit models without covariates.

When the `binormal` option is specified, `roccomp` calculates the AUC for input classifiers according to the maximum likelihood algorithm of `rocfit`. The `rocfit` algorithm expects discrete classifiers but can slice continuous classifiers into discrete partitions. Further, the case and control distributions are both assumed normal. Actually, the observed classification values are taken as discrete indicators of the latent normally distributed classification values. This method is documented in [Dorfman and Alf \(1969\)](#).

Alonzo and Pepe (2002) compared their estimating equations probability density function method (with empirical estimation of the false-positive rates) to the maximum likelihood approach of Dorfman and Alf (1969) and found that they had similar efficiency and mean squared error. So we should expect rocfite and rocreg to give similar results when fitting a simple probit model.

► Example 8: Parametric ROC, marginal model

We return to the Hanley and McNeil (1982) data. We will fit a probit model to the ROC curve, assuming that the rating variable is a discrete indicator of an underlying latent normal random variable in both the case and control populations of disease. We invoke rocfite with the default options. rocreg is invoked with the probit option. The percentile values are calculated empirically. Because there are fewer categories than 10, there will be fewer than 10 false-positive rates that trigger a different true-positive rate value. So for efficiency, we invoke rocreg with the ctrlfprall option.

|        |                      |           |                     | .8475004             | .9607949 (BC) |

We see that the intercept and slope parameter estimates are close. The intercept (`_cons` in the main table) is clearly nonzero. Under `rocreg`, the slope (`_cons` in the `probit` table) and its percentile and bias-corrected confidence intervals are close to those of `rocfit`. The area under the ROC curve for each of the `rocreg` and `rocfit` estimators also matches closely.

Now, we will compare the parametric fit of `rocreg` under the constant probit model with `roccomp`.

### ▷ Example 9: Parametric ROC, marginal model, multiple classifiers

We now use the fictitious dataset generated from [Hanley and McNeil \(1983\)](#). To fit a probit model using `roccomp`, we specify the `binormal` option. Our specification of `rocreg` remains the same as before.

`rocregplot` is used to render the model produced by `rocreg`. We specify several graph options to both `roccomp` and `rocregplot` to ease comparison. When the `binormal` option is specified along with `graph`, `roccomp` will draw the binormal fitted lines in addition to connected line plots of the empirical false-positive and true-positive rates.

In this plot, we overlay scatterplots of the empirical false-positive rates (because percentile value calculation defaulted to pvc(empirical)) and the parametric true-positive rates.

```
. graph combine a b, xsize(5)
```

We see differing true-positive rate values in the scattered points, which is expected because `roccomp` gives the empirical estimate and `rocreg` gives the parametric estimate. However, the estimated curves and areas under the ROC curve look similar. Using the Wald test based on the bootstrap covariance, `rocreg` rejects the null hypothesis that each test has the same AUC at the 0.1 significance level. `roccomp` formulates the asymptotic covariance using the `rocfit` estimates of AUC. Examination of its output leads to rejection of the null hypothesis that the AUCs are equal across each test at the 0.05 significance level.

### Parametric ROC curves: Maximum likelihood

The [Alonzo and Pepe \(2002\)](#) method of fitting a parametric model to the ROC curve is powerful because it can be generally applied, but that can be a limitation as well. Whenever we invoke the method and want anything other than point estimates of the parameters, we must perform bootstrap resampling.

An alternative is to use maximum likelihood inference to fit the ROC curve. This method can save computational time by avoiding the bootstrap.

`rocreg` implements maximum likelihood estimation for ROC curve analysis when both the case and control populations are normal. Particularly, the classifier is a normal linear model on certain covariates, and the covariate effect and variance of the classifier may change between the case and control populations. This model is defined in [Pepe \(2003, 145\)](#).

$$y = \mathbf{z}'\beta_0 + D\mathbf{x}'\beta_1 + \sigma(D)\epsilon$$

Our error term,  $\epsilon$ , is a standard normal random variable. The variable  $D$  is our true status variable, being 1 for the case population observations and 0 for the control population observations. The variance function  $\sigma$  is defined as

$$\sigma(D) = \sigma_0(D = 0) + \sigma_1(D = 1)$$

This provides two variance parameters in the model and does not depend on covariate values.

Suppose a covariate  $x_i$  is present in  $\mathbf{z}$  and  $\mathbf{x}$ . The coefficient  $\beta_{1i}$  represents the interaction effect of the  $x_i$  and  $D$ . It is the extra effect that  $x_i$  has on classifier  $y$  under the case population,  $D = 1$ , beyond the main effect  $\beta_{0i}$ . These  $\beta_1$  coefficients are directly related to the ROC curve of  $y$ .

Under this model, the ROC curve is derived to be

$$\text{ROC}(u) = \Phi \left[ \frac{1}{\sigma_1} \{ \mathbf{x}' \boldsymbol{\beta}_1 + \sigma_0 \Phi^{-1}(u) \} \right]$$

For convenience, we reparameterize the model at this point, creating the parameters  $\beta_i = \sigma_1^{-1} \beta_{1i}$  and  $\alpha = \sigma_1^{-1} \sigma_0$ . We refer to  $\beta_0$  as the constant intercept, `i_cons`. The parameter  $\alpha$  is referred to as the constant slope, `s_cons`.

$$\text{ROC}(u) = \Phi \{ \mathbf{x}' \boldsymbol{\beta} + \alpha \Phi^{-1}(u) \}$$

We may interpret the final coefficients as the standardized linear effect of the ROC covariate on the classifier under the case population. The marginal effect of the covariate on the classifier in the control population is removed, and it is rescaled by the case population standard deviation of the classifier when all ROC covariate effects are removed. An appreciable effect on the classifier by a ROC covariate in this measure leads to an appreciable effect on the classifier's ROC curve by the ROC covariate.

The advantage of estimating the control coefficients  $\beta_0$  is similar to the gains of estimating the covariate control models in the estimating equations ROC method and nonparametric ROC estimation. This model would similarly apply when evaluating a test that is conditioned on control covariates.

Again, we note that under parametric estimation, all the summary measures we defined earlier except the AUC are not calculated until postestimation. In models with covariates, each covariate combination would yield a different ROC curve and thus different summary parameters, so no summary parameters are estimated initially. In marginal parametric models, we will calculate the AUC and leave the other measures for postestimation. There is a simple closed-form formula for the AUC under the probit model. Using this formula, the delta method can be invoked for inference on the AUC. Details on AUC estimation for probit marginal models are found in *Methods and formulas*.

We will demonstrate the maximum likelihood method of `rocreg` by revisiting the models of the previous section.

### ▷ Example 10: Maximum likelihood ROC, single classifier

Returning to the hearing test study of [Stover et al. \(1996\)](#), we use a similar covariate grouping as before. The frequency `xf` and intensity `x1` are control covariates ( $\mathbf{z}$ ), while all three covariates `xf`, `x1`, and hearing loss degree `xd` are case covariates ( $\mathbf{x}$ ). In [example 7](#), we fit this model using the [Alonzo and Pepe \(2002\)](#) method. Earlier we stratified on the control covariates and estimated the conditioned control distribution of `nsnr` empirically. Now, we assume a normal linear model for `nsnr` on `xf` and `x1` under the control population.

We fit the model by specifying the control covariates in the `ctrlcov()` option and the case covariates in the `roccov()` option. The `ml` option tells `rocreg` to perform maximum likelihood estimation.

We find the results are similar to those of [example 7](#). Frequency (`xf`) and intensity (`x1`) have a negative effect on the classifier `nsnr` in the control population.

The negative control effect is mitigated for `xf` in the case population, but the effect for `x1` is even more negative there. Hearing loss severity, `xd`, has a positive effect on `nsnr` in the case population, and it is undefined in the control population.

The ROC coefficients are shown in the ROC Model table. Each are different from 0 at the 0.05 level. At this level, we also cannot conclude that the variances differ from case to control populations, because 1 is in the 95% confidence interval for `s_cons`, the ratio of the case to control standard deviation parameters.

Both frequency (`xf`) and hearing loss severity (`xd`) make a positive contribution to the ROC curve and thus make the test more powerful. Intensity (`x1`) has a negative effect on the ROC curve and weakens the test. We previously saw in [example 5](#) that the control distribution appears to be normal, so using maximum likelihood to fit this model is a reasonable approach.

This model was also fit in [Pepe \(2003, 147\)](#). Pepe used separate least-squares estimates for the case and control samples. We obtain similar results for the coefficients, but the maximum likelihood fitting yields slightly different standard deviations by considering both case and control observations concurrently. In addition, a misprint in [Pepe \(2003, 147\)](#) reports a coefficient of  $-4.91$  for `x1` in the case population instead of  $-3.19$  as reported by Stata.

◀

Inference on multiple classifiers using the [Alonzo and Pepe \(2002\)](#) estimating equation method is performed by fitting each model separately and bootstrapping to determine the dependence of the estimates. Using the maximum likelihood method, we also fit each model separately. We use `suest` (see [\[R\] suest](#)) to estimate the joint variance–covariance of our parameter estimates.

For our models, we can view the score equation for each model as an estimating equation. The estimate that solves the estimating equation (that makes the score 0) is asymptotically normal with a variance matrix that can be estimated using the inverse of the squared scores. By stacking the score equations of the separate models, we can estimate the variance matrix for all the parameter estimates by using this rule. This is an informal explanation; further details can be found in [\[R\] suest](#) and in the references [Rogers \(1993\)](#); [White \(1982 and 1996\)](#).

Now, we will examine a case with multiple classification variables.

▷ Example 11: Maximum likelihood ROC, multiple classifiers

We return to the neonatal audiology study with gender and age covariates (Norton et al. 2000). In example 6, we fit a model with male and currage as control covariates, and currage as a ROC covariate for the classifier y1 (DPOAE 65 at 2 kHz). We will refit this model, extending it to include the classifier y2 (TEOAE 80 at 2 kHz).

```
. use https://www.stata-press.com/data/r19/nnhs
(Norton - neonatal audiology data)
. rocreg d y1 y2, probit ml ctrlcov(currage male) roccov(currage) cluster(id)
> nolog

Both classifiers have similar results. The results for y1 show the same direction as the estimating equation results in [example 6](#). However, we can now reject the null hypothesis that the ROC currage coefficient is 0 at the 0.05 level.

In [example 6](#), we could not reject that the slope parameter s\_cons was 1 and that the constant intercept or ROC coefficient for current age was 0. The resulting ROC curve implied a noninformative test using y1 as a classifier. This is not the case with our current results. As currage increases, we expect a steeper ROC curve and thus a more powerful test, for both classifiers y1 (DPOAE 65 at 2 kHz) and y2 (TEOAE 80 at 2 kHz).

In [example 10](#), the clustering of observations within infant id was adjusted in the individual fit of nsnr. In our current example, the adjustment for the clustering of observations within id is performed during concurrent estimation, as opposed to during the individual classifier fits (as in [example 10](#)). This adjustment, performed by suest, is still accurate.

Now, we will fit constant probit models and compare rocreg with rocf it and roccomp with the binormal option. Our first applications of rocf it and roccomp are taken directly from [examples 8](#) and [9](#). The [Dorfman and Alf \(1969\)](#) algorithm that rocf it works with uses discrete classifiers or uses slicing to make a classifier discrete. So we are applying the maximum likelihood method of rocreg on discrete classification data here, where it expects continuous data. We expect to see some discrepancies, but we do not find great divergence in the estimates. After revisiting [examples 8](#) and [9](#), we will fit a probit model with a continuous classifier and no covariates using rocreg, and we will compare the results with those from rocf it.

▷ Example 12: Maximum likelihood ROC, marginal model

Using the Hanley and McNeil (1982) data, discussed in example 1 and in example 8, we fit a constant probit model of the classifier rating with true status disease. rocreg is invoked with the ml option and compared with rocfits.

ROC Model :
```

|        | Coefficient | Std. err. | z     | P> z  | [95% conf. interval] |          |
|--------|-------------|-----------|-------|-------|----------------------|----------|
| rating |             |           |       |       |                      |          |
| i_cons | 2.090802    | .2941411  | 7.11  | 0.000 | 1.514297             | 2.667308 |
| s_cons | 1.181151    | .1603263  | 7.37  | 0.000 | .8669177             | 1.495385 |
| auc    | .9116494    | .0261658  | 34.84 | 0.000 | .8603654             | .9629333 |

We compare the estimates for these models:

|                 | rocfit | rocreg, ml |
|-----------------|--------|------------|
| slope           | 0.7130 | 1.1812     |
| SE of slope     | 0.2159 | 0.1603     |
| intercept       | 1.6568 | 2.0908     |
| SE of intercept | 0.3105 | 0.2941     |
| AUC             | 0.9113 | 0.9116     |
| SE of AUC       | 0.0295 | 0.0262     |

We find that both the intercept and the slope are estimated as higher with the maximum likelihood method under rocreg than with rocfit. The AUC (ROC area in rocfit) is close for both commands. We find that the standard errors of each of these estimates is slightly lower under rocreg than rocfit as well.

Both rocfit and rocreg suggest that the slope parameter of the ROC curve (slope in rocfit and s\_cons in rocreg) is not significantly different from 1. Thus, we cannot reject that the classifier has the same variance in both case and control populations. There is, however, significant evidence that the intercepts (i\_cons in rocreg and intercept in rocfit) differ from 0. Because of the positive direction of the intercept estimates, the ROC curve for rating as a classifier of disease suggests that rating provides an informative test. This is also suggested by the high AUC, which is significantly different from 0.5, that is, a flip of a coin.

▷ Example 13: Maximum likelihood ROC, marginal model, multiple classifiers

We use the fictitious dataset generated from Hanley and McNeil (1983), which we previously used in example 2 and in example 9. To fit a probit model using roccomp, we specify the binormal option. We perform parametric, maximum likelihood ROC analysis using rocreg. We use rocregplot to plot the ROC curves created by rocreg.

H0: All classifiers have equal AUC values  
 Ha: At least one classifier has a different AUC value  
 P-value: .0808808

```
. rocregplot, title(rocreg) nodraw name(b)
> plot1opts(msymbol(o)) plot2opts(msymbol(s)) plot3opts(msymbol(t))
. graph combine a b, xsize(5)
```

We compare the AUC estimates for these models:

|      | roccomp | rocreg, ml |
|------|---------|------------|
| mod1 | 0.8945  | 0.9047     |
| mod2 | 0.9382  | 0.9580     |
| mod3 | 0.9376  | 0.9453     |

Each classifier has a higher estimated AUC under `rocreg` than `roccomp`. Each curve appears to be raised and smoothed in the `rocreg` fit as compared with `roccomp`. They are different, but not drastically different. The inference on whether the curve areas are the same is similar to [example 9](#). We reject equality at the 0.10 level under `rocreg` and at the 0.05 level under `roccomp`.

Each intercept is significantly different from 0 at the 0.05 level and is estimated in a positive direction. Though all but classifier `mod2` has 1 in their slope confidence intervals, the high intercepts suggest steep ROC curves and powerful tests.

Also note that the false-positive and true-positive rate points are calculated empirically in the `roccomp` graph and parametrically in `rocreg`. In [example 9](#), the false-positive rates calculated by `rocreg` were calculated empirically, similar to `roccomp`. But in this example, the rates are calculated based on normal percentiles.

Now, we will generate an example to compare `rocfit` and `rocreg` under maximum likelihood estimation of a continuous classifier.

▷ **Example 14: Maximum likelihood ROC, graphical comparison with `rocfit`**

We generate 500 realizations of a population under threat of disease. One quarter of the population has the disease. A classifier `x` is measured, which has a control distribution of  $N(1, 3)$  and a case distribution of  $N(1 + 5, 2)$ . We will invoke `rocreg` with the `ml` option on this generated data. We specify the `continuous()` option for `rocfit` and invoke it on the data as well. The `continuous()` option tells `rocfit` how many discrete slices to partition the data into before fitting.

For comparison of the two curves, we will use the `rocf` postestimation command, `rocplot`; see [R] [rocf](#) postestimation. This command graphs the empirical false-positive and true-positive rates with an overlaid fit of the binormal curve estimated by `rocf`. `rocplot` also supports an `addplot()` option. We use the saved variables from `rocreg` in this option to overlay a line plot of the `rocreg` fit.

```
. clear
. set seed 8675309
. set obs 500
Number of observations (_N) was 0, now 500.
. generate d = runiform() < .25
. quietly generate double epsilon = 3*invnormal(runiform()) if d == 0
. quietly replace epsilon = 2*invnormal(runiform()) if d == 1
. quietly generate double x = 1 + d*5 + epsilon
. rocreg d x, probit ml nolog
Parametric ROC estimation Number of obs = 112

(\*) z test for slope==1

```
. rocplot, plotopts(msymbol(i)) lineopts(lpattern(dash))
> norefline addplot(line_roc_x_fpr_x, sort(_fpr_x _roc_x))
> lpattern(solid) aspectratio(1) legend(off)
```

We find that the curves are close. As before, the `rocfit` estimates are lower for the slope and intercept than under `rocreg`. The AUC estimates are close. Though the slope confidence interval contains 1, a high ROC intercept suggests a steep ROC curve and thus a powerful test.

## Stored results

Nonparametric `rocreg` stores the following in `e()`:

### Scalars

|                          |                                    |

|-----------------------|-----------------------------------------------------------------------------------------------------------------------|
| <code>r(table)</code> | matrix containing the coefficients with their standard errors, test statistics, $p$ -values, and confidence intervals |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------|

Note that results stored in `r()` are updated when the command is replayed and will be replaced when any `r-class` command is run after the estimation command.

## Methods and formulas

Assume that we applied a diagnostic test to each of  $N_0$  control and  $N_1$  case subjects. Further assume that the higher the outcome value of the diagnostic test, the higher the risk of the subject being abnormal. Let  $y_{1i}$ ,  $i = 1, 2, \dots, N_1$ , and  $y_{0j}$ ,  $j = 1, 2, \dots, N_0$ , be the values of the diagnostic test for the case and control subjects, respectively. The true status variable  $D$  identifies an observation as case  $D = 1$  or control  $D = 0$ . The CDF of the classifier  $Y$  is  $F$ . Conditional on  $D$ , we write the CDF as  $F_D$ .

Methods and formulas are presented under the following headings:

- ROC statistics*
- Covariate-adjusted ROC curves*
- Parametric ROC curves: Estimating equations*
- Parametric ROC curves: Maximum likelihood*

## ROC statistics

We obtain these definitions and their estimates from [Pepe \(2003\)](#) and [Pepe, Longton, and Janes \(2009\)](#). The false-positive and true-positive rates at cutoff  $c$  are defined as

$$\text{FPR}(y) = P(Y \geq y | D = 0)$$

$$\text{TPR}(y) = P(Y \geq y | D = 1)$$

The true-positive rate, or ROC value at false-positive rate  $u$ , is given by

$$\text{ROC}(u) = P(1 - F_0(Y) \leq u | D = 1)$$

When  $Y$  is continuous, the false-positive rate can be written as

$$\text{FPR}(y) = 1 - F_0(y)$$

The empirical CDF for the sample  $z_1, \dots, z_n$  is given by

$$\hat{F}(z) = \sum_{i=1}^n \frac{I(z < z_i)}{n}$$

The empirical estimates  $\widehat{\text{FPR}}$  and  $\widehat{\text{ROC}}$  both use this empirical CDF estimator.

The area under the ROC curve is defined as

$$\text{AUC} = \int_0^1 \text{ROC}(u) d_u$$

The partial area under the ROC curve for false-positive rate  $a$  is defined as

$$\text{pAUC}(a) = \int_0^a \text{ROC}(u) d_u$$

The nonparametric estimate for the AUC is given by

$$\widehat{\text{AUC}} = \sum_{i=1}^{N_1} \frac{1 - \widehat{\text{FPR}}(y_{1i})}{N_1}$$

The nonparametric estimate of pAUC is given by

$$\widehat{\text{pAUC}}(a) = \sum_{i=1}^{N_1} \frac{\max\{1 - \widehat{\text{FPR}}(y_{1i}) - (1 - a), 0\}}{N_1}$$

For discrete classifiers, a correction term is subtracted from the false-positive rate estimate so that the  $\widehat{\text{AUC}}$  and  $\widehat{\text{pAUC}}$  estimates correspond with a trapezoidal approximation to the area of the ROC curve.

$$\text{FPR}^c(y) = 1 - \hat{F}_0(y) - \frac{1}{2} \sum_{j=1}^{N_0} \frac{I(y = y_{0j})}{N_0}$$

In the nonparametric estimation of the ROC curve, all inference is performed using the bootstrap command (see [R] [bootstrap](#)). `rocreg` also allows users to calculate the ROC curve and related statistics by assuming a normal control distribution. So these formulas are updated by replacing  $F_0$  by  $\Phi$  (with adjustment of the marginal mean and variance of the control distribution).

## Covariate-adjusted ROC curves

Suppose we observe covariate vector  $Z$  in addition to the classifier  $Y$ . Let  $Z_{1i}, i = 1, 2, \dots, N_1$ , and  $Z_{0j}, j = 1, 2, \dots, N_0$ , be the values of the covariates for the case and control subjects, respectively.

The covariate-adjusted ROC curve is defined by [Janes and Pepe \(2009\)](#) as

$$\text{AROC}(t) = E\{\text{ROC}(t|Z_0)\}$$

It is calculated by replacing the marginal control CDF estimate,  $\hat{F}_0$ , with the conditional control CDF estimate,  $\hat{F}_{0Z}$ . If we used a normal control CDF, then we would replace the marginal control mean and variance with the conditional control mean and variance. The formulas of the previous section can be updated for covariate-adjustment by making this substitution of the conditional CDF for the marginal CDF in the false-positive rate calculation.

Because the calculation of the ROC value is now performed based on the conditionally calculated false-positive rate, no further conditioning is made in its calculation under nonparametric estimation.

`rocreg` supports covariate adjustment with stratification and linear regression. Under stratification, separate parameters are estimated for the control distribution at each level of the covariates. Under linear regression, the classifier is regressed on the covariates over the control distribution, and the resulting coefficients serve as parameters for  $\hat{F}_{0Z}$ .

## Parametric ROC curves: Estimating equations

Under nonparametric estimation of the ROC curve with covariate adjustment, no further conditioning occurs in the ROC curve calculation beyond the use of covariate-adjusted false-positive rates as inputs.

Under parametric estimation of the ROC curve, we can relax this restriction. We model the ROC curve as a cumulative distribution function  $g$  (standard normal  $\Phi$ ) invoked with input of a linear polynomial in the corresponding quantile function (here  $\Phi^{-1}$ ) invoked on the false-positive rate  $u$ . The constant intercept of the polynomial may depend on covariates; the slope term  $\alpha$  (quantile coefficient) may not.

$$\text{ROC}(u) = g\{\mathbf{x}'\boldsymbol{\beta} + \alpha g^{-1}(u)\}$$

[Pepe \(2003\)](#) notes that having a binormal ROC ( $g = \Phi$ ) is equivalent to specifying that some monotone transformation of the data exists to make the case and control classifiers normally distributed. This specification applies to the marginal case and control.

Under weak assumptions about the control distribution of the classifier, we can fit this model by using estimating equations ([Alonzo and Pepe 2002](#)). The method can be used without covariate effects in the second stage, assuming a parametric model for the single ROC curve. Using the [Alonzo and Pepe \(2002\)](#) method, the covariate-adjusted ROC curve may be fit parametrically. The marginal ROC curve, involving no covariates in either stage of estimation, can be fit parametrically as well. In addition to the [Alonzo and Pepe \(2002\)](#) explanation, further details are given in [Pepe, Longton, and Janes \(2009\)](#); [Janes, Longton, and Pepe \(2009\)](#); [Pepe \(2003\)](#); and [Janes and Pepe \(2009\)](#).

The algorithm can be described as follows:

1. Estimate the false-positive rates of the classifier  $\text{fpr}$ . These may be computed in any fashion outlined so far: covariate-adjusted, empirically, etc.
2. Determine a set of  $n_p$  false-positive rates to use as fitting points  $f_1, \dots, f_{n_p}$ . These may be an equispaced grid on  $(0, 1)$  or the set of observed false-positive rates from part 1.
3. Expand the case observation portion of the data to include a subobservation for each fitting point. So there are now  $N_1(n_p - 1)$  additional observations in the data.
4. Generate a new dummy variable  $u$ . For subobservation  $j$ ,  $u = I(\text{fpr} \leq f_j)$ .
5. Generate a new variable  $\text{quant}$  containing the quantiles of the false-positive rate fitting points. For subobservation  $j$ ,  $\text{quant} = g^{-1}(f_j)$ .
6. Perform a binary regression (probit,  $g = \Phi$ ) of  $\text{fpr}$  on the covariates  $\mathbf{x}$  and quantile variable  $\text{quant}$ .

The coefficients of part 6 are the coefficients of the ROC model. The coefficients of the covariates coincide naturally with estimates of  $\beta$ , and the  $\alpha$  parameter is estimated by the coefficient on  $\text{quant}$ . Because the method is so general and makes few distributional assumptions, bootstrapping must be performed for inference. If multiple classifiers are to be fit, the algorithm is performed separately for each in each bootstrap, and the bootstrap is used to estimate covariances.

We mentioned earlier that in parametric estimation, the AUC was the only summary parameter that could be estimated initially. This is true when we fit the marginal probit model because there are no covariates in part 6 of the algorithm.

To calculate the AUC statistic under a marginal probit model, we use the formula

$$\text{AUC} = \Phi\left(\frac{\beta_0}{\sqrt{1 + \alpha^2}}\right)$$

Alternatively, the AUC for the probit model can be calculated as  $\text{pAUC}(1)$  in postestimation. Under both models, bootstrapping is performed for inference on the AUC.

## Parametric ROC curves: Maximum likelihood

`rocreg` supports another form of parametric ROC estimation: maximum likelihood with a normally distributed classifier. This method assumes that the classifier is a normal linear model on certain covariates, and the covariate effect and variance of the classifier may change between the case and control populations. The model is defined in [Pepe \(2003, 145\)](#).

$$y = \mathbf{z}'\beta_0 + D\mathbf{x}'\beta_1 + \sigma(D)\epsilon$$

Our error term,  $\epsilon$ , is a standard normal random variable. The variable  $D$  is our true status variable, being 1 for the case population observations and 0 for the control population observations. The variance function  $\sigma$  is defined as

$$\sigma(D) = \sigma_0(D = 0) + \sigma_1(D = 1)$$

This provides two variance parameters in the model and does not depend on covariate values.

Under this model, the ROC curve is easily derived to be

$$\text{ROC}(u) = \Phi \left[ \frac{1}{\sigma_1} \{ \mathbf{x}'\boldsymbol{\beta}_1 + \sigma_0 \Phi^{-1}(u) \} \right]$$

We reparameterize the model, creating the parameters  $\beta_i = \sigma_1^{-1} \beta_{1i}$  and  $\alpha = \sigma_1^{-1} \sigma_0$ . We refer to  $\beta_0$  as the constant intercept, `i_cons`. The parameter  $\alpha$  is referred to as the constant slope, `s_cons`.

$$\text{ROC}(u) = \Phi \{ \mathbf{x}'\boldsymbol{\beta} + \alpha \Phi^{-1}(u) \}$$

The original model defining the classifier  $y$  leads to the following single observation likelihoods for  $D = 0$  and  $D = 1$ :

$$L(\boldsymbol{\beta}_0, \boldsymbol{\beta}_1, \sigma_1, \sigma_0, |D = 0, y, \mathbf{z}, \mathbf{x}) = \frac{1}{\sqrt{2\pi}\sigma_0} \exp \frac{-(y - \mathbf{z}'\boldsymbol{\beta}_0)^2}{2\sigma_0^2}$$

$$L(\boldsymbol{\beta}_0, \boldsymbol{\beta}_1, \sigma_1, \sigma_0, |D = 1, y, \mathbf{z}, \mathbf{x}) = \frac{1}{\sqrt{2\pi}\sigma_1} \exp \frac{-(y - \mathbf{z}'\boldsymbol{\beta}_0 - \mathbf{x}'\boldsymbol{\beta}_1)^2}{2\sigma_1^2}$$

These can be combined to yield the observation-level log likelihood:

$$\begin{aligned} \ln L(\boldsymbol{\beta}_0, \boldsymbol{\beta}_1, \sigma_1, \sigma_0, |D, y, \mathbf{z}, \mathbf{x}) &= -\frac{\ln 2\pi}{2} \\ &\quad - I(D = 0) \left\{ \ln \sigma_0 + \frac{(y - \mathbf{z}'\boldsymbol{\beta}_0)^2}{2\sigma_0^2} \right\} \\ &\quad - I(D = 1) \left\{ \ln \sigma_1 + \frac{(y - \mathbf{z}'\boldsymbol{\beta}_0 - \mathbf{x}'\boldsymbol{\beta}_1)^2}{2\sigma_1^2} \right\} \end{aligned}$$

When there are multiple classifiers, each classifier is fit separately with maximum likelihood. Then, the results are combined by stacking the scores and using the sandwich variance estimator. For more information, see [R] `suest` and the references White (1982); Rogers (1993); and White (1996).

## Acknowledgments

We thank Margaret S. Pepe, Holly Janes, and Gary Longton (retired) of the Fred Hutchinson Cancer Research Center for providing the inspiration for the `rocreg` command and for illuminating many useful datasets for its documentation.

| <a href="#">test</a>      | Wald tests of simple and composite linear hypotheses                                              |
| <a href="#">testnl</a>    | Wald tests of nonlinear hypotheses                                                                |

# predict

## Description for predict

Use of `predict` after fitting a parametric model with `rocreg` allows calculation of all the ROC curve summary statistics for covariate-specific ROC curves. The ROC values for given false-positive rates, false-positive rate for given ROC values, area under the ROC curve (AUC), and partial areas under the ROC curve (pAUC) for a given false-positive rate can all be calculated.

Statistics > Postestimation

## Syntax for predict

```
predict [type] newvar [if] [in] [, statistic options]
```

| <i>statistic</i>                         | Description                                                                          |
|------------------------------------------|--------------------------------------------------------------------------------------|
| Main                                     |                                                                                      |
| <code>at</code> ( <i>varname</i> )       | input variable for statistic                                                         |
| <code>auc</code>                         | total area under the ROC curve; the default                                          |
| <code>roc</code>                         | ROC values for given false-positive rates in <code>at()</code>                       |
| <code>invroc</code>                      | false-positive rate for given ROC values in <code>at()</code>                        |
| <code>pauc</code>                        | partial area under the ROC curve up to each false-positive rate in <code>at()</code> |
| <code>classvar</code> ( <i>varname</i> ) | statistic for given classifier                                                       |

| <i>options</i>                                           | Description                                                                                                                                        |
|----------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| Options                                                  |                                                                                                                                                    |
| <code>intpts</code> (#)                                  | points in numeric integration of pAUC calculation                                                                                                  |
| <code>se</code> ( <i>newvar</i> )                        | predict standard errors                                                                                                                            |
| <code>ci</code> ( <i>stubname</i> )                      | produce confidence intervals, stored as variables with prefix <i>stubname</i> and suffixes <code>_l</code> and <code>_u</code>                     |
| <code>level</code> (#)                                   | set confidence level; default is <code>level(95)</code>                                                                                            |
| * <code>bfile</code> ( <i>filename</i> , ...)            | load dataset containing bootstrap replicates from <code>rocreg</code>                                                                              |
| * <code>btype</code> ( <i>n</i>   <i>p</i>   <i>bc</i> ) | produce normal-based ( <i>n</i> ), percentile ( <i>p</i> ), or bias-corrected ( <i>bc</i> ) confidence intervals; default is <code>btype(n)</code> |

\*`bfile()` and `btype()` are only allowed with parametric analysis using bootstrap inference.

## Options for predict

### Main

`at(varname)` records the variable to be used as input for the above predictions.

`auc` predicts the total area under the ROC curve defined by the covariate values in the data. This is the default statistic.

`roc` predicts the ROC values for false-positive rates stored in *varname* specified in `at()`.

`invroc` predicts the false-positive rates for given ROC values stored in *varname* specified in `at()`.

`pauc` predicts the partial area under the ROC curve up to each false-positive rate stored in *varname* specified in `at()`.

`classvar(varname)` performs the prediction for the specified classifier.

### Options

`intpts(#)` specifies that # points be used in the pAUC calculation.

`se(newvar)` specifies that standard errors be produced and stored in *newvar*.

`ci(stubname)` requests that confidence intervals be produced and the lower and upper bounds be stored in *stubname\_l* and *stubname\_u*, respectively.

`level(#)` specifies the confidence level, as a percentage, for confidence intervals. The default is `level(95)` or as set by `set level`; see [\[U\] 20.8 Specifying the width of confidence intervals](#).

`bfile(filename, ...)` uses bootstrap replicates of parameters from `rocreg` stored in *filename* to estimate standard errors and confidence intervals of predictions.

`btype(n | p | bc)` specifies whether to produce normal-based (*n*), percentile (*p*), or bias-corrected (*bc*) confidence intervals. The default is `btype(n)`.

## estat

### Description for estat

`estat nproc` allows calculation of all the ROC curve summary statistics for covariate-specific ROC curves, as well as for a nonparametric ROC estimation. Under nonparametric estimation, a single ROC curve is estimated by `rocreg`. Covariates can affect this estimation, but there are no separate covariate-specific ROC curves. Thus, the input arguments for `estat nproc` are taken in the command line rather than from the data as variable values.

### Menu for estat

Statistics > Postestimation

### Syntax for estat nproc

```
estat nproc [, estat_nproc_options]
```

| <i>estat_nproc_options</i>          | Description                                                              |
|-------------------------------------|--------------------------------------------------------------------------|
| Main                                |                                                                          |
| <code>auc</code>                    | estimate total area under the ROC curve                                  |
| <code>roc(<i>numlist</i>)</code>    | estimate ROC values for given false-positive rates                       |
| <code>invroc(<i>numlist</i>)</code> | estimate false-positive rate for given ROC values                        |
| <code>pauc(<i>numlist</i>)</code>   | estimate partial area under the ROC curve up to each false-positive rate |

At least one option must be specified.

### Options for estat nproc

#### Main

`auc` estimates the total area under the ROC curve.

`roc(numlist)` estimates the ROC for each of the false-positive rates in *numlist*. The values in *numlist* must be in the range (0,1).

`invroc(numlist)` estimates the false-positive rate for each of the ROC values in *numlist*. The values in *numlist* must be in the range (0,1).

`pauc(numlist)` estimates the partial area under the ROC curve up to each false-positive rate in *numlist*. The values in *numlist* must be in the range (0,1].

### Remarks and examples

Remarks are presented under the following headings:

*Using predict after rocreg*  
*Using estat nproc*

## Using predict after rocreg

`predict`, after parametric `rocreg`, predicts the AUC, the ROC value, the false-positive rate (invROC), or the pAUC value. The default is `auc`.

We begin by estimating the area under the ROC curve for each of the three age-specific ROC curves in [example 1](#) of [R] `rocregplot`: 30, 40, and 50 months.

### ▷ Example 1: Parametric ROC, AUC

In [example 6](#) of [R] `rocreg`, a probit ROC model was fit to audiology test data from [Norton et al. \(2000\)](#). The estimating equations method of [Alonzo and Pepe \(2002\)](#) was used to fit the model. Gender and age were covariates that affected the control distribution of the classifier `y1` (DPOAE 65 at 2 kHz). Age was a ROC covariate for the model, so we fit separate ROC curves at each age.

Following [Janes, Longton, and Pepe \(2009\)](#), we drew the ROC curves for ages 30, 40, and 50 months in [example 1](#) of [R] `rocregplot`. Now, we use `predict` to estimate the AUC for the ROC curve at each of those ages.

The bootstrap dataset saved by `rocreg` in [example 6](#) of [R] `rocreg`, `nnhs2y1.dta`, is used in the `bfile()` option.

We will store the AUC prediction in the new variable `predAUC`. We specify the `se()` option with the new variable name `seAUC` to produce an estimate of the prediction's standard error. By specifying the stubname `cin` in `ci()`, we tell `predict` to create normal-based confidence intervals (the default) as new variables `cin_l` and `cin_u`.

```
. use https://www.stata-press.com/data/r19/nnhs
(Norton - neonatal audiology data)
. rocreg d y1, probit ctrlcov(currage male) ctrlmodel(linear) roccov(currage)
> cluster(id) bseed(56930) bsave(nnhs2y1)
(output omitted)
. set obs 5061
Number of observations (_N) was 5,058, now 5,061.
. quietly replace currage = 30 in 5059
. quietly replace currage = 40 in 5060
. quietly replace currage = 50 in 5061
. predict predAUC in 5059/5061, auc se(seAUC) ci(cin) bfile(nnhs2y1)
. list currage predAUC seAUC cin* in 5059/5061
```

|       | currage | predAUC  | seAUC    | cin_l    | cin_u    |
|-------|---------|----------|----------|----------|----------|
| 5059. | 30      | .5209999 | .076013  | .3720171 | .6699827 |
| 5060. | 40      | .6479176 | .0284218 | .592212  | .7036232 |
| 5061. | 50      | .7601378 | .0794346 | .6044489 | .9158267 |

As expected, we find the AUC to increase with age.

Essentially, we have a stored bootstrap sample of ROC covariate coefficient estimates in `nnhs2y1.dta`. We calculate the AUC using each set of coefficient estimates, resulting in a sample of AUC estimates. Then, the bootstrap standard error and confidence intervals are calculated based on this AUC sample. Further details of the computation of the standard error and percentile confidence intervals can be found in [Methods and formulas](#) and in [R] `bootstrap`.

We can also produce percentile or bias-corrected confidence intervals by specifying `btype(p)` or `btype(bc)`, which we now demonstrate.

```
. drop *AUC*
. predict predAUC in 5059/5061, auc se(seAUC) ci(cip) bfile(nnhs2y1) btype(p)
. list currage predAUC cip* in 5059/5061
```

|       | currage | predAUC  | cip_l    | cip_u    |
|-------|---------|----------|----------|----------|
| 5059. | 30      | .5209999 | .3625608 | .6615624 |
| 5060. | 40      | .6479176 | .5874361 | .702619  |
| 5061. | 50      | .7601378 | .5836248 | .8910214 |

```
. drop *AUC*
. predict predAUC in 5059/5061, auc se(seAUC) ci(cibc) bfile(nnhs2y1) btype(bc)
. list currage predAUC cibc* in 5059/5061
```

|       | currage | predAUC  | cibc_l   | cibc_u   |
|-------|---------|----------|----------|----------|
| 5059. | 30      | .5209999 | .3733315 | .6669934 |
| 5060. | 40      | .6479176 | .5901812 | .7038136 |
| 5061. | 50      | .7601378 | .5738162 | .8882028 |

◀

`predict` can also estimate the ROC value and the false-positive rate (`invROC`).

### ▷ Example 2: Parametric ROC, `invROC`, and ROC value

In [example 7](#) of [\[R\] rocreg](#), we fit the ROC curve for status variable hearing loss (`d`) and classifier negative signal-to-noise ratio `nsnr` with ROC covariates frequency (`xf`), intensity (`x1`), and hearing loss severity (`xd`). The data were obtained from [Stover et al. \(1996\)](#). The model fit was probit with bootstrap resampling. We saved 50 bootstrap replications in the dataset `nsnrf.dta`.

The covariate value combinations `xf = 10.01`, `x1 = 5.5`, and `xd = .5`, and `xf = 10.01`, `x1 = 6.5`, and `xd = 4` are of interest. In [example 3](#) of [\[R\] rocregplot](#), we estimated the ROC values for false-positive rates 0.2 and 0.7 and the false-positive rate for a ROC value of 0.5 by using `rocregplot`. We will use `predict` to replicate the estimation.

We begin by appending observations with our desired covariate combinations to the data. We also create two new variables: `rocinp`, which contains the ROC values for which we wish to predict the corresponding `invROC` values, and `invrocinp`, which contains the `invROC` values corresponding to the ROC values we wish to predict.

```

. clear
. input xf xl xd rocinp invrocinp
 xf xl xd rocinp invrocinp
1. 10.01 5.5 .5 .2 .
2. 10.01 6.5 4 .2 .
3. 10.01 5.5 .5 .7 .5
4. 10.01 6.5 4 .7 .5
5. end
. save newdata
file newdata.dta saved
. use https://www.stata-press.com/data/r19/dp
(Stover - DPOAE test data)
. quietly rocreg d nsnr, ctrlcov(xf xl) roccov(xf xl xd) probit cluster(id)
> nobstrata ctrlfprall bseed(156385) breps(50) ctrlmodel(strata) bsave(nsnrf)
. append using newdata
. list xf xl xd invrocinp rocinp in 1849/1852

```

|       | xf    | xl  | xd | invroc~p | rocinp |
|-------|-------|-----|----|----------|--------|
| 1849. | 10.01 | 5.5 | .5 | .        | .2     |
| 1850. | 10.01 | 6.5 | 4  | .        | .2     |
| 1851. | 10.01 | 5.5 | .5 | .5       | .7     |
| 1852. | 10.01 | 6.5 | 4  | .5       | .7     |

Now, we will use `predict` to estimate the ROC value for the false-positive rates stored in `rocinp`. We specify the `roc` option, and we specify `rocinp` in the `at()` option. The other options, `se()` and `ci()`, are used to obtain standard errors and confidence intervals, respectively. The dataset of bootstrap samples, `nsnrf.dta`, is specified in `bfile()`. After prediction, we list the point estimates and standard errors.

```

. predict rocit in 1849/1852, roc at(rocinp) se(seroc) ci(cin) bfile(nsnrf)
. list xf xl xd rocinp rocit seroc if !missing(rocit)

```

|       | xf    | xl  | xd | rocinp | rocit    | seroc    |
|-------|-------|-----|----|--------|----------|----------|
| 1849. | 10.01 | 5.5 | .5 | .2     | .7652956 | .0624187 |
| 1850. | 10.01 | 6.5 | 4  | .2     | .9672505 | .0162785 |
| 1851. | 10.01 | 5.5 | .5 | .7     | .9835816 | .0133583 |
| 1852. | 10.01 | 6.5 | 4  | .7     | .999428  | .0007784 |

These results match [example 3](#) of [\[R\] rocregplot](#). We list the confidence intervals next. These also conform to the `rocregplot` results from [example 3](#) in [\[R\] rocregplot](#). We begin with the confidence intervals for ROC under the covariate values `xf=10.01`, `xl=5.5`, and `xd=.5`.

```

. list xf xl xd rocinp rocit cin* if inlist(_n, 1849, 1851)

```

|       | xf    | xl  | xd | rocinp | rocit    | cin_l    | cin_u    |
|-------|-------|-----|----|--------|----------|----------|----------|
| 1849. | 10.01 | 5.5 | .5 | .2     | .7652956 | .6429572 | .887634  |
| 1851. | 10.01 | 5.5 | .5 | .7     | .9835816 | .9573998 | 1.009763 |

Now, we list the ROC confidence intervals under the covariate values  $xf=10.01$ ,  $x1=6.5$ , and  $xd=4$ .

```
. list xf x1 xd rocinp rocit cin* if inlist(_n, 1850, 1852)
```

|       | xf    | x1  | xd | rocinp | rocit    | cin_l    | cin_u    |
|-------|-------|-----|----|--------|----------|----------|----------|
| 1850. | 10.01 | 6.5 | 4  | .2     | .9672505 | .9353452 | .9991558 |
| 1852. | 10.01 | 6.5 | 4  | .7     | .999428  | .9979024 | 1.000954 |

Now, we will predict the false-positive rate for a ROC value by specifying the `invroc` option. We pass the `invrocinp` variable as an argument to the `at()` option. Again, we list the point estimates and standard errors first.

```
. drop ci*
. predict invrocit in 1849/1852, invroc at(invrocinp) se(serocinv) ci(cin)
> bfile(nsnrf)
. list xf x1 xd invrocinp invrocit serocinv if !missing(invrocit)
```

|       | xf    | x1  | xd | invroc-p | invrocit | serocinv |
|-------|-------|-----|----|----------|----------|----------|
| 1851. | 10.01 | 5.5 | .5 | .5       | .0615144 | .0209516 |
| 1852. | 10.01 | 6.5 | 4  | .5       | .0043298 | .003835  |

These also match those of [example 3](#) of [R] [rocregplot](#). Listing the confidence intervals shows identical results as well. First, we list the confidence intervals under the covariate values  $xf=10.01$ ,  $x1=5.5$ , and  $xd=.5$ .

```
. list xf x1 xd invrocinp invrocit cin* in 1851
```

|       | xf    | x1  | xd | invroc-p | invrocit | cin_l    | cin_u    |
|-------|-------|-----|----|----------|----------|----------|----------|
| 1851. | 10.01 | 5.5 | .5 | .5       | .0615144 | .0204499 | .1025789 |

Now, we list the confidence intervals for false-positive rate under the covariate values  $xf=10.01$ ,  $x1=6.5$ , and  $xd=4$ .

```
. list xf x1 xd invrocinp invrocit cin* in 1852
```

|       | xf    | x1  | xd | invroc-p | invrocit | cin_l     | cin_u    |
|-------|-------|-----|----|----------|----------|-----------|----------|
| 1852. | 10.01 | 6.5 | 4  | .5       | .0043298 | -.0031867 | .0118463 |

The `predict` command can also be used after a maximum-likelihood ROC model is fit.

### ► Example 3: Maximum likelihood ROC, invROC, and ROC value

In the [previous example](#), we revisited the estimating equations fit of a probit model with ROC covariates frequency (xf), intensity (xl), and hearing loss severity (xd) to the [Stover et al. \(1996\)](#) audiology study data. A maximum likelihood fit of the same model was performed in [example 10](#) of [\[R\] rocreg](#). In [example 2](#) of [\[R\] rocregplot](#), we used `rocregplot` to estimate ROC values and false-positive rates for this model under two covariate configurations. We will use `predict` to obtain the same estimates. We will also estimate the partial area under the ROC curve.

We append the data as in the [previous example](#). This leads to the following four final observations in the data.

```
. use https://www.stata-press.com/data/r19/dp, clear
(Stover - DPOAE test data)
. rocreg d nsnr, probit ctrlcov(xf xl) roccov(xf xl xd) ml cluster(id)
(output omitted)
. append using newdata
. list xf xl xd invrocinp rocinp in 1849/1852
```

|       | xf    | xl  | xd | invroc~p | rocinp |
|-------|-------|-----|----|----------|--------|
| 1849. | 10.01 | 5.5 | .5 | .        | .2     |
| 1850. | 10.01 | 6.5 | 4  | .        | .2     |
| 1851. | 10.01 | 5.5 | .5 | .5       | .7     |
| 1852. | 10.01 | 6.5 | 4  | .5       | .7     |

Now, we predict the ROC value for false-positive rates of 0.2 and 0.7. Under maximum likelihood prediction, only Wald-type confidence intervals are produced. We specify a new variable name for the standard error in the `se()` option and a stubname for the confidence interval variables in the `ci()` option.

```
. predict rocit in 1849/1852, roc at(rocinp) se(seroc) ci(ci)
. list xf xl xd rocinp rocit seroc ci_l ci_u if !missing(rocit), noobs
```

|  | xf    | xl  | xd | rocinp | rocit    | seroc    | ci_l     | ci_u     |
|--|-------|-----|----|--------|----------|----------|----------|----------|
|  | 10.01 | 5.5 | .5 | .2     | .7608593 | .0510501 | .660803  | .8609157 |
|  | 10.01 | 6.5 | 4  | .2     | .9499408 | .0179824 | .914696  | .9851856 |
|  | 10.01 | 5.5 | .5 | .7     | .978951  | .0097382 | .9598644 | .9980376 |
|  | 10.01 | 6.5 | 4  | .7     | .9985001 | .0009657 | .9966073 | 1.000393 |

These results match our estimates in [example 2](#) of [\[R\] rocregplot](#). We also match [example 2](#) of [\[R\] rocregplot](#) when we estimate the false-positive rate for a ROC value of 0.5.

```
. drop ci*
. predict invrocit in 1851/1852, invroc at(invrocinp) se(serocinv) ci(ci)
. list xf xl xd invrocinp invrocit serocinv ci_l ci_u if !missing(invrocit),
> noobs
```

|  | xf    | xl  | xd | invroc~p | invrocit | serocinv | ci_l      | ci_u     |
|--|-------|-----|----|----------|----------|----------|-----------|----------|
|  | 10.01 | 5.5 | .5 | .5       | .0578036 | .0198626 | .0188736  | .0967336 |
|  | 10.01 | 6.5 | 4  | .5       | .0055624 | .0032645 | -.0008359 | .0119607 |

### ► Example 4: Maximum likelihood ROC, pAUC, and ROC value

In [example 13](#) of [R] [rocreg](#), we fit a maximum-likelihood marginal probit model to each classifier of the fictitious dataset generated from [Hanley and McNeil \(1983\)](#). In [example 5](#) of [R] [rocregplot](#), `rocregplot` was used to draw the ROC for the `mod1` and `mod3` classifiers. Estimates of the ROC value and false-positive rate were also obtained with Wald-type confidence intervals.

We return to this example, this time using `predict` to estimate the ROC value and false-positive rate. We will also estimate the pAUC for the false-positive rates of 0.3 and 0.8.

First, we add the input variables to the data. The variable `paucinp` will hold the 0.3 and 0.8 false-positive rates that we will input to `pAUC`. The variable `invrocinp` holds the ROC value of 0.8 for which we will estimate the false-positive rate. Finally, the variable `rocinp` holds the false-positive rates of 0.15 and 0.75 for which we will estimate the ROC value.

```
. use https://www.stata-press.com/data/r19/ct2, clear
(Reconstruction of CT images)
. rocreg status mod1 mod2 mod3, probit ml
 (output omitted)
. quietly generate paucinp = .3 in 111
. quietly replace paucinp = .8 in 112
. quietly generate invrocinp = .8 in 112
. quietly generate rocinp = .15 in 111
. quietly replace rocinp = .75 in 112
```

Then, we estimate the ROC value for false-positive rates 0.15 and 0.75 under classifier `mod1`. The point estimate is stored in `roc1`. Wald confidence intervals and standard errors are also estimated. We find that these results match those of [example 5](#) of [R] [rocregplot](#).

```
. predict roc1 in 111/112, classvar(mod1) roc at(rocinp) se(sr1) ci(cir1)
. list rocinp roc1 sr1 cir1* in 111/112
```

|      | rocinp | roc1     | sr1      | cir1_l   | cir1_u   |
|------|--------|----------|----------|----------|----------|
| 111. | .15    | .7934935 | .0801363 | .6364293 | .9505578 |
| 112. | .75    | .9931655 | .0069689 | .9795067 | 1.006824 |

Now, we perform the same estimation under the classifier `mod3`.

```
. predict roc3 in 111/112, classvar(mod3) roc at(roci) se(sr3) ci(cir3)
. list rocinp roc3 sr3 cir3* in 111/112
```

|      | rocinp | roc3     | sr3      | cir3_l   | cir3_u   |
|------|--------|----------|----------|----------|----------|
| 111. | .15    | .8888596 | .0520118 | .7869184 | .9908009 |
| 112. | .75    | .9953942 | .0043435 | .9868811 | 1.003907 |

Next, we estimate the false-positive rate for the ROC value of 0.8. These results also match [example 5](#) of [R] [rocregplot](#).

```
. predict invroc1 in 112, classvar(mod1) invroc at(invrocinp) se(sir1) ci(ciir1)
. list invrocinp invroc1 sir1 ciir1* in 112
```

|      | invroc~p | invroc1  | sir1    | ciir1_l  | ciir1_u |
|------|----------|----------|---------|----------|---------|
| 112. | .8       | .1556435 | .069699 | .0190361 | .292251 |

```
. predict invroc3 in 112, classvar(mod3) invroc at(invrocinp) se(sir3) ci(ciir3)
. list invrocinp invroc3 sir3 ciir3* in 112
```

|      | invroc~p | invroc3  | sir3    | ciir3_l   | ciir3_u  |
|------|----------|----------|---------|-----------|----------|
| 112. | .8       | .0661719 | .045316 | -.0226458 | .1549896 |

Finally, we estimate the pAUC for false-positive rates of 0.3 and 0.8. The point estimate is calculated by numeric integration. Wald confidence intervals are obtained with the delta method. Further details are presented in [Methods and formulas](#).

```
. predict pauc1 in 111/112, classvar(mod1) pauc at(paucinp) se(sp1) ci(cip1)
. list paucinp pauc1 sp1 cip1* in 111/112
```

|      | paucinp | pauc1    | sp1      | cip1_l   | cip1_u   |

. list paucinp pauc3 sp3 cip3* in 111/112
```

|      | paucinp | pauc3    | sp3      | cip3_l   | cip3_u   |
|------|---------|----------|----------|----------|----------|
| 111. | .3      | .2540215 | .0173474 | .2200213 | .2880217 |
| 112. | .8      | .7420408 | .0225192 | .6979041 | .7861776 |

◀

## Using estat nproc

When you initially use `rocreg` to fit a nonparametric ROC curve, you can obtain bootstrap estimates of a ROC value, false-positive rate, area under the ROC curve, and partial area under the ROC curve. The `estat nproc` command allows the user to estimate these parameters after `rocreg` has originally been used.

The seed and resampling settings used by `rocreg` are used by `estat nproc`. So the results for these new statistics are identical to what they would be if they had been initially estimated in the `rocreg` command. These new statistics, together with those previously estimated in `rocreg`, are returned in `r()`.

We demonstrate with an example.

▷ Example 5: Nonparametric ROC, invROC, and pAUC

In example 3 of [R] `rocreg`, we examined data from a pancreatic cancer study (Wieand et al. 1989). Two continuous classifiers, `y1` (CA 19-9) and `y2` (CA 125), were used for the true status variable `d`. In that example, we estimated various quantities including the false-positive rate for a ROC value of 0.6 and the pAUC for a false-positive rate of 0.5. Here we replicate that estimation with a call to `rocreg` to estimate the former and follow that with a call to `estat nproc` to estimate the latter. For simplicity, we restrict estimation to classifier `y1` (CA 19-9).

We start by executing `rocreg`, estimating the false-positive rate for a ROC value of 0.6. This value is specified in `invroc()`. Case-control resampling is used by specifying the `bootcc` option.

```
. use https://research.fredhutch.org/content/dam/stripe/diagnostic-biomarkers-
> statistical-center/files/wiedat2b.dta, clear
(S. Wieand - Pancreatic cancer diagnostic marker data)
. rocreg d y1, invroc(.6) bseed(8378923) bootcc nodots
```

Bootstrap results

```
Number of strata = 2 Number of obs = 141
 Replications = 1,000
```

Nonparametric ROC estimation

Control standardization: empirical

ROC method : empirical

False-positive rate

Status : d

Classifier: y1

| invROC | Observed<br>coefficient | Bias     | Bootstrap<br>std. err. | [95% conf. interval] |               |
|--------|-------------------------|----------|------------------------|----------------------|---------------|
| .6     | 0                       | .0149412 | .0255885               | -.0501525            | .0501525 (N)  |
|        |                         |          |                        | 0                    | .0784314 (P)  |
|        |                         |          |                        | 0                    | .1372549 (BC) |

Now, we will estimate the pAUC for the false-positive rate of 0.5 using estat nproc and the pauc() option.

```

The advantages of using `estat nproc` are twofold. First, you can estimate additional parameters of interest without having to respecify the bootstrap settings you did with `rocreg`; instead `estat nproc` uses the bootstrap settings that were stored by `rocreg`. Second, parameters estimated with `estat nproc` are added to those parameters estimated by `rocreg` and returned in the matrices `r(b)` (parameter estimates) and `r(V)` (variance–covariance matrix). Thus, you can also obtain correlations between any quantities you wish to estimate.

## Stored results

`estat nproc` stores the following in `r()`:

Matrices

|                               |                                              |

| <code>r(ci_bc)</code>         | bias-corrected confidence intervals          |

## Methods and formulas

Details on computation of the nonparametric ROC curve and the estimation of the parametric ROC curve model coefficients can be found in [R] [rocreg](#). Here we describe how to estimate the ROC curve summary statistics for a parametric model. The cumulative distribution function,  $g$ , can be the standard normal cumulative distribution function,  $\Phi$ .

Methods and formulas are presented under the following headings:

*Parametric model: Summary parameter definition*  
*Maximum likelihood estimation*  
*Estimating equations estimation*

## Parametric model: Summary parameter definition

Conditioning on covariates  $\mathbf{x}$ , we have the following ROC curve model:

$$\text{ROC}(u) = g\{\mathbf{x}'\boldsymbol{\beta} + \alpha g^{-1}(u)\}$$

$\mathbf{x}$  can be constant, and  $\boldsymbol{\beta} = \beta_0$ , the constant intercept.

We can solve this equation to obtain the false-positive rate value  $u$  for a ROC value of  $r$ :

$$u = g\{[g^{-1}(r) - \mathbf{x}'\boldsymbol{\beta}]\alpha^{-1}\}$$

The partial area under the ROC curve for the false-positive rate  $u$  is defined by

$$\text{pAUC}(u) = \int_0^u g\{\mathbf{x}'\boldsymbol{\beta} + \alpha g^{-1}(t)\} dt$$

The area under the ROC curve is defined by

$$\text{AUC} = \int_0^1 g\{\mathbf{x}'\boldsymbol{\beta} + \alpha g^{-1}(t)\} dt$$

When  $g$  is the standard normal cumulative distribution function  $\Phi$ , we can express the AUC as

$$\text{AUC} = \Phi\left(\frac{\mathbf{x}'\boldsymbol{\beta}}{\sqrt{1 + \alpha^2}}\right)$$

## Maximum likelihood estimation

We allow maximum likelihood estimation under probit parametric models, so  $g = \Phi$ . The ROC value, false-positive rate, and AUC parameters all have closed-form expressions in terms of the covariate values  $\mathbf{x}$ , coefficient vector  $\boldsymbol{\beta}$ , and slope parameter  $\alpha$ . So to estimate these three types of summary parameters, we use the delta method (Oehlert 1992; Phillips and Park 1988). Particularly, we use the `nlcom` command (see [R] [nlcom](#)) to implement the delta method.

To estimate the partial area under the ROC curve for false-positive rate  $u$ , we use numeric integration. A trapezoidal approximation is used in calculating the integrals. A numeric integral of the  $\text{ROC}(t)$  function conditioned on the covariate values  $\mathbf{x}$ , coefficient vector estimate  $\widehat{\boldsymbol{\beta}}$ , and slope parameter estimate  $\widehat{\alpha}$  is computed over the range  $t = [0, u]$ . This gives us the point estimate of  $\text{pAUC}(u)$ .

To calculate the standard error and confidence intervals for the point estimate of  $\text{pAUC}(u)$ , we again use the delta method. Details on the delta method algorithm can be found in [Methods and formulas](#) of [R] [nlcom](#) and the earlier mentioned references.

Under maximum likelihood estimation, the coefficient estimates  $\widehat{\boldsymbol{\beta}}$  and slope estimate  $\widehat{\alpha}$  are asymptotically normal with variance matrix  $\mathbf{V}$ . For convenience, we rename the parameter vector  $[\boldsymbol{\beta}', \alpha]$  to the  $k$ -parameter vector  $\boldsymbol{\theta} = [\theta_1, \dots, \theta_k]$ . We will also explicitly refer to the conditioning of the ROC curve by  $\boldsymbol{\theta}$  in its mention as  $\text{ROC}(t, \boldsymbol{\theta})$ .

Under the delta method, the continuous scalar function of the estimate  $\hat{\theta}$ ,  $f(\hat{\theta})$  has asymptotic mean  $f(\theta)$  and asymptotic covariance

$$\widehat{\text{Var}} \{f(\hat{\theta})\} = \mathbf{fVf}$$

where  $\mathbf{f}$  is the  $1 \times k$  matrix of derivatives for which

$$\mathbf{f}_{1j} = \frac{\partial f(\theta)}{\partial \theta_j} \quad j = 1, \dots, k$$

The asymptotic covariance of  $f(\hat{\theta})$  is estimated and then used in conjunction with  $f(\hat{\theta})$  for further inference, including Wald confidence intervals, standard errors, and hypothesis testing.

In the case of  $\text{pAUC}(u)$  estimation, our  $f(\hat{\theta})$  is the aforementioned numeric integral of the ROC curve. It estimates  $f(\theta)$ , the true integral of the ROC curve on the  $[0, u]$  range. The  $\mathbf{V}$  variance matrix is estimated using the likelihood information that rocreg calculated, and the estimation is performed by rocreg itself.

The partial derivatives of  $f(\theta)$  can be determined by using Leibnitz's rule ([Weisstein 2011](#)):

$$\mathbf{f}_{1j} = \frac{\partial}{\partial \theta_j} \int_0^u \text{ROC}(t, \theta) dt = \int_0^u \frac{\partial}{\partial \theta_j} \text{ROC}(t, \theta) dt \quad j = 1, \dots, k$$

When  $\theta_j$  corresponds with the slope parameter  $\alpha$ , we obtain the following partial derivative:

$$\frac{\partial}{\partial \alpha} \text{pAUC}(u) = \int_0^u \phi\{\mathbf{x}'\boldsymbol{\beta} + \alpha\Phi^{-1}(t)\}\Phi^{-1}(t) dt$$

The partial derivative of  $f(\theta)$  [ $\text{pAUC}(u)$ ] for  $\beta_0$  is the following:

$$\frac{\partial}{\partial \beta_0} \text{pAUC}(u) = \int_0^u \phi\{\mathbf{x}'\boldsymbol{\beta} + \alpha\Phi^{-1}(t)\} dt$$

For a nonintercept coefficient, we obtain the following:

$$\frac{\partial}{\partial \beta_i} \text{pAUC}(u) = \int_0^u x_i \phi\{\mathbf{x}'\boldsymbol{\beta} + \alpha\Phi^{-1}(t)\} dt$$

We can estimate each of these integrals by numeric integration, plugging in the estimates  $\hat{\beta}$  and  $\hat{\alpha}$  for the parameters. This, together with the previously calculated estimate  $\widehat{\mathbf{V}}$ , provides an estimate of the asymptotic covariance of  $f(\hat{\theta}) = \widehat{\text{pAUC}}(u)$ , which allows us to perform further statistical inference on  $\widehat{\text{pAUC}}(u)$ .

## Estimating equations estimation

When we fit a model using the [Alonzo and Pepe \(2002\)](#) estimating equations method, we use the bootstrap to perform inference on the ROC curve summary parameters. Each bootstrap sample provides a sample of the coefficient estimates  $\boldsymbol{\beta}$  and the slope estimates  $\alpha$ . Using the formulas in [Parametric model: Summary parameter definition](#) under *Methods and formulas*, we can obtain an estimate of the ROC, false-positive rate, or AUC for each resample. Using numeric integration (with the trapezoidal approximation), we can also estimate the  $\text{pAUC}$  of the resample.

By making these calculations, we obtain a bootstrap sample of our summary parameter estimate. We then obtain bootstrap standard errors, normal approximation confidence intervals, percentile confidence intervals, and bias-corrected confidence intervals using this bootstrap sample. Further details can be found in [R] [bootstrap](#).

## Description

Under parametric estimation, `rocregplot` plots the fitted ROC curves for specified covariate values and classifiers. If `rocreg`, `probit` or `rocreg`, `probit ml` were previously used, the false-positive rates (for specified ROC values) and ROC values (for specified false-positive rates) for each curve may also be plotted, along with confidence intervals.

Under nonparametric estimation, `rocregplot` will plot the fitted ROC curves using the `_fpr_*` and `_roc_*` variables produced by `rocreg`. Point estimates and confidence intervals for false-positive rates and ROC values that were computed in `rocreg` may be plotted as well.

## Quick start

Plot ROC curve after any `rocreg` command

```
rocregplot
```

Name graph `mygraph` and save as `myfile.gph`

```
rocregplot, name(mygraph) saving(myfile)
```

Plot ROC curve only for `v2` after fitting a model with `v1` and `v2`

```
rocregplot, classvars(v2)
```

Add bias-corrected CI for the ROC value at a false-positive rate of 0.7 from estimation with bootstrap resampling that specified `roc(.7)`

```
rocregplot, btype(bc)
```

*Plots following parametric estimation only*

Plot curve evaluated at `x = 30` and `x = 50`

```
rocregplot, at1(x=30) at2(x=50)
```

After bootstrap resampling with resampled observations saved in `myfile.dta`

```
rocregplot, at1(x=30) at2(x=50) bfile(myfile)
```

And draw CI for ROC values at false-positive rates 0.1, 0.2, and 0.3

```
rocregplot, at1(x=30) at2(x=50) roc(.1 .2 .3) bfile(myfile)
```

## Menu

Statistics > Epidemiology and related > ROC analysis > ROC curves after rocreg

## Syntax

Plot ROC curve after nonparametric analysis

```
rocregplot [, common_options boot_options]
```

Plot ROC curve after parametric analysis using bootstrap

```
rocregplot [, probit_options common_options boot_options]
```

Plot ROC curve after parametric analysis using maximum likelihood

```
rocregplot [, probit_options common_options]
```

## probit\_options

### Main

`at(varname=# ...)` requests that the covariates specified by `varname` be set to `#`. By default, `rocregplot` evaluates the function by setting each covariate to its mean value. This option causes the ROC curve to be evaluated at the value of the covariates listed in `at()` and at the mean of all unlisted covariates.

`at1(varname=# ...)`, `at2(varname=# ...)`, ..., `at10(varname=# ...)` specify that ROC curves (up to 10) be plotted on the same graph. `at1()`, `at2()`, ..., `at10()` work like the `at()` option. They request that the function be evaluated at the value of the covariates specified and at the mean of all unlisted covariates. `at1()` specifies the values of the covariates for the first curve, `at2()` specifies the values of the covariates for the second curve, and so on.

`roc(numlist)` specifies that estimated ROC values for given false-positive rates be graphed.

`invroc(numlist)` specifies that estimated false-positive rates for given ROC values be graphed.

`level(#)` specifies the confidence level, as a percentage, for confidence intervals. The default is `level(95)` or as set by `set level`; see [U] 20.8 Specifying the width of confidence intervals. `level()` may be specified with either `roc()` or `invroc()`.

### Curve

`line#opts(cline_options)` affects the rendition of ROC curve `#`. See [G-3] *cline\_options*.

## common\_options

### Main

`classvars(varlist)` restricts plotting ROC curves to specified classification variables.

`noreflines` suppresses plotting the reference line.

### Scatter

`plot#opts(scatter_options)` affects the rendition of classifier `#`'s false-positive rate and ROC scatter points. This option applies only to non-ROC covariate estimation graphing. See [G-2] **graph twoway scatter**.

### Reference line

`rlopts(cline_options)` affects the rendition of the reference line. See [G-3] *cline\_options*.

---

 Y axis, X axis, Titles, Legend, Overall
 

---

*twoway\_options* are any of the options documented in [G-3] *twoway\_options*, excluding `by()`. These include options for titling the graph (see [G-3] *title\_options*) and options for saving the graph to disk (see [G-3] *saving\_option*).

## boot\_options

---

 Bootstrap
 

---

`bfile(filename)` uses bootstrap replicates of parameters from `rocreg` stored in *filename* to estimate standard errors and confidence intervals of predictions. `bfile()` must be specified with either `roc()` or `invroc()` if parametric estimation with bootstrapping was used.

`btype(n | p | bc)` indicates the desired type of confidence interval rendering. `n` draws normal-based, `p` draws percentile, and `bc` draws bias-corrected confidence intervals for specified false-positive rates and ROC values in `roc()` and `invroc()`. The default is `btype(n)`.

## Remarks and examples

Remarks are presented under the following headings:

*Plotting covariate-specific ROC curves*  
*Plotting marginal ROC curves*

### Plotting covariate-specific ROC curves

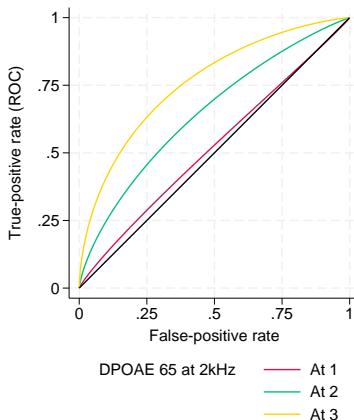

The `rocregplot` command is also demonstrated in [R] [rocreg](#). We will further demonstrate its use with several examples. Particularly, we will show how `rocregplot` can draw the ROC curves of covariate models that have been fit using `rocreg`.

#### ► Example 1: Parametric ROC

In [example 6](#) of [R] [rocreg](#), we fit a probit ROC model to audiology test data from [Norton et al. \(2000\)](#). The estimating equation method of [Alonzo and Pepe \(2002\)](#) was used to fit the model. Gender and age were covariates that affected the control distribution of the classifier `y1` (DPOAE 65 at 2 kHz). Age was a ROC covariate for the model, so we fit separate ROC curves at each age.

Following [Janes, Longton, and Pepe \(2009\)](#), we draw the ROC curves for ages 30, 40, and 50 months. The `at1()`, `at2()`, and `at3()` options are used to specify the age covariates.

```
. use https://www.stata-press.com/data/r19/nhns
(Norton - neonatal audiology data)
. rocreg d y1, probit ctrlcov(currage male) ctrlmodel(linear) roccov(currage)
> cluster(id) bseed(56930) bsave(nhns2y1, replace)
(output omitted)
. rocregplot, at1(currage=30) at2(currage=40) at3(currage=50)
```

Here we use the default entries of the legend, which indicate the “at #” within the specified `at*` options and the classifier to which the curve corresponds. ROC curve one corresponds with `currage=30`, two with `currage=40`, and three with `currage=50`. The positive effect of age on the ROC curve is evident. At an age of 30 months (`currage=30`), the ROC curve of `y1` (DPOAE 65 at 2 kHz) is nearly equivalent to that of a noninformative test that gives equal probability to hearing loss. At age 50 months (`currage=50`), corresponding to some of the oldest children in the study, the ROC curve shows that test `y1` (DPOAE 65 at 2 kHz) is considerably more powerful than the noninformative test.

You may create your own legend by specifying the `legend()` option. The default legend is designed for the possibility of multiple covariates. Here we could change the legend entries to `currage` values and gain some extra clarity. However, this may not be feasible when there are many covariates present.

We can also use `rocregplot` after maximum likelihood estimation.

### ▷ Example 2: Maximum likelihood ROC

We return to the audiology study with frequency (`xf`), intensity (`x1`), and hearing loss severity (`xd`) covariates from [Stover et al. \(1996\)](#) that we examined in [example 10](#) of [\[R\] rocreg](#). Negative signal-to-noise ratio is again used as a classifier. Using maximum likelihood, we fit a probit model to these data with the indicated ROC covariates.

After fitting the model, we wish to compare the ROC curves of two covariate combinations. The first has an intensity value of 5.5 (the lowest intensity, corresponding to 55 decibels) and a frequency of 10.01 (the lowest frequency, corresponding to 1001 hertz). We give the first combination a hearing loss severity value of 0.5 (the lowest). The second covariate combination has the same frequency, but the highest intensity value of 6.5 (65 decibels). We give this second covariate set a higher severity value of 4. We will visually compare the two ROC curves resulting from these two covariate value combinations.

We specify false-positive rates of 0.7 first followed by 0.2 in the roc() option to visually compare the size of the ROC curve at large and small false-positive rates. Because maximum likelihood estimation was used to fit the model, a Wald confidence interval is produced for the estimated ROC value and false-positive rate parameters. Further details are found in *Methods and formulas*.

```
. use https://www.stata-press.com/data/r19/dp
(Stover - DPOAE test data)
. rocreg d nsnr, probit ctrlcov(xf xl) roccov(xf xl xd) ml cluster(id)
(output omitted)
. rocregplot, at1(xf=10.01, xl=5.5, xd=.5) at2(xf=10.01, xl=6.5, xd=4) roc(.7)
```

| .2  | .9499408    | .0179824  | .914696              | .9851856 |

The lower false-positive rate of 0.2 shows clearly distinguishable ROC values. Now, we specify option `invroc(.5)` to view how the false-positive rates vary at a ROC value of 0.5.

```
. rocregplot, at1(xf=10.01, xl=5.5, xd=.5) at2(xf=10.01, xl=6.5, xd=4) invroc(.5)
```

False-positive rate

Status : d  
Classifier: nsnr

Under covariates:

|    | at1   |  |  |
|----|-------|--|--|
| xf | 10.01 |  |  |
| xl | 5.5   |  |  |
| xd | .5    |  |  |

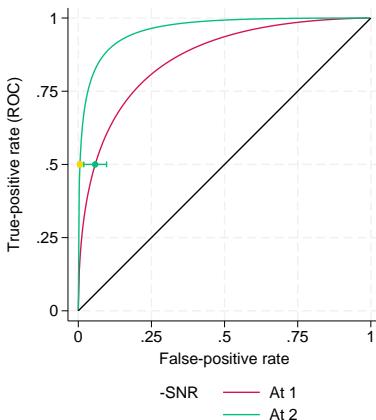

| invROC | Coefficient | Std. err. | [95% conf. interval] |          |
|--------|-------------|-----------|----------------------|----------|
| .5     | .0578036    | .0198626  | .0188736             | .0967336 |

Under covariates:

|    | at2   |  |  |
|----|-------|--|--|
| xf | 10.01 |  |  |
| xl | 6.5   |  |  |
| xd | 4     |  |  |

| invROC | Coefficient | Std. err. | [95% conf. interval] |          |
|--------|-------------|-----------|----------------------|----------|
| .5     | .0055624    | .0032645  | -.0008359            | .0119607 |

At a ROC value of 0.5, the false-positive rates for both curves are small and close to one another.

## □ Technical note

We can use the `testnl` command to support our visual observations with statistical inference. We use it to perform a Wald test of the null hypothesis that the two ROC curves just rendered are equal at a false-positive rate of 0.7.

```
. testnl normal(_b[i_cons]+10.01*_b[xf]+5.5*_b[x1]
> +.5*_b[xd]+_b[s_cons]*invnormal(.7)) =
> normal(_b[i_cons]+10.01*_b[xf]+6.5*_b[x1]
> + 4*_b[xd]+_b[s_cons]*invnormal(.7))
(1) normal(_b[i_cons]+10.01*_b[xf]+5.5*_b[x1] +.5*_b[xd]+_b[s_cons]*invnormal(.7)) =
 normal(_b[i_cons]+10.01*_b[xf]+6.5*_b[x1] + 4*_b[xd]+_b[s_cons]*invnormal(.7))
 chi2(1) = 4.53
 Prob > chi2 = 0.0332
```

The test is significant at the 0.05 level, and thus we find that the two curves are significantly different. Now, we will use `testnl` again to test equality of the false-positive rates for each curve with a ROC value of 0.5. The inverse ROC formula used is derived in [Methods and formulas](#).

```
. testnl normal((invnormal(.5)-(_b[i_cons]+10.01*_b[xf]+5.5*_b[x1]+.5*_b[xd]))
> /_b[s_cons]) =
> normal((invnormal(.5)-(_b[i_cons]+10.01*_b[xf]+6.5*_b[x1]+4*_b[xd]))
> /_b[s_cons])
(1) normal((invnormal(.5)-(_b[i_cons]+10.01*_b[xf]+5.5*_b[x1]+.5*_b[xd]))
> /_b[s_cons]) = normal((invnormal(.5)-(_b[i_cons]+10.01*_b[xf]+6.5*_b[x1]
> +4*_b[xd])) /_b[s_cons])
 chi2(1) = 8.01
 Prob > chi2 = 0.0046
```

We again reject the null hypothesis that the two curves are equal at the 0.05 level.

□

The model of our last example was also fit using the estimating equations method in [example 7](#) of [\[R\] rocreg](#). We will demonstrate `rocregplot` after that model fit as well.

► Example 3: Parametric ROC, invROC, and ROC value

In [example 2](#), we used `rocregplot` after a maximum likelihood model fit of the ROC curve for classifier `nsnr` and covariates `frequency` (`xf`), `intensity` (`x1`), and `hearing loss severity` (`xd`). The data were obtained from the audiology study described in [Stover et al. \(1996\)](#). In [example 7](#) of [\[R\] rocreg](#), we fit the model using the estimating equations method of [Alonzo and Pepe \(2002\)](#). Under this method, bootstrap resampling is used to make inferences. We saved 50 bootstrap replications in `nsnrf.dta`, which we re-create below.

We use `rocregplot` to draw the ROC curves for `nsnr` under the covariate values `xf = 10.01`, `x1 = 5.5`, and `xd = .5`, and `xf = 10.01`, `x1 = 6.5`, and `xd = 4`. The `at#()` options are used to specify the covariate values. The previous bootstrap results are made available to `rocregplot` with the `bfile()` option. As before, we will specify 0.2 and 0.7 as false-positive rates in the `roc()` option and 0.5 as a ROC value in the `invroc()` option. We do not specify `btype()` and thus our graph will contain normal-based bootstrap confidence bands, the default.

```

| xd | 4     |

(Replications based on 208 clusters in id)

| invROC | Observed coefficient | Bias     | Bootstrap std. err. | [95% conf. interval] |               |
|--------|----------------------|----------|---------------------|----------------------|---------------|
| .5     | .0043298             | -.000139 | .003835             | -.0031867            | .0118463 (N)  |
|        |                      |          |                     | .0002028             | .0136293 (P)  |
|        |                      |          |                     | .0012615             | .0192129 (BC) |

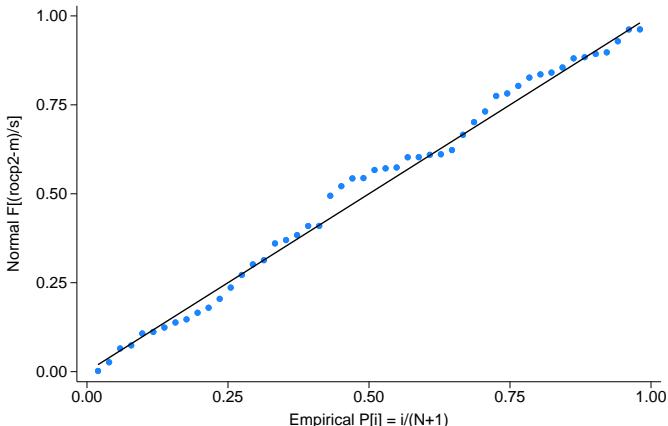

The point estimates of the ROC value and false-positive rate are both computed directly using the point estimates of the ROC coefficients. Calculation of the standard errors and confidence intervals is slightly more complicated. Essentially, we have stored a sample of our ROC covariate coefficient estimates in `nsnrf.dta`. We then calculate the ROC value or false-positive rate estimates using each set of coefficient estimates, resulting in a sample of point estimates. Then, the bootstrap standard error and confidence intervals are calculated based on these bootstrap samples. Details of the computation of the standard error and percentile confidence intervals can be found in [Methods and formulas](#) and in [\[R\] bootstrap](#).

As mentioned in [\[R\] rocreg](#), 50 resamples is a reasonable lower bound for obtaining bootstrap standard errors ([Mooney and Duval 1993](#)). However, it may be too low for obtaining percentile and bias-corrected confidence intervals. Normal-based confidence intervals are valid when the bootstrap distribution exhibits normality. See [\[R\] bootstrap postestimation](#) for more details.

We can assess the normality of the bootstrap distribution by using a normal probability plot. Stata provides this in the `pnorm` command (see [\[R\] Diagnostic plots](#)). We will use `nsnrf.dta` to draw a normal probability plot for the ROC estimate corresponding to a false-positive rate of 0.2. We use the covariate values `xf = 10.01`, `x1 = 6.5`, and `xd = 4`.

```
. use nsnrf
(bootstrap: rocregstat)
. generate double rocp2 = nsnr_b_i_cons + 10.01*nsnr_b_xf + 6.5*nsnr_b_x1 +
> 4*nsnr_b_xd+nsnr_b_s_cons*invnormal(.2)
. replace rocp2 = normal(rocp2)
(50 real changes made)
```

```
. pnorm rocp2
```

The closeness of the points to the horizontal line on the normal probability plot shows us that the bootstrap distribution is approximately normal. So it is reasonable to use the normal-based confidence intervals for ROC at a false-positive rate of 0.2 under covariate values  $xf = 10.01$ ,  $x1 = 6.5$ , and  $xd = 4$ .

◀

## Plotting marginal ROC curves

The `rocgplot` command can also be used after fitting models with no covariates. We will demonstrate this with an empirical ROC model fit in [\[R\] rocreg](#).

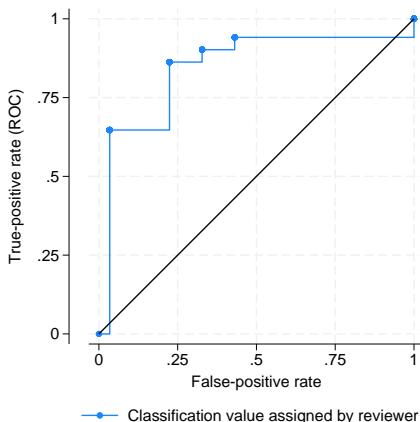

### ▷ Example 4: Nonparametric ROC

We run `rocgplot` after fitting the single-classifier, empirical ROC model shown in [example 1](#) of [\[R\] rocreg](#). There we empirically predicted the ROC curve of the classifier rating for the true status variable disease from the [Hanley and McNeil \(1982\)](#) data. The `rocreg` command saves variables `_roc_rating` and `_fpr_rating`, which give the ROC values and false-positive rates, respectively, for every value of `rating`. These variables are used by `rocgplot` to render the ROC curve.

```
. use https://www.stata-press.com/data/r19/hanley, clear
(Tomographic images)
. rocreg disease rating, noboot
Nonparametric ROC estimation Number of obs = 109
Control standardization: empirical
ROC method : empirical
Area under the ROC curve
 Status : disease
 Classifier: rating
```

| AUC | Observed coefficient | Bias | Bootstrap std. err. | [95% conf. interval] |
|-----|----------------------|------|---------------------|----------------------|
|     | .8407708             | .    | .                   | . (N)                |
|     |                      |      |                     | . (P)                |
|     |                      |      |                     | . (BC)               |

```
. rocregplot
```

We end our discussion of rocregplot by showing its use after a marginal probit model.

► Example 5: Maximum likelihood ROC, invROC, and ROC value

In [example 13](#) of [\[R\] rocreg](#), we fit a maximum-likelihood probit model to each classifier of the fictitious dataset generated from [Hanley and McNeil \(1983\)](#).

We use rocregplot after the original rocreg command to draw the ROC curves for classifiers mod1 and mod3. This is accomplished by specifying the two variables in the classvars() option. We will use the roc() option to obtain confidence intervals for ROC values at false-positive rates of 0.15 and 0.75. We will specify the invroc() option to obtain false-positive rate confidence intervals for a ROC value of 0.8. As mentioned previously, these are Wald confidence intervals.

First, we will view results for a false-positive rate of 0.75.

```
. use https://www.stata-press.com/data/r19/ct2, clear
(Reconstruction of CT images)
. rocreg status mod1 mod2 mod3, probit ml
(output omitted)
. rocregplot, classvars(mod1 mod3) roc(.75)
```

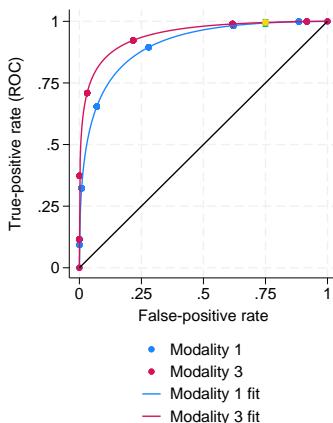

ROC curve

Status : status  
Classifier: mod1

| ROC | Coefficient | Std. err. | [95% conf. interval] |          |
|-----|-------------|-----------|----------------------|----------|
| .75 | .9931655    | .0069689  | .9795067             | 1.006824 |

Status : status  
Classifier: mod3

| ROC | Coefficient | Std. err. | [95% conf. interval] |          |
|-----|-------------|-----------|----------------------|----------|
| .75 | .9953942    | .0043435  | .9868811             | 1.003907 |

We see that the estimates for each of the two ROC curves are close. Because this is a marginal model, the actual false-positive rate and the true-positive rate for each observation are plotted in the graph. The added point estimates of the ROC value at false-positive rate 0.75 are shown as diamond (mod3) and circle (mod1) symbols in the upper-right-hand corner of the graph at FPR = 0.75. Confidence bands are also plotted at FPR = 0.75 but are so narrow that they are barely noticeable. Under both classifiers, the ROC value at 0.75 is very high. Now, we will compare these results to those with a lower false-positive rate of 0.15.

```
. rocregplot, classvars(mod1 mod3) roc(.15)
```

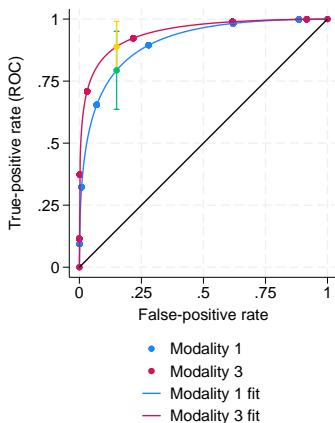

ROC curve

Status : status  
Classifier: mod1

| ROC | Coefficient | Std. err. | [95% conf. interval] |          |
|-----|-------------|-----------|----------------------|----------|
| .15 | .7934935    | .0801363  | .6364292             | .9505578 |

Status : status  
Classifier: mod3

| ROC | Coefficient | Std. err. | [95% conf. interval] |          |
|-----|-------------|-----------|----------------------|----------|
| .15 | .8888596    | .0520118  | .7869184             | .9908008 |

The ROC value for the false-positive rate of 0.15 is more separated in the two classifiers. Here we see that mod3 has a larger ROC value than mod1 for this false-positive rate, but the confidence intervals of the estimates overlap.

By specifying `invroc(.8)`, we obtain `invROC` confidence intervals corresponding to a ROC value of 0.8.

```
. rocregplot, classvars(mod1 mod3) invroc(.8)
```

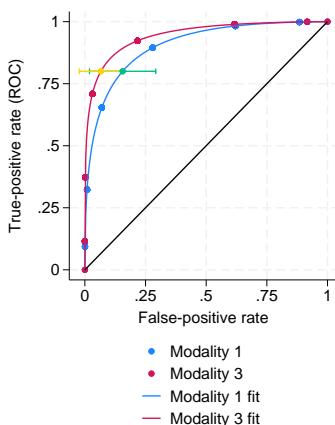

False-positive rate

Status : status  
Classifier: mod1

| invROC | Coefficient | Std. err. | [95% conf. interval] |          |
|--------|-------------|-----------|----------------------|----------|
| .8     | .1556435    | .069699   | .019036              | .2922509 |

Status : status  
Classifier: mod3

| invROC | Coefficient | Std. err. | [95% conf. interval] |          |
|--------|-------------|-----------|----------------------|----------|
| .8     | .0661719    | .045316   | -.0226458            | .1549896 |

For estimation of the false-positive rate at a ROC value of 0.8, the confidence intervals overlap. Both classifiers require only a small false-positive rate to achieve a ROC value of 0.8.

## Methods and formulas

Details on computation of the nonparametric ROC curve and the estimation of the parametric ROC curve model coefficients can be found in [R] [rocreg](#). Here we describe how to estimate the ROC values and false-positive rates of a parametric model. The cumulative distribution function  $g$  can be the standard normal cumulative distribution function.

Methods and formulas are presented under the following headings:

- [Parametric model: Summary parameter definition](#)
- [Maximum likelihood estimation](#)
- [Estimating equations estimation](#)

## Parametric model: Summary parameter definition

Conditioning on covariates  $\mathbf{x}$ , we have the following ROC curve model:

$$\text{ROC}(u) = g\{\mathbf{x}'\boldsymbol{\beta} + \alpha g^{-1}(u)\}$$

$\mathbf{x}$  can be constant, and  $\boldsymbol{\beta} = \beta_0$ , the constant intercept.

With simple algebra, we can solve this equation to obtain the false-positive rate value  $u$  for a ROC value of  $r$ :

$$u = g[\{g^{-1}(r) - \mathbf{x}'\boldsymbol{\beta}\}\alpha^{-1}]$$

## Maximum likelihood estimation

We allow maximum likelihood estimation under probit parametric models, so  $g = \Phi$ . The ROC value and false-positive rate parameters all have closed-form expressions in terms of the covariate values  $\mathbf{x}$ , coefficient vector  $\boldsymbol{\beta}$ , and slope parameter  $\alpha$ . Thus to estimate these two types of summary parameters, we use the delta method (Oehlert 1992; Phillips and Park 1988). Particularly, we use the `nlcom` command (see [R] `nlcom`) to implement the delta method.

Under maximum likelihood estimation, the coefficient estimates  $\widehat{\boldsymbol{\beta}}$  and slope estimate  $\widehat{\alpha}$  are asymptotically normal with variance matrix  $\mathbf{V}$ . For convenience, we rename the parameter vector  $[\boldsymbol{\beta}', \alpha]$  to the  $k$ -parameter vector  $\boldsymbol{\theta} = [\theta_1, \dots, \theta_k]$ . We will also explicitly refer to the conditioning of the ROC curve by  $\boldsymbol{\theta}$  in its mention as  $\text{ROC}(t, \boldsymbol{\theta})$ .

Under the delta method, the continuous scalar function of the estimate  $\widehat{\boldsymbol{\theta}}$ ,  $f(\widehat{\boldsymbol{\theta}})$  has asymptotic mean  $f(\boldsymbol{\theta})$  and asymptotic covariance

$$\widehat{\text{Var}}\{f(\widehat{\boldsymbol{\theta}})\} = \mathbf{f}\mathbf{V}\mathbf{f}'$$

where  $\mathbf{f}$  is the  $1 \times k$  matrix of derivatives for which

$$\mathbf{f}_{1j} = \frac{\partial f(\boldsymbol{\theta})}{\partial \theta_j} \quad j = 1, \dots, k$$

The asymptotic covariance of  $f(\widehat{\boldsymbol{\theta}})$  is estimated and then used in conjunction with  $f(\widehat{\boldsymbol{\theta}})$  for further inference, including Wald confidence intervals, standard errors, and hypothesis testing.

## Estimating equations estimation

When we fit a model using the Alonzo and Pepe (2002) estimating equations method, we use the bootstrap to perform inference on the ROC curve summary parameters. Each bootstrap sample provides a sample of the coefficient estimates  $\boldsymbol{\beta}$  and the slope estimates  $\alpha$ . Using the formulas above, we can obtain an estimate of the ROC value or false-positive rate for each resample.

By making these calculations, we obtain a bootstrap sample of our summary parameter estimate. We then obtain bootstrap standard errors, normal approximation confidence intervals, percentile confidence intervals, and bias-corrected confidence intervals using this bootstrap sample. Further details can be found in [R] `bootstrap`.

## Description

The above command is used to perform receiver operating characteristic (ROC) analyses with rating and discrete classification data.

The two variables *refvar* and *classvar* must be numeric. The reference variable indicates the true state of the observation, such as diseased and nondiseased or normal and abnormal, and must be coded as 0 and 1. The rating or outcome of the diagnostic test or test modality is recorded in *classvar*, which must be at least ordinal, with higher values indicating higher risk.

`roctab` performs nonparametric ROC analyses. By default, `roctab` calculates the area under the ROC curve. Optionally, `roctab` can plot the ROC curve, display the data in tabular form, and produce Lorenz-like plots.

See [\[R\] rocf](#) for a command that fits maximum-likelihood ROC models.

## Quick start

AUC, standard error, and CI for ROC curve of binary true state, `true`, as a function of classification variable `v`

```
roctab true v
```

Also plot the ROC curve

```
roctab true v, graph summary
```

Same as above, but plot sensitivity versus specificity instead of the ROC curve

```
roctab true v, specificity summary
```

Exact binomial CI instead of asymptotic normal CI for AUC estimate

```
roctab true v, binomial
```

Gini and Pietra indices

```
roctab true v, lorenz
```

## Menu

Statistics > Epidemiology and related > ROC analysis > Nonparametric ROC analysis without covariates

## Syntax

```
roctab refvar classvar [if] [in] [weight] [, options]
```

## Options

### Main

`lorenz` specifies that the Gini and Pietra indices be reported. Optionally, `graph` will plot the Lorenz-like curve.

`binomial` specifies that exact binomial confidence intervals be calculated.

`no label` specifies that numeric codes be displayed rather than value labels.

`detail` outputs a table displaying the sensitivity, specificity, the percentage of subjects correctly classified, and two likelihood ratios for each possible cutpoint of *classvar*.

`table` outputs a  $2 \times k$  contingency table displaying the raw data.

`bamber` specifies that the standard error for the area under the ROC curve be calculated using the method suggested by [Bamber \(1975\)](#). Otherwise, standard errors are obtained as suggested by [DeLong, DeLong, and Clarke-Pearson \(1988\)](#).

`hanley` specifies that the standard error for the area under the ROC curve be calculated using the method suggested by [Hanley and McNeil \(1982\)](#). Otherwise, standard errors are obtained as suggested by [DeLong, DeLong, and Clarke-Pearson \(1988\)](#).

`graph` produces graphical output of the ROC curve. If `lorenz` is specified, graphical output of a Lorenz-like curve will be produced.

`noreflines` suppresses plotting the 45-degree reference line from the graphical output of the ROC curve.

`summary` reports the area under the ROC curve, its standard error, and its confidence interval. If `lorenz` is specified, Lorenz indices are reported. This option is needed only when also specifying `graph`.

`specificity` produces a graph of sensitivity versus specificity instead of sensitivity versus  $(1 - \text{specificity})$ . `specificity` implies `graph`.

`level(#)` specifies the confidence level, as a percentage, for the confidence intervals. The default is `level(95)` or as set by `set level`; see [\[R\] level](#).

#### Plot

`plotopts(plot_options)` affects the rendition of the plotted ROC curve—the curve’s plotted points connected by lines. The *plot\_options* can affect the size and color of markers, whether and how the markers are labeled, and whether and how the points are connected; see [\[G-3\] marker\\_options](#), [\[G-3\] marker\\_label\\_options](#), and [\[G-3\] cline\\_options](#).

#### Reference line

`rlopts(cline_options)` affects the rendition of the reference line; see [\[G-3\] cline\\_options](#).

#### Add plots

`addplot(plot)` provides a way to add other plots to the generated graph; see [\[G-3\] addplot\\_option](#).

#### Y axis, X axis, Titles, Legend, Overall

*twoway\_options* are any of the options documented in [\[G-3\] twoway\\_options](#), excluding `by()`. These include options for titling the graph (see [\[G-3\] title\\_options](#)) and for saving the graph to disk (see [\[G-3\] saving\\_option](#)).

## Remarks and examples

Remarks are presented under the following headings:

[Introduction](#)  
[Nonparametric ROC curves](#)  
[Lorenz-like curves](#)

## Introduction

The `roctab` command provides nonparametric estimation of the ROC for a given classifier and true-status reference variable. The Lorenz curve functionality of `roctab`, which provides an alternative to standard ROC analysis, is discussed in *Lorenz-like curves*.

See [Pepe \(2003\)](#) for a discussion of ROC analysis. Pepe has posted Stata datasets and programs used to reproduce results presented in the book (<https://www.stata.com/bookstore/pepe.html>).

## Nonparametric ROC curves

The points on the nonparametric ROC curve are generated using each possible outcome of the diagnostic test as a classification cutpoint and computing the corresponding sensitivity and  $1 - \text{specificity}$ . These points are then connected by straight lines, and the area under the resulting ROC curve is computed using the trapezoidal rule.

### ▷ Example 1

[Hanley and McNeil \(1982\)](#) presented data from a study in which a reviewer was asked to classify, using a five-point scale, a random sample of 109 tomographic images from patients with neurological problems. The rating scale was as follows: 1 = definitely normal, 2 = probably normal, 3 = questionable, 4 = probably abnormal, and 5 = definitely abnormal. The true disease status was normal for 58 of the patients and abnormal for the remaining 51 patients.

Here we list 9 of the 109 observations:

```
. use https://www.stata-press.com/data/r19/hanley
(Tomographic images)
. list disease rating in 1/9
```

|    | disease | rating |
|----|---------|--------|
| 1. | 1       | 5      |
| 2. | 0       | 1      |
| 3. | 1       | 5      |
| 4. | 0       | 4      |
| 5. | 0       | 1      |
| 6. | 0       | 3      |
| 7. | 1       | 5      |
| 8. | 0       | 5      |
| 9. | 0       | 1      |

For each observation, `disease` identifies the true disease status of the subject (0 = normal, 1 = abnormal), and `rating` contains the classification value assigned by the reviewer.

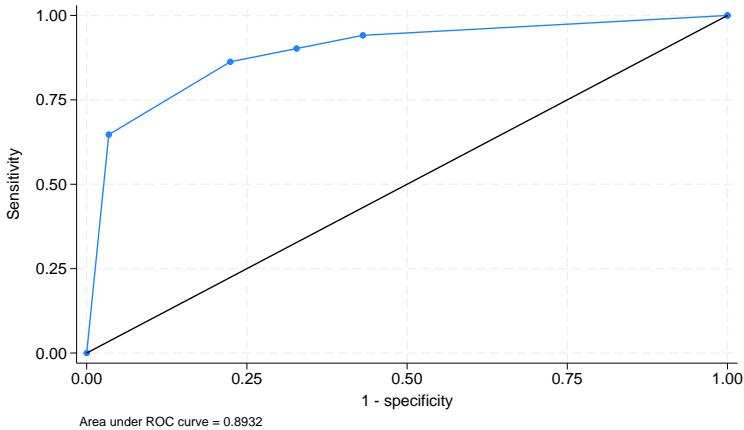

We can use `roctab` to calculate and plot the nonparametric ROC curve by specifying both the `summary` and `graph` options. By also specifying the `table` option, we obtain a contingency table summarizing our dataset.

```
. roctab disease rating, table graph summary
```

| True<br>disease<br>status of<br>subject | rating |   |   |    |    | Total |
|-----------------------------------------|--------|---|---|----|----|-------|
|                                         | 1      | 2 | 3 | 4  | 5  |       |
| 0                                       | 33     | 6 | 6 | 11 | 2  | 58    |
| 1                                       | 3      | 2 | 2 | 11 | 33 | 51    |
| Total                                   | 36     | 8 | 8 | 22 | 35 | 109   |

| Obs | ROC<br>area | Std. err. | Asymptotic normal<br>[95% conf. interval] |         |
|-----|-------------|-----------|-------------------------------------------|---------|
| 109 | 0.8932      | 0.0307    | 0.83295                                   | 0.95339 |

By default, `roctab` reports the area under the curve, its standard error, and its confidence interval. The `graph` option can be used to plot the ROC curve.

The ROC curve is plotted by computing the sensitivity and specificity using each value of the rating variable as a possible cutpoint. A point is plotted on the graph for each of the cutpoints. These plotted points are joined by straight lines to form the ROC curve, and the area under the ROC curve is computed using the trapezoidal rule.

We can tabulate the computed sensitivities and specificities for each of the possible cutpoints by specifying `detail`.

```
. roctab disease rating, detail
Detailed report of sensitivity and specificity
```

| Cutpoint | Sensitivity | Specificity | Correctly classified | LR+     | LR-    |
|----------|-------------|-------------|----------------------|---------|--------|
| ( >= 1 ) | 100.00%     | 0.00%       | 46.79%               | 1.0000  |        |
| ( >= 2 ) | 94.12%      | 56.90%      | 74.31%               | 2.1835  | 0.1034 |
| ( >= 3 ) | 90.20%      | 67.24%      | 77.98%               | 2.7534  | 0.1458 |
| ( >= 4 ) | 86.27%      | 77.59%      | 81.65%               | 3.8492  | 0.1769 |
| ( >= 5 ) | 64.71%      | 96.55%      | 81.65%               | 18.7647 | 0.3655 |
| ( > 5 )  | 0.00%       | 100.00%     | 53.21%               |         | 1.0000 |

| Obs | ROC area | Std. err. | Asymptotic normal<br>[95% conf. interval] |         |
|-----|----------|-----------|-------------------------------------------|---------|
| 109 | 0.8932   | 0.0307    | 0.83295                                   | 0.95339 |

Each cutpoint in the table indicates the ratings used to classify tomographs as being from an abnormal subject. For example, the first cutpoint ( $\geq 1$ ) indicates that all tomographs rated as 1 or greater are classified as coming from abnormal subjects. Because all tomographs have a rating of 1 or greater, all are considered abnormal. Consequently, all abnormal cases are correctly classified (sensitivity = 100%), but none of the normal patients is classified correctly (specificity = 0%). For the second cutpoint ( $\geq 2$ ), tomographs with ratings of 1 are classified as normal, and those with ratings of 2 or greater are classified as abnormal. The resulting sensitivity and specificity are 94.12% and 56.90%, respectively. Using this cutpoint, we correctly classified 74.31% of the 109 tomographs. Similar interpretations can be used on the remaining cutpoints. As mentioned, each cutpoint corresponds to a point on the nonparametric ROC curve. The first cutpoint ( $\geq 1$ ) corresponds to the point at (1,1), and the last cutpoint ( $> 5$ ) corresponds to the point at (0,0).

`detail` also reports two likelihood ratios suggested by Choi (1998): the likelihood ratio for a positive test result (LR+) and the likelihood ratio for a negative test result (LR-). The LR+ is the ratio of the probability of a positive test among the truly positive subjects to the probability of a positive test among the truly negative subjects. The LR- is the ratio of the probability of a negative test among the truly positive subjects to the probability of a negative test among the truly negative subjects. Choi points out that LR+ corresponds to the slope of the line from the origin to the point on the ROC curve determined by the cutpoint. Similarly, LR- corresponds to the slope from the point (1,1) to the point on the ROC curve determined by the cutpoint.

By default, roctab calculates the standard error for the area under the curve by using an algorithm suggested by DeLong, DeLong, and Clarke-Pearson (1988) and asymptotic normal confidence intervals. Optionally, standard errors based on methods suggested by Bamber (1975) or Hanley and McNeil (1982) can be computed by specifying `bamber` or `hanley`, respectively, and an exact binomial confidence interval can be obtained by specifying `binomial`.

```
. roctab disease rating, bamber
```

| Obs | ROC area | Bamber std. err. | Asymptotic normal [95% conf. interval] |         |
|-----|----------|------------------|----------------------------------------|---------|
| 109 | 0.8932   | 0.0306           | 0.83317                                | 0.95317 |

```
. roctab disease rating, hanley binomial
```

| Obs | ROC area | Hanley std. err. | Binomial exact [95% conf. interval] |         |
|-----|----------|------------------|-------------------------------------|---------|
| 109 | 0.8932   | 0.0320           | 0.81559                             | 0.94180 |

◀

## Lorenz-like curves

For applications where it is known that the risk status increases or decreases monotonically with increasing values of the diagnostic test, the ROC curve and associated indices are useful in assessing the overall performance of a diagnostic test. When the risk status does not vary monotonically with increasing values of the diagnostic test, however, the resulting ROC curve can be nonconvex and its indices can be unreliable. For these situations, Lee (1999) proposed an alternative to the ROC analysis based on Lorenz-like curves and the associated Pietra and Gini indices.

Lee (1999) mentions at least three specific situations where results from Lorenz curves are superior to those obtained from ROC curves: 1) a diagnostic test with similar means but very different standard deviations in the abnormal and normal populations, 2) a diagnostic test with bimodal distributions in either the normal or abnormal population, and 3) a diagnostic test distributed symmetrically in the normal population and skewed in the abnormal.

When the risk status increases or decreases monotonically with increasing values of the diagnostic test, the ROC and Lorenz curves yield interchangeable results.

## ▷ Example 2

To illustrate the use of the `lorenz` option, we constructed a fictitious dataset that yields results similar to those presented in Table III of Lee (1999). The data assume that a 12-point rating scale was used to classify 442 diseased and 442 healthy subjects. We list a few of the observations.

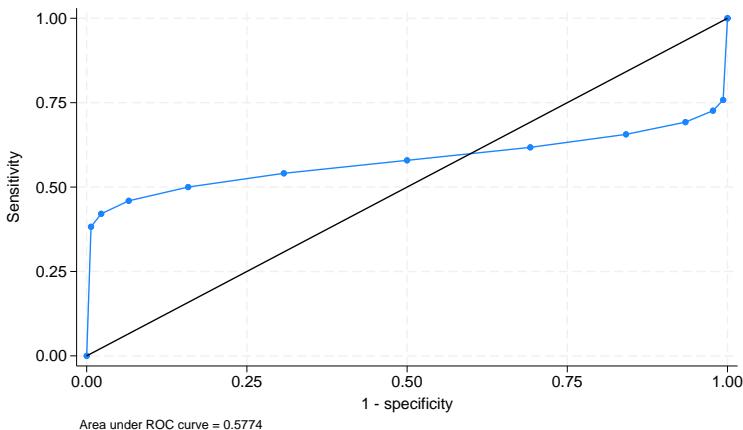

```
. use https://www.stata-press.com/data/r19/lorenz, clear
. list in 1/7, noobs sep(0)
```

| disease | class | pop |
|---------|-------|-----|
| 0       | 5     | 66  |
| 1       | 11    | 17  |
| 0       | 6     | 85  |
| 0       | 3     | 19  |
| 0       | 10    | 19  |
| 0       | 2     | 7   |
| 1       | 4     | 16  |

The data consist of 24 observations: 12 observations from diseased individuals and 12 from nondiseased individuals. Each observation corresponds to one of the 12 classification values of the rating-scale variable, `class`. The number of subjects represented by each observation is given by the `pop` variable, making this a frequency-weighted dataset. The data were generated assuming a binormal distribution of the latent variable with similar means for the normal and abnormal populations but with the standard deviation for the abnormal population five times greater than that of the normal population.

```
. roctab disease class [fweight=pop], graph summary
```

| Obs | ROC area | Std. err. | Asymptotic normal<br>[95% conf. interval] |         |
|-----|----------|-----------|-------------------------------------------|---------|
| 884 | 0.5774   | 0.0215    | 0.53517                                   | 0.61959 |

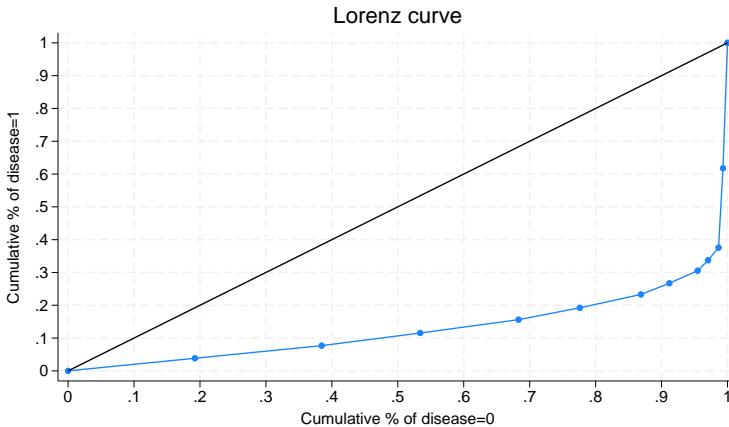

The resulting ROC curve is nonconvex or, as termed by Lee, “wiggly”. Lee argues that for this and similar situations, the Lorenz curve and indices are preferred.

```
. roctab disease class [fweight=pop], lorenz summary graph
```

```
Lorenz curve
```

```
Pietra index = 0.6493
```

```
Gini index = 0.7441
```

Like ROC curves, a more bowed Lorenz curve suggests a better diagnostic test. This bowedness is quantified by the Pietra index, which is geometrically equivalent to twice the largest triangle that can be inscribed in the area between the curve and the diagonal line, and the Gini index, which is equivalent to twice the area between the Lorenz curve and the diagonal. [Lee \(1999\)](#) provides several additional interpretations for the Pietra and Gini indices.

◀

## Stored results

roctab stores the following in `r()`:

### Scalars

|                        |                                                    |
|------------------------|----------------------------------------------------|

### Matrices

`r(detail)` matrix with details on sensitivity and specificity for each cutpoint (detail only)

## Methods and formulas

Assume that we applied a diagnostic test to each of  $N_n$  normal and  $N_a$  abnormal subjects. Further assume that the higher the outcome value of the diagnostic test, the higher the risk of the subject being abnormal. Let  $\hat{\theta}$  be the estimated area under the curve, and let  $X_i, i = 1, 2, \dots, N_a$  and  $Y_j, j = 1, 2, \dots, N_n$  be the values of the diagnostic test for the abnormal and normal subjects, respectively.

The points on the nonparametric ROC curve are generated using each possible outcome of the diagnostic test as a classification cutpoint and computing the corresponding sensitivity and  $1 - \text{specificity}$ . These points are then connected by straight lines, and the area under the resulting ROC curve is computed using the trapezoidal rule.

The default standard error for the area under the ROC curve is computed using the algorithm described by DeLong, DeLong, and Clarke-Pearson (1988). For each abnormal subject,  $i$ , define

$$V_{10}(X_i) = \frac{1}{N_n} \sum_{j=1}^{N_n} \psi(X_i, Y_j)$$

and for each normal subject,  $j$ , define

$$V_{01}(Y_j) = \frac{1}{N_a} \sum_{i=1}^{N_a} \psi(X_i, Y_j)$$

where

$$\psi(X, Y) = \begin{cases} 1 & Y < X \\ \frac{1}{2} & Y = X \\ 0 & Y > X \end{cases}$$

Define

$$S_{10} = \frac{1}{N_a - 1} \sum_{i=1}^{N_a} \{V_{10}(X_i) - \hat{\theta}\}^2$$

and

$$S_{01} = \frac{1}{N_n - 1} \sum_{j=1}^{N_n} \{V_{01}(Y_j) - \hat{\theta}\}^2$$

The variance of the estimated area under the ROC curve is given by

$$\text{var}(\hat{\theta}) = \frac{1}{N_a} S_{10} + \frac{1}{N_n} S_{01}$$

The Hanley standard error for the area under the ROC curve is computed using the algorithm described by Hanley and McNeil (1982). It requires the calculation of two quantities:  $Q_1$  is  $\text{Pr}(\text{two randomly selected abnormal subjects will both have a higher score than a randomly selected normal subject})$ , and  $Q_2$  is  $\text{Pr}(\text{one randomly selected abnormal subject will have a higher score than any two randomly selected normal subjects})$ . The Hanley and McNeil variance of the estimated area under the ROC curve is

$$\text{var}(\hat{\theta}) = \frac{\hat{\theta}(1 - \hat{\theta}) + (N_a - 1)(Q_1 - \hat{\theta}^2) + (N_n - 1)(Q_2 - \hat{\theta}^2)}{N_a N_n}$$

The Bamber standard error for the area under the ROC curve is computed using the algorithm described by Bamber (1975). For any two  $Y$  values,  $Y_j$  and  $Y_k$ , and any  $X_i$  value, define

$$b_{yyx} = p(Y_j, Y_k < X_i) + p(X_i < Y_j, Y_k) - 2p(Y_j < X_i < Y_k)$$

and similarly, for any two  $X$  values,  $X_i$  and  $X_l$ , and any  $Y_j$  value, define

$$b_{xxy} = p(X_i, X_l < Y_j) + p(Y_j < X_i, X_l) - 2p(X_i < Y_j < X_l)$$

Bamber's unbiased estimate of the variance for the area under the ROC curve is

$$\text{var}(\hat{\theta}) = \frac{1}{4}(N_a - 1)(N_n - 1)\{p(X \neq Y) + (N_a - 1)b_{xxy} + (N_n - 1)b_{yyx} - 4(N_a + N_n - 1)(\hat{\theta} - 0.5)^2\}$$

Asymptotic confidence intervals are constructed and reported by default, assuming a normal distribution for the area under the ROC curve.

Exact binomial confidence intervals are calculated as described in [R] ci, with  $p$  equal to the area under the ROC curve.

## Description

`rreg` performs one version of robust regression of *depvar* on *indepvars*.

Also see [Robust standard errors](#) in [\[R\] regress](#) for standard regression with robust variance estimates and [\[R\] qreg](#) for quantile (including median) regression.

## Quick start

Robust regression of *y* on *x*

```
rreg y x
```

Add a categorical covariate *a* using factor-variable syntax

```
rreg y x i.a
```

Same as above, but set the tuning parameter to 8

```
rreg y x i.a, tune(8)
```

Generate a new variable *wvar* containing the final weight for each observation

```
rreg y x i.a, genwt(wvar)
```

Set confidence level to 99%

```
rreg y x i.a, level(99)
```

## Menu

Statistics > Linear models and related > Other > Robust regression

## Syntax

```
rreg depvar [indepvars] [if] [in] [, options]
```

| <i>options</i>                    | Description                                                                                                                                      |

*indepvars* may contain factor variables; see [U] 11.4.3 **Factor variables**.

*depvar* and *indepvars* may contain time-series operators; see [U] 11.4.4 **Time-series varlists**.

by, collect, mfp, mi estimate, rolling, and statsby are allowed; see [U] 11.1.10 **Prefix commands**.

coeflegend does not appear in the dialog box.

See [U] 20 **Estimation and postestimation commands** for more capabilities of estimation commands.

## Options

### Model

`tune(#)` is the biweight tuning constant. The default is `tune(7)`, meaning seven times the median absolute deviation from the median residual; see *Methods and formulas*. Lower tuning constants downweight outliers rapidly but may lead to unstable estimates (less than 6 is not recommended). Higher tuning constants produce milder downweighting.

### Reporting

`level(#)`; see [R] **Estimation options**.

`genwt(newvar)` creates the new variable *newvar* containing the weights assigned to each observation.

`display_options`: `nocl`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `no1stretch`; see [R] **Estimation options**.

### Optimization

`optimization_options`: `iterate(#)`, `tolerance(#)`, `[no]log`. `iterate()` specifies the maximum number of iterations; iterations stop when the maximum change in weights drops below `tolerance()`; and `log/nolog` specifies whether to show the iteration log (see `set iterlog` in [R] *set iter*). These options are seldom used.

graph allows you to graphically watch the convergence of the iterative technique. The weights obtained from the most recent round of estimation are graphed against the weights obtained from the previous round.

The following option is available with rreg but is not shown in the dialog box:

coeflegend; see [R] Estimation options.

## Remarks and examples

rreg first performs an initial screening based on Cook’s distance  $> 1$  to eliminate gross outliers before calculating starting values and then performs Huber iterations followed by biweight iterations, as suggested by Li (1985).

### ▷ Example 1

We wish to examine the relationship between mileage rating, weight, and location of manufacture for the 74 cars in the auto.dta. As a point of comparison, we begin by fitting an ordinary regression:

```
. use https://www.stata-press.com/data/r19/auto
(1978 automobile data)
. regress mpg weight foreign
```

| Source   | SS         | df | MS         | Number of obs | = | 74     |
|----------|------------|----|------------|---------------|---|--------|
| Model    | 1619.2877  | 2  | 809.643849 | F(2, 71)      | = | 69.75  |
| Residual | 824.171761 | 71 | 11.608053  | Prob > F      | = | 0.0000 |
|          |            |    |            | R-squared     | = | 0.6627 |
|          |            |    |            | Adj R-squared | = | 0.6532 |
| Total    | 2443.45946 | 73 | 33.4720474 | Root MSE      | = | 3.4071 |

| mpg     | Coefficient | Std. err. | t      | P> t  | [95% conf. interval] |
|---------|-------------|-----------|--------|-------|----------------------|
| weight  | -.0065879   | .0006371  | -10.34 | 0.000 | -.0078583 -.0053175  |
| foreign | -1.650029   | 1.075994  | -1.53  | 0.130 | -3.7955 .4954422     |
| _cons   | 41.6797     | 2.165547  | 19.25  | 0.000 | 37.36172 45.99768    |

We now compare this with the results from rreg:

```
. rreg mpg weight foreign
Huber iteration 1: Maximum difference in weights = .80280176
Huber iteration 2: Maximum difference in weights = .2915438
Huber iteration 3: Maximum difference in weights = .08911171
Huber iteration 4: Maximum difference in weights = .02697328
Biweight iteration 5: Maximum difference in weights = .29186818
Biweight iteration 6: Maximum difference in weights = .11988101
Biweight iteration 7: Maximum difference in weights = .03315872
Biweight iteration 8: Maximum difference in weights = .00721325
Robust regression
```

| mpg     | Coefficient | Std. err. | t      | P> t  | [95% conf. interval] |
|---------|-------------|-----------|--------|-------|----------------------|
| weight  | -.0063976   | .0003718  | -17.21 | 0.000 | -.007139 -.0056562   |
| foreign | -3.182639   | .627964   | -5.07  | 0.000 | -4.434763 -1.930514  |
| _cons   | 40.64022    | 1.263841  | 32.16  | 0.000 | 38.1202 43.16025     |

Note the large change in the foreign coefficient.

□ Technical note

It would have been better if we had fit the previous robust regression by typing `rreg mpg weight foreign, genwt(w)`. The new variable, `w`, would then contain the estimated weights. Let's pretend that we did this:

```
. rreg mpg weight foreign, genwt(w)
(output omitted)
. summarize w, detail
```

| Robust Regression Weight |          |          |             |           |
|--------------------------|----------|----------|-------------|-----------|
| Percentiles              | Smallest |          |             |           |
| 1%                       | 0        | 0        |             |           |
| 5%                       | .0442957 | 0        |             |           |
| 10%                      | .4674935 | 0        | Obs         | 74        |
| 25%                      | .8894815 | .0442957 | Sum of wgt. | 74        |
| 50%                      | .9690193 |          | Mean        | .8509966  |
|                          |          | Largest  | Std. dev.   | .2746451  |
| 75%                      | .9949395 | .9996715 |             |           |
| 90%                      | .9989245 | .9996953 | Variance    | .0754299  |
| 95%                      | .9996715 | .9997343 | Skewness    | -2.287952 |
| 99%                      | .9998585 | .9998585 | Kurtosis    | 6.874605  |

We discover that 3 observations in our data were dropped altogether (they have weight 0). We could further explore our data:

```
. sort w
. list make mpg weight w if w <.467, sep(0)
```

|    | make           | mpg | weight | w         |
|----|----------------|-----|--------|-----------|
| 1. | Datsun 210     | 35  | 2,020  | 0         |
| 2. | Subaru         | 35  | 2,050  | 0         |
| 3. | VW Diesel      | 41  | 2,040  | 0         |
| 4. | Plym. Arrow    | 28  | 3,260  | .04429567 |
| 5. | Cad. Seville   | 21  | 4,290  | .08241943 |
| 6. | Toyota Corolla | 31  | 2,200  | .10443129 |
| 7. | Olds 98        | 21  | 4,060  | .28141296 |

Being familiar with the automobile data, we immediately spotted two things: the VW is the only diesel car in our data, and the weight recorded for the Plymouth Arrow is incorrect.

## ▷ Example 2

If we specify no explanatory variables, `rreg` produces a robust estimate of the mean:

```
. rreg mpg
 Huber iteration 1: Maximum difference in weights = .64471879
 Huber iteration 2: Maximum difference in weights = .05098336
 Huber iteration 3: Maximum difference in weights = .0099887
 Biweight iteration 4: Maximum difference in weights = .25197391
 Biweight iteration 5: Maximum difference in weights = .00358606
Robust regression Number of obs = 74
 F(0, 73) = 0.00
 Prob > F = .
```

| mpg   | Coefficient | Std. err. | t     | P> t  | [95% conf. interval] |          |
|-------|-------------|-----------|-------|-------|----------------------|----------|
| _cons | 20.68825    | .641813   | 32.23 | 0.000 | 19.40912             | 21.96738 |

The estimate is given by the coefficient on `_cons`. The mean is 20.69 with an estimated standard error of 0.6418. The 95% confidence interval is [19.4, 22.0]. By comparison, `ci means` (see [R] `ci`) gives us the standard calculation:

```
. ci means mpg
 Variable | Obs Mean Std. err. [95% conf. interval]
 -----+-----
 mpg | 74 21.2973 .6725511 19.9569 22.63769
```

Stata has an active user community working in the area of robust statistics. You may also be interested in robust estimators and outlier detection tools from [Verardi and McCathie \(2012\)](#), [Verardi and Dehon \(2010\)](#), [Jann \(2010\)](#), and [Verardi and Croux \(2009\)](#), to name a few. See [R] `ssc` for how to install community-contributed packages.

## Stored results

rreg stores the following in `e()`:

### Scalars

|                      |                             |
|----------------------|-----------------------------|
| <code>e(N)</code>    | number of observations      |
| <code>e(mss)</code>  | model sum of squares        |
| <code>e(df_m)</code> | model degrees of freedom    |
| <code>e(rss)</code>  | residual sum of squares     |
| <code>e(df_r)</code> | residual degrees of freedom |
| <code>e(r2)</code>   | $R^2$                       |
| <code>e(r2_a)</code> | adjusted $R^2$              |
| <code>e(F)</code>    | $F$ statistic               |
| <code>e(rmse)</code> | root mean squared error     |
| <code>e(rank)</code> | rank of $e(V)$              |

### Macros

|                            |                                      |
|----------------------------|--------------------------------------|
| <code>e(cmd)</code>        | rreg                                 |
| <code>e(cmdline)</code>    | command as typed                     |
| <code>e(depvar)</code>     | name of dependent variable           |
| <code>e(genwt)</code>      | variable containing the weights      |
| <code>e(title)</code>      | title in estimation output           |
| <code>e(model)</code>      | ols                                  |
| <code>e(properties)</code> | b V                                  |
| <code>e(predict)</code>    | program used to implement predict    |
| <code>e(marginsok)</code>  | predictions allowed by margins       |
| <code>e(asbalanced)</code> | factor variables fvset as asbalanced |
| <code>e(asobserved)</code> | factor variables fvset as asobserved |

### Matrices

|                   |                                              |
|-------------------|----------------------------------------------|
| <code>e(b)</code> | coefficient vector                           |
| <code>e(V)</code> | variance–covariance matrix of the estimators |

### Functions

|                        |                         |
|------------------------|-------------------------|
| <code>e(sample)</code> | marks estimation sample |
|------------------------|-------------------------|

In addition to the above, the following is stored in `r()`:

### Matrices

|                       |                                                                                                                       |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------|
| <code>r(table)</code> | matrix containing the coefficients with their standard errors, test statistics, $p$ -values, and confidence intervals |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------|

Note that results stored in `r()` are updated when the command is replayed and will be replaced when any `r`-class command is run after the estimation command.

## Methods and formulas

See Berk (1990), Goodall (1983), and Rousseeuw and Leroy (1987) for a general description of the issues and methods. Hamilton (1991a, 1992) provides a more detailed description of rreg and some Monte Carlo evaluations.

rreg begins by fitting the regression (see [R] regress), calculating Cook's  $D$  (see [R] predict and [R] regress postestimation), and excluding any observation for which  $D > 1$ .

Thereafter, rreg works iteratively: it performs a regression, calculates case weights from absolute residuals, and regresses again using those weights. Iterations stop when the maximum change in weights drops below `tolerance()`. Weights derive from one of two weight functions, Huber weights and biweights. Huber weights (Huber 1964) are used until convergence, and then, from that result, biweights are used until convergence. The biweight was proposed by Beaton and Tukey (1974, 151–152) after

the Princeton robustness study (Andrews et al. 1972) had compared various estimators. Both weighting functions are used because Huber weights have problems dealing with severe outliers, whereas biweights sometimes fail to converge or have multiple solutions. The initial Huber weighting should improve the behavior of the biweight estimator.

In Huber weighting, cases with small residuals receive weights of 1; cases with larger residuals receive gradually smaller weights. Let  $e_i = y_i - \mathbf{X}_i \mathbf{b}$  represent the  $i$ th-case residual. The  $i$ th scaled residual  $u_i = e_i/s$  is calculated, where  $s = M/0.6745$  is the residual scale estimate and  $M = \text{med}(|e_i - \text{med}(e_i)|)$  is the median absolute deviation from the median residual. Huber estimation obtains case weights:

$$w_i = \begin{cases} 1 & \text{if } |u_i| \leq c_h \\ c_h/|u_i| & \text{otherwise} \end{cases}$$

rreg defines  $c_h = 1.345$ , so downweighting begins with cases whose absolute residual exceeds  $(1.345/0.6745)M \approx 2M$ .

With biweights, all cases with nonzero residuals receive some downweighting, according to the smoothly decreasing biweight function

$$w_i = \begin{cases} \{1 - (u_i/c_b)^2\}^2 & \text{if } |u_i| \leq c_b \\ 0 & \text{otherwise} \end{cases}$$

where  $c_b = 4.685 \times \text{tune}()/7$ . Thus when  $\text{tune}() = 7$ , cases with absolute residuals of  $(4.685/0.6745)M \approx 7M$  or more are assigned 0 weight and thus are effectively dropped. Goodall (1983, 377) suggests using a value between 6 and 9, inclusive, for  $\text{tune}()$  in the biweight case and states that performance is good between 6 and 12, inclusive.

The tuning constants  $c_h = 1.345$  and  $c_b = 4.685$  (assuming  $\text{tune}()$  is set at the default 7) give rreg about 95% of the efficiency of OLS when applied to data with normally distributed errors (Hamilton 1991b). Lower tuning constants downweight outliers more drastically (but give up Gaussian efficiency); higher tuning constants make the estimator more like OLS.

Standard errors are calculated using the pseudovalues approach described in Street, Carroll, and Rupert (1988).

## Acknowledgment

The current version of rreg is due to the work of Lawrence Hamilton of the Department of Sociology at the University of New Hampshire.

## Postestimation commands

The following postestimation commands are available after `rreg`:

| Command                      | Description                                                                                       |
|------------------------------|---------------------------------------------------------------------------------------------------|
| <code>contrast</code>        | contrasts and ANOVA-style joint tests of parameters                                               |
| <code>estat summarize</code> | summary statistics for the estimation sample                                                      |
| <code>estat vce</code>       | variance–covariance matrix of the estimators (VCE)                                                |
| <code>estimates</code>       | cataloging estimation results                                                                     |
| <code>etable</code>          | table of estimation results                                                                       |
| * <code>forecast</code>      | dynamic forecasts and simulations                                                                 |
| <code>lincom</code>          | point estimates, standard errors, testing, and inference for linear combinations of parameters    |
| <code>margins</code>         | marginal means, predictive margins, marginal effects, and average marginal effects                |
| <code>marginsplot</code>     | graph the results from margins (profile plots, interaction plots, etc.)                           |
| <code>nlcom</code>           | point estimates, standard errors, testing, and inference for nonlinear combinations of parameters |
| <code>predict</code>         | predictions and their SEs, residuals, etc.                                                        |
| <code>predictnl</code>       | point estimates, standard errors, testing, and inference for generalized predictions              |
| <code>pwcompare</code>       | pairwise comparisons of parameters                                                                |
| <code>test</code>            | Wald tests of simple and composite linear hypotheses                                              |
| <code>testnl</code>          | Wald tests of nonlinear hypotheses                                                                |

\*`forecast` is not appropriate with `mi` estimation results.

# predict

## Description for predict

`predict` creates a new variable containing predictions such as linear predictions, standard errors, residuals, and diagonal elements of the hat matrix.

## Menu for predict

Statistics > Postestimation

## Syntax for predict

```
predict [type] newvar [if] [in] [, statistic]
```

| <i>statistic</i> | Description |
|------------------|-------------|
|------------------|-------------|

---

Main

|                        |                                         |
|------------------------|-----------------------------------------|
| <code>xb</code>        | linear prediction; the default          |
| <code>stdp</code>      | standard error of the linear prediction |
| <code>residuals</code> | residuals                               |
| <code>hat</code>       | diagonal elements of the hat matrix     |

---

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

## Options for predict

Main

`xb`, the default, calculates the linear prediction.

`stdp` calculates the standard error of the linear prediction.

`residuals` calculates the residuals.

`hat` calculates the diagonal elements of the hat matrix. You must have run the `rreg` command with the `genwt()` option.

# margins

## Description for margins

`margins` estimates margins of response for linear predictions.

## Menu for margins

Statistics > Postestimation

## Syntax for margins

```
margins [marginlist] [, options]
```

```
margins [marginlist] , predict(statistic ...) [options]
```

| <i>statistic</i>              | Description                           |
|-------------------------------|---------------------------------------|
| <code>xb</code>               | linear prediction; the default        |
| <code>stdp</code>             | not allowed with <code>margins</code> |
| <code><u>r</u>esiduals</code> | not allowed with <code>margins</code> |
| <code>hat</code>              | not allowed with <code>margins</code> |

Statistics not allowed with `margins` are functions of stochastic quantities other than  $e(b)$ .

For the full syntax, see [\[R\] margins](#).

## Also see

[\[R\] rreg](#) — Robust regression

[\[U\] 20 Estimation and postestimation commands](#)

[Description](#)[Options](#)[Acknowledgment](#)[Quick start](#)[Remarks and examples](#)[References](#)[Menu](#)[Stored results](#)[Syntax](#)[Methods and formulas](#)

## Description

`runtest` tests whether the observations of *varname* are serially independent—that is, whether they occur in a random order—by counting how many runs there are above and below a threshold. By default, the median is used as the threshold. A small number of runs indicates positive serial correlation; a large number indicates negative serial correlation.

## Quick start

Run test for the serial independence of the observations of `v1`

```
runtest v1
```

Use the mean of `v1`, rather than the median, as the threshold for counting runs

```
runtest v1, mean
```

Use 10 as the threshold for counting runs

```
runtest v1, threshold(10)
```

Same as above, but ignore any values of `v1` equal to the threshold when counting runs

```
runtest v1, threshold(10) drop
```

## Menu

Statistics > Nonparametric analysis > Tests of hypotheses > Test for random order

## Syntax

```
runtest varname [in] [, options]
```

| <i>options</i>            | Description                                                                                                |
|---------------------------|------------------------------------------------------------------------------------------------------------|
| <code>continuity</code>   | continuity correction                                                                                      |
| <code>drop</code>         | ignore values equal to the threshold                                                                       |
| <code>split</code>        | randomly split values equal to the threshold as above or below the threshold; default is to count as below |
| <code>mean</code>         | use mean as threshold; default is median                                                                   |
| <code>threshold(#)</code> | assign arbitrary threshold; default is median                                                              |

`collect` is allowed; see [U] 11.1.10 Prefix commands.

## Options

`continuity` specifies a continuity correction that may be helpful in small samples. If there are fewer than 10 observations either above or below the threshold, however, the tables in [Swed and Eisenhart \(1943\)](#) provide more reliable critical values. By default, no continuity correction is used.

`drop` directs `runtest` to ignore any values of *varname* that are equal to the threshold value when counting runs and tabulating observations. By default, `runtest` counts a value as being above the threshold when it is strictly above the threshold and as being below the threshold when it is less than or equal to the threshold.

`split` directs `runtest` to randomly split values of *varname* that are equal to the threshold. In other words, when *varname* is equal to threshold, a “coin” is flipped. If it comes up heads, the value is counted as above the threshold. If it comes up tails, the value is counted as below the threshold.

`mean` directs `runtest` to tabulate runs above and below the mean rather than the median.

`threshold(#)` specifies an arbitrary threshold to use in counting runs. For example, if *varname* has already been coded as a 0/1 variable, the median generally will not be a meaningful separating value.

## Remarks and examples

`runtest` performs a nonparametric test of the hypothesis that the observations of *varname* occur in a random order by counting how many runs there are above and below a threshold. If *varname* is positively serially correlated, it will tend to remain above or below its median for several observations in a row; that is, there will be relatively few runs. If, on the other hand, *varname* is negatively serially correlated, observations above the median will tend to be followed by observations below the median and vice versa; that is, there will be relatively many runs.

By default, `runtest` uses the median for the threshold, and this is not necessarily the best choice. If `mean` is specified, the mean is used instead of the median. If `threshold(#)` is specified, `#` is used. Because `runtest` divides the data into two states—above and below the threshold—it is appropriate for data that are already binary; for example, win or lose, live or die, rich or poor, etc. Such variables are often coded as 0 for one state and 1 for the other. Here you should specify `threshold(0)` because, by default, `runtest` separates the observations into those that are greater than the threshold and those that are less than or equal to the threshold.

As with most nonparametric procedures, the treatment of ties complicates the test. Observations equal to the threshold value are ties and can be treated in one of three ways. By default, they are treated as if they were below the threshold. If `drop` is specified, they are omitted from the calculation and the total number of observations is adjusted. If `split` is specified, each is randomly assigned to the above- and below-threshold groups. The random assignment is different each time the procedure is run unless you specify the random-number seed; see [R] [set seed](#).

### ▷ Example 1

We can use `runtest` to check regression residuals for serial correlation.

```
. use https://www.stata-press.com/data/r19/run1
. scatter resid year, connect(1) yline(0) title(Regression residuals)
```

The graph gives the impression that these residuals are positively correlated. Excursions above or below zero—the natural threshold for regression residuals—tend to last for several observations. `runtest` can evaluate the statistical significance of this impression.

```
. runttest resid, thresh(0)
N(resid <= 0) = 8
N(resid > 0) = 8
 obs = 16
 N(runs) = 5
 z = -2.07
 Prob>|z| = .04
```

There are five runs in these 16 observations. Using the normal approximation to the true distribution of the number of runs, the five runs in this series are fewer than would be expected if the residuals were serially independent. The  $p$ -value is 0.04, indicating a two-sided significant result at the 5% level. If the alternative hypothesis is positive serial correlation, rather than any deviation from randomness, then the one-sided  $p$ -value is  $0.04/2 = 0.015$ . With so few observations, however, the normal approximation may be inaccurate. (Tables compiled by Swed and Eisenhart list five runs as the 5% critical value for a one-sided test.)

`runtest` is a nonparametric test. It ignores the magnitudes of the observations and notes only whether the values are above or below the threshold. We can demonstrate this feature by reducing the information about the regression residuals in this example to a 0/1 variable that indicates only whether a residual is positive or negative.

```
. generate byte sign = resid>0
. runtest sign, thresh(0)
N(sign <= 0) = 8
N(sign > 0) = 8
 obs = 16
 N(runs) = 5
 z = -2.07
 Prob>|z| = .04
```

As expected, runtest produces the same answer as before.

### □ Technical note

The run test can also be used to test the null hypothesis that two samples are drawn from the same underlying distribution. The run test is sensitive to differences in the shapes, as well as the locations, of the empirical distributions.

Suppose, for example, that two different additives are added to the oil in 10 different cars during an oil change. The cars are run until a viscosity test determines that another oil change is needed, and the number of miles traveled between oil changes is recorded. The data are

```
. use https://www.stata-press.com/data/r19/additive, clear
. list
```

|     | additive | miles |
|-----|----------|-------|
| 1.  | 1        | 4024  |
| 2.  | 1        | 4756  |
| 3.  | 1        | 7993  |
| 4.  | 1        | 5025  |
| 5.  | 1        | 4188  |
| 6.  | 2        | 3007  |
| 7.  | 2        | 1988  |
| 8.  | 2        | 1051  |
| 9.  | 2        | 4478  |
| 10. | 2        | 4232  |

To test whether the additives generate different distributions of miles between oil changes, we sort the data by miles and then use runtest to see whether the marker for each additive occurs in random order:

```
. sort miles
. runtest additive, thresh(1)
N(additive <= 1) = 5
N(additive > 1) = 5
 obs = 10
 N(runs) = 4
 z = -1.34
 Prob>|z| = .18
```

Here the additives do not produce statistically different results.

□ Technical note

A test that is related to the run test is the runs up-and-down test. In the latter test, the data are classified not by whether they lie above or below a threshold but by whether they are steadily increasing or decreasing. Thus an unbroken string of increases in the variable of interest is counted as one run, as is an unbroken string of decreases. According to Madansky (1988), the run test is superior to the runs up-and-down test for detecting trends in the data, but the runs up-and-down test is superior for detecting autocorrelation.

runtest can be used to perform a runs up-and-down test. Using the regression residuals from the example above, we can perform a runtest on their first differences:

```
. use https://www.stata-press.com/data/r19/run1
. generate resid_D = resid - resid[_n-1]
(1 missing value generated)
. runtest resid_D, thresh(0)
N(resid_D <= 0) = 7
N(resid_D > 0) = 8
 obs = 15
 N(runs) = 6
 z = -1.33
 Prob>|z| = .18
```

Edgington (1961) has compiled a table of the small-sample distribution of the runs up-and-down statistic, and this table is reprinted in Madansky (1988). For large samples, the  $z$  statistic reported by runtest is incorrect for the runs up-and-down test. Let  $N$  be the number of observations (15 here), and let  $r$  be the number of runs (6). The expected number of runs in the runs up-and-down test is

$$\mu_r = \frac{2N - 1}{3}$$

the variance is

$$\sigma_r^2 = \frac{16N - 29}{90}$$

and the correct  $z$  statistic is

$$\hat{z} = \frac{r - \mu_r}{\sigma_r}$$

□

□ Technical note

runtest will tolerate missing values at the beginning or end of a series, as occurred in the technical note above (generating first differences resulted in a missing value for the first observation). runtest, however, will issue an error message if there are any missing observations in the interior of the series (in the portion covered by the in range qualifier). To perform the test anyway, simply drop the missing observations before using runtest.

□

## Stored results

runtest stores the following in `r()`:

Scalars

|                         |                            |                        |                                |
|-------------------------|----------------------------|------------------------|--------------------------------|
| <code>r(N)</code>       | number of observations     | <code>r(p)</code>      | <i>p</i> -value of <i>z</i>    |
| <code>r(N_below)</code> | number below the threshold | <code>r(z)</code>      | <i>z</i> statistic             |
| <code>r(N_above)</code> | number above the threshold | <code>r(n_runs)</code> | number of runs                 |
| <code>r(mean)</code>    | expected number of runs    | <code>r(Var)</code>    | variance of the number of runs |

## Methods and formulas

runtest begins by calculating the number of observations below the threshold,  $n_0$ ; the number of observations above the threshold,  $n_1$ ; the total number of observations,  $N = n_0 + n_1$ ; and the number of runs,  $r$ . These statistics are always reported, so the exact tables of critical values in [Swed and Eisenhart \(1943\)](#) may be consulted if necessary.

The expected number of runs under the null is

$$\mu_r = \frac{2n_0n_1}{N} + 1$$

the variance is

$$\sigma_r^2 = \frac{2n_0n_1(2n_0n_1 - N)}{N^2(N - 1)}$$

and the normal approximation test statistic is

$$\hat{z} = \frac{r - \mu_r}{\sigma_r}$$

## Acknowledgment

runtest was written by Sean Beckett, author of the Stata Press book [Introduction to Time Series Using Stata, Revised Edition](#).

## Description

`rwgen bsample` and `rwgen bayes` generate replicate weights for each observation that can be used by the `bootstrap` prefix to enhance reproducibility during bootstrap estimation.

`rwgen bsample` executes the `bsample` command on the original dataset one or more times, saving the generated frequency weights in newly created variables. These frequency weights can be specified in the `fweights()` option of the `bootstrap` prefix.

`rwgen bayes` generates weights using Bayesian bootstrap methods. These weights can be specified in the `iweights()` option of the `bootstrap` prefix.

## Quick start

Generate bootstrap frequency weights for the default 50 replications, and store them in new variables `stubvar1` through `stubvar50`

```
rwgen bsample stubvar
```

Same as above, but sample only five observations for each replication

```
rwgen bsample stubvar, size(5)
```

Generate bootstrap frequency weights for each stratum defined by `x1`

```
rwgen bsample stubvar, strata(x1)
```

Generate bootstrap frequency weights by sampling clusters identified by values of `cvar`

```
rwgen bsample stubvar, cluster(cvar)
```

Same as above, but create a new unique identifier for sampled clusters, and store it in `newcvar`

```
rwgen bsample stubvar, cluster(cvar) idcluster(newcvar)
```

Generate Bayesian bootstrap weights using default prior powers for 100 replications

```
rwgen bayes stubvar, reps(100)
```

Same as above, but use the values of variable `x1` as the prior powers for each observation

```
rwgen bayes stubvar, reps(100) priorpowers(x1)
```

Same as above but use a combination of `x2` and `x3` to uniquely identify the observations

```
rwgen bayes stubvar, reps(100) priorpowers(x1) id(x2 x3)
```

## Menu

Statistics > Resampling > Generate bootstrap replicate weights

## Syntax

Generate replicate weights using random sampling with replacement

```
rwgen bsample stub [if] [in] [, bsample_options]
```

Generate replicate weights using Bayesian bootstrap methods

```
rwgen bayes stub [if] [in] [, bayes_options]
```

| <i>bsample_options</i>                | Description                                                                                                   |

## Options

Options are presented under the following headings:

[Options for `rwgen bsample`](#)

[Options for `rwgen bayes`](#)

### Options for `rwgen bsample`

#### Main

`reps(#)` specifies the number of replicate weight variables to generate; the default is `reps(50)`. The generated weights are stored in new variables named `stub1`, `stub2`, ..., `stub#`.

`size(exp)` specifies the size of the sample and must be less than or equal to `_N` when neither the `cluster()` nor the `strata()` option is specified; default is `_N`.

`strata(varlist)` specifies the variables that identify strata. If `strata()` is specified, bootstrap samples are selected within each stratum, and `size()` must be less than or equal to `_N` within the defined strata.

`cluster(varlist)` specifies the variables identifying resampling clusters. If `cluster()` is specified, the sample drawn during each replication is a bootstrap sample of clusters, and `size()` must be less than or equal to `N_c` (the number of clusters identified by `cluster()`). If `strata()` is also specified, `size()` must be less than or equal to the number of within-strata clusters.

`idcluster(newvar)` creates a new variable containing a unique identifier for each resampled cluster.

`rseed(#)` sets the random-number seed. This option can be used to reproduce results. `rseed(#)` is equivalent to typing `set seed #` prior to calling `rwgen`; see [R] [set seed](#).

## Options for `rwgen bayes`

Main

`reps(#)` specifies the number of replicate weight variables to generate; the default is `reps(50)`. The generated weights are stored in new variables named `stub1`, `stub2`, ..., `stub#`.

`priorpowers(#varname)` specifies the power value  $l_i$  of the prior distribution for the  $i$ th observation,  $i = 1, 2, \dots, n$ . The default is `priorpowers(-1)`, which corresponds to an improper noninformative prior. `priorpowers(#)` specifies the same power `#` for all observations. Alternatively, you can specify different power values in `varname`. See [Methods and formulas](#). The variable specified in `priorpowers()` may not be specified in `id()`.

`id(varlist)` specifies the variables used to uniquely identify each observation. By default, `rwgen bayes` considers all variables in the dataset to assess uniqueness. Any variables specified in `id()` may not be specified in `priorpowers()`.

`rseed(#)` sets the random-number seed. This option can be used to reproduce results. `rseed(#)` is equivalent to typing `set seed #` prior to calling `rwgen`; see [R] [set seed](#).

## Remarks and examples

The `rwgen bsample` and `rwgen bayes` commands generate replicate weights that can be used by the bootstrap prefix to enhance reproducibility during bootstrap estimation.

`rwgen bsample` executes the `bsample` command on the original dataset one or more times to generate replicate weights. You can randomly resample observations, observations within strata, or clusters. The frequency weights generated by `rwgen bsample` can then be specified in the `fweights()` option of the bootstrap prefix.

`rwgen bayes` generates weights using Bayesian bootstrap methods. These weights can be specified in the `weights()` option of the bootstrap prefix.

### ► Example 1: Generate replicate weights for bootstrap

We wish to compute bootstrap estimates for the standard errors of the coefficients from a regression of car price on car weight and origin. We first load `auto.dta`:

```
. use https://www.stata-press.com/data/r19/auto
(1978 automobile data)
```

We use `rwgen bsample` to draw random samples of the data, with replacement, and specify that we want 100 replications. For reproducibility, we set the seed using the `rseed()` option. `rwgen bsample` will store the frequency weights in newly generated variables using the stub we specify, `freq_`.

```
. rwgen bsample freq_, reps(100) rseed(20)
```

After we run the command, our dataset now contains 100 newly generated variables named `freq_1`, `freq_2`, ..., `freq_100`. Below, we list the first 10 observations of `freq_1` through `freq_5`:

```
. list freq_1-freq_5 in 1/10
```

|       | freq_1 | freq_2 | freq_3 | freq_4 | freq_5 |
|-------|--------|--------|--------|--------|--------|
| 1.    | 2      | 0      | 1      | 0      | 0      |
| 2.    | 1      | 2      | 2      | 0      | 1      |
| 3.    | 2      | 2      | 2      | 0      | 3      |
| 4.    | 0      | 0      | 1      | 0      | 2      |
| 5.    | 0      | 1      | 1      | 0      | 0      |
| <hr/> |        |        |        |        |        |
| 6.    | 1      | 1      | 1      | 0      | 0      |
| 7.    | 2      | 1      | 1      | 1      | 4      |
| 8.    | 1      | 2      | 1      | 2      | 1      |
| 9.    | 1      | 2      | 0      | 2      | 0      |
| 10.   | 2      | 0      | 2      | 1      | 0      |

Each of these frequency weights represents and can be used to generate a random sample with replacement. For instance, in the first bootstrap sample, neither the fourth nor the fifth observation is present. However, in the fifth sample, the fourth observation appears two times.

The sum of the values in any of the newly generated weights will give us the sample size:

```
. quietly summarize freq_1
. display r(sum)
74
```

The result above matches the number of observations in our original dataset.

Now that we have generated the frequency weights, we can specify them in the `fweights()` option of the bootstrap prefix to perform a regression using the bootstrap sampled datasets:

```
. bootstrap, fweights(freq_1-freq_100): regress price weight i.foreign
(running regress on estimation sample)
Bootstrap replications (100):10.....20.....30.....40.....
>50.....60.....70.....80.....90.....100 done
Linear regression Number of obs = 74
 Replications = 100
 Wald chi2(2) = 50.08
 Prob > chi2 = 0.0000
 R-squared = 0.4989
 Adj R-squared = 0.4848
 Root MSE = 2117.0206
```

| price   | Observed coefficient | Bootstrap std. err. | z     | P> z  | Normal-based [95% conf. interval] |           |
|---------|----------------------|---------------------|-------|-------|-----------------------------------|-----------|
| weight  | 3.320737             | .493339             | 6.73  | 0.000 | 2.35381                           | 4.287663  |
| foreign |                      |                     |       |       |                                   |           |
| Foreign | 3637.001             | 584.5176            | 6.22  | 0.000 | 2491.368                          | 4782.635  |
| _cons   | -4942.844            | 1526.99             | -3.24 | 0.001 | -7935.689                         | -1949.998 |

We can also perform our analysis using any one of the bootstrap sampled datasets. For example, if we want to refit the model using only the first bootstrap sampled dataset, we can simply type

```
. regress price weight i.foreign [fweight=freq_1]
```

| Source   | SS        | df | MS         | Number of obs | = | 74     |
|----------|-----------|----|------------|---------------|---|--------|
| Model    | 428736736 | 2  | 214368368  | F(2, 71)      | = | 42.81  |
| Residual | 355506733 | 71 | 5007137.08 | Prob > F      | = | 0.0000 |
|          |           |    |            | R-squared     | = | 0.5467 |
|          |           |    |            | Adj R-squared | = | 0.5339 |
| Total    | 784243469 | 73 | 10743061.2 | Root MSE      | = | 2237.7 |

| price   | Coefficient | Std. err. | t     | P> t  | [95% conf. interval] |           |
|---------|-------------|-----------|-------|-------|----------------------|-----------|
| weight  | 3.377376    | .3677504  | 9.18  | 0.000 | 2.644103             | 4.11065   |

| Foreign | 3469.655    | 660.6613  | 5.25  | 0.000 | 2152.334             | 4786.976  |
| _cons   | -4707.386   | 1212      | -3.88 | 0.000 | -7124.045            | -2290.726 |

### ▷ Example 2: Adjust sample size

By default, `rwgen bsample` generates bootstrap samples of the same size as the original dataset. In our previous example, `auto.dta` contained 74 observations; thus, our frequency weights summed to 74 for each replication. However, we can use the `size()` option to control the number of observations drawn in each bootstrap sample. For example, below we sample 10 observations with replacement from the original `auto` dataset:

```
. use https://www.stata-press.com/data/r19/auto, clear
(1978 automobile data)
. rwgen bsample frq_, reps(1) size(10)
. quietly summarize frq_1
. display r(sum)
10
```

The weights now sum to 10.

### ▷ Example 3: Resample clusters

If we are interested in generating bootstrap samples of entire clusters rather than individual observations, we can use the `cluster()` option. For example, we have clustered data in `bsample2.dta`.

```
. use https://www.stata-press.com/data/r19/bsample2, clear
. tabulate group
```

| group | Freq. | Percent | Cum.   |
|-------|-------|---------|--------|
| A     | 15    | 19.74   | 19.74  |
| B     | 10    | 13.16   | 32.89  |
| C     | 11    | 14.47   | 47.37  |
| D     | 11    | 14.47   | 61.84  |
| E     | 29    | 38.16   | 100.00 |
| Total | 76    | 100.00  |        |

We have five distinct groups in our data. Below, we resample clusters using `group` as the cluster variable for bootstrap sampling.

```
. rwgen bsample fc_, reps(5) cluster(group)
```

Note that we are resampling clusters rather than individual observations. Let's list the frequencies for the cluster defined by `group == "B"`

```
. list group fc_1-fc_5 if group == "B"
```

|     | group | fc_1 | fc_2 | fc_3 | fc_4 | fc_5 |
|-----|-------|------|------|------|------|------|
| 16. | B     | 1    | 1    | 2    | 1    | 2    |
| 17. | B     | 1    | 1    | 2    | 1    | 2    |
| 18. | B     | 1    | 1    | 2    | 1    | 2    |
| 19. | B     | 1    | 1    | 2    | 1    | 2    |
| 20. | B     | 1    | 1    | 2    | 1    | 2    |
| 21. | B     | 1    | 1    | 2    | 1    | 2    |
| 22. | B     | 1    | 1    | 2    | 1    | 2    |
| 23. | B     | 1    | 1    | 2    | 1    | 2    |
| 24. | B     | 1    | 1    | 2    | 1    | 2    |
| 25. | B     | 1    | 1    | 2    | 1    | 2    |

Frequencies remain constant within clusters because the entire cluster is treated as a single unit during the resampling process. This approach ensures that all observations within a cluster are sampled together, maintaining the cluster structure in the bootstrap samples.

◀

#### ▷ Example 4: Stratified samples with unequal sizes

In this example, we demonstrate how to perform stratified sampling with unequal sizes again using `auto.dta`. This method allows us to sample different numbers of observations from distinct groups within the dataset. To sample 10 foreign cars and 5 domestic cars from the original dataset, we first need to create a variable that specifies the desired sample size for each group. We can do this by generating a new variable that assigns the value 10 to foreign cars and 5 to domestic cars:

```
. use https://www.stata-press.com/data/r19/auto, clear
(1978 automobile data)
. generate nsamp = cond(foreign,10,5)
```

Once this variable is created, we can specify it in the `size()` option of the `rwgen bsample` command in addition to specifying the strata variable `foreign` in the `strata()` option:

```
. rwgen bsample fs_, reps(1) strata(foreign) size(nsamp)
. tabulate foreign [fweight=fs_1]
```

| Car origin | Freq. | Percent | Cum.   |
|------------|-------|---------|--------|
| Domestic   | 5     | 33.33   | 33.33  |
| Foreign    | 10    | 66.67   | 100.00 |
| Total      | 15    | 100.00  |        |

◀

### ▷ Example 5: Using matched case–control data with the `idcluster()` option

In this example, we demonstrate how to resample clusters using matched case–control data. We have a dataset of infants who are paired by being matched on their mother’s age. These data were presented in [Hosmer, Lemeshow, and Sturdivant \(2013\)](#) and examined in [example 7](#) of [\[R\] bootstrap](#).

The matching information is stored in the variable `pairid`. Specifying this matching variable in the `group()` or `strata()` option of estimation commands, such as `clogit`, allows us to account for the inherent dependencies in the data when fitting our models.

When resampling from groups, or clusters, we need to make sure that we are preserving the matching information and that the resampled clusters are uniquely identified in each bootstrap sample. Thus, we use the `idcluster()` option with `rwgen bsample` to generate a new variable to uniquely identify these resampled groups. This ensures that the bootstrap samples maintain the correct matching structure, enabling accurate estimation of standard errors for matched case–control studies.

Below, we specify `pairid` in the `cluster()` option to preserve the original matching information and generate a new variable named `newpairid` to uniquely identify the newly resampled groups:

```
. use https://www.stata-press.com/data/r19/lowbirth2, clear
(Applied Logistic Regression, Hosmer & Lemeshow)
. rwgen bsample frq_, reps(50) rseed(1) cluster(pairid) idcluster(newpairid)
```

Now we can specify our newly generated frequency weights in the `fweights()` option of the bootstrap prefix to reconstruct the resampling process and obtain estimates of the standard errors that account for the matching information.

```
. bootstrap ratio=exp(_b[smoke]-_b[ptd]), fweights(frq_1-frq_50):
> clogit low lwt smoke ptd ht ui i.race, group(newpairid)
(running clogit on estimation sample)
Bootstrap replications (50):10.....20.....30.....40.....
> ...50 done

Bootstrap results Number of obs = 112
 Replications = 50

Command: clogit low lwt smoke ptd ht ui i.race, group(newpairid)
 ratio: exp(_b[smoke]-_b[ptd])
 (Replications based on 56 clusters in pairid)
```

|       | Observed<br>coefficient | Bootstrap<br>std. err. | z    | P> z  | Normal-based<br>[95% conf. interval] |          |
|-------|-------------------------|------------------------|------|-------|--------------------------------------|----------|
| ratio | .6654095                | 1.156848               | 0.58 | 0.565 | -1.601972                            | 2.932791 |

◀

### ▷ Example 6: Bayesian bootstrap

In this example, we will demonstrate how to use the Bayesian bootstrap technique with the `rwgen bayes` command to analyze `auto.dta`. We first load the data:

```
. use https://www.stata-press.com/data/r19/auto, clear
(1978 automobile data)
```

According to [Rubin \(1981\)](#), the Bayesian bootstrap requires specifying a prior for each unique observation, representing our prior beliefs about the outcome probabilities. By default, the `rwgen bayes` command assigns a prior power value of `-1` to all observations, which corresponds to an improper non-informative prior.

We use the following command to generate 100 replicate weights for each observation, which will be stored in new variables named `ival1_1` through `ival1_100`, and we specify the `rseed(20)` option for reproducibility:

```
. rwgen bayes ival1_, reps(100) rseed(20)
```

The `rwgen bayes` command generates weights in the  $[0, 1]$  interval, with the summation of weights equal to 1. These weights represent a sample of the posterior probability distribution over the observations, incorporating our prior beliefs. For example, below we display summary statistics for the first set of replicate weights (`ival1_1`):

```
. summarize ival1_1
Variable | Obs Mean Std. dev. Min Max
-----+-----+-----+-----+-----+-----
 ival1_1 | 74 .0135135 .0114578 .0001009 .0443107
. display r(sum)
1
```

The generated weights can be specified in the `weights()` option of the `bootstrap` prefix. `weights()` stands for importance weights, and they allow us to perform weighted analyses, accounting for the varying probabilities of each observation as specified by the Bayesian bootstrap. To demonstrate, we will use the `regress` command with the generated replicate weights:

```
. bootstrap, iweights(ival1_1-ival1_100): regress mpg weight foreign
(running regress on estimation sample)
Bootstrap replications (100):10.....20.....30.....40.....
>50.....60.....70.....80.....90.....100 done
Linear regression Number of obs = 74
Replications = 100
Wald chi2(2) = 169.45
Prob > chi2 = 0.0000
R-squared = 0.6627
Adj R-squared = 0.6532
Root MSE = 3.4071
```

| mpg     | Observed coefficient | Bootstrap std. err. | z      | P> z  | Normal-based [95% conf. interval] |           |
|---------|----------------------|---------------------|--------|-------|-----------------------------------|-----------|
| weight  | -.0065879            | .0005116            | -12.88 | 0.000 | -.0075906                         | -.0055852 |
| foreign | -1.650029            | .9949633            | -1.66  | 0.097 | -3.600121                         | .3000631  |
| _cons   | 41.6797              | 1.695628            | 24.58  | 0.000 | 38.35633                          | 45.00307  |

### ▷ Example 7: Changing prior power specification in Bayesian bootstrap

Below, we will build upon the previous example to demonstrate how altering the prior power specification affects the estimated results using the Bayesian bootstrap technique.

By default, `rwgen bayes` assigns a prior power value of  $-1$  for all observations. This corresponds to using a noninformative prior for all observations. First, let's generate a new variable with higher values for the prior powers; these values will influence the posterior importance weights assigned to each observation.

```
. generate double prior_12 = runiform(5, 15)
```

Next, we use `rwgen bayes` to generate a new set of replicate weights based on the new prior powers. This will create new variables `ival2_1` through `ival2_100`:

```
. rwgen bayes ival2_, reps(100) priorpowers(prior_l2)
```

Recall that the importance weights `ival1_1` through `ival1_100` were generated based on the default prior powers of `-1`. To compare the weights generated from the two different prior power values, we calculate the variance for `ival1_1` through `ival1_100` and `ival2_1` through `ival2_100`:

```
. mata: variance(st_data(1, "ival1_1-ival1_100"))
 .0001778708
. mata: variance(st_data(1, "ival2_1-ival2_100"))
 .000016411
```

By examining the summary statistics, you will notice that the variance of the generated replicate weights is much smaller when using the higher prior power value. This is expected because the posterior probability represented by these variables follows a Dirichlet distribution. A higher prior power value results in more concentrated weights, reflecting greater certainty in the prior information.

Now, let's use the `bootstrap` prefix with the newly generated importance weights `ival2_1` through `ival2_100`.

```
. bootstrap, iweights(ival2_1-ival2_100): regress mpg weight foreign
(running regress on estimation sample)

Bootstrap replications (100):10.....20.....30.....40.....
>50.....60.....70.....80.....90.....100 done

Linear regression Number of obs = 74
Replications = 100
Wald chi2(2) = 1745.44
Prob > chi2 = 0.0000
R-squared = 0.6627
Adj R-squared = 0.6532
Root MSE = 3.4071
```

|         | Observed<br>coefficient | Bootstrap<br>std. err. | z      | P> z  | Normal-based<br>[95% conf. interval] |           |
|---------|-------------------------|------------------------|--------|-------|--------------------------------------|-----------|
| weight  | -.0065879               | .0001582               | -41.63 | 0.000 | -.006898                             | -.0062778 |
| foreign | -1.650029               | .3246217               | -5.08  | 0.000 | -2.286276                            | -1.013782 |
| _cons   | 41.6797                 | .5088586               | 81.91  | 0.000 | 40.68236                             | 42.67705  |

Notice that the standard errors are smaller because we used a more informative prior.

### ▷ Example 8: Influence of uniqueness on posterior estimation of importance weights

In this example, we will explain how the definition of uniqueness influences the importance weights in the Bayesian bootstrap. According to [Rubin \(1981\)](#), the posterior distribution follows a Dirichlet distribution, which combines prior information with the frequency of observations in the sample. The frequency count is based on how uniqueness is defined for the observations.

By default, all variables are used to determine whether an observation is unique. However, we also provide the `id()` option, which allows users to alter the criteria for determining uniqueness.

We continue the previous example using `auto.dta`. In the following command, we use the `foreign` variable to determine uniqueness. This means that all observations with the same value for the `foreign` variable will be treated as identical when calculating the frequency counts for the posterior distribution:

```
. rwgen bayes uiv_, reps(1) id(foreign)
```

By using the `foreign` variable to determine uniqueness, the generated weights will be the same for all observations where `foreign` is equal to “Domestic”, and similarly, the weights will be the same for all observations where `foreign` is equal to “Foreign”.

```
. by foreign: summarize uiv_1
```

```
-> foreign = Domestic
```

| Variable | Obs | Mean     | Std. dev. | Min      | Max      |
|----------|-----|----------|-----------|----------|----------|
| uiv_1    | 52  | .0140812 | 0         | .0140812 | .0140812 |

```
-> foreign = Foreign
```

| Variable | Obs | Mean     | Std. dev. | Min      | Max      |
|----------|-----|----------|-----------|----------|----------|
| uiv_1    | 22  | .0121716 | 0         | .0121716 | .0121716 |

◀

## Stored results

`rwgen bsample` stores the following in `r()`:

### Scalars

`r(N)` sample size  
`r(N_reps)` number of replications  
`r(N_strata)` number of strata  
`r(N_clust)` number of clusters

### Macros

`r(method)` `bsample`  
`r(stub)` *stub* of new variables  
`r(rngstate)` random-number state used  
`r(size)` from the `size(exp)` option  
`r(strata)` strata variables  
`r(cluster)` cluster variables  
`r(idcluster)` new cluster ID variable  
`r(newvarlist)` generated weight variables

`rwgen bayes` stores the following in `r()`:

### Scalars

`r(N)` sample size  
`r(N_reps)` number of replications

### Macros

`r(method)` `bayes`  
`r(stub)` *stub* of new variables  
`r(rngstate)` random-number state used  
`r(id)` variables used to uniquely identify observations  
`r(priorpowers)` prior powers  
`r(newvarlist)` generated weight variables

## Methods and formulas

The classical bootstrap ([R] **bootstrap**) is a resampling method used to approximate the distribution of a statistic across a sample. Consider a sample  $(x_1, x_2, \dots, x_n)$  from a random variable  $X$ . A bootstrap replication is a sample of size  $m$  drawn with replacement from  $(x_1, x_2, \dots, x_n)$ . In most cases,  $m$  will be equal to  $n$ , the sample size.

Viewed from a probabilistic perspective, this process involves assigning probabilities to each observation in the sample. A bootstrap sample is drawn from a multinomial distribution with  $n$  categories and  $m$  independent trials, where success (outcome) probabilities are nonnegative and their sum equals 1. In this setup, each point in the sample has a probability  $1/n$  of selection in any draw, although the randomness of the process may result in some points being selected multiple times, or not at all, within a single replication.

Introduced by [Rubin \(1981\)](#), the Bayesian bootstrap modifies the traditional bootstrap technique by adopting a Bayesian approach. Instead of discrete resampling with replacement, it assigns probabilities to each observation, forming an  $n$ -vector of weights that follow a specified posterior distribution. This method captures the uncertainty about the representativeness of each observation in the overall distribution, allowing for greater variability in the analysis.

We follow Rubin’s framework outlined in [Rubin \(1981\)](#), particularly focusing on section 4, to describe the procedures for calculating Bayesian bootstrap weights.

Consider a discrete random variable  $\tilde{X}$  that can take on  $K$  distinct values  $d_1, d_2, \dots, d_K$ . Each unique value in this set has an associated probability  $\pi_k = P(\tilde{X} = d_k | \boldsymbol{\pi})$ , where  $\boldsymbol{\pi} = (\pi_1, \pi_2, \dots, \pi_K)$ . For an i.i.d. sample  $(x_1, x_2, \dots, x_n)$  drawn from  $\tilde{X}$ , let  $n_k$  denote the frequency of each  $d_k$  in the sample. For continuous random variables, each observation in the sample is unique, so  $K = n$  and  $n_i = 1$  for all  $i$ .

The Bayesian bootstrap introduces a prior distribution for  $\boldsymbol{\pi}$ , proportional to  $\prod_{k=1}^K \pi_k^{l_k}$ , reflecting prior beliefs about the outcome probabilities. Updating this prior with the categorical data, the posterior distribution of  $\boldsymbol{\pi}$  follows a  $(K - 1)$ -variate Dirichlet distribution,  $\text{Dirichlet}(n_1 + l_1 + 1, n_2 + l_2 + 1, \dots, n_K + l_K + 1)$  proportional to  $\prod_{k=1}^K \pi_k^{n_k + l_k}$ .

For notational simplicity, let’s assume  $K = n$ . Following [Rubin \(1981\)](#) and [Hastie, Tibshirani, and Friedman \(2009\)](#), the default prior is set to an improper noninformative prior proportional to  $\prod_{k=1}^K \pi_k^{-1}$ , with  $l_k = -1$  for  $k = 1, 2, \dots, n$ . This way, the posterior distribution is  $\text{Dirichlet}(1, 1, \dots, 1)$ , meaning each data point has the same posterior probability. For more advanced usage, the `priorpowers()` option allows you to specify your own values for  $l_k$ . However, you need to make sure that those values produce an actual posterior distribution (that is, the formula for the posterior distribution function has a finite integral on its domain); a sufficient condition, for example, would be that  $n_k + l_k + 1$  be positive for all observations.

`rwgen bayes` uses Mata’s `rdirichlet()` function (see `help mata rdirichlet()`) to generate Bayesian bootstrap weights  $w_k$ ’s from the posterior Dirichlet distribution with shape vector  $A = (n_1 + l_1 + 1, n_2 + l_2 + 1, \dots, n_K + l_K + 1)$ . Note that for every element  $a$  of  $A$ ,  $1e-3 < a < 1e+8$ . When  $K < n$ , the generated weights are distributed evenly among duplicate observations with a unique value  $d_k$  as  $w_k/n_k$  for  $k = 1, 2, \dots, K$ . This approach ensures that the sum of the weights across all observations accurately reflects the true posterior probability distribution, integrating both the empirical data and prior beliefs into our analysis.

## Description

`scobit` fits a maximum-likelihood skewed logit model.

## Quick start

Skewed logistic regression of binary variable `y` on `x1` and `x2`

```
scobit y x1 x2
```

With robust standard errors

```
scobit y x1 x2, vce(robust)
```

Same as above, and display coefficients and std. err. with two digits to the right of the decimal

```
scobit y x1 x2, vce(robust) cformat(%8.2f)
```

Same as above, and also display  $p$ -values with two digits to the right of the decimal

```
scobit y x1 x2, vce(robust) cformat(%8.2f) pformat(%5.2f)
```

```

| <i>options</i>                               | Description                                                                                                                                                                 |
|----------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Model</b>                                 |                                                                                                                                                                             |
| <code>noconstant</code>                      | suppress constant term                                                                                                                                                      |
| <code>offset(<i>varname</i>)</code>          | include <i>varname</i> in model with coefficient constrained to 1                                                                                                           |
| <code>asis</code>                            | retain perfect predictor variables                                                                                                                                          |
| <code>constraints(<i>constraints</i>)</code> | apply specified linear constraints                                                                                                                                          |
| <b>SE/Robust</b>                             |                                                                                                                                                                             |
| <code>vce(<i>vcetype</i>)</code>             | <i>vcetype</i> may be <code>oim</code> , <code>robust</code> , <code>cluster <i>clustvar</i></code> , <code>opg</code> , <code>bootstrap</code> , or <code>jackknife</code> |
| <b>Reporting</b>                             |                                                                                                                                                                             |
| <code>level(#)</code>                        | set confidence level; default is <code>level(95)</code>                                                                                                                     |
| <code>nocnsreport</code>                     | do not display constraints                                                                                                                                                  |
| <code>display_options</code>                 | control columns and column formats, row spacing, line width, display of omitted variables and base and empty cells, and factor-variable labeling                            |
| <b>Maximization</b>                          |                                                                                                                                                                             |
| <code>maximize_options</code>                | control the maximization process                                                                                                                                            |
| <code>collinear</code>                       | keep collinear variables                                                                                                                                                    |
| <code>coeflegend</code>                      | display legend instead of statistics                                                                                                                                        |

*indepvars* may contain factor variables; see [U] 11.4.3 **Factor variables**.

`bayesboot`, `bootstrap`, `by`, `collect`, `fp`, `jackknife`, `nestreg`, `rolling`, `statsby`, `stepwise`, and `svy` are allowed; see [U] 11.1.10 **Prefix commands**.

Weights are not allowed with the `bootstrap` prefix; see [R] **bootstrap**.

`vce()` and weights are not allowed with the `svy` prefix; see [SVY] **svy**.

`fweights`, `iweights`, and `pweights` are allowed; see [U] 11.1.6 **weight**.

`collinear` and `coeflegend` do not appear in the dialog box.

See [U] 20 **Estimation and postestimation commands** for more capabilities of estimation commands.

## Options

### Model

`noconstant`, `offset(varname)`, `constraints(constraints)`; see [R] **Estimation options**.

`asis` forces retention of perfect predictor variables and their associated perfectly predicted observations and may produce instabilities in maximization; see [R] **probit**.

### SE/Robust

`vce(vcetype)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory (`oim`, `opg`), that are robust to some kinds of misspecification (`robust`), that allow for intragroup correlation (`cluster clustvar`), and that use bootstrap or jackknife methods (`bootstrap`, `jackknife`); see [R] **vce\_option**.

## Reporting

`level(#)`; see [R] [Estimation options](#).

`nocnsreport`; see [R] [Estimation options](#).

*display\_options*: `nocl`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `nolstretch`; see [R] [Estimation options](#).

## Maximization

*maximize\_options*: `difficult`, `technique(algorithm_spec)`, `iterate(#)`, `[no]log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `ltolerance(#)`, `nrtolerance(#)`, `nonrtolerance`, and `from(init_specs)`; see [R] [Maximize](#). These options are seldom used.

Setting the optimization type to `technique(bhhh)` resets the default `vcetype` to `vce(opg)`.

The following options are available with `scobit` but are not shown in the dialog box:

`collinear`, `coeflegend`; see [R] [Estimation options](#).

## Remarks and examples

Remarks are presented under the following headings:

*Skewed logistic model*

*Robust standard errors*

## Skewed logistic model

`scobit` fits maximum likelihood models with dichotomous dependent variables coded as 0/1 (or, more precisely, coded as 0 and not 0).

### ► Example 1

We have data on the make, weight, and mileage rating of 22 foreign and 52 domestic automobiles. We wish to fit a model explaining whether a car is foreign based on its mileage. Here is an overview of our data:

```
. use https://www.stata-press.com/data/r19/auto
(1978 automobile data)
. keep make mpg weight foreign
. describe
Contains data from https://www.stata-press.com/data/r19/auto.dta
Observations: 74 1978 automobile data
Variables: 4 13 Apr 2024 17:45
 (_dta has notes)
```

| Variable name | Storage type | Display format | Value label | Variable label |
|---------------|--------------|----------------|-------------|----------------|
| make          | str18        | %-18s          |             | Make and model |
| mpg           | int          | %8.0g          |             | Mileage (mpg)  |
| weight        | int          | %8.0gc         |             | Weight (lbs.)  |
| foreign       | byte         | %8.0g          | origin      | Car origin     |

```
Sorted by: foreign
Note: Dataset has changed since last saved.
```

```
. inspect foreign
foreign: Car origin
```

|     |          | Number of observations |          |             |
|-----|----------|------------------------|----------|-------------|
|     |          | Total                  | Integers | Nonintegers |
| #   | Negative | -                      | -        | -           |
| #   | Zero     | 52                     | 52       | -           |
| #   | Positive | 22                     | 22       | -           |
| #   |          |                        |          |             |
| # # | Total    | 74                     | 74       | -           |
| # # | Missing  | -                      |          |             |
| 0   |          | 74                     |          |             |
| 1   |          |                        |          |             |

(2 unique values)

foreign is labeled and all values are documented in the label.

The variable `foreign` takes on two unique values, 0 and 1. The value 0 denotes a domestic car, and 1 denotes a foreign car.

The model that we wish to fit is

$$\Pr(\text{foreign} = 1) = F(\beta_0 + \beta_1 \text{mpg})$$

where  $F(z) = 1 - 1/\{1 + \exp(z)\}^\alpha$ .

To fit this model, we type

```
. scobit foreign mpg
Fitting logistic model:
Iteration 0: Log likelihood = -45.03321
Iteration 1: Log likelihood = -39.380959
Iteration 2: Log likelihood = -39.288802
Iteration 3: Log likelihood = -39.28864
Iteration 4: Log likelihood = -39.28864
Fitting full model:
Iteration 0: Log likelihood = -39.28864
Iteration 1: Log likelihood = -39.286393
Iteration 2: Log likelihood = -39.284415
Iteration 3: Log likelihood = -39.284234
Iteration 4: Log likelihood = -39.284197
Iteration 5: Log likelihood = -39.284196
```

```
Skewed logistic regression Number of obs = 74
 Zero outcomes = 52
Log likelihood = -39.2842 Nonzero outcomes = 22
```

| foreign  | Coefficient | Std. err. | z     | P> z  | [95% conf. interval] |           |
|----------|-------------|-----------|-------|-------|----------------------|-----------|
| mpg      | .1813879    | .2407362  | 0.75  | 0.451 | -.2904463            | .6532222  |
| _cons    | -4.274883   | 1.399305  | -3.06 | 0.002 | -7.017471            | -1.532295 |
| /lnalpha | -.4450405   | 3.879885  | -0.11 | 0.909 | -8.049476            | 7.159395  |
| alpha    | .6407983    | 2.486224  |       |       | .0003193             | 1286.133  |

```
LR test of alpha=1: chi2(1) = 0.01 Prob > chi2 = 0.9249
```

Note: Likelihood-ratio tests are recommended for inference with scobit models.

We find that cars yielding better gas mileage are less likely to be foreign. The likelihood-ratio test at the bottom of the output indicates that the model is not significantly different from a logit model. Therefore, we should use the more parsimonious model.

◀

## □ Technical note

Stata interprets a value of 0 as a negative outcome (failure) and treats all other values (except missing) as positive outcomes (successes). Thus if the dependent variable takes on the values 0 and 1, then 0 is interpreted as failure and 1 as success. If the dependent variable takes on the values 0, 1, and 2, then 0 is still interpreted as failure, but both 1 and 2 are treated as successes.

Formally, when we type `scobit y x`, Stata fits the model

$$\Pr(y_j \neq 0 \mid \mathbf{x}_j) = 1 - 1 / \left\{ 1 + \exp(\mathbf{x}_j \beta) \right\}^\alpha$$

□

## Robust standard errors

If you specify the `vce(robust)` option, `scobit` reports robust standard errors as described in [U] 20.22 **Obtaining robust variance estimates**. For the model of `foreign` on `mpg`, the robust calculation increases the standard error of the coefficient on `mpg` by around 25%:

```
. scobit foreign mpg, vce(robust) nolog
Skewed logistic regression Number of obs = 74
 Zero outcomes = 52
Log pseudolikelihood = -39.2842 Nonzero outcomes = 22
```

| foreign  | Coefficient | Robust<br>std. err. | z     | P> z  | [95% conf. interval] |           |
|----------|-------------|---------------------|-------|-------|----------------------|-----------|
| mpg      | .1813879    | .3028487            | 0.60  | 0.549 | -.4121847            | .7749606  |
| _cons    | -4.274883   | 1.335521            | -3.20 | 0.001 | -6.892455            | -1.657311 |
| /lnalpha | -.4450405   | 4.71561             | -0.09 | 0.925 | -9.687466            | 8.797385  |
| alpha    | .6407983    | 3.021755            |       |       | .0000621             | 6616.919  |

Without `vce(robust)`, the standard error for the coefficient on `mpg` was reported to be 0.241, with a resulting confidence interval of  $[-0.29, 0.65]$ .

Specifying the `vce(cluster clustvar)` option relaxes the independence assumption required by the skewed logit estimator to being just independence between clusters. To demonstrate this, we will switch to a different dataset.

## ▷ Example 2

We are studying the unionization of women in the United States and have a dataset with 26,200 observations on 4,434 women between 1970 and 1988. For our purposes, we will use the variables `age` (the women were 14–26 in 1968 and the data thus span the age range of 16–46), `grade` (years of schooling completed, ranging from 0 to 18), `not_smsa` (28% of the person-time was spent living outside an SMSA—standard metropolitan statistical area), `south` (41% of the person-time was in the South), and `year`. Each of these variables is included in the regression as a covariate along with the interaction between `south` and `year`. This interaction, along with the `south` and `year` variables, is specified in the `scobit` command using factor-variables notation, `south##c.year`. We also have variable `union`. Overall, 22% of the person-time is marked as time under union membership and 44% of these women have belonged to a union.

We fit the following model, ignoring that women are observed an average of 5.9 times each in these data:

```
. use https://www.stata-press.com/data/r19/union, clear
(NLS Women 14-24 in 1968)
. scobit union age grade not_smsa south##c.year, nrtol(1e-3)
(output omitted)
```

```
Skewed logistic regression Number of obs = 26,200
 Zero outcomes = 20,389
Log likelihood = -13540.61 Nonzero outcomes = 5,811
```

|                           | Coefficient | Std. err. | z     | P> z  | [95% conf. interval] |           |
|---------------------------|-------------|-----------|-------|-------|----------------------|-----------|
| <code>union</code>        |             |           |       |       |                      |           |
| <code>age</code>          | .0185363    | .0043615  | 4.25  | 0.000 | .0099879             | .0270848  |
| <code>grade</code>        | .0452801    | .0057124  | 7.93  | 0.000 | .034084              | .0564761  |
| <code>not_smsa</code>     | -.1886826   | .0317801  | -5.94 | 0.000 | -.2509705            | -.1263947 |
| <code>1.south</code>      | -1.422372   | .3949301  | -3.60 | 0.000 | -2.196421            | -.6483233 |

| <code>south#c.year</code> |             |           |       |       |                      |           |
| <code>1</code>            | .0105663    | .0049233  | 2.15  | 0.032 | .0009167             | .0202158  |
| <code>_cons</code>        | -10.3557    | 68.9757   | -0.15 | 0.881 | -145.5456            | 124.8342  |
| <code>/lnalpha</code>     | 9.136018    | 68.97395  | 0.13  | 0.895 | -126.0504            | 144.3225  |
| <code>alpha</code>        | 9283.719    | 640334.8  |       |       | 1.81e-55             | 4.77e+62  |

```
LR test of alpha=1: chi2(1) = 3.76 Prob > chi2 = 0.0524
```

```
Note: Likelihood-ratio tests are recommended for inference with scobit models.
```

The reported standard errors in this model are probably meaningless. Women are observed repeatedly, so the observations are not independent. Looking at the coefficients, we find a large southern effect against unionization and a different time trend for the south. The `vce(cluster clustvar)` option provides a way to fit this model and obtains correct standard errors:

```
. scobit union age grade not_smsa south##c.year, vce(cluster id) nrtol(1e-3)
(output omitted)
Skewed logistic regression Number of obs = 26,200
 Zero outcomes = 20,389
Log pseudolikelihood = -13540.61 Nonzero outcomes = 5,811
 (Std. err. adjusted for 4,434 clusters in idcode)
```

| union        | Coefficient | Robust<br>std. err. | z      | P> z  | [95% conf. interval] |           |
|--------------|-------------|---------------------|--------|-------|----------------------|-----------|

`scobit`, `vce(cluster clustvar)` is robust to assumptions about within-cluster correlation. That is, it inefficiently sums within cluster for the standard error calculation rather than attempting to exploit what might be assumed about the within-cluster correlation (as do the `xtgee` population-averaged models; see [XT] `xtgee`).

◀

### □ Technical note

The `scobit` model can be difficult to fit because of the functional form. Often, it requires many iterations, or the optimizer prints out warning and informative messages during the optimization. For example, without the `nrtol(1e-3)` option, the model using the `union` dataset will not converge. See [R] `Maximize` for details about the optimizer.

□

### □ Technical note

The main reason for using `scobit` rather than `logit` is that the effects of the regressors on the probability of success are not constrained to be the largest when the probability is 0.5. Rather, the independent variables might show their largest impact when the probability of success is 0.3 or 0.6. This added flexibility results because the `scobit` function, unlike the `logit` function, can be skewed and is not constrained to be mirror symmetric about the 0.5 probability of success.

As Nagler (1994) pointed out, the point of maximum impact is constrained under the `scobit` model to fall within the interval  $(0, 1 - e^{(-1)})$  or approximately  $(0, 0.63)$ . Achen (2002) notes that if we believe the maximum impact to be outside that range, we can instead fit the “power logit” model by simply reversing the 0s and 1s of our outcome variable and fitting a `scobit` model on failure, rather than success. We would need to reverse the signs of the coefficients if we wanted to interpret them in terms of impact on success,

or we could leave them as they are and interpret them in terms of impact on failure. The important thing to remember is that the scobit model, unlike the logit model, is not invariant to the choice of which result is assigned to success. □

## Stored results

scobit stores the following in `e()`:

### Scalars

|                           |                                          |
|---------------------------|------------------------------------------|
| <code>e(N)</code>         | number of observations                   |
| <code>e(k)</code>         | number of parameters                     |
| <code>e(k_eq)</code>      | number of equations in <code>e(b)</code> |
| <code>e(k_aux)</code>     | number of auxiliary parameters           |
| <code>e(k_dv)</code>      | number of dependent variables            |
| <code>e(ll)</code>        | log likelihood                           |
| <code>e(ll_c)</code>      | log likelihood, comparison model         |
| <code>e(N_f)</code>       | number of failures (zero outcomes)       |
| <code>e(N_s)</code>       | number of successes (nonzero outcomes)   |
| <code>e(alpha)</code>     | alpha                                    |
| <code>e(N_clust)</code>   | number of clusters                       |
| <code>e(chi2_c)</code>    | $\chi^2$ for comparison test             |
| <code>e(rank)</code>      | rank of <code>e(V)</code>                |
| <code>e(ic)</code>        | number of iterations                     |
| <code>e(rc)</code>        | return code                              |
| <code>e(converged)</code> | 1 if converged, 0 otherwise              |

### Macros

|                            |                                                                                 |
|----------------------------|---------------------------------------------------------------------------------|
| <code>e(cmd)</code>        | scobit                                                                          |
| <code>e(cmdline)</code>    | command as typed                                                                |
| <code>e(depvar)</code>     | name of dependent variable                                                      |
| <code>e(wtype)</code>      | weight type                                                                     |
| <code>e(wexp)</code>       | weight expression                                                               |
| <code>e(title)</code>      | title in estimation output                                                      |
| <code>e(clustvar)</code>   | name of cluster variable                                                        |
| <code>e(offset)</code>     | linear offset variable                                                          |
| <code>e(chi2_ct)</code>    | Wald or LR; type of model $\chi^2$ test corresponding to <code>e(chi2_c)</code> |
| <code>e(vce)</code>        | <i>vce</i> type specified in <code>vce()</code>                                 |
| <code>e(vcetype)</code>    | title used to label Std. err.                                                   |
| <code>e(opt)</code>        | type of optimization                                                            |
| <code>e(which)</code>      | max or min; whether optimizer is to perform maximization or minimization        |
| <code>e(ml_method)</code>  | type of ml method                                                               |
| <code>e(user)</code>       | name of likelihood-evaluator program                                            |
| <code>e(technique)</code>  | maximization technique                                                          |
| <code>e(properties)</code> | b V                                                                             |
| <code>e(predict)</code>    | program used to implement <code>predict</code>                                  |
| <code>e(footnote)</code>   | program used to implement the footnote display                                  |
| <code>e(asbalanced)</code> | factor variables <code>fvset</code> as <code>asbalanced</code>                  |
| <code>e(asobserved)</code> | factor variables <code>fvset</code> as <code>asobserved</code>                  |

### Matrices

|                              |                                              |
|------------------------------|----------------------------------------------|
| <code>e(b)</code>            | coefficient vector                           |
| <code>e(Cns)</code>          | constraints matrix                           |
| <code>e(ilog)</code>         | iteration log (up to 20 iterations)          |
| <code>e(gradient)</code>     | gradient vector                              |
| <code>e(V)</code>            | variance–covariance matrix of the estimators |
| <code>e(V_modelbased)</code> | model-based variance                         |

### Functions

|                        |                         |
|------------------------|-------------------------|
| <code>e(sample)</code> | marks estimation sample |
|------------------------|-------------------------|

In addition to the above, the following is stored in `r()`:

Matrices

`r(table)`

matrix containing the coefficients with their standard errors, test statistics,  $p$ -values, and confidence intervals

Note that results stored in `r()` are updated when the command is replayed and will be replaced when any `r-class` command is run after the estimation command.

## Methods and formulas

Skewed logit analysis is an alternative to logit that relaxes the assumption that individuals with initial probability of 0.5 are most sensitive to changes in independent variables.

The log-likelihood function for skewed logit is

$$\ln L = \sum_{j \in S} w_j \ln F(\mathbf{x}_j \mathbf{b}) + \sum_{j \notin S} w_j \ln \{1 - F(\mathbf{x}_j \mathbf{b})\}$$

where  $S$  is the set of all observations  $j$  such that  $y_j \neq 0$ ,  $F(z) = 1 - 1/\{1 + \exp(z)\}^\alpha$ , and  $w_j$  denotes the optional weights.  $\ln L$  is maximized as described in [R] **Maximize**.

This command supports the Huber/White/sandwich estimator of the variance and its clustered version using `vce(robust)` and `vce(cluster clustvar)`, respectively. See [P] **\_robust**, particularly *Maximum likelihood estimators* and *Methods and formulas*.

`scobit` also supports estimation with survey data. For details on VCEs with survey data, see [SVY] **Variance estimation**.

## Postestimation commands

The following postestimation commands are available after `scobit`:

| Command                      | Description                                                                                                                             |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <code>contrast</code>        | contrasts and ANOVA-style joint tests of parameters                                                                                     |
| <code>estat ic</code>        | Akaike's, consistent Akaike's, corrected Akaike's, and Schwarz's Bayesian information criteria (AIC, CAIC, AICc, and BIC, respectively) |
| <code>estat summarize</code> | summary statistics for the estimation sample                                                                                            |
| <code>estat vce</code>       | variance–covariance matrix of the estimators (VCE)                                                                                      |
| <code>estat (svy)</code>     | postestimation statistics for survey data                                                                                               |
| <code>estimates</code>       | cataloging estimation results                                                                                                           |
| <code>etable</code>          | table of estimation results                                                                                                             |
| * <code>forecast</code>      | dynamic forecasts and simulations                                                                                                       |
| <code>lincom</code>          | point estimates, standard errors, testing, and inference for linear combinations of parameters                                          |
| * <code>lrtest</code>        | likelihood-ratio test                                                                                                                   |
| <code>margins</code>         | marginal means, predictive margins, marginal effects, and average marginal effects                                                      |
| <code>marginsplot</code>     | graph the results from margins (profile plots, interaction plots, etc.)                                                                 |
| <code>nlcom</code>           | point estimates, standard errors, testing, and inference for nonlinear combinations of parameters                                       |
| <code>predict</code>         | probabilities, linear predictions and their SEs, etc.                                                                                   |
| <code>predictnl</code>       | point estimates, standard errors, testing, and inference for generalized predictions                                                    |
| <code>pwcompare</code>       | pairwise comparisons of parameters                                                                                                      |
| <code>suest</code>           | seemingly unrelated estimation                                                                                                          |
| <code>test</code>            | Wald tests of simple and composite linear hypotheses                                                                                    |
| <code>testnl</code>          | Wald tests of nonlinear hypotheses                                                                                                      |

\*`forecast` and `lrtest` are not appropriate with `svy` estimation results.

# predict

## Description for predict

`predict` creates a new variable containing predictions such as probabilities, linear predictions, and standard errors.

## Menu for predict

Statistics > Postestimation

## Syntax for predict

```
predict [type] newvar [if] [in] [, statistic nooffset]
```

```
predict [type] stub* [if] [in] , scores
```

| <i>statistic</i> | Description |
|------------------|-------------|
|------------------|-------------|

Main

|                   |                                                |
|-------------------|------------------------------------------------|
| <code>pr</code>   | probability of a positive outcome; the default |
| <code>xb</code>   | $\mathbf{x}_j\mathbf{b}$ , linear prediction   |
| <code>stdp</code> | standard error of the linear prediction        |

These statistics are available both in and out of sample; type `predict . . . if e(sample) . . .` if wanted only for the estimation sample.

## Options for predict

Main

`pr`, the default, calculates the probability of a positive outcome.

`xb` calculates the linear prediction.

`stdp` calculates the standard error of the linear prediction.

`nooffset` is relevant only if you specified `offset(varname)` for `scobit`. It modifies the calculations made by `predict` so that they ignore the offset variable; the linear prediction is treated as  $\mathbf{x}_j\mathbf{b}$  rather than as  $\mathbf{x}_j\mathbf{b} + \text{offset}_j$ .

`scores` calculates equation-level score variables.

The first new variable will contain  $\partial \ln L / \partial (\mathbf{x}_j\boldsymbol{\beta})$ .

The second new variable will contain  $\partial \ln L / \partial \ln \alpha$ .

# margins

## Description for margins

`margins` estimates margins of response for probabilities and linear predictions.

## Menu for margins

Statistics > Postestimation

## Syntax for margins

```
margins [marginlist] [, options]
```

```
margins [marginlist] , predict(statistic ...) [predict(statistic ...) ...] [options]
```

| <i>statistic</i>  | Description                                    |
|-------------------|------------------------------------------------|
| <code>pr</code>   | probability of a positive outcome; the default |
| <code>xb</code>   | $\mathbf{x}_j\mathbf{b}$ , linear prediction   |
| <code>stdp</code> | not allowed with <code>margins</code>          |

Statistics not allowed with `margins` are functions of stochastic quantities other than  $e(\mathbf{b})$ .

For the full syntax, see [R] [margins](#).

## Remarks and examples

Once you have fit a model, you can obtain the predicted probabilities by using the `predict` command for both the estimation sample and other samples; see [U] [20 Estimation and postestimation commands](#) and [R] [predict](#). Here we will make only a few additional comments.

`predict` without arguments calculates the predicted probability of a positive outcome. With the `xb` option, it calculates the linear combination  $\mathbf{x}_j\mathbf{b}$ , where  $\mathbf{x}_j$  are the independent variables in the  $j$ th observation and  $\mathbf{b}$  is the estimated parameter vector.

With the `stdp` option, `predict` calculates the standard error of the prediction, which is *not* adjusted for replicated covariate patterns in the data.

## ▷ Example 1

In [example 1](#) of [\[R\] scobit](#), we fit the model `scobit foreign mpg`. To obtain predicted probabilities, we type

```
. use https://www.stata-press.com/data/r19/auto
(1978 automobile data)
. keep make mpg weight foreign
. scobit foreign mpg
(output omitted)
. predict p
(option pr assumed; Pr(foreign))
. summarize foreign p
```

| Variable | Obs | Mean     | Std. dev. | Min      | Max     |
|----------|-----|----------|-----------|----------|---------|

## Description

`sdtest` performs tests on the equality of standard deviations (variances). In the first form, `sdtest` tests that the standard deviation of *varname* is *#*. In the second form, `sdtest` performs the same test, using the standard deviations of the two groups defined by *groupvar*. In the third form, `sdtest` tests that *varname*<sub>1</sub> and *varname*<sub>2</sub> have the same standard deviation.

`sdtesti` is the immediate form of `sdtest`; see [\[U\] 19 Immediate commands](#).

Both the traditional *F* test for the homogeneity of variances and Bartlett's generalization of this test to *K* samples are sensitive to the assumption that the data are drawn from an underlying Gaussian distribution. See, for example, the cautionary results discussed by [Markowski and Markowski \(1990\)](#). [Levene \(1960\)](#) proposed a test statistic for equality of variance that was found to be robust under nonnormality. Then [Brown and Forsythe \(1974\)](#) proposed alternative formulations of Levene's test statistic that use more robust estimators of central tendency in place of the mean. These reformulations were demonstrated to be more robust than Levene's test when dealing with skewed populations.

`robvar` reports Levene's robust test statistic ( $W_0$ ) for the equality of variances between the groups defined by *groupvar* and the two statistics proposed by Brown and Forsythe that replace the mean in Levene's formula with alternative location estimators. The first alternative ( $W_{50}$ ) replaces the mean with the median. The second alternative replaces the mean with the 10% trimmed mean ( $W_{10}$ ).

## Quick start

Test that the standard deviation of *v1* is equal to 2

```
sdtest v1=2
```

Equality of standard deviations (variances) test for *v1* comparing the two groups defined by *catvar1*

```
sdtest v1, by(catvar1)
```

Robust equality of variances test for *v1* comparing the groups defined by *catvar1*

```
robvar v1, by(catvar1)
```

Compare the variances of *v2* and *v3*

```
sdtest v2 == v3
```

Same as above, but with separate tests for each group defined by *catvar2*

```
by catvar2, sort: sdtest v2 == v3
```

Test  $sd_1 = sd_2$  for  $sd_1 = 34$ ,  $sd_2 = 45$ ,  $N_1 = 143$ , and  $N_2 = 184$

```
sdtesti 143 . 34 184 . 45
```

## Menu

### sdtest

Statistics > Summaries, tables, and tests > Classical tests of hypotheses > Variance-comparison test

### sdtesti

Statistics > Summaries, tables, and tests > Classical tests of hypotheses > Variance-comparison test calculator

### robvar

Statistics > Summaries, tables, and tests > Classical tests of hypotheses > Robust equal-variance test

## Syntax

*One-sample variance-comparison test*

```
sdtest varname == # [if] [in] [, level(#)]
```

*Two-sample variance-comparison test using groups*

```
sdtest varname [if] [in] , by(groupvar) [level(#)]
```

*Two-sample variance-comparison test using variables*

```
sdtest varname1 == varname2 [if] [in] [, level(#)]
```

*Immediate form of one-sample variance-comparison test*

```
sdtesti #obs { #mean | . } #sd #val [, level(#)]
```

*Immediate form of two-sample variance-comparison test*

```
sdtesti #obs,1 { #mean,1 | . } #sd,1 #obs,2 { #mean,2 | . } #sd,2 [, level(#)]
```

*Robust tests for equality of variances*

```
robvar varname [if] [in] , by(groupvar)
```

by and collect are allowed with sdtest and robvar, and collect is allowed with sdtesti; see [\[U\] 11.1.10 Prefix commands](#).

## Options

*level*(#) specifies the confidence level, as a percentage, for confidence intervals of the means. The default is *level*(95) or as set by *set level*; see [\[U\] 20.8 Specifying the width of confidence intervals](#).

by(*groupvar*) specifies the *groupvar* that defines the groups to be compared. For sdtest, there should be two groups, but for robvar there may be more than two groups. Do not confuse the by() option with the by prefix; both may be specified.

## Remarks and examples

Remarks are presented under the following headings:

*Basic form*  
*Immediate form*  
*Robust test*

### Basic form

sdtest performs two different statistical tests: one testing equality of variances and the other testing that the standard deviation is equal to a known constant. Which test it performs is determined by whether you type a variable name or a number to the right of the equal sign.

#### ▷ Example 1: One-sample test of variance

We have a sample of 74 automobiles. For each automobile, we know the mileage rating. We wish to test whether the overall standard deviation is 5 mpg:

```
. use https://www.stata-press.com/data/r19/auto
(1978 automobile data)
. sdtest mpg == 5
```

One-sample test of variance

| Variable | Obs | Mean    | Std. err. | Std. dev. | [95% conf. interval] |          |
|----------|-----|---------|-----------|-----------|----------------------|----------|
| mpg      | 74  | 21.2973 | .6725511  | 5.785503  | 19.9569              | 22.63769 |

```
sd = sd(mpg)
HO: sd = 5
Ha: sd < 5
Pr(C < c) = 0.9717

c = chi2 = 97.7384
Degrees of freedom = 73
Ha: sd != 5
Pr(C > c) = 0.0565

Ha: sd > 5
Pr(C > c) = 0.0283
```

#### ▷ Example 2: Variance ratio test

We are testing the effectiveness of a new fuel additive. We run an experiment on 12 cars, running each without and with the additive. The data can be found in [R] [ttest](#). The results for each car are stored in the variables mpg1 and mpg2:

```
. use https://www.stata-press.com/data/r19/fuel
. sdtest mpg1==mpg2
```

Variance ratio test

| Variable | Obs | Mean   | Std. err. | Std. dev. | [95% conf. interval] |          |
|----------|-----|--------|-----------|-----------|----------------------|----------|
| mpg1     | 12  | 21     | .7881701  | 2.730301  | 19.26525             | 22.73475 |
| mpg2     | 12  | 22.75  | .9384465  | 3.250874  | 20.68449             | 24.81551 |
| Combined | 24  | 21.875 | .6264476  | 3.068954  | 20.57909             | 23.17091 |

```
ratio = sd(mpg1) / sd(mpg2)
HO: ratio = 1
Ha: ratio < 1
Pr(F < f) = 0.2862

f = 0.7054
Degrees of freedom = 11, 11
Ha: ratio != 1
Pr(F < f) = 0.5725

Ha: ratio > 1
Pr(F > f) = 0.7138
```

We cannot reject the hypothesis that the standard deviations are the same.

In [R] `ttest`, we draw an important distinction between paired and unpaired data, which, in this example, means whether there are 12 cars in a before-and-after experiment or 24 different cars. For `sdtest`, on the other hand, there is no distinction. If the data had been unpaired and stored as described in [R] `ttest`, we could have typed `sdtest mpg, by(treated)`, and the results would have been the same.

## Immediate form

### ▷ Example 3: `sdtesti`

Immediate commands are used not with data, but with reported summary statistics. For instance, to test whether a variable on which we have 75 observations and a reported standard deviation of 6.5 comes from a population with underlying standard deviation 6, we would type

```
. sdtesti 75 . 6.5 6
One-sample test of variance
```

|   | Obs | Mean | Std. err. | Std. dev. | [95% conf. interval] |
|---|-----|------|-----------|-----------|----------------------|
| x | 75  | .    | .7505553  | 6.5       | . .                  |

```

sd = sd(x) c = chi2 = 86.8472
HO: sd = 6 Degrees of freedom = 74
Ha: sd < 6 Ha: sd != 6 Ha: sd > 6
Pr(C < c) = 0.8542 2*Pr(C > c) = 0.2916 Pr(C > c) = 0.1458

```

The mean plays no role in the calculation, so it may be omitted.

To test whether the variable comes from a population with the same standard deviation as another for which we have a calculated standard deviation of 7.5 over 65 observations, we would type

```
. sdtesti 75 . 6.5 65 . 7.5
Variance ratio test
```

|          | Obs | Mean | Std. err. | Std. dev. | [95% conf. interval] |
|----------|-----|------|-----------|-----------|----------------------|
| x        | 75  | .    | .7505553  | 6.5       | . .                  |
| y        | 65  | .    | .9302605  | 7.5       | . .                  |
| Combined | 140 | .    | .         | .         | . .                  |

```

ratio = sd(x) / sd(y) f = 0.7511
HO: ratio = 1 Degrees of freedom = 74, 64
Ha: ratio < 1 Ha: ratio != 1 Ha: ratio > 1
Pr(F < f) = 0.1172 2*Pr(F < f) = 0.2344 Pr(F > f) = 0.8828

```

## Robust test

### ▷ Example 4: robvar

We wish to test whether the standard deviation of the length of stay for patients hospitalized for a given medical procedure differs by gender. Our data consist of observations on the length of hospital stay for 1778 patients: 884 males and 894 females. Length of stay, `lengthstay`, is highly skewed (skewness coefficient = 4.912591) and thus violates Bartlett's normality assumption. Therefore, we use `robvar` to compare the variances.

```
. use https://www.stata-press.com/data/r19/stay
. robvar lengthstay, by(sex)
```

| Gender | Summary of Length of stay in days |           |       |
|--------|-----------------------------------|-----------|-------|
|        | Mean                              | Std. dev. | Freq. |
| Male   | 9.0874434                         | 9.7884747 | 884   |
| Female | 8.800671                          | 9.1081478 | 894   |
| Total  | 8.9432508                         | 9.4509466 | 1,778 |

```
W0 = 0.55505315 df(1, 1776) Pr > F = 0.45635888
W50 = 0.42714734 df(1, 1776) Pr > F = 0.51347664
W10 = 0.44577674 df(1, 1776) Pr > F = 0.50443411
```

For these data, we cannot reject the null hypothesis that the variances are equal. However, Bartlett's test yields a significance probability of 0.0319 because of the pronounced skewness of the data.

### □ Technical note

`robvar` implements both the conventional Levene's test centered at the mean and a median-centered test. In a simulation study, [Conover, Johnson, and Johnson \(1981\)](#) compare the properties of the two tests and recommend using the median test for asymmetric data, although for small sample sizes the test is somewhat conservative. See [Carroll and Schneider \(1985\)](#) for an explanation of why both mean- and median-centered tests have approximately the same level for symmetric distributions, but for asymmetric distributions the median test is closer to the correct level.

## Stored results

`sdtest` and `sdtesti` store the following in `r()`:

Scalars

|                      |                                        |
|----------------------|----------------------------------------|
| <code>r(N)</code>    | number of observations                 |
| <code>r(p_l)</code>  | lower one-sided $p$ -value             |
| <code>r(p_u)</code>  | upper one-sided $p$ -value             |
| <code>r(p)</code>    | two-sided $p$ -value                   |
| <code>r(F)</code>    | $F$ statistic                          |
| <code>r(sd)</code>   | standard deviation                     |
| <code>r(sd_1)</code> | standard deviation for first variable  |
| <code>r(sd_2)</code> | standard deviation for second variable |
| <code>r(df)</code>   | degrees of freedom                     |
| <code>r(df_1)</code> | numerator degrees of freedom           |
| <code>r(df_2)</code> | denominator degrees of freedom         |
| <code>r(chi2)</code> | $\chi^2$                               |

`robvar` stores the following in `r()`:

Scalars

|                       |                                                   |
|-----------------------|---------------------------------------------------|
| <code>r(N)</code>     | number of observations                            |
| <code>r(w50)</code>   | Brown and Forsythe's $F$ statistic (median)       |
| <code>r(p_w50)</code> | Brown and Forsythe's $p$ -value                   |
| <code>r(w0)</code>    | Levene's $F$ statistic                            |
| <code>r(p_w0)</code>  | Levene's $p$ -value                               |
| <code>r(w10)</code>   | Brown and Forsythe's $F$ statistic (trimmed mean) |
| <code>r(p_w10)</code> | Brown and Forsythe's $p$ -value (trimmed mean)    |
| <code>r(df_1)</code>  | numerator degrees of freedom                      |
| <code>r(df_2)</code>  | denominator degrees of freedom                    |

## Methods and formulas

See Armitage et al. (2002, 149–153) or Bland (2015, 144–145) for an introduction and explanation of the calculation of these tests.

The test for  $\sigma = \sigma_0$  is given by

$$\chi^2 = \frac{(n-1)s^2}{\sigma_0^2}$$

which is distributed as  $\chi^2$  with  $n-1$  degrees of freedom.

The test for  $\sigma_x^2 = \sigma_y^2$  is given by

$$F = \frac{s_x^2}{s_y^2}$$

which is distributed as  $F$  with  $n_x-1$  and  $n_y-1$  degrees of freedom.

Let  $X_{ij}$  be the  $j$ th observation of  $X$  for the  $i$ th group. Let  $Z_{ij} = |X_{ij} - \bar{X}_i|$ , where  $\bar{X}_i$  is the mean of  $X$  in the  $i$ th group. Levene's test statistic is

$$W_0 = \frac{\sum_i n_i (\bar{Z}_i - \bar{Z})^2 / (g-1)}{\sum_i \sum_j (Z_{ij} - \bar{Z}_i)^2 / \sum_i (n_i - 1)}$$

where  $n_i$  is the number of observations in group  $i$  and  $g$  is the number of groups.  $W_{50}$  is obtained by replacing  $\bar{X}_i$  with the  $i$ th group median of  $X_{ij}$ , whereas  $W_{10}$  is obtained by replacing  $\bar{X}_i$  with the 10% trimmed mean for group  $i$ .

[Menu](#)

[Option for set searchdefault](#)

[Also see](#)

## Description

`search` searches a keyword database and the internet for Stata materials related to your query.

Capitalization of the words following `search` is irrelevant, as is the inclusion or exclusion of special characters such as commas and hyphens.

`set searchdefault` affects the default behavior of the `search` command. `all` is the default.

`search`, `all` is the best way to search for information on a topic across all sources, including the system help, the FAQs at the Stata website, the *Stata Journal*, and all Stata-related internet sources including community-contributed additions. From the results, you can click to go to a source or to install additions.

## Quick start

Search local keyword database and materials available via Stata's `net` command for all words (`word1`, `word2`, and `word3`)

```
search word1 word2 word3
```

Same as above, but match any word (`word1`, `word2`, or `word3`)

```
search word1 word2 word3, or
```

Search for *Stata Journal* articles about new commands like `regress`

```
search regress, sj
```

Search the manuals for entries about `tabulate` and related commands

```
search tabulate, manual
```

## Menu

Help > Search...

## Syntax

```
search word [word ...] [, search_options]
```

```
set searchdefault { all | local | net } [, permanently]
```

| <i>search_options</i>   | Description                                                                                             |
|-------------------------|---------------------------------------------------------------------------------------------------------|
| <code>all</code>        | search across both the local keyword database and the net material; the default                         |
| <code>local</code>      | search using Stata's keyword database                                                                   |
| <code>net</code>        | search across materials available via Stata's net command                                               |
| <code>author</code>     | search by author's name                                                                                 |
| <code>entry</code>      | search by entry ID                                                                                      |
| <code>exact</code>      | search across both the local keyword database and the net materials; prevents matching on abbreviations |
| <code>faq</code>        | search the FAQs posted to the Stata and other select websites                                           |
| <code>historical</code> | search entries that are of historical interest only                                                     |
| <code>or</code>         | list an entry if <i>any</i> of the words typed after search are associated with the entry               |
| <code>manual</code>     | search the entries in the <i>Stata Documentation</i>                                                    |
| <code>sj</code>         | search the entries in the <i>Stata Journal</i>                                                          |

## Options for search

`all`, the default (unless changed by `set searchdefault`), specifies that the search be performed across both the local keyword database and the net materials. The results of a search performed with `all` and no other options will be displayed in the Viewer window.

`local` specifies that the search be performed using only Stata's keyword database. The results of a search performed with `local` and no other options will be displayed in the Viewer window.

`net` specifies that the search be performed across the materials available via Stata's net command. Using `search word [word ...]`, `net` is equivalent to typing `net search word [word ...]` (without options); see [R] [net search](#). The results of a search performed with `net` and no other options will be displayed in the Viewer window.

`author` specifies that the search be performed on the basis of the author's name rather than keywords. A search with the `author` option is performed on the local keyword database only, and the results are displayed in the Results window.

`entry` specifies that the search be performed on the basis of entry IDs rather than keywords. A search with the `entry` option is performed on the local keyword database only, and the results are displayed in the Results window.

`exact` prevents matching on abbreviations. A search with the `exact` option is performed across both the local keyword database and the net materials, and the results are displayed in the Results window.

`faq` limits the search to the FAQs on the [Stata](#) and other select websites. A search with the `faq` option is performed on the local keyword database only, and the results are displayed in the Results window.

`historical` adds to the search entries that are of historical interest only. By default, such entries are not listed. Past entries are classified as historical if they discuss a feature that later became an official part of Stata. Updates to historical entries will always be found, even if `historical` is not specified. A search with the `historical` option is performed on the local keyword database only, and the results are displayed in the Results window.

`or` specifies that an entry be listed if any of the words typed after `search` are associated with the entry. The default is to list the entry only if all the words specified are associated with the entry. A search with the `or` option is performed on the local keyword database only, and the results are displayed in the Results window.

`manual` limits the search to entries in the *Stata Documentation*; that is, the search is limited to the *User's Guide* and all the reference manuals. A search with the `manual` option is performed on the local keyword database only, and the results are displayed in the Results window.

`sj` limits the search to entries in the *Stata Journal*; see [\[R\] sj](#). A search with the `sj` option is performed on the local keyword database only, and the results are displayed in the Results window.

## Option for set searchdefault

`permanently` specifies that, in addition to making the change right now, the `searchdefault` setting be remembered and become the default setting when you invoke Stata.

## Remarks and examples

Remarks are presented under the following headings:

- [Introduction](#)
- [Internet searches](#)
- [Author searches](#)
- [Entry ID searches](#)
- [Return codes](#)

## Introduction

See [\[U\] 4 Stata's help and search facilities](#) for a tutorial introduction to `search`. `search` is one of Stata's most useful commands. To understand the advanced features of `search`, you need to know how it works.

`search` has a database—files—containing the titles, etc., of every entry in the [Stata Documentation](#), undocumented help files, NetCourses, Stata Press books, FAQs posted on the Stata website, videos posted on the Stata YouTube channel, selected articles on StataCorp's official blog, selected community-contributed FAQs and examples, and the articles in the *Stata Journal*. In these files is a list of words, called keywords, associated with each entry.

When you type `search xyz`, `search` reads the database and compares the list of keywords with `xyz`. If it finds `xyz` in the list or a keyword that allows an abbreviation of `xyz`, it displays the entry.

When you type `search xyz abc`, `search` does the same thing but displays an entry only if it contains both keywords. The order does not matter, so you can `search linear regression` or `search regression linear`.

Obviously, how many entries `search` finds depends on how the search database was constructed. We have included a plethora of keywords under the theory that, for a given request, it is better to list too much rather than risk listing nothing at all. Still, you are in the position of guessing the keywords. Do you look up normality test, normality tests, or tests of normality? Well, normality test would be best, but all would work. In general, use the singular, and strike the unnecessary words. For guidelines for specifying keywords, see [U] 4.6 More on search.

`set searchdefault` allows you to specify where `search` searches. `set searchdefault all`, the default, indicates that both the keyword database and the internet are to be searched. `set searchdefault local` restricts `search` to using only Stata's keyword database. `set searchdefault net` restricts `search` to searching only the internet.

## Internet searches

`search` with the `net` option searches the internet for community-contributed additions to Stata, including, but not limited to, community-contributed additions published in the *Stata Journal* (SJ). `search keywords`, `net` performs the same search as the command `net search` (with no options); see [R] net search.

```
. search random effect, net
Search of web resources from Stata and other users
(contacting https://www.stata.com)
packages found (Stata Journal listed first)

(output omitted)
st0468_1 from http://www.stata-journal.com/software/sj18-4
 SJ18-4 st0468_1. Update: Estimate hybrid and... / Update: Estimate hybrid
 and correlated random- / effects and Mundlak mixed-effects models for /
 linear and nonlinear outcomes / by Reinhard Schunck, GESIS --
 Leibniz-Institute / for the Social Sciences, Cologne, Germany / Francisco
st0543 from http://www.stata-journal.com/software/sj18-4
 SJ18-4 st0543. Fit dynamic random-effects probit... / Fit dynamic
 random-effects probit models with / unobserved heterogeneity / by Raffaele
 Grotti, / Department of Political and Social Sciences / European
 University Institute / San Domenico di Fiesole, Italy / Giorgio Cutuli,
(output omitted)
(end of search)
```

## Author searches

`search` ordinarily compares the words following `search` with the keywords for the entry. If you specify the `author` option, however, it compares the words with the author's name. In the search database, we have filled in author names for all SJ inserts.

For instance, in the *Acknowledgments* of [R] `kdensity`, you will discover the name Isaías H. Salgado-Ugarte. You want to know if he has written any articles in the SJ. To find out, you type

```
. search Salgado-Ugarte, author
(output omitted)
```

Names like Salgado-Ugarte are confusing to many people. `search` does not require you to specify the entire name; what you type is compared with each “word” of the name and, if any part matches, the entry is listed. The hyphen is a special character, and you can omit it. Thus, you can obtain the same list by looking up Salgado, Ugarte, or Salgado Ugarte without the hyphen.

## Entry ID searches

If you specify the `entry` option, `search` compares what you have typed with the entry ID. The entry ID is not the title—it is the reference listed to the left of the title that tells you where to look. For instance, in

```
regress Linear regression
(help regress)
```

[R] `regress` is the entry ID. This is a reference, of course, to this manual. In

```
FAQ Analysis of multiple failure-time survival data
. M. Cleves and I. Canette
07/09 How do I analyze multiple failure-time data using Stata?
 https://www.stata.com/support/faqs/statistics/multiple-failure-
 type-data/
```

“FAQ” is the entry ID. In

```
SJ-7-1 st0118 . . A survey on survey stat.: What is and can be done in Stata
. F. Kreuter and R. Valliant
Q1/07 SJ7(1):1--21 (no commands)
discusses survey issues in analyzing complex survey
data and describes some of Stata’s capabilities for
such analyses
```

“SJ-7-1” is the entry ID.

`search` with the `entry` option searches these entry IDs.

Thus you could generate a table of contents for the *User’s Guide* by typing

```
. search [U], entry
(output omitted)
```

You could generate a table of contents for *Stata Journal*, Volume 1, Issue 1, by typing

```
. search sj-1-1, entry
(output omitted)
```

## Return codes

In addition to indexing the entries in the *User's Guide* and all the *Reference* manuals, `search` also can be used to search return codes.

To see information on return code 131, type

```
. search rc 131
[P] error Return code 131
 not possible with test;
 You requested a test of a hypothesis that is nonlinear in the
 variables. test tests only linear hypotheses. Use testnl.
(output omitted)
```

If you want a list of all Stata return codes, type

```
. search error, entry
(output omitted)
```

## Acknowledgment

We thank Nicholas J. Cox of the Department of Geography at Durham University, UK, who is coeditor of the *Stata Journal* and author of *Speaking Stata Graphics* for his contributions to the `search` command.

## Description

`serrbar` is typically used with a dataset containing means, standard deviations or standard errors, and an *xvar*. `serrbar` uses these data to create a standard error bar chart. The means are plotted against *xvar*, and error bars around the means have a width determined by the standard deviation or standard error. While it is most common to use `serrbar` with this type of data, `serrbar` may also be used to create a scatterplot with error bars for other types of data.

## Quick start

Plot of *y* versus *x* with error bars representing  $y \pm s$

```
serrbar y s x
```

Same as above, but with error bars for  $y \pm 2 \times s$

```
serrbar y s x, scale(2)
```

## Menu

Statistics > Other > Quality control > Standard error bar chart

## Syntax

```
serrbar mvar svar xvar [if] [in] [, options]
```

| <i>options</i>                                 | Description                                                                                 |
|------------------------------------------------|---------------------------------------------------------------------------------------------|

| <b>Add plots</b>                               |                                                                                             |
| <code>addplot(plot)</code>                     | add other plots to generated graph                                                          |
| <b>Y axis, X axis, Titles, Legend, Overall</b> |                                                                                             |
| <code>twoway_options</code>                    | any options other than <code>by()</code> documented in [G-3] <a href="#">twoway_options</a> |

## Options

### Main

`scale(#)` controls the length of the bars. The upper and lower limits of the bars will be  $mvar + scale() \times svar$  and  $mvar - scale() \times svar$ . The default is `scale(1)`.

### Error bars

`rcap_options` affect the rendition of the plotted error bars (the capped spikes). See [G-2] [graph twoway rcap](#).

### Plotted points

`mvopts(scatter_options)` affects the rendition of the plotted points (*mvar* versus *xvar*). See [G-2] [graph twoway scatter](#).

### Add plots

`addplot(plot)` provides a way to add other plots to the generated graph; see [G-3] [addplot\\_option](#).

### Y axis, X axis, Titles, Legend, Overall

`twoway_options` are any of the options documented in [G-3] [twoway\\_options](#), excluding `by()`. These include options for titling the graph (see [G-3] [title\\_options](#)) and for saving the graph to disk (see [G-3] [saving\\_option](#)).

## Remarks and examples

### ▷ Example 1

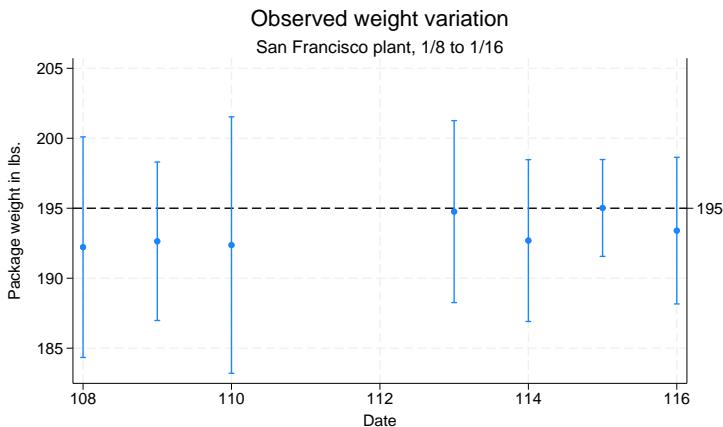

In quality-control applications, the three most commonly used variables with this command are the process mean, process standard deviation, and time. For instance, we have data on the average weights and standard deviations from an assembly line in San Francisco for the period January 8 to January 16. Our data are

```
. use https://www.stata-press.com/data/r19/assembly
. list, sep(0) divider
```

|    | date | mean   | std  |
|----|------|--------|------|
| 1. | 108  | 192.22 | 3.94 |
| 2. | 109  | 192.64 | 2.83 |
| 3. | 110  | 192.37 | 4.58 |
| 4. | 113  | 194.76 | 3.25 |
| 5. | 114  | 192.69 | 2.89 |
| 6. | 115  | 195.02 | 1.73 |
| 7. | 116  | 193.40 | 2.62 |

We type `serrbar mean std date, scale(2)` but, after seeing the result, decide to make it fancier:

```
. serrbar mean std date, scale(2) title("Observed weight variation")
> sub("San Francisco plant, 1/8 to 1/16") yline(195) yaxis(1 2)
> ylab(195, axis(2)) ytitle("", axis(2))
```

## Acknowledgment

`serrbar` was written by Nicholas J. Cox of the Department of Geography at Durham University, UK, who is coeditor of the *Stata Journal* and author of *Speaking Stata Graphics*.

## Also see

[R] [QC](#) — Quality control charts

[Description](#)[Syntax](#)[Remarks and examples](#)[Also see](#)

## Description

This entry provides a reference to Stata's `set` commands. For many entries, more thorough information is provided elsewhere; see the Reference field in each entry below for the location of this information.

To reset system parameters to factory defaults, see [\[R\] `set\_defaults`](#).

## Syntax

```
set [setcommand ...]
```

`set` typed without arguments is equivalent to `query` typed without arguments.

## Remarks and examples

`set adosize`

Syntax: `set adosize # [ , permanently ]`

Default: 1,000

Description: sets the maximum amount of memory that automatically loaded do-files may consume.  $10 \leq \# \leq 10000$ .

Reference: [\[P\] `sysdir`](#)

`set autotabgraphs` (Windows only)

Syntax: `set autotabgraphs {on|off} [ , permanently ]`

Default: off

Description: determines whether graphs are created as tabs within one window or as separate windows.

Reference: `help autotabgraphs`

`set cformat`

Syntax: `set cformat [fmt] [ , permanently ]`

Description: specifies the output format of coefficients, standard errors, and confidence limits in coefficient tables. *fmt* is a numerical format; see [\[D\] `format`](#).

Reference: [\[R\] `set cformat`](#)

`set clevel`

Syntax: `set clevel # [ , permanently ]`

Default: 95

Description: sets the default credible level for credible intervals for all commands that report credible intervals.  $10.00 \leq \# \leq 99.99$ , and  $\#$  can have at most two digits after the decimal point.

Reference: [\[BAYES\] `set clevel`](#)

**set coeftabresults**

Syntax: set coeftabresults {on|off}  
Default: on  
Description: determines whether coefficient table results are stored in `r()`.  
There is no permanently option because permanently is implied.  
Reference: help coeftabresults

**set collect\_double**

Syntax: set collect\_double {on|off} [, permanently]  
Default: on  
Description: controls the storage type for numeric values that are saved in collections when using `collect save`.  
Reference: [TABLES] [set collect\\_double](#)

**set collect\_label**

Syntax: set collect\_label {default|*label*} [, permanently]  
Default: default  
Description: controls the default labels used in tables created by `collect`.  
Reference: [TABLES] [set collect\\_label](#)

**set collect\_style**

Syntax: set collect\_style {default|*style*} [, permanently]  
Default: default  
Description: controls the default styles used in tables created by `collect`.  
Reference: [TABLES] [set collect\\_style](#)

**set collect\_warn**

Syntax: set collect\_warn {on|off} [, permanently]  
Default: on  
Description: controls whether `collect` shows notes warning about unrecognized tags.  
Reference: [TABLES] [set collect\\_warn](#)

## set conren (Unix console only)

Syntax 1: set conren

Syntax 2: set conren clear

Syntax 3: set conren [*sf* | *bf* | *it*]  
                   {*result* | [*txt* | *text*] | *input* | *error* | *link* | *hilite*}  
                   [*char*[*char*...]]

Syntax 4: set conren {*ulon* | *uloff*} [*char* [*char*...]]

Syntax 5: set conren reset [*char* [*char*...]]

Description: can possibly make the output on your screen appear prettier.

set conren displays a list of the currently defined display codes.

set conren clear clears all codes.

set conren followed by a font type (*bf*, *sf*, or *it*) and display context (*result*, *error*, *link*, or *hilite*) and then followed by a series of space-separated characters sets the code for the specified font type and display context. If the font type is omitted, the code is set to the same specified code for all three font types.

set conren ulon and set conren uloff set the codes for turning on and off underlining.

set conren reset sets the code that will turn off all display and underlining codes.

Reference: [\[GSU\] conren](#)

## set copycolor (Mac and Windows only)

Syntax: set copycolor {*automatic* | *asis* | *gs1* | *gs2* | *gs3*} [, *permanently*]

Default: automatic

Description: determines how colors are handled when graphs are copied to the Clipboard.

Reference: [\[G-2\] set printcolor](#)

## set dockable (Windows only)

Syntax: set dockable {*on* | *off*} [, *permanently*]

Default: on

Description: determines whether to enable the use of dockable window characteristics, including the ability to dock or tab a window into another window.

Reference: help dockable

## set docx\_hardbreak

Syntax: set docx\_hardbreak {*on* | *off*}

Default: off

Description: determines whether spaces are added after hard line breaks within text blocks.

Reference: [\[RPT\] set docx](#)

## set docx\_maxtable

Syntax: set docx\_maxtable # [, *permanently*]

Default: 500

Description: sets the maximum number of tables allowed in putdocx.

Reference: [\[RPT\] putdocx table](#)

**set docx\_paramode**

Syntax: set docx\_paramode {on | off}

Default: off

Description: determines whether empty lines in a text block signal the beginning of a new paragraph.

Reference: [\[RPT\] set docx](#)

**set doeditbackup**

Syntax: set doeditbackup {on | off}

Default: on

Description: determines whether to enable automatic backups of documents in the Do-file Editor.

Reference: [help doeditbackup](#)

**set dots**

Syntax: set dots {on | off} [ , permanently]

Default: on

Description: enables or disables commands that support the dots() option from reporting a dot each time statistics are computed from a sample or resample of the dataset.

Reference: [help dots](#)

**set doublebuffer (Windows only)**

Syntax: set doublebuffer {on | off} [ , permanently]

Default: on

Description: enables or disables double buffering of the Results, Viewer, and Data Editor windows. Double buffering prevents the windows from flickering when redrawn or resized. Users who encounter performance problems such as the Results window outputting very slowly should disable double buffering.

Reference: [help doublebuffer](#)

**set dp**

Syntax: set dp {comma | period} [ , permanently]

Default: period

Description: determines whether a period or a comma is to be used as the decimal point.

Reference: [\[D\] format](#)

**set dtable\_style**

Syntax: set dtable\_style {dtable | *style*} [ , permanently]

Default: dtable

Description: controls the default styles used in tables created by dtable.

Reference: [\[TABLES\] set dtable\\_style](#)

**set dtascomplevel**

Syntax: set dtascomplevel #  
Default: 1  
Description: sets the compression level for `frames save`, where # can be any integer between 0 and 9.  
Reference: help dtascomplevel

**set emptycells**

Syntax: set emptycells {keep|drop} [ , permanently ]  
Default: keep  
Description: sets what to do with empty cells in interactions.  
Reference: [R] [set emptycells](#)

**set etable\_style**

Syntax: set etable\_style {etable|style} [ , permanently ]  
Default: etable  
Description: controls the default styles used in tables created by etable.  
Reference: [TABLES] [set etable\\_style](#)

**set fastscroll (Unix and Windows only)**

Syntax: set fastscroll {on|off} [ , permanently ]  
Default: on  
Description: sets the scrolling method for new output in the Results window. Setting fastscroll to on is faster but can be jumpy. Setting fastscroll to off is slower but smoother.  
Reference: help fastscroll

**set floatwindows (Windows only)**

Syntax: set floatwindows {on|off}  
Default: off  
Description: determines whether to enable floating window behavior for dialog boxes and dockable window. The term “float” in this context means that a window will always float over the main Stata window; these windows cannot be placed behind the main Stata window. There is no permanently option because permanently is implied.  
Reference: help floatwindows

**set fredkey**

Syntax: set fredkey *key* [ , permanently ]  
Description: sets the API key for importing data from the Federal Reserve Economic Data.  
Reference: [D] [import fred](#)

**set fvbase**

Syntax: set fvbase {on|off}  
Description: specifies whether to automatically determine the default base level for factor variables.  
Reference: help fvbase

**set fvlabel**

Syntax: `set fvlabel { on | off } [ , permanently ]`  
Description: specifies whether to display factor-variable value labels in coefficient tables.  
Reference: [R] [set showbaselevels](#)

**set fvtrack**

Syntax: `set fvtrack { term | factor } [ , permanently ]`  
Description: allows you to control how Stata keeps track of factor levels when you use factor-variables notation.  
Reference: `help fvtrack`

**set fvwrap**

Syntax: `set fvwrap # [ , permanently ]`  
Description: specifies that long value labels wrap # lines in coefficient tables.  
Reference: [R] [set showbaselevels](#)

**set fvwrapon**

Syntax: `set fvwrapon { word | width } [ , permanently ]`  
Description: specifies whether value labels that wrap will break at word boundaries or break based on available space.  
Reference: [R] [set showbaselevels](#)

**set graphics**

Syntax: `set graphics { on | off }`  
Default: on; default is off for console Stata  
Description: determines whether graphs are displayed on your monitor.  
Reference: [G-2] [set graphics](#)

**set haverdir**

Syntax: `set haverdir "path" [ , permanently ]`  
Description: specifies the directory where the Haver databases are stored.  
Reference: [D] [import haver](#)

**set httpproxy**

Syntax: `set httpproxy { on | off } [ , init ]`  
Default: off  
Description: turns on/off the use of a proxy server. There is no permanently option because permanently is implied.  
Reference: [R] [netio](#)

**set httpproxyauth**

Syntax: `set httpproxyauth { on | off }`  
Default: off  
Description: determines whether authorization is required for the proxy server. There is no permanently option because permanently is implied.  
Reference: [R] [netio](#)

**set httpproxyhost**

Syntax: `set httpproxyhost ["name"]`

Description: sets the name of a host to be used as a proxy server. There is no permanently option because permanently is implied.

Reference: [\[R\] netio](#)

**set httpproxyport**

Syntax: `set httpproxyport #`

Default: 8080 if Stata cannot autodetect the proper setting for your computer.

Description: sets the port number for a proxy server. There is no permanently option because permanently is implied.

Reference: [\[R\] netio](#)

**set httpproxypw**

Syntax: `set httpproxypw ["password"]`

Description: sets the appropriate password. There is no permanently option because permanently is implied.

Reference: [\[R\] netio](#)

**set httpproxyuser**

Syntax: `set httpproxyuser ["name"]`

Description: sets the appropriate user ID. There is no permanently option because permanently is implied.

Reference: [\[R\] netio](#)

**set include\_bitmap (Mac only)**

Syntax: `set include_bitmap {on|off} [, permanently]`

Default: on

Description: sets the output behavior when copying an image to the Clipboard.

Reference: `help include_bitmap`

**set iterlog**

Syntax: `set iterlog {on|off} [, permanently]`

Description: specifies whether to display an iteration log.

Reference: [\[R\] set iter](#)

**set java\_heapmax**

Syntax: `set java_heapmax {default | #[m|g]}`

Description: sets the maximum amount of heap memory allocated for the Java Virtual Machine.

Reference: `set java_heapmax` is a synonym for `java set heapmax`; see [\[P\] Java utilities](#)

**set java\_home**

Syntax: `set java_home {default | "path_to_java_home_dir" }`

Description: sets the path to the Java Runtime Environment.

Reference: `set java_home` is a synonym for `java set home`; see [\[P\] Java utilities](#)

**set kmp\_blocktime**

Syntax: set kmp\_blocktime # [ , permanently ]

Default: -1

Description: controls the behavior of the OpenMP runtime library regarding the suspension of threads in Stata when they are idle. This can be changed only in Stata/MP.

Reference: help kmp\_blocktime

**set lapack\_mkl**

Syntax: set lapack\_mkl { on | off } [ , permanently ]

Default: on

Description: specifies whether to use Intel MKL LAPACK routines.

Reference: [\[M-1\] LAPACK](#)

**set lapack\_mkl\_cnr**

Syntax: set lapack\_mkl\_cnr { default | auto | compatible | off }

Default: on

Description: sets the conditional numerical reproducibility mode for Intel MKL LAPACK routines.

Reference: [\[M-1\] LAPACK](#)

**set lapack\_openblas**

Syntax: set lapack\_openblas { on | off } [ , permanently ]

Default: on

Description: sets whether to use the LAPACK library from OpenBLAS.

Reference: [\[M-1\] LAPACK](#)

**set level**

Syntax: set level # [ , permanently ]

Default: 95

Description: sets the default confidence level for confidence intervals for all commands that report confidence intervals.  $10.00 \leq \# \leq 99.99$ , and # can have at most two digits after the decimal point.

Reference: [\[R\] level](#)

**set linegap**

Syntax: set linegap #

Default: 1

Description: sets the space between lines, in pixels, in the Results window. There is no permanently option because permanently is implied.

Reference: help linegap

**set linesize**

Syntax: set linesize #

Default: 1 less than the full width of the screen

Description: sets the line width, in characters, for both the screen and the log file.

Reference: [\[R\] log](#)

**set locale\_functions**

Syntax: set locale\_functions *locale*

Default: en\_US

Description: sets the locale to be used by functions that take *locale* as an optional argument.

Reference: [P] [set locale\\_functions](#)

**set locale\_ui**

Syntax: set locale\_ui *locale*

Default: en\_US

Description: sets the locale that Stata uses for the user interface.

Reference: [P] [set locale\\_ui](#)

**set locksplitters (Windows only)**

Syntax: set locksplitters {on|off} [, permanently]

Default: off

Description: determines whether splitters should be locked so that docked windows cannot be resized.

Reference: help locksplitters

**set logmsg**

Syntax: set logmsg {on|off}

Default: on

Description: specifies whether the default message is displayed at the top and bottom of log files.

Reference: [R] [log](#)

**set logtype**

Syntax: set logtype {text|smcl} [, permanently]

Default: smcl

Description: sets the default log filetype.

Reference: [R] [log](#)

**set lstretch**

Syntax: set lstretch [on|off] [, permanently]

Default: on

Description: specifies whether to automatically widen the coefficient table up to the width of the Results window to accommodate longer variable names.

Reference: help lstretch

set matacache, set matafavor, set matalibs, set matalnum, set matamofirst,  
set mataoptimize, set matasolveto1, and set matastrict; see [M-3] [mata set](#).

## set maxbezierpath (Mac only)

Syntax: set maxbezierpath # [ , permanently ]

Default: 0

Description: sets the maximum number of lines that can be added to a Bézier path when rendering a Stata graph to the screen.

Reference: help maxbezierpath

## set maxdb

Syntax: set maxdb # [ , permanently ]

Default: 50

Description: sets the maximum number of dialog boxes whose contents are remembered from one invocation to the next during a session.  $5 \leq \# \leq 1000$

Reference: [R] db

## set maxiter

Syntax: set maxiter # [ , permanently ]

Default: 300

Description: sets the default maximum number of iterations for estimation commands.  $0 \leq \# \leq 16000$

Reference: [R] set iter

## set max\_memory

Syntax: set max\_memory #[b | k | m | g] [ , permanently ]

Default: . (all the memory the operating system will supply)

Description: specifies the maximum amount of memory Stata can use to store your data.  $2 \times \text{segmentsize} \leq \# \leq .$

Reference: [D] memory

## set max\_preservemem

Syntax: set max\_preservemem #[b | k | m | g] [ , permanently ]

Default: 1g (1 gigabyte)

Description: controls the maximum amount of memory preserve will use to store preserved datasets in memory.

Reference: [P] preserve

## set maxvar

Syntax: set maxvar # [ , permanently ]

Default: 5000 for Stata/MP and Stata/SE and 2048 for Stata/BE

Description: sets the maximum number of variables. This can be changed only in Stata/MP and Stata/SE.  $2048 \leq \# \leq 32767$

Reference: [D] memory

**set min\_memory**

Syntax: `set min_memory #[b|k|m|g] [ , permanently]`

Default: 0

Description: specifies an amount of memory Stata will not fall below. This setting affects efficiency, not the size of datasets you can analyze.  $0 \leq \# \leq \text{max\_memory}$

Reference: [\[D\] memory](#)

**set more**

Syntax: `set more {on|off} [ , permanently]`

Default: off

Description: pauses when `—more—` is displayed, continuing only when the user presses a key.

Reference: [\[R\] more](#)

**set niceness**

Syntax: `set niceness # [ , permanently]`

Default: 5

Description: affects how soon Stata gives back unused segments to the operating system.  
 $0 \leq \# \leq 10$

Reference: [\[D\] memory](#)

**set notifyuser (Mac only)**

Syntax: `set notifyuser {on|off} [ , permanently]`

Default: on

Description: sets the default Notification Manager behavior in Stata.

Reference: `help notifyuser`

**set obs**

Syntax: `set obs #`

Default: current number of observations

Description: changes the number of observations in the current dataset. `#` must be at least as large as the current number of observations. If there are variables in memory, the values of all new observations are set to *missing*.

Reference: [\[D\] obs](#)

**set odbcdriver**

Syntax: `set odbcdriver {unicode|ansi} [ , permanently]`

Default: unicode

Description: determines whether Unicode or ANSI is your ODBC driver.

Reference: [\[D\] odbc](#)

**set odbcmgr (Mac and Unix only)**

Syntax: `set odbcmgr {iodbc|unixodbc} [ , permanently]`

Default: iodbc

Description: determines whether iODBC or unixODBC is your ODBC driver manager.

Reference: [\[D\] odbc](#)

## set output

Syntax: set output {proc | inform | error}

Default: proc

Description: specifies the output to be displayed. proc means display all output; inform suppresses procedure output but displays informative messages and error messages; error suppresses all output except error messages. set output is seldom used.

Reference: [P] [quietly](#)

## set pagesize

Syntax: set pagesize #

Default: 2 less than the physical number of lines on the screen

Description: sets the number of lines between `—more—` messages.

Reference: [R] [more](#)

## set pdf\_maxtable

Syntax: set pdf\_maxtable # [ , permanently ]

Default: 500

Description: sets the maximum number of tables allowed in `putpdf`.

Reference: [RPT] [putpdf table](#)

## set pformat

Syntax: set pformat [*fmt*] [ , permanently ]

Description: specifies the output format of *p*-values in coefficient tables.  
*fmt* is a numerical format; see [D] [format](#).

Reference: [R] [set cformat](#)

## set pinnable (Windows only)

Syntax: set pinnable {on | off} [ , permanently ]

Default: on

Description: determines whether to enable the use of pinnable window characteristics for certain windows in Stata.

Reference: `help pinnable`

## set playsnd (Mac only)

Syntax: set playsnd {on | off} [ , permanently ]

Default: on

Description: sets the sound behavior for the Notification Manager behavior in Stata.

Reference: `help playsnd`

## set printcolor

Syntax: set printcolor {automatic | asis | gs1 | gs2 | gs3} [ , permanently ]

Default: automatic

Description: determines how colors are handled when graphs are printed.

Reference: [G-2] [set printcolor](#)

**set processors**

Syntax:     **set processors #**  
 Description: sets the number of processors or cores that Stata/MP will use. The default is the number of processors available on the computer, or the number of processors allowed by Stata/MP's license, whichever is less.  
 Reference:   **help processors**

**set python\_exec**

Syntax:     **set python\_exec *pyexecutable* [ , permanently ]**  
 Description: sets which version of Python to use.  
 Reference:   **set python\_exec** is a synonym for **python set exec**;  
               see [P] [PyStata integration](#)

**set python\_userpath**

Syntax:     **set python\_userpath *path* [*path* ...] [ , permanently prepend ]**  
 Description: sets the user's own module search paths in addition to the system search paths.  
 Reference:   **set python\_userpath** is a synonym for **python set userpath**;  
               see [P] [PyStata integration](#)

**set reshape\_favor**

Syntax:     **set reshape\_favor {default|memory|speed} [ , permanently ]**  
 Description: sets the default method for reshaping data.  
 Reference:   [D] [reshape](#)

**set reventries**

Syntax:     **set reventries # [ , permanently ]**  
 Default:     5000  
 Description: sets the number of scrollbar lines available in the History window.  
                $5 \leq \# \leq 32000$ .  
 Reference:   **help reventries**

**set revkeyboard (Mac only)**

Syntax:     **set revkeyboard {on|off} [ , permanently ]**  
 Default:     on  
 Description: sets the keyboard navigation behavior for the History window. **on** indicates that you can use the keyboard to navigate and enter items from the History window into the Command window. **off** indicates that all keyboard input be directed at the Command window; items can be entered from the History window only by using the mouse.  
 Reference:   **help revkeyboard**

**set rmsg**

Syntax: `set rmsg {on|off} [ , permanently ]`

Default: `off`

Description: indicates whether a return message telling the execution time is to be displayed at the completion of each command.

Reference: [\[P\] rmsg](#)

**set rng**

Syntax: `set rng {default|mt64|mt64s|kiss32}`

Default: `default`

Description: determines which random-number generator Stata's random-number functions and commands will use.

Reference: [\[R\] set rng](#)

**set rngstate**

Syntax: `set rngstate statecode`

Description: resets the state of the random-number generator to the value specified.

Reference: [\[R\] set seed](#)

**set rngstream**

Syntax: `set rngstream #`

Description: specifies the stream from which Stata's stream random-number generator should draw random numbers.

Reference: [\[R\] set rngstream](#)

**set scheme**

Syntax: `set scheme schemename [ , permanently ]`

Default: `s2color`

Description: determines the overall look for graphs.

Reference: [\[G-2\] set scheme](#)

**set scrollbarbufsize**

Syntax: `set scrollbarbufsize #`

Default: `200000`

Description: sets the scrollbar buffer size, in bytes, for the Results window; may be set between 10,000 and 2,000,000.

Reference: `help scrollbarbufsize`

**set searchdefault**

Syntax: `set searchdefault {local|net|all} [ , permanently ]`

Default: `local`

Description: sets the default behavior of the search command. `set searchdefault local` restricts search to use only Stata's keyword database. `set searchdefault net` restricts search to searching only the internet. `set searchdefault all` indicates that both the keyword database and the internet are to be searched.

Reference: [\[R\] search](#)

**set seed**

Syntax: `set seed #`

Default: `123456789`

Description: specifies initial value of the random-number seed used by the [random-number functions](#), such as `runiform()` and `rnormal()`.

Reference: [\[R\] set seed](#)

**set segmentsize**

Syntax: `set segmentsize #[b|k|m|g] [ , permanently ]`

Default: `32m` for 64-bit machines

Description: Stata allocates memory for data in units of `segmentsize`. This setting changes the amount of memory in a single segment.  
 $1m \leq \# \leq 32g$  for 64-bit machines

Reference: [\[D\] memory](#)

**set sformat**

Syntax: `set sformat [fmt] [ , permanently ]`

Description: specifies the output format of test statistics in coefficient tables.  
*fmt* is a numerical format; see [\[D\] format](#).

Reference: [\[R\] set cformat](#)

**set showbaselevels**

Syntax: `set showbaselevels {on|off|all} [ , permanently ]`

Description: specifies whether to display base levels of factor variables and their interactions in coefficient tables.

Reference: [\[R\] set showbaselevels](#)

**set showemptycells**

Syntax: `set showemptycells {on|off} [ , permanently ]`

Description: specifies whether to display empty cells in coefficient tables.

Reference: [\[R\] set showbaselevels](#)

**set showomitted**

Syntax: `set showomitted {on|off} [ , permanently ]`

Description: specifies whether to display omitted coefficients in coefficient tables.

Reference: [\[R\] set showbaselevels](#)

**set smoothfonts** (Mac only)

Syntax: set **smoothfonts** {on | off}

Default: on

Description: determines whether to use font smoothing (antialiased text) in the Results, Viewer, and Data Editor windows.

Reference: help smoothfonts

**set sortmethod**

Syntax: set sortmethod {default | fsort | qsort}

Default: default

Description: determines which sorting method will be used by **sort**, **gsort**, and any other commands that use sorting as part of their computation.

Reference: [P] [set sortmethod](#)

**set sortrngstate**

Syntax: set sortrngstate #

Default: 1001XZA112210f4b16c1cb10507a1f38cb440c40003c9a83566fa1201b69...

Description: specifies the initial value of the state used for the random-number generator that randomizes data before they are sorted. This value is used by **sort**, **gsort**, and any other commands that use sorting as part of their computation.

Reference: [P] [set sortrngstate](#)

**set svy\_tab\_comps**

Syntax: set svy\_tab\_comps *style* [, permanently]

Default: svy\_tabulate\_composites

Description: controls the default styles containing the composite results defined for two-way tests of independence reported by svy: tabulate

Reference: [TABLES] [set tabulate\\_style](#)

**set table\_style**

Syntax: set table\_style *style* [, permanently]

Default: table

Description: controls the default styles used in tables created by table.

Reference: [TABLES] [set table\\_style](#)

**set tabulate\_comps**

Syntax: set tabulate\_comps *style* [, permanently]

Default: tabulate\_composites

Description: controls the default styles containing the composite results defined for two-way measures of association reported by tabulate, tab2, and tabi

Reference: [TABLES] [set tabulate\\_style](#)

**set tabulate\_style**

Syntax: set tabulate\_style *style* [ , permanently ]  
Default: tabulate  
Description: controls the default styles used in tables created by `tabulate`, `tab1`, `tab2`, `tabi`, and `svy: tabulate`.  
Reference: [TABLES] [set tabulate\\_style](#)

**set taskbargroups (Windows only)**

Syntax: set taskbargroups {on | off}  
Default: on  
Description: determines whether to enable taskbar grouping of windows in Stata.  
Reference: `help taskbargroups`

**set trace**

Syntax: set trace {on | off}  
Default: off  
Description: determines whether to trace the execution of programs for debugging.  
Reference: [P] [trace](#)

**set tracedepth**

Syntax: set tracedepth #  
Default: 32000 (equivalent to  $\infty$ )  
Description: if `trace` is set on, traces execution of programs and nested programs up to `tracedepth`. For example, if `tracedepth` is 2, the current program and any subroutine called would be traced, but subroutines of subroutines would not be traced.  
Reference: [P] [trace](#)

**set traceexpand**

Syntax: set traceexpand {on | off} [ , permanently ]  
Default: on  
Description: if `trace` is set on, shows lines both before and after macro expansion. If `traceexpand` is set off, only the line before macro expansion is shown.  
Reference: [P] [trace](#)

**set tracehilite**

Syntax: set tracehilite "*pattern*" [ , word ]  
Default: ""  
Description: highlights *pattern* in the trace output.  
Reference: [P] [trace](#)

**set traceindent**

Syntax: set traceindent {on | off} [ , permanently ]

Default: on

Description: if trace is set on, indents displayed lines according to their nesting level. The lines of the main program are not indented. Two spaces of indentation are used for each level of nested subroutine.

Reference: [P] [trace](#)

**set tracenumber**

Syntax: set tracenumber {on | off} [ , permanently ]

Default: off

Description: if trace is set on, shows the nesting level numerically in front of the line. Lines of the main program are preceded by 01, lines of subroutines called by the main program are preceded by 02, etc.

Reference: [P] [trace](#)

**set tracesep**

Syntax: set tracesep {on | off} [ , permanently ]

Default: on

Description: if trace is set on, displays a horizontal separator line that displays the name of the subroutine whenever a subroutine is called or exits.

Reference: [P] [trace](#)

**set type**

Syntax: set type {float | double} [ , permanently ]

Default: float

Description: specifies the default storage type assigned to new variables.

Reference: [D] [generate](#)

**set update\_interval (Mac and Windows only)**

Syntax: set update\_interval #

Default: 7

Description: sets the number of days to elapse before performing the next automatic update query.

Reference: [R] [update](#)

**set update\_prompt (Mac and Windows only)**

Syntax: set update\_prompt {on | off}

Default: on

Description: determines whether a dialog is to be displayed before performing an automatic update query. There is no permanently option because permanently is implied.

Reference: [R] [update](#)

set update\_query (Mac and Windows only)

Syntax: set update\_query {on | off}

Default: on

Description: determines whether update query is to be automatically performed when Stata is launched. There is no permanently option because permanently is implied.

Reference: [R] [update](#)

set varabbrev

Syntax: set varabbrev {on | off} [ , permanently]

Default: on

Description: indicates whether Stata should allow variable abbreviations.

Reference: [P] [varabbrev](#)

set varkeyboard (Mac only)

Syntax: set varkeyboard {on | off} [ , permanently]

Default: on

Description: sets the keyboard navigation behavior for the Variables window. `on` indicates that you can use the keyboard to navigate and enter items from the Variables window into the Command window. `off` indicates that all keyboard input be directed at the Command window; items can be entered from the Variables window only by using the mouse.

Reference: help varkeyboard

## Also see

[R] [query](#) — Display system parameters

[R] [set\\_defaults](#) — Reset system parameters to original Stata defaults

[M-3] [mata set](#) — Set and display Mata system parameters

[P] [creturn](#) — Return c-class values

## Description

`set cformat` specifies the output format of coefficients, standard errors, and confidence limits in coefficient tables.

`set pformat` specifies the output format of  $p$ -values in coefficient tables.

`set sformat` specifies the output format of test statistics in coefficient tables.

## Syntax

```
set cformat [fmt] [, permanently]
```

```
set pformat [fmt] [, permanently]
```

```
set sformat [fmt] [, permanently]
```

where *fmt* is a [numerical format](#).

## Option

`permanently` specifies that, in addition to making the change right now, the setting be remembered and become the default setting when you invoke Stata.

## Remarks and examples

The formatting of the numbers in the coefficient table can be controlled by using the `set cformat`, `set pformat`, and `set sformat` commands or by using the `cformat(%fmt)`, `pformat(%fmt)`, and `sformat(%fmt)` options at the time of estimation or on replay of the estimation command. See [\[R\] Estimation options](#).

The maximum format widths for `set cformat`, `set pformat`, and `set sformat` in coefficient tables are 9, 5, and 8, respectively.

► Example 1

We use auto.dta to illustrate.

```
. use https://www.stata-press.com/data/r19/auto
(1978 automobile data)
```

```
. regress mpg weight displacement
```

[U] [20.9 Formatting the coefficient table](#)

## Description

`set_defaults` resets settings made by `set` to the original default settings that were shipped with Stata.

`set_defaults` may not be used with `java`, `lapack`, `putdocx`, `python`, `rng`, or `sort` system-parameter categories.

## Syntax

```
set_defaults { category | _all } [, permanently]
```

where *category* is one of memory | output | interface | graphics |

network | update | trace | mata | unicode | other

## Option

`permanently` specifies that, in addition to making the change right now, the settings be remembered and become the default settings when you invoke Stata.

## Remarks and examples

### ► Example 1

To assist us in debugging a new command, we modified some of the `trace` settings. To return them to their original values, we type

```
. set_defaults trace
-> set trace off
-> set tracedepth 32000
-> set traceexpand on
-> set tracesep on
-> set traceindent on
-> set tracenumber off
-> set tracehilite ""
(preferences reset)
```

◀

## Description

`set emptycells` allows you to control how Stata handles interaction terms with empty cells. Stata can keep empty cells or drop them. The default is to keep empty cells.

## Syntax

```
set emptycells { keep | drop } [, permanently]
```

## Option

`permanently` specifies that, in addition to making the change right now, the setting be remembered and become the default setting when you invoke Stata.

## Remarks and examples

By default, Stata keeps empty cells so they can be reported in the coefficient table. For example, type

```
. use https://www.stata-press.com/data/r19/auto
. regress mpg rep78#foreign, baselevels
```

and you will see a regression of `mpg` on 10 indicator variables because `rep78` takes on 5 values and `foreign` takes on 2 values in the `auto` dataset. Two of those cells will be reported as empty because the data contain no observations of foreign cars with a `rep78` value of 1 or 2.

Many real datasets contain a large number of empty cells, and this could cause the “unable to allocate matrix” error message, `r(915)`. In that case, type

```
. set emptycells drop
```

to get Stata to drop empty cells from the list of coefficients. If you commonly fit models with empty cells, you can permanently set Stata to drop empty cells by typing the following:

```
. set emptycells drop, permanently
```

## Description

`set iterlog` and `set maxiter` control the display of the iteration log and the maximum number of iterations, respectively, for estimation commands that iterate and for the Mata optimization functions `moptimize()`, `optimize()`, and `solvenl()`.

`set iterlog` specifies whether to display the iteration log. The default setting is `on`, which displays the log. You can specify `set iterlog off` to suppress it. To change whether the iteration log is displayed for a particular estimation command, you need not reset `iterlog`; you can specify the `log` or `nolog` option with that command. If you do not specify `log` or `nolog`, the `iterlog` setting is used. To view the current setting of `iterlog`, type `display c(iterlog)`.

`set maxiter` specifies the default maximum number of iterations. To change the maximum number of iterations performed by a particular estimation command, you need not reset `maxiter`; you can specify the `iterate(#)` option with that command. If you do not specify `iterate(#)`, the `maxiter` value is used. To view the current setting of `maxiter`, type `display c(maxiter)`.

## Syntax

*Set whether to display the iteration log*

```
set iterlog { on | off } [, permanently]
```

*Set default maximum iterations*

```
set maxiter # [, permanently]
```

# is any number between 0 and 16,000; the initial value is set to 300.

## Option

`permanently` specifies that, in addition to making the change right now, the setting be remembered and become the default setting when you invoke Stata.

## Remarks and examples

The `iterlog` setting is particularly useful in combination with the `nolog` and `log` options; see [example 1](#) below. Also see [\[R\] Maximize](#) for details about the options. The `iterlog` setting has no effect on commands that suppress the iteration log by default, for example, commands prefixed with `svy`. To display the log with those commands, you need to use the `log` option.

You will rarely need to modify the `maxiter` setting to change the maximum number of iterations used by Stata's iterative commands. Instead, you may want to specify the `iterate()` option with these commands. For example, specifying `iterate(0)` is useful for viewing results evaluated at the initial value of the coefficient vector.

The `iterlog` and `maxiter` settings also control the default output displayed by the Mata optimization functions `moptimize()`, `optimize()`, and `solvenl()`.

### ▷ Example 1: Display and suppress the iteration log

Stata estimation commands that iterate usually display the iteration log by default:

```
. sysuse auto
(1978 automobile data)
. logit foreign mpg
Iteration 0: Log likelihood = -45.03321
Iteration 1: Log likelihood = -39.380959
Iteration 2: Log likelihood = -39.288802
Iteration 3: Log likelihood = -39.28864
Iteration 4: Log likelihood = -39.28864
Logistic regression
Log likelihood = -39.28864
```

|                 |        |
|-----------------|--------|
| Number of obs = | 74     |
| LR chi2(1) =    | 11.49  |
| Prob > chi2 =   | 0.0007 |
| Pseudo R2 =     | 0.1276 |

| foreign | Coefficient | Std. err. | z     | P> z  | [95% conf. interval] |           |
|---------|-------------|-----------|-------|-------|----------------------|-----------|
| mpg     | .1597621    | .0525876  | 3.04  | 0.002 | .0566922             | .262832   |
| _cons   | -4.378866   | 1.211295  | -3.62 | 0.000 | -6.752961            | -2.004771 |

You can suppress the log by specifying the `nolog` option:

```
. logit foreign mpg, nolog
Logistic regression
Log likelihood = -39.28864
```

|                 |        |
|-----------------|--------|
| Number of obs = | 74     |
| LR chi2(1) =    | 11.49  |
| Prob > chi2 =   | 0.0007 |
| Pseudo R2 =     | 0.1276 |

| foreign | Coefficient | Std. err. | z     | P> z  | [95% conf. interval] |           |
|---------|-------------|-----------|-------|-------|----------------------|-----------|
| mpg     | .1597621    | .0525876  | 3.04  | 0.002 | .0566922             | .262832   |
| _cons   | -4.378866   | 1.211295  | -3.62 | 0.000 | -6.752961            | -2.004771 |

If you want to suppress the iteration log from all estimation commands every time they are run within the current Stata session, type

```
. set iterlog off
```

We can run logit again but now without the nolog option, and the iteration log will not be displayed:

```
. logit foreign mpg
Logistic regression
Log likelihood = -39.28864
Number of obs = 74
LR chi2(1) = 11.49
Prob > chi2 = 0.0007
Pseudo R2 = 0.1276
```

| foreign | Coefficient | Std. err. | z     | P> z  | [95% conf. interval] |           |
|---------|-------------|-----------|-------|-------|----------------------|-----------|
| mpg     | .1597621    | .0525876  | 3.04  | 0.002 | .0566922             | .262832   |
| _cons   | -4.378866   | 1.211295  | -3.62 | 0.000 | -6.752961            | -2.004771 |

Or we can run a different command, for example, mlogit, and the log will still be suppressed:

```
. mlogit rep78 mpg
Multinomial logistic regression
Log likelihood = -85.752375
Number of obs = 69
LR chi2(4) = 15.88
Prob > chi2 = 0.0032
Pseudo R2 = 0.0847
```

| rep78 | Coefficient    | Std. err. | z     | P> z  | [95% conf. interval] |           |
|-------|----------------|-----------|-------|-------|----------------------|-----------|
| 1     |                |           |       |       |                      |           |
| mpg   | .0708122       | .1471461  | 0.48  | 0.630 | -.2175888            | .3592132  |
| _cons | -4.137144      | 3.15707   | -1.31 | 0.190 | -10.32489            | 2.0506    |
| 2     |                |           |       |       |                      |           |
| mpg   | -.0164251      | .0926724  | -0.18 | 0.859 | -.1980597            | .1652096  |
| _cons | -1.005118      | 1.822129  | -0.55 | 0.581 | -4.576426            | 2.56619   |
| 3     | (base outcome) |           |       |       |                      |           |
| 4     |                |           |       |       |                      |           |
| mpg   | .0958626       | .0633329  | 1.51  | 0.130 | -.0282676            | .2199927  |
| _cons | -2.474187      | 1.341131  | -1.84 | 0.065 | -5.102756            | .1543813  |
| 5     |                |           |       |       |                      |           |
| mpg   | .2477469       | .0764076  | 3.24  | 0.001 | .0979908             | .397503   |
| _cons | -6.653164      | 1.841794  | -3.61 | 0.000 | -10.26301            | -3.043314 |

With the `iterlog` setting off, we can display the iteration log for specific commands by specifying the `log` option:

```
. mlogit rep78 mpg, log
Iteration 0: Log likelihood = -93.692061
Iteration 1: Log likelihood = -86.581485
Iteration 2: Log likelihood = -85.767758
Iteration 3: Log likelihood = -85.752385
Iteration 4: Log likelihood = -85.752375
Iteration 5: Log likelihood = -85.752375

Multinomial logistic regression Number of obs = 69
LR chi2(4) = 15.88
Prob > chi2 = 0.0032
Pseudo R2 = 0.0847

Log likelihood = -85.752375
```

|   | rep78 | Coefficient    | Std. err. | z     | P> z  | [95% conf. interval] |           |
|---|-------|----------------|-----------|-------|-------|----------------------|-----------|
| 1 |       |                |           |       |       |                      |           |
|   | mpg   | .0708122       | .1471461  | 0.48  | 0.630 | -.2175888            | .3592132  |
|   | _cons | -4.137144      | 3.15707   | -1.31 | 0.190 | -10.32489            | 2.0506    |
| 2 |       |                |           |       |       |                      |           |
|   | mpg   | -.0164251      | .0926724  | -0.18 | 0.859 | -.1980597            | .1652096  |
|   | _cons | -1.005118      | 1.822129  | -0.55 | 0.581 | -4.576426            | 2.56619   |
| 3 |       | (base outcome) |           |       |       |                      |           |
| 4 |       |                |           |       |       |                      |           |
|   | mpg   | .0958626       | .0633329  | 1.51  | 0.130 | -.0282676            | .2199927  |
|   | _cons | -2.474187      | 1.341131  | -1.84 | 0.065 | -5.102756            | .1543813  |
| 5 |       |                |           |       |       |                      |           |
|   | mpg   | .2477469       | .0764076  | 3.24  | 0.001 | .0979908             | .397503   |
|   | _cons | -6.653164      | 1.841794  | -3.61 | 0.000 | -10.26301            | -3.043314 |

You can switch back to displaying iteration logs by typing

```
. set iterlog on
```

The default setting will be restored automatically the next time you invoke Stata. If you want the setting to be remembered for future Stata sessions, specify the permanently option with `set iterlog`.

## Description

`set rng` determines which random-number generator (RNG) Stata's [random-number functions](#) and commands will use.

## Syntax

```
set rng { default | mt64 | mt64s | kiss32 }
```

## Remarks and examples

Remarks are presented under the following headings:

[Introduction](#)

[Random-number generators in Stata](#)

### Introduction

By default, Stata uses the 64-bit Mersenne Twister (`mt64`) RNG. `mt64s` is a stream RNG based on the 64-bit Mersenne Twister. Earlier versions of Stata used the 32-bit KISS (keep it simple stupid) (`kiss32`) RNG.

With `set rng default` (the default), code running under [version control](#) will automatically use the appropriate RNG—`mt64` in Stata 14 and later and `kiss32` for earlier code.

The scope of `set rng` is the Stata session, do-file, or program in which `rng` is set.

Unless you want to simultaneously draw random numbers in separate instances of Stata, we recommend that you do not change Stata's default behavior for its RNGs. See [\[R\] set rngstream](#) for an introduction to simultaneously drawing random numbers in separate instances of Stata.

See [\[FN\] Random-number functions](#), [\[R\] set seed](#), and [\[R\] set rngstream](#) for more information.

### Random-number generators in Stata

The default RNG in Stata is the 64-bit Mersenne Twister. See [Matsumoto and Nishimura \(1998\)](#) for more details. The default RNG in Stata 13 and earlier versions was George Marsaglia's 32-bit KISS generator (G. Marsaglia, 1994, pers. comm.). The KISS generator is still available under version control or via `set rng`. Multiple independent random-number streams (based on the 64-bit Mersenne Twister) are also supported for use in multiple simultaneous instances of Stata; see [\[R\] set rngstream](#) for more information on this. The abbreviations `mt64`, `kiss32`, and `mt64s` are used, respectively, to specify these three generators in Stata commands and functions.

So far, we have discussed two ways you can specify the RNG: with `set rng` and through version control. Another way to specify the RNG is with functions and system parameters explicitly named after the generators. In fact, all random-number functions have variants that are explicitly named after each generator, using the generator abbreviation as the suffix. For example, `runiform_mt64()`, `runiform_kiss32()`, and `runiform_mt64s()` are variants of `runiform()` for each generator. Similarly, we have `rnormal_mt64()`, `rnormal_kiss32()`, `rnormal_mt64s()`, etc.

The system parameters `seed` and `rngstate` also have variants explicitly named after each generator: `seed_mt64`, `seed_kiss32`, `seed_mt64s`, `rngstate_mt64`, `rngstate_kiss32`, and `rngstate_mt64s`.

For example, here is how you can use functions and parameters specific to `mt64` to set the seed, generate random numbers, preserve a state, generate more numbers, and restore the previously preserved state:

```
. set seed_mt64 482637
. generate u = runiform_mt64()
. local state = c(rngstate_mt64)
. generate l = rlogistic_mt64()
. set rngstate_mt64 'state'
```

Note that calling functions and setting parameters specific to, say, `kiss32`, will not change the current RNG, the seed of the current RNG, or the state of the current RNG—unless the current RNG is `kiss32`.

## Description

`set rngstream` specifies the subsequence, known as a stream, from which Stata's stream random-number generator should draw random numbers. When performing a bootstrap estimation or a Monte Carlo simulation in parallel on multiple machines, you should set the same seed on all machines but set a different stream on each machine. This will ensure that random numbers drawn on different machines are independent. We strongly recommend that you set the seed and the stream only once in each Stata session.

## Syntax

```
set rngstream #
```

# is any integer between 1 and 32,767.

## Remarks and examples

Stata's stream random-number generator, the stream 64-bit Mersenne Twister (`mt64s`), allows separate instances of Stata to simultaneously draw independent random numbers. This feature enables you to use `bootstrap` and to run Monte Carlo simulations in parallel on multiple machines.

What we call random numbers are elements in a sequence of deterministic numbers that appear to be random. A seed specifies a starting value in this sequence. In figure 1, each tick is an element in a random sequence and setting the seed to 12345 means that the tick identified by the arrow below is the first number drawn.

Figure 1. Seed specifies first number in random sequence

A stream random-number generator partitions a sequence of random numbers into nonoverlapping subsequences known as streams. The random numbers in each stream are independent of those in other streams because they come from distinct nonoverlapping subsets of the original sequence.

Figure 2 depicts a stream version of the generator depicted in figure 1. The stream version also starts at the place implied by seed 12345, but it additionally partitions the random numbers into 4 streams and a set of unused numbers.

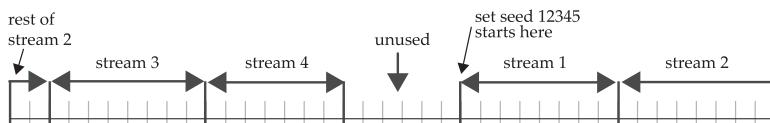

Figure 2. A stream version of figure 1 generator

In contrast to nonstream random-number generators, setting the seed for a random-number generator controls not just where the sequence starts but also how the sequence is partitioned. Compare figure 2 with figure 3 for an illustration.

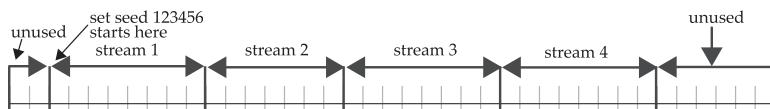

Figure 3. Changing the seed changes the streams

Seed 123456 specifies the first random number, and the streams of random numbers in figure 3 differ from those in figure 2.

The `mt64s` generator is a stream version of Stata's default generator, the 64-bit Mersenne Twister implemented in `mt64`; see [Matsumoto and Nishimura \(1998\)](#) and *Random-number generators in Stata* in [R] `set rng` for more details. Our implementation of the method discussed in [Haramoto et al. \(2008\)](#) partitions the `mt64` sequence into 32,767 streams, each containing  $2^{128}$  random numbers. The remaining numbers are unused. The `mt64s` seed determines the starting point of every stream in the Mersenne Twister sequence.

Stream 1 of `mt64s` has the same starting point as the `mt64` generator. That is, given the same seed, `mt64s` with `rngstream` set to 1 will generate the same random numbers as `mt64`.

The `mt64s` generator is designed to simultaneously draw independent random numbers on different machines. To draw from different streams that guarantee independence, use the same seed and change the stream. For example, to draw some `uniform(0,1)` random numbers from stream 10 of the `mt64s` generator under seed 123, type

```
. set rng mt64s
. set rngstream 10
. set seed 123
. generate u = runiform()
```

If we wanted to simultaneously draw some `uniform(0,1)` random numbers on another machine from stream 11 of the `mt64s` generator, we would type

```
. set rng mt64s
. set rngstream 11
. set seed 123
. generate u = runiform()
```

Again, each seed creates a different partition of the `mt64` sequence into nonoverlapping subsets.

We strongly recommend that you set the stream and the seed once in each Stata session and draw numbers only from this stream.

`c(rngstream)` returns the current stream number. `c(rngseed_mt64s)` returns the last seed that was set for `mt64s`. See [P] [creturn](#) for more details. See [R] [set seed](#) for details about storing and restoring the current position in the random sequence.

As with the single-stream generators, use `local state = c(rngstate)` to store the current position in the current random stream; see [R] [set seed](#) for details. The `mt64s` state encodes the seed used in addition to the stream number, because the seed determines the position of every random number in every stream. Unlike the case of single-stream generators, restoring the state also restores the seed. For example, suppose you save an `mt64s` state with `local state = c(rngstate)` change the seed and the stream, and later restore that state with `set rngstate 'state'`. The current `mt64s` seed is changed to the one encoded in `state`. In addition to changing the current stream to the one encoded in `state`, the current `mt64s` seed is changed to the one encoded in `state`. This behavior ensures any subsequent stream changes draw from nonoverlapping subsets.

`set rngstream` also sets the [random-number generator](#) to `mt64s`.

### ▷ Example 1: Using stream random numbers to parallelize a bootstrap

We illustrate how to simultaneously perform 100 bootstrap replications on machine 1 and 100 bootstrap replications on machine 2. We focus on the mechanics of distributing the draws over machines using stream random numbers; see [R] [bootstrap](#) for an introduction to the bootstrap.

On machine 1, we type

```
. clear all
. use https://www.stata-press.com/data/r19/auto
(1978 automobile data)
. set rng mt64s
. set rngstream 1
. set seed 12345
. bootstrap, reps(100) saving(machine1, replace): regress mpg weight gear foreign
(running regress on estimation sample)
(file machine1.dta not found)
Bootstrap replications (100):10.....20.....30.....40.....
> ...50.....60.....70.....80.....90.....100 done
Linear regression Number of obs = 74
 Replications = 100
 Wald chi2(3) = 191.66
 Prob > chi2 = 0.0000
 R-squared = 0.6670
 Adj R-squared = 0.6527
 Root MSE = 3.4096
```

| mpg        | Observed<br>coefficient | Bootstrap<br>std. err. | z      | P> z  | Normal-based<br>[95% conf. interval] |           |
|------------|-------------------------|------------------------|--------|-------|--------------------------------------|-----------|

| _cons      | 36.10135             | 4.562644            | 7.91   | 0.000 | 27.15873                          | 45.04397  |

We used `regress` in this example, but the divide-and-conquer strategy reduces computation time for any command that works with `bootstrap`. In fact, problems that take longer produce more noticeable speed improvements. For computationally intensive problems, the two-machine time will be about one-half the one-machine time. Using distinct streams on many different machines can dramatically reduce the time required for computationally intensive problems.

◀

### ▷ Example 2: Using stream random numbers to parallelize a Monte Carlo simulation

We want to simultaneously perform 100 Monte Carlo replications on machine 3 and 100 Monte Carlo replications on machine 4. Again, we focus entirely on the mechanics of distributing the draws over machines. See [Drukker \(2015\)](#) for an introduction to Monte Carlo simulations using Stata.

As discussed in [\[R\] simulate](#), the `simulate` command uses an ado-file that draws from the population of interest; it then computes and returns the estimates. Our program `chi2sim` draws from a  $\chi^2$  distribution with one degree of freedom.

```

program define chi2sim, rclass
 version 19.5 // (or version 19 if you do not have StataNow)
 drop _all
 set obs 200
 tempvar z
 generate `z' = rchi2(1)
 summarize `z'
 return scalar mean = r(mean)
 return scalar Var = r(Var)
end

```

On machine 3, we type

```

. set rng mt64s
. set rngstream 3
. set seed 12345
. simulate mean=r(mean) var=r(Var), reps(500) saving(machine3, replace): chi2sim
 Command: chi2sim
 mean: r(mean)
 var: r(Var)
(file machine3.dta not found)
Simulations (500):10.....20.....30.....40.....50.....
> ...60.....70.....80.....90.....100.....110.....120.....
> ...130.....140.....150.....160.....170.....180.....1
> 90.....200.....210.....220.....230.....240.....250.....
> ...260.....270.....280.....290.....300.....310.....3
> 20.....330.....340.....350.....360.....370.....380.....
> ...390.....400.....410.....420.....430.....440.....4
> 50.....460.....470.....480.....490.....500 done

```

On machine 4, we run a do-file that performs

```
. set rng mt64s
. set rngstream 4
. set seed 12345
. simulate mean=r(mean) var=r(Var), reps(500) saving(machine4, replace): chi2sim
 Command: chi2sim
 mean: r(mean)
 var: r(Var)
(file machine4.dta not found)
Simulations (500):10.....20.....30.....40.....50.....
> ...60.....70.....80.....90.....100.....110.....120.....
>130.....140.....150.....160.....170.....180.....1
> 90.....200.....210.....220.....230.....240.....250....
>260.....270.....280.....290.....300.....310.....3
> 20.....330.....340.....350.....360.....370.....380....
>390.....400.....410.....420.....430.....440.....4
> 50.....460.....470.....480.....490.....500 done
```

After copying `machine4.dta` from machine 4 to the working directory on machine 3, we combine the results by typing

```
. clear all
. use machine3
(simulate: chi2sim)
. append using machine4
. summarize mean var
```

| Variable | Obs   | Mean    | Std. dev. | Min      | Max      |
|----------|-------|---------|-----------|----------|----------|
| mean     | 1,000 | 1.00296 | .1011507  | .7098877 | 1.330305 |
| var      | 1,000 | 2.01955 | .5194171  | .8931134 | 4.381884 |

As in [example 1](#), more machines enable further parallelization.

## □ Technical note

While `mt64s` has been made robust to switching between streams within a Stata session, convoluted combinations of `set rngstream #` and `set seed #` can lead to drawing the same random numbers, just as it can in the case of single-stream generators. We strongly recommend that you do not switch between streams within a session.

### ► Example 3: Position within a stream is stored

This example illustrates that the sequence picks up where it left off when the stream is switched, and it illustrates that `clear rngstream` resets all streams to their beginning positions. These features facilitate advanced programming techniques, and we recommend against using this feature in standard use.

```
. clear all
. set obs 10
Number of observations (_N) was 0, now 10.
. set rng mt64s
. set rngstream 5
. set seed 12345
. generate x = runiform() in 1/5
(5 missing values generated)
. set rngstream 6
. generate y = runiform()
. set rngstream 5
. replace x = runiform() in 6/10
(5 real changes made)
. clear rngstream
. set rngstream 5
. generate z = runiform()
. list
```

|     | x        | y        | z        |
|-----|----------|----------|----------|
| 1.  | .5095264 | .8838338 | .5095264 |
| 2.  | .9766202 | .7677673 | .9766202 |
| 3.  | .3933811 | .5665985 | .3933811 |
| 4.  | .950057  | .3141659 | .950057  |
| 5.  | .5862163 | .6635106 | .5862163 |
| 6.  | .4837167 | .6781911 | .4837167 |
| 7.  | .1752382 | .7169843 | .1752382 |
| 8.  | .2302023 | .7554966 | .2302023 |
| 9.  | .4927879 | .8685812 | .4927879 |
| 10. | .9114158 | .5634732 | .9114158 |

After setting the `rngstream` to 5 and setting the seed, we put the first 5 draws from stream 5 into observations 1–5 of `x`, switch to `rngstream` 6, put the first 10 random draws from stream 6 into `y`, return to `rngstream` 5, and put the next 5 draws from stream 5 into observations 6–10 of `x`. Then we use `clear rngstream` to initialize each `rngstream` at its initial position for seed 12345 and put the first 10 draws from stream 5 into `z`.

That the random numbers in `x` match those in `z` illustrates that the sequence picks up where it left off when the stream is switched and the seed has not been changed.

## Description

`set seed #` specifies the initial value of the random-number seed used by the [random-number functions](#), such as `runiform()` and `rnormal()`.

`set rngstate statecode` resets the state of the random-number generator to the value specified, which is a state previously obtained from [creturn](#) value `c(rngstate)`.

`set seed #` and `set rngstate statecode` apply to the current random-number generator. Every random-number generator in Stata has its own seed and state encoding.

## Syntax

```
set seed #
```

```
set rngstate statecode
```

# is any number between 0 and  $2^{31} - 1$  (or 2,147,483,647).

*statecode* is a random-number state previously obtained from [creturn](#) value `c(rngstate)`.

## Remarks and examples

Remarks are presented under the following headings:

[Examples](#)

[Setting the seed](#)

[How to choose a seed](#)

[Do not set the seed too often](#)

[Preserving and restoring the random-number generator state](#)

## Examples

1. Specify initial value of random-number seed

```
. set seed 339487731
```

2. Create variable `u` containing uniformly distributed pseudorandom numbers on the interval (0, 1)

```
. generate u = runiform()
```

3. Create variable `z` containing normally distributed random numbers with mean 0 and standard deviation 1

```
. generate z = rnormal()
```

4. Obtain state of pseudorandom-number generator and store it in a local macro named `state`

```
. local state = c(rngstate)
```

5. Restore pseudorandom-number generator state to that previously stored in local macro named `state`

```
. set rngstate `state'
```

## Setting the seed

Stata's random-number generation functions, such as `runiform()` and `rnormal()`, do not really produce random numbers. These functions are deterministic algorithms that produce numbers that can pass for random. `runiform()` produces numbers that can pass for independent draws from a rectangular distribution over  $(0, 1)$ ; `rnormal()` produces numbers that can pass for independent draws from  $N(0, 1)$ . Stata's random-number functions are formally called pseudorandom-number functions. The default pseudorandom-number generator introduced in Stata 14 is the 64-bit Mersenne Twister. See [Matsumoto and Nishimura \(1998\)](#) and *Random-number generators in Stata* in [R] [set rng](#) for more details.

The sequences the random-number functions produce are determined by the seed, which is just a number and which is set to 123456789 every time Stata is launched. This means that `runiform()` produces the same sequence each time you start Stata. The first time you use `runiform()` after Stata is launched, `runiform()` returns 0.348871704556195. The second time you use it, `runiform()` returns 0.266885709753138. The third time you use it, . . . .

To obtain different sequences, you must specify different seeds using the `set seed` command. You might specify the seed 472195:

```
. set seed 472195
```

If you were now to use `runiform()`, the first call would return 0.713028143573182, the second call would return 0.920524469911484, and so on. Whenever you `set seed 472195`, `runiform()` will return those numbers the first two times you use it.

Thus, you set the seed to obtain different pseudorandom sequences from the pseudorandom-number functions.

If you record the seed you set, pseudorandom results such as results from a simulation or imputed values from `mi impute` can be reproduced later. Whatever you do after setting the seed, if you set the seed to the same value and repeat what you did, you will obtain the same results.

## How to choose a seed

Your best choice for the seed is an element chosen randomly from the set  $\{0, 1, \dots, 2^{31} - 1\}$  (where  $2^{31} - 1 = 2,147,483,647$ ). We recommend that, but that is difficult to achieve because finding easy-to-access, truly random sources is difficult.

One person we know uses digits from the serial numbers from dollar bills he finds in his wallet. Of course, the numbers he obtains are not really random, but they are good enough, and they are probably a good deal more random than the seeds most people choose. Some people use dates and times, although we recommend against that because, over the day, it just gets later and later, and that is a pattern. Others try to make up a random number, figuring if they include enough digits, the result just has to be random. This is a variation on the five-second rule for dropped food, and we admit to using both of these rules.

It does not really matter how you set the seed, as long as there is no obvious pattern in the seeds that you set and as long as you do not set the seed too often during a session.

Nonetheless, here are two methods that we have seen used but you should not use:

1. The first time you set the seed, you set the number 1. The next time, you set 2, and then 3, and so on. Variations on this included setting 1001, 1002, 1003, . . . , or setting 1001, 2001, 3001, and so on.

Do not follow any of these procedures. The seeds you set must not exhibit a pattern.

2. To set the seed, you obtain a pseudorandom number from `runiform()` and then use the digits from that to form the seed.

This is a bad idea because the pseudorandom-number generator can converge to a cycle. If you obtained the pseudorandom-number generator unrelated to those in Stata, this would work well, but then you would have to find a rule to set the first generator's seed.

Choosing seeds that do not exhibit a pattern is of great importance. That the seeds satisfy the other properties of randomness is minor by comparison.

## Do not set the seed too often

We cannot emphasize this enough: Do not set the seed too often.

To see why this is such a bad idea, consider the limiting case: You set the seed, draw one pseudorandom number, reset the seed, draw again, and so continue. The pseudorandom numbers you obtain will be nothing more than the seeds you run through a mathematical function. The results you obtain will not pass for random unless the seeds you choose pass for random. If you already had such numbers, why are you even bothering to use the pseudorandom-number generator?

The definition of too often is more than once per problem.

If you are running a simulation of 10,000 replications, set the seed at the start of the simulation and do not reset it until the 10,000th replication is finished. The pseudorandom-number generators provided by Stata have long periods. The longer you go between setting the seed, the more random-like are the numbers produced.

It is sometimes useful later to be able to reproduce in isolation any one of the replications, and so you might be tempted to set the seed to a known value for each of the replications. We negatively mentioned setting the seed to 1, 2, ..., and it is in exactly such situations that we have seen this done. The advantage, however, is that you could reproduce the fifth replication merely by setting the seed to 5 and then repeating whatever it is that is to be replicated. If this is your goal, you do not need to reset the seed. You can record the state of the random-number generator, save the state with your replication results, and then use the recorded states later to reproduce whichever of the replications that you wish. This will be discussed in [Preserving and restoring the random-number generator state](#).

There is another reason you might be tempted to set the seed more than once per problem. It sometimes happens that you run a simulation, let's say for 5,000 replications, and then you decide you should have run it for 10,000 replications. Instead of running all 10,000 replications afresh, you decide to save time by running another 5,000 replications and then combining those results with your previous 5,000 results. That is okay. We at StataCorp do this kind of thing. If you do this, it is important that you set the seed especially well, particularly if you repeat this process to add yet another 5,000 replications. It is also important that in each run there be a large enough number of replications, which is say thousands of them.

Even so, do not do this: You want 500,000 replications. To obtain them, you run in batches of 1,000, setting the seed 500 times. Unless you have a truly random source for the seeds, it is unlikely you can produce a patternless sequence of 500 seeds. The fact that you ran 1,000 replications in between choosing the seeds does not mitigate the requirement that there be no pattern to the seeds you set.

In all cases, the best solution is to set the seed only once and then use the method we suggest in the next section.

## Preserving and restoring the random-number generator state

In the previous section, we discussed the case in which you might be tempted to set the seed more frequently than otherwise necessary, either to save time or to be able to rerun any one of the replications. In such cases, there is an alternative to setting a new seed: recording the state of the pseudorandom-number generator and then restoring the state later should the need arise.

The state of the default random-number generator in Stata, the 64-bit Mersenne Twister, is a string of about 5,000 characters. The state can be displayed by typing `display c(rngstate)`. It is more practical to save the state, say, in a local macro named `state`:

```
. local state = c(rngstate)
```

The state can later be restored by typing

```
. set rngstate `state'
```

The state string specifies an entry point into the sequence produced by the pseudorandom-number generator. Let us explain.

The best way to use a pseudorandom-number generator would be to choose a seed once, draw random numbers until you use up the generator, and then get a new generator and choose a new key. Pseudorandom-number generators have a period, after which they repeat the original sequence. That is what we mean by using up a generator. The period of the 64-bit Mersenne Twister, the default pseudorandom-number generator in Stata, is  $2^{19937} - 1$ . This is roughly  $10^{6000}$ . It is difficult to imagine that you could ever use up this generator.

The string reported by `c(rngstate)` is an encoded form of the information necessary for Stata to reestablish exactly where it is located in the pseudorandom-number generator's sequence.

We are not seriously suggesting you choose only one seed over your entire lifetime, but let's look at how you might do that. Sometime after birth, when you needed your first random number, you would set your seed,

```
. set seed 1073741823
```

On that day, you would draw, say, 10,000 pseudorandom numbers, perhaps to impute some missing values. Being done for the day, you can save the state, and then later restore it.

When you type `set rngstate` followed by a saved state string, Stata reestablishes the previous state. Thus, the next time you draw a pseudorandom number, Stata will produce the 10,001st result after setting seed 1073741823. Let's assume that you draw 100,000 numbers this day. Done for the day, you save the state string.

On the third day, after setting the state to the saved state string above, you will be in a position to draw the 110,001st pseudorandom number.

In this way, you would eat your way through the  $2^{19937} - 1$  random numbers, but you would be unlikely ever to make it to the end.

We do not expect you to set the seed just once in your life, but using the state string makes it easy to set the seed just once for a problem.

When we do simulations at StataCorp, we record `c(rngstate)` for each replication. Just like everybody else, we record results from replications as observations in datasets; we just happen to have an extra variable in the dataset, namely, a string variable named `state`. That string is filled in observation by observation from the then-current values of `c(rngstate)`, which is a function and so can be used in any context that a function can be used in Stata.

Anytime we want to reproduce a particular replication, we thus have the information we need to reset the pseudorandom-number generator, and having it in the dataset is convenient because we had to go there anyway to determine which replication we wanted to reproduce. If we want to add more replications later, we have a state string that we can use to continue from where we left off.

## Description

`set showbaselevels` specifies whether to display base levels of factor variables and their interactions in coefficient tables. `set showbaselevels on` specifies that base levels be reported for factor variables and for interactions whose bases cannot be inferred from their component factor variables. `set showbaselevels all` specifies that all base levels of factor variables and interactions be reported.

`set showemptycells` specifies whether to display empty cells in coefficient tables.

`set showomitted` specifies whether to display omitted coefficients in coefficient tables.

`set fvlabel` specifies whether to display factor-variable value labels in coefficient tables. `set fvlabel on`, the default, specifies that the labels be displayed. `set fvlabel off` specifies that the levels of factor variables rather than the labels be displayed.

`set fvwrap #` specifies that long value labels wrap # lines in the coefficient table. The default is `set fvwrap 1`, which means that long value labels will be abbreviated to fit on one line.

`set fvwrapon` specifies whether value labels that wrap will break at word boundaries or break based on available space. `set fvwrapon word`, the default, specifies that value labels break at word boundaries. `set fvwrapon width` specifies that value labels break based on available space.

## Syntax

```
set showbaselevels { on | off | all } [, permanently]
```

```
set showemptycells { on | off } [, permanently]
```

```
set showomitted { on | off } [, permanently]
```

```
set fvlabel { on | off } [, permanently]
```

```
set fvwrap # [, permanently]
```

```
set fvwrapon { word | width } [, permanently]
```

## Option

`permanently` specifies that, in addition to making the change right now, the setting be remembered and become the default setting when you invoke Stata.

## Remarks and examples

### ▷ Example 1

We illustrate the first three set commands using cholesterol2.dta.

```
. use https://www.stata-press.com/data/r19/cholesterol2
(Artificial cholesterol data, empty cells)

. generate x = race

. regress chol race##agegrp x
note: 2.race#2.agegrp identifies no observations in the sample.
note: x omitted because of collinearity.
```

## Description

`signrank` tests the equality of matched pairs of observations by using the Wilcoxon matched-pairs signed-rank test (Wilcoxon 1945). The null hypothesis is that both distributions are the same.

`signtest` also tests the equality of matched pairs of observations (Arbuthnott [1710], but better explained by Snedecor and Cochran [1989]) by calculating the differences between *varname* and the expression. The null hypothesis is that the median of the differences is zero; no further assumptions are made about the distributions. This, in turn, is equivalent to the hypothesis that the true proportion of positive (negative) signs is one-half.

For equality tests on unmatched data, see [R] [ranksum](#).

## Quick start

Wilcoxon matched-pairs signed-rank test for *v1* and *v2*

```
signrank v1 = v2
```

Compute an exact *p*-value for the signed-rank test

```
signrank v1 = v2, exact
```

Conduct signed-rank test separately for groups defined by levels of *catvar*

```
by catvar: signrank v1 = v2
```

Test that the median of differences between matched pairs *v1* and *v2* is 0

```
signtest v1 = v2
```

## Menu

### **signrank**

Statistics > Nonparametric analysis > Tests of hypotheses > Wilcoxon matched-pairs signed-rank test

### **signtest**

Statistics > Nonparametric analysis > Tests of hypotheses > Test equality of matched pairs

## Syntax

*Wilcoxon matched-pairs signed-rank test*

```
signrank varname = exp [if] [in] [, exact]
```

*Sign test of matched pairs*

```
signtest varname = exp [if] [in]
```

`by` and `collect` are allowed with `signrank` and `signtest`; see [\[U\] 11.1.10 Prefix commands](#).

## Option for signrank

Main

`exact` specifies that the exact  $p$ -value be computed in addition to the approximate  $p$ -value. The exact  $p$ -value is based on the actual randomization distribution of the test statistic. The approximate  $p$ -value is based on a normal approximation to the randomization distribution. By default, the exact  $p$ -value is computed for sample sizes  $n \leq 200$  because the normal approximation may not be precise in small samples. The exact computation can be suppressed by specifying `noexact`. For sample sizes larger than 200, you must specify `exact` to compute the exact  $p$ -value. The exact computation is available for sample sizes  $n \leq 2000$ .

## Remarks and examples

### ► Example 1: signrank

We are testing the effectiveness of a new fuel additive. We run an experiment with 12 cars. We first run each car without the fuel treatment and measure the mileage. We then add the fuel treatment and repeat the experiment. The results of the experiment are

| Without<br>treatment | With<br>treatment | Without<br>treatment | With<br>treatment |
|----------------------|-------------------|----------------------|-------------------|
| 20                   | 24                | 18                   | 17                |
| 23                   | 25                | 24                   | 28                |
| 21                   | 21                | 20                   | 24                |
| 25                   | 22                | 24                   | 27                |
| 18                   | 23                | 23                   | 21                |
| 17                   | 18                | 19                   | 23                |

We create two variables called mpg1 and mpg2, representing mileage without and with the treatment, respectively. We can test the null hypothesis that the treatment had no effect by typing

```
. use https://www.stata-press.com/data/r19/fuel
. signrank mpg1 = mpg2
Wilcoxon signed-rank test
```

| Sign     | Obs | Sum ranks | Expected |
|----------|-----|-----------|----------|
| Positive | 3   | 13.5      | 38.5     |
| Negative | 8   | 63.5      | 38.5     |
| Zero     | 1   | 1         | 1        |
| All      | 12  | 78        | 78       |

```
Unadjusted variance 162.50
Adjustment for ties -1.62
Adjustment for zeros -0.25

Adjusted variance 160.62
H0: mpg1 = mpg2
 z = -1.973
Prob > |z| = 0.0485
Exact prob = 0.0479
```

Despite the small sample size, the  $p$ -value computed using a normal approximation, 0.0485, is similar to the exact  $p$ -value, 0.0479. These results indicate that we can reject the null hypothesis at a significance level of 0.05.

## ▶ Example 2: signtest

signtest tests that the median of the differences is zero, making no further assumptions, whereas signrank assumed that the distributions are equal as well. Using the data above, we type

```
. signtest mpg1 = mpg2
Sign test
```

| Sign     | Observed | Expected |
|----------|----------|----------|
| Positive | 3        | 5.5      |
| Negative | 8        | 5.5      |
| Zero     | 1        | 1        |
| All      | 12       | 12       |

```
One-sided tests:
H0: median of mpg1 - mpg2 = 0 vs.
Ha: median of mpg1 - mpg2 > 0
Pr(#positive >= 3) =
 Binomial(n = 11, x >= 3, p = 0.5) = 0.9673
H0: median of mpg1 - mpg2 = 0 vs.
Ha: median of mpg1 - mpg2 < 0
Pr(#negative >= 8) =
 Binomial(n = 11, x >= 8, p = 0.5) = 0.1133
Two-sided test:
H0: median of mpg1 - mpg2 = 0 vs.
Ha: median of mpg1 - mpg2 != 0
Pr(#positive >= 8 or #negative >= 8) =
 min(1, 2*Binomial(n = 11, x >= 8, p = 0.5)) = 0.2266
```

The summary table indicates that there were three comparisons for which mpg1 exceeded mpg2, eight comparisons for which mpg2 exceeded mpg1, and one comparison for which they were the same.

The  $p$ -values displayed below the summary table are based on a binomial( $n, p = 1/2$ ) distribution for the test statistic, which is the number of positive or negative signs. Zeros are ignored. The  $n$  for the test is the number of nonzero differences. Because no approximation is used, the  $p$ -values are “exact”  $p$ -values. The  $p$ -value for the one-sided test, where the alternative hypothesis is that the median of mpg1 – mpg2 is smaller than zero, is 0.1133. The  $p$ -value for the two-sided test, where the alternative hypothesis is simply that the median of the differences is different from zero, is  $0.2266 = 2 \times 0.1133$ .

## Stored results

signrank stores the following in `r()`:

Scalars

|                           |                                                      |
|---------------------------|------------------------------------------------------|
| <code>r(N)</code>         | sample size                                          |
| <code>r(N_pos)</code>     | number of positive comparisons                       |
| <code>r(N_neg)</code>     | number of negative comparisons                       |
| <code>r(N_tie)</code>     | number of tied comparisons                           |
| <code>r(z)</code>         | $z$ statistic                                        |
| <code>r(Var_a)</code>     | adjusted variance                                    |
| <code>r(sum_pos)</code>   | sum of the positive ranks                            |
| <code>r(sum_neg)</code>   | sum of the negative ranks                            |
| <code>r(p)</code>         | two-sided $p$ -value from normal approximation       |
| <code>r(p_l)</code>       | lower one-sided $p$ -value from normal approximation |
| <code>r(p_u)</code>       | upper one-sided $p$ -value from normal approximation |
| <code>r(p_exact)</code>   | two-sided exact $p$ -value                           |
| <code>r(p_l_exact)</code> | lower one-sided exact $p$ -value                     |
| <code>r(p_u_exact)</code> | upper one-sided exact $p$ -value                     |

signtest stores the following in `r()`:

Scalars

|                       |                                |
|-----------------------|--------------------------------|
| <code>r(N)</code>     | sample size                    |
| <code>r(N_pos)</code> | number of positive comparisons |
| <code>r(N_neg)</code> | number of negative comparisons |
| <code>r(N_tie)</code> | number of tied comparisons     |
| <code>r(p)</code>     | two-sided $p$ -value           |
| <code>r(p_l)</code>   | lower one-sided $p$ -value     |
| <code>r(p_u)</code>   | upper one-sided $p$ -value     |

## Methods and formulas

For a practical introduction to these techniques with an emphasis on examples rather than theory, see [Bland \(2015\)](#) or [Sprent and Smeeton \(2007\)](#). For a summary of these tests, see [Snedecor and Cochran \(1989\)](#).

Methods and formulas are presented under the following headings:

[\*signrank\*](#)  
[\*signtest\*](#)

## signrank

Both the sign test and Wilcoxon signed-rank tests test the null hypothesis that the distribution of a random variable  $D = \text{varname} - \text{exp}$  has median zero. The sign test makes no additional assumptions, but the Wilcoxon signed-rank test makes the additional assumption that the distribution of  $D$  is symmetric. If  $D = X_1 - X_2$ , where  $X_1$  and  $X_2$  have the same distribution, then it follows that the distribution of  $D$  is symmetric about zero. Thus, the Wilcoxon signed-rank test is often described as a test of the hypothesis that two distributions are the same, that is,  $X_1 \sim X_2$ .

Let  $d_j$  denote the difference for any matched pair of observations,

$$d_j = x_{1j} - x_{2j} = \text{varname} - \text{exp}$$

for  $j = 1, 2, \dots, n$ .

Rank the absolute values of the differences,  $|d_j|$ , and assign any tied values the average rank. Consider the signs of  $d_j$ , and let

$$r_j = \text{sign}(d_j) \text{rank}(|d_j|)$$

be the signed ranks. The test statistic is

$$T_{\text{obs}} = \sum_{j=1}^n r_j = (\text{sum of ranks for } + \text{ signs}) - (\text{sum of ranks for } - \text{ signs})$$

The distribution of the test statistic is based on Fisher's principle of randomization (Fisher 1935). Fisher's idea (stated in a modern way) was to look at a family of transformations of the observed data such that the a priori likelihood (under the null hypothesis) of the transformed data is the same as the likelihood of the observed data. The distribution of the test statistic is then produced by calculating its value for each of the transformed "randomization" datasets, assuming that each dataset is equally likely.

The null hypothesis is that the distribution of  $d_j$  is symmetric about 0. Hence, the likelihood is unchanged if we flip signs on the  $d_j$ . The randomization distribution of our test statistic,  $T$ , is all of its values resulting from the  $2^n$  possible sign changes for the  $d_j$ . Namely, the distribution is all the  $2^n$  possible values of

$$T = \sum_{j=1}^n S_j r_j$$

where  $r_j$  are the observed signed ranks (considered fixed) and  $S_j$  is either  $+1$  or  $-1$ . When the exact option is specified (or implied for  $n \leq 200$ ), this distribution is computed using a recursive algorithm whose computational time is proportional to  $n^3$ . (See Fisher [1935] for the principle of randomization; Wilcoxon, Katti, and Wilcox [1970] for the computation with untied ranks; and Baker and Tilbury [1993] for the general recursive algorithm.)

$p$ -values can also be computed using a normal approximation to the randomization distribution. For the randomization distribution, the mean and variance are given by

$$E(T) = 0 \quad \text{and} \quad \text{Var}_{\text{adj}}(T) = \sum_{j=1}^n r_j^2$$

The test statistic for the Wilcoxon signed-rank test is often expressed (equivalently) as the sum of the positive signed ranks,  $T_+$ , where

$$E(T_+) = \frac{n(n+1)}{4} \quad \text{and} \quad \text{Var}_{\text{adj}}(T_+) = \frac{1}{4} \sum_{j=1}^n r_j^2$$

Zeros and ties do not affect the theory above, and the exact variance is still given by the above formula for  $\text{Var}_{\text{adj}}(T_+)$ . When  $d_j = 0$  is observed,  $r_j$  will always be zero in each of the randomization datasets, using  $\text{sign}(0) = 0$ . (This method of handling zeros is based on the theoretical arguments made by Pratt [1959].) When there are ties, averaged ranks are assigned for each group of ties and then treated the same as other ranks.

The “unadjusted variance” reported by `signrank` is the variance that the randomization distribution would have had if there had been no ties or zeros:

$$\text{Var}_{\text{unadj}}(T_+) = \frac{1}{4} \sum_{j=1}^n j^2 = \frac{n(n+1)(2n+1)}{24}$$

The adjustment for zeros is the change in the variance when the ranks for the zeros are signed to make  $r_j = 0$ ,

$$\Delta \text{Var}_{\text{zero adj}}(T_+) = -\frac{1}{4} \sum_{j=1}^{n_0} j^2 = -\frac{n_0(n_0+1)(2n_0+1)}{24}$$

where  $n_0$  is the number of zeros. The adjustment for ties is the change in the variance when the ranks (for nonzero observations) are replaced by averaged ranks:

$$\Delta \text{Var}_{\text{ties adj}}(T_+) = \text{Var}_{\text{adj}}(T_+) - \text{Var}_{\text{unadj}}(T_+) - \Delta \text{Var}_{\text{zero adj}}(T_+)$$

A normal approximation is used to calculate

$$z = \frac{T_+ - E(T_+)}{\sqrt{\text{Var}_{\text{adj}}(T_+)}}$$

## signtest

The test statistic for the sign test is the number  $n_+$  of differences

$$d_j = x_{1j} - x_{2j} = \text{varname} - \text{exp}$$

greater than zero.

Again, the distribution of the test statistic is based on Fisher’s principle of randomization, which we described above for `signrank`. For the sign test, the “data” are simply the set of signs of the differences. Under the null hypothesis of the sign test, the probability that  $d_j$  is less than zero is equal to the probability that  $d_j$  is greater than zero. Thus, you can transform the observed signs by flipping any number of them, and the set of signs will have the same likelihood. The  $2^n$  possible sign changes form the family of randomization datasets. If you have no zeros, this procedure leads to  $n_+ \sim \text{binomial}(n, p = 1/2)$ .

But what if some differences are zero? If you do have zeros, changing their signs leaves them as zeros. So, if you observe  $n_0$  zeros, each of the  $2^n$  sign-change datasets will also have  $n_0$  zeros. Hence, the values of  $n_+$  calculated over the sign-change datasets range from 0 to  $n - n_0$ , and the “randomization” distribution of  $n_+$  is  $\text{binomial}(n - n_0, p = 1/2)$ .

The work of [Arbuthnott \(1710\)](#) and later eighteenth-century contributions is discussed by [Hald \(2003, chap. 17\)](#).

[Frank Wilcoxon \(1892–1965\)](#) was born in Ireland to American parents. After working in various occupations (including merchant seaman, oil-well pump attendant, and tree surgeon), he settled in chemistry, gaining degrees from Rutgers and Cornell and employment from various companies. Working mainly on the development of fungicides and insecticides, Wilcoxon became interested in statistics in 1925 and made several key contributions to nonparametric methods. After retiring from industry, he taught statistics at Florida State until his death.

[Description](#)[Remarks and examples](#)[Quick start](#)[References](#)[Syntax](#)[Also see](#)[Options](#)

## Description

`simulate` eases the programming task of performing Monte Carlo–type simulations. Typing

```
. simulate exp_list, reps(#): command
```

runs *command* for # replications and collects the results in *exp\_list*.

*command* defines the command that performs one simulation. Most Stata commands and user-written programs can be used with `simulate`, as long as they follow standard Stata syntax; see [\[U\] 11 Language syntax](#). The `by` prefix may not be part of *command*.

*exp\_list* specifies the expression to be calculated from the execution of *command*. If no expressions are given, *exp\_list* assumes a default, depending upon whether *command* changes results in `e()` or `r()`. If *command* changes results in `e()`, the default is `_b`. If *command* changes results in `r()` (but not `e()`), the default is all the scalars posted to `r()`. It is an error not to specify an expression in *exp\_list* otherwise.

## Quick start

*Simple program for use with simulate*

Define program `myreg` to generate data and fit a linear regression

```
program myreg, eclass
 drop _all
 set obs 25
 generate x = rnormal()
 generate y = 3*x + 1 + rnormal()
 regress y x
end
```

*Perform simulation*

Record coefficients and SEs from 1,000 simulated replications of program `myreg`

```
simulate _b _se, reps(1000): myreg
```

Same as above, and set random-number seed to 5,762 for reproducible results

```
simulate _b _se, reps(1000) seed(5762): myreg
```

## Syntax

```
simulate [exp_list], reps(#) [options] : command
```

| <i>options</i>                     | Description                            |
|------------------------------------|----------------------------------------|
| <code>nodots</code>                | suppress replication dots              |
| <code>dots(#)</code>               | display dots every # replications      |
| <code>noisily</code>               | display any output from <i>command</i> |
| <code>trace</code>                 | trace <i>command</i>                   |
| <code>saving(filename, ...)</code> | save results to <i>filename</i>        |
| <code>nolegend</code>              | suppress table legend                  |
| <code>verbose</code>               | display the full table legend          |
| <code>seed(#)</code>               | set random-number seed to #            |

All weight types supported by *command* are allowed; see [U] 11.1.6 **weight**.

|                          |                                                               |
|--------------------------|---------------------------------------------------------------|

| <i>elist</i> contains    | <i>newvar</i> = ( <i>exp</i> )<br>( <i>exp</i> )              |
| <i>eexp</i> is           | <i>specname</i><br>[ <i>eqno</i> ] <i>specname</i>            |
| <i>specname</i> is       | _b<br>_b []<br>_se<br>_se []                                  |
| <i>eqno</i> is           | # #<br><i>name</i>                                            |

*exp* is a standard Stata expression; see [U] 13 **Functions and expressions**.

Distinguish between [], which are to be typed, and [], which indicate optional arguments.

## Options

`reps(#)` is required—it specifies the number of replications to be performed.

`nodots` and `dots(#)` specify whether to display replication dots. By default, one dot character is displayed for each successful replication. An “x” is displayed if *command* returns an error or if any value in *exp\_list* is missing. You can also control whether dots are displayed using `set dots`; see [R] **set**.

`nodots` suppresses display of the replication dots.

`dots(#)` displays dots every # replications. `dots(0)` is a synonym for `nodots`.

`noisily` requests that any output from *command* be displayed. This option implies the `nodots` option.

`trace` causes a trace of the execution of *command* to be displayed. This option implies the `noisily` option.

`saving(filename[ , suboptions ])` creates a Stata data file (`.dta` file) consisting of (for each statistic in *exp\_list*) a variable containing the replicates.

`double` specifies that the results for each replication be saved as doubles, meaning 8-byte reals. By default, they are saved as floats, meaning 4-byte reals.

`every(#)` specifies that results be written to disk every *#*th replication. `every()` should be specified only in conjunction with `saving()` when *command* takes a long time for each replication. This will allow recovery of partial results should some other software crash your computer. See [P] [postfile](#).

`replace` specifies that *filename* be overwritten if it exists.

`nolegend` suppresses display of the table legend. The table legend identifies the rows of the table with the expressions they represent.

`verbose` requests that the full table legend be displayed. By default, coefficients and standard errors are not displayed.

`seed(#)` sets the random-number seed. Specifying this option is equivalent to typing the following command before calling `simulate`:

```
. set seed #
```

## Remarks and examples

For an introduction to Monte Carlo methods, see [Cameron and Trivedi \(2022, chap. 5\)](#). [White \(2010\)](#) provides a command for analyzing results of simulation studies.

### ► Example 1: Simulating basic summary statistics

We have a dataset containing means and variances of 100-observation samples from a lognormal distribution (as a first step in evaluating, say, the coverage of a 95%, *t*-based confidence interval). Then we perform the experiment 1,000 times.

The following command definition will generate 100 independent observations from a lognormal distribution and compute the summary statistics for this sample.

```
program lnsim, rclass
 version 19.5 // (or version 19 if you do not have StataNow)
 drop _all
 set obs 100
 generate z = exp(rnormal())
 summarize z
 return scalar mean = r(mean)
 return scalar Var = r(Var)
end
```

We can save 1,000 simulated means and variances from `lnsim` by typing

```
. set seed 1234
. simulate mean=r(mean) var=r(Var), reps(1000) nodots: lnsim
Command: lnsim
 mean: r(mean)
 var: r(Var)
```

```
. describe *
```

| Variable name | Storage type | Display format | Value label | Variable label |
|---------------|--------------|----------------|-------------|----------------|
| mean          | float        | %9.0g          |             | r(mean)        |
| var           | float        | %9.0g          |             | r(Var)         |

```
. summarize
```

| Variable | Obs   | Mean     | Std. dev. | Min      | Max      |
|----------|-------|----------|-----------|----------|----------|
| mean     | 1,000 | 1.630648 | .2173062  | 1.106372 | 2.612052 |
| var      | 1,000 | 4.60798  | 4.502166  | .966087  | 70.5597  |

## □ Technical note

Before executing our `lnsim` simulator, we can verify that it works by executing it interactively.

```
. set seed 1234
. lnsim
Number of observations (_N) was 0, now 100.
```

| Variable | Obs | Mean     | Std. dev. | Min      | Max      |
|----------|-----|----------|-----------|----------|----------|
| z        | 100 | 1.534256 | 1.584568  | .0400387 | 9.818309 |

```
. return list
scalars:
 r(Var) = 2.510857086217961
 r(mean) = 1.53425569280982
```

## ▷ Example 2: Simulating a regression model

Consider a more complicated problem. Let's experiment with fitting  $y_j = a + bx_j + u_j$  when the true model has  $a = 1$ ,  $b = 2$ ,  $u_j = z_j + cx_j$ , and when  $z_j$  is  $N(0, 1)$ . We will save the parameter estimates and standard errors and experiment with varying  $c$ .  $x_j$  will be fixed across experiments but will originally be generated as  $N(0, 1)$ . We begin by interactively making the true data:

```
. drop _all
. set obs 100
Number of observations (_N) was 0, now 100.
. set seed 54321
. generate x = rnormal()
. generate true_y = 1+2*x
. save truth
file truth.dta saved
```

Our program is

```
program hetero1
 version 19.5 // (or version 19 if you do not have StataNow)
 args c
 use truth, clear
 generate y = true_y + (rnormal() + 'c'*x)
 regress y x
end
```

Note the use of ‘c’ in our statement for generating y. c is a local macro generated from args c and thus refers to the first argument supplied to hetero1. If we want  $c = 3$  for our experiment, we type

```
. simulate _b _se, reps(10000): hetero1 3
 (output omitted)
```

Our program hetero1 could, however, be more efficient because it rereads the file truth once every replication. It would be better if we could read the data just once. In fact, if we read in the data right before running simulate, we really should not have to reread for each subsequent replication. A faster version reads

```
program hetero2
 version 19.5 // (or version 19 if you do not have StataNow)
 args c
 capture drop y
 generate y = true_y + (rnormal() + 'c'*x)
 regress y x
end
```

Requiring that the current dataset has the variables true\_y and x may become inconvenient. Another improvement would be to require that the user supply variable names, such as in

```
program hetero3
 version 19.5 // (or version 19 if you do not have StataNow)
 args truey x c
 capture drop y
 generate y = 'truey' + (rnormal() + 'c'*'x')
 regress y x
end
```

Thus, we can type

```
. simulate _b _se, reps(10000): hetero3 true_y x 3
 (output omitted)
```

### ▷ Example 3: Simulating a ratio of statistics

Now, let’s consider the problem of simulating the ratio of two medians. Suppose that each sample of size  $n_i$  comes from a normal population with a mean  $\mu_i$  and standard deviation  $\sigma_i$ , where  $i = 1, 2$ . We write the program below and save it as a text file called myratio.ado (see [U] 17 Ado-files). Our program is an rclass command that requires six arguments as input, identified by the local macros n1, mu1, sigma1, n2, mu2, and sigma2, which correspond to  $n_1$ ,  $\mu_1$ ,  $\sigma_1$ ,  $n_2$ ,  $\mu_2$ , and  $\sigma_2$ , respectively. With these arguments, myratio will generate the data for the two samples, use summarize to compute the two medians and store the ratio of the medians in r(ratio).

```
program myratio, rclass
 version 19.5 // (or version 19 if you do not have StataNow)
 args n1 mu1 sigma1 n2 mu2 sigma2
 // generate the data
 drop _all
 local N = 'n1'+‘n2’
 set obs ‘N’
 tempvar y
 generate ‘y’ = rnormal()
 replace ‘y’ = cond(_n<=‘n1’, ‘mu1’+‘y’*‘sigma1’, ‘mu2’+‘y’*‘sigma2’)
 // calculate the medians
 tempname m1
```

```

summarize 'y' if _n<='n1', detail
scalar 'm1' = r(p50)
summarize 'y' if _n>'n1', detail
// store the results
return scalar ratio = 'm1' / r(p50)
end

```

The result of running our simulation is

```

. set seed 19192
. simulate ratio=r(ratio), reps(1000) nodots: myratio 5 3 1 10 3 2
 Command: myratio 5 3 1 10 3 2
 ratio: r(ratio)

. summarize

```

| Variable | Obs   | Mean    | Std. dev. | Min      | Max      |
|----------|-------|---------|-----------|----------|----------|
| ratio    | 1,000 | 1.10875 | .5219166  | .3606606 | 9.857285 |

◀

## □ Technical note

Stata lets us do simulations of simulations and simulations of bootstraps. Stata's `bootstrap` command (see [R] [bootstrap](#)) works much like `simulate`, except that it feeds the user-written program a bootstrap sample. Say that we want to evaluate the bootstrap estimator of the standard error of the median when applied to lognormally distributed data. We want to perform a simulation, resulting in a dataset of medians and bootstrap estimated standard errors.

As background, `summarize` (see [R] [summarize](#)) calculates summary statistics, leaving the mean in `r(mean)` and the standard deviation in `r(sd)`. `summarize` with the `detail` option also calculates summary statistics, but more of them, and leaves the median in `r(p50)`.

Thus, our plan is to perform simulations by randomly drawing a dataset: we calculate the median of our random sample, we use `bootstrap` to obtain a dataset of medians calculated from bootstrap samples of our random sample, the standard deviation of those medians is our estimate of the standard error, and the summary statistics are stored in the results of `summarize`.

Our simulator is

```

program define bsse, rclass
version 19.5 // (or version 19 if you do not have StataNow)
drop _all
set obs 100
generate x = rnormal()
tempfile bsfile
bootstrap midp=r(p50), rep(100) saving('bsfile'): summarize x, detail
use 'bsfile', clear
summarize midp
return scalar mean = r(mean)
return scalar sd = r(sd)
end

```

We can obtain final results, running our simulation 1,000 times, by typing

```
. set seed 48901
. simulate med=r(mean) bs_se=r(sd), reps(1000): bsse
 Command: bsse
 med: r(mean)
 bs_se: r(sd)
Simulations (1,000):10.....20.....30.....40.....50....
>60.....70.....80.....90.....100.....110.....120..
>130.....140.....150.....160.....170.....180.....
>190.....200.....210.....220.....230.....240.....250..
>260.....270.....280.....290.....300.....310.....
>320.....330.....340.....350.....360.....370.....380..
>390.....400.....410.....420.....430.....440.....
>450.....460.....470.....480.....490.....500.....510..
>520.....530.....540.....550.....560.....570.....
>580.....590.....600.....610.....620.....630.....640..
>650.....660.....670.....680.....690.....700.....
>710.....720.....730.....740.....750.....760.....770..
>780.....790.....800.....810.....820.....830.....
>840.....850.....860.....870.....880.....890.....900..
>910.....920.....930.....940.....950.....960.....
>970.....980.....990.....1,000 done
. summarize
```

| Variable | Obs   | Mean      | Std. dev. | Min       | Max      |
|----------|-------|-----------|-----------|-----------|----------|
| med      | 1,000 | -.0013359 | .1221602  | -.3795549 | .3656219 |
| bs_se    | 1,000 | .1278773  | .0303109  | .0614031  | .2484805 |

This is a case where the simulation dots (drawn by default, unless the `nodots` option is specified) will give us an idea of how long this simulation will take to finish as it runs.

## Description

The *Stata Journal* (SJ) is a quarterly journal containing articles about statistics, data analysis, teaching methods, and effective use of Stata's language. The SJ publishes reviewed articles with shorter notes and comments, regular columns, tips, book reviews, and other material of interest to researchers applying statistics in a variety of disciplines. The SJ began publication in the fourth quarter of 2001 with SJ Volume 1 Number 1. You can read all about the SJ at <https://www.stata-journal.com>.

The SJ is a printed and electronic journal with corresponding software. You must subscribe to the SJ; see <https://www.stata-journal.com/subscription/> to purchase a subscription or an individual article. Electronic copies of SJ articles that are older than three years are available at no charge from <https://www.stata-journal.com/archives.html>.

The software is available at no charge; see [below](#) for installation instructions.

## Remarks and examples

Remarks are presented under the following headings:

*Installing the Stata Journal software*

*Obtaining from the internet by pointing and clicking*

*Obtaining from the internet via command mode*

## Installing the Stata Journal software

Each issue of the *Stata Journal* is labeled Volume #, Number #. Volume 1 refers to the first year of publication, Volume 2 to the second, and so on. Issues are numbered 1, 2, 3, and 4 within each year. The first issue of the *Journal* was published in the fourth quarter of 2001, and that issue is numbered Volume 1, Number 1. For installation purposes, we refer to this issue as `sj1-1`.

The articles, columns, notes, and comments that make up the *Stata Journal* are assigned a letter-and-number code, called an insert tag, such as `st0001`, `an0034`, or `ds0011`. The letters represent a category: `st` is the statistics category, `an` is the announcements category, etc. The numbers are assigned sequentially, so `st0001` is the first article in the statistics category.

Sometimes inserts are subsequently updated, either to fix bugs or to add new features. A number such as `st0001_1` indicates that this article, column, note, or comment is an update to the original `st0001` article. Updates are complete; that is, installing `st0001_1` provides all the features of the original article and more.

The *Stata Journal* software may be obtained by pointing and clicking or by using command mode.

The sections below detail how to install an insert. In all cases, pretend that you wish to install insert `st0274` from `sj12-4`.

## Obtaining from the internet by pointing and clicking

1. Select **Help > SJ and community-contributed features**.
2. Click on *Stata Journal*.
3. Click on *sj12-4*.
4. Click on *st0274*.
5. Click on (*click here to install*).

## Obtaining from the internet via command mode

Type the following:

```
. net from https://www.stata-journal.com/software
. net cd sj12-4
. net describe st0274
. net install st0274
```

The above could be shortened to

```
. net from https://www.stata-journal.com/software/sj12-4
. net describe st0274
. net install st0274
```

Alternatively, you could type

```
. net sj 12-4
. net describe st0274
. net install st0274
```

but going about it the long way is more entertaining, at least the first time.

## Description

For each variable in *varlist*, `sktest` presents a test for normality based on skewness and another based on kurtosis and then combines the two tests into an overall test statistic. `sktest` requires a minimum of eight observations to make its calculations. See [MV] [mvtest normality](#) for multivariate tests of normality.

## Quick start

Test for normality of *v1* based on skewness and kurtosis

```
sktest v1
```

Separate tests for *v1* and *v2*

```
sktest v1 v2
```

With frequency weights in *wvar*

```
sktest v1 v2 [fweight=wvar]
```

Suppress adjustment to the overall  $\chi^2$  test

```
sktest v1 v2, noadjust
```

## Menu

Statistics > Summaries, tables, and tests > Distributional plots and tests > Skewness and kurtosis normality tests

## Syntax

```
sktest varlist [if] [in] [weight] [, options]
```

| <i>options</i> | Description |
|----------------|-------------|
|----------------|-------------|

Main

|                        |                                                                      |
|------------------------|----------------------------------------------------------------------|
| <code>noadjust</code>  | do not adjust the overall $\chi^2$ test statistic and its $p$ -value |
| <code>nostretch</code> | do not automatically widen table for long variable names             |

`collect` is allowed; see [U] 11.1.10 Prefix commands.

`aweight`s and `fweight`s are allowed; see [U] 11.1.6 weight.

`nostretch` does not appear in the dialog box.

## Option

Main

`noadjust` suppresses the empirical adjustment made by Royston (1991c) to the overall  $\chi^2$  test statistic and its  $p$ -value and presents the unaltered test as described by D'Agostino, Belanger, and D'Agostino (1990).

The following option is available with `sktest` but is not shown in the dialog box:

`nostretch`; see [R] Estimation options.

## Remarks and examples

Also see [R] `swilk` for the Shapiro–Wilk and Shapiro–Francia tests for normality. Those tests are, in general, preferred for nonaggregated data (Gould and Rogers 1991; Gould 1992; Royston 1991c). Moreover, a normal quantile plot should be used with any test for normality; see [R] Diagnostic plots for more information.

### ▷ Example 1

Using our automobile dataset, we will test whether the variables `mpg` and `trunk` are normally distributed:

```
. use https://www.stata-press.com/data/r19/auto
(1978 automobile data)
```

```
. sktest mpg trunk
```

```
Skewness and kurtosis tests for normality
```

| Variable | Obs | Pr(skewness) | Pr(kurtosis) | Joint test  |           |
|----------|-----|--------------|--------------|-------------|-----------|
|          |     |              |              | Adj chi2(2) | Prob>chi2 |
| mpg      | 74  | 0.0015       | 0.0804       | 10.95       | 0.0042    |
| trunk    | 74  | 0.9115       | 0.0445       | 4.19        | 0.1228    |

We can reject the hypothesis that `mpg` is normally distributed, but we cannot reject the hypothesis that `trunk` is normally distributed, at least at the 12% level. The kurtosis for `trunk` is 2.19, as can be verified by issuing the command

```
. summarize trunk, detail
 (output omitted)
```

and the  $p$ -value of 0.0445 shown in the table above indicates that it is significantly different from the kurtosis of a normal distribution at the 5% significance level. However, on the basis of skewness alone, we cannot reject the hypothesis that `trunk` is normally distributed.

◀

## □ Technical note

`sktest` implements the test as described by [D'Agostino, Belanger, and D'Agostino \(1990\)](#) but with the adjustment made by [Royston \(1991c\)](#). In the above example, if we had specified the `noadjust` option, the  $\chi^2$  values would have been 13.13 for `mpg` and 4.05 for `trunk`. With the adjustment, the  $\chi^2$  value might show as `.'`. This result should be interpreted as an absurdly large number; the data are most certainly not normal.

□

## Stored results

`sktest` stores the following in `r()`:

### Scalars

|                        |                                       |
|------------------------|---------------------------------------|
| <code>r(N)</code>      | number of observations                |
| <code>r(chi2)</code>   | overall $\chi^2$                      |
| <code>r(p_skew)</code> | $p$ -value for test based on skewness |
| <code>r(p_kurt)</code> | $p$ -value for test based on kurtosis |
| <code>r(p_chi2)</code> | $p$ -value for overall $\chi^2$ test  |

### Matrices

|                       |                                                   |
|-----------------------|---------------------------------------------------|
| <code>r(table)</code> | matrix of displayed results, one row per variable |
|-----------------------|---------------------------------------------------|

## Methods and formulas

`sktest` implements the test described by [D'Agostino, Belanger, and D'Agostino \(1990\)](#) with the empirical correction developed by [Royston \(1991c\)](#).

Let  $g_1$  denote the coefficient of skewness and  $b_2$  denote the coefficient of kurtosis as calculated by `summarize`, and let  $n$  denote the sample size. If weights are specified, then  $g_1$ ,  $b_2$ , and  $n$  denote the weighted coefficients of skewness and kurtosis and weighted sample size, respectively. See [\[R\] summarize](#) for the formulas for skewness and kurtosis.

To perform the test of skewness, we compute

$$Y = g_1 \left\{ \frac{(n+1)(n+3)}{6(n-2)} \right\}^{1/2}$$

$$\beta_2(g_1) = \frac{3(n^2 + 27n - 70)(n+1)(n+3)}{(n-2)(n+5)(n+7)(n+9)}$$

$$W^2 = -1 + [2\{\beta_2(g_1) - 1\}]^{1/2}$$

and

$$\alpha = \{2/(W^2 - 1)\}^{1/2}$$

Then, the distribution of the test statistic

$$Z_1 = \frac{1}{\sqrt{\ln W}} \ln \left[ Y/\alpha + \{(Y/\alpha)^2 + 1\}^{1/2} \right]$$

is approximately standard normal under the null hypothesis that the data are distributed normally.

To perform the test of kurtosis, we compute

$$E(b_2) = \frac{3(n-1)}{n+1}$$

$$\text{var}(b_2) = \frac{24n(n-2)(n-3)}{(n+1)^2(n+3)(n+5)}$$

$$X = \{b_2 - E(b_2)\} / \sqrt{\text{var}(b_2)}$$

$$\sqrt{\beta_1(b_2)} = \frac{6(n^2 - 5n + 2)}{(n+7)(n+9)} \left\{ \frac{6(n+3)(n+5)}{n(n-2)(n-3)} \right\}^{1/2}$$

and

$$A = 6 + \frac{8}{\sqrt{\beta_1(b_2)}} \left[ \frac{2}{\sqrt{\beta_1(b_2)}} + \left\{ 1 + \frac{4}{\beta_1(b_2)} \right\}^{1/2} \right]$$

Then, the distribution of the test statistic

$$Z_2 = \frac{1}{\sqrt{2/(9A)}} \left[ \left( 1 - \frac{2}{9A} \right) - \left\{ \frac{1 - 2/A}{1 + X\sqrt{2/(A-4)}} \right\}^{1/3} \right]$$

is approximately standard normal under the null hypothesis that the data are distributed normally.

D'Agostino, Balanger, and D'Agostino Jr.'s omnibus test of normality uses the statistic

$$K^2 = Z_1^2 + Z_2^2$$

which has approximately a  $\chi^2$  distribution with 2 degrees of freedom under the null of normality.

Royston (1991c) proposed the following adjustment to the test of normality, which `sktest` uses by default. Let  $\Phi(x)$  denote the cumulative standard normal distribution function for  $x$ , and let  $\Phi^{-1}(p)$  denote the inverse cumulative standard normal function [that is,  $x = \Phi^{-1}\{\Phi(x)\}$ ]. Define the following terms:

$$\begin{aligned} Z_c &= -\Phi^{-1}\left\{\exp\left(-\frac{1}{2}K^2\right)\right\} \\ Z_t &= 0.55n^{0.2} - 0.21 \\ a_1 &= (-5 + 3.46 \ln n) \exp(-1.37 \ln n) \\ b_1 &= 1 + (0.854 - 0.148 \ln n) \exp(-0.55 \ln n) \\ a_2 &= a_1 - \{2.13/(1 - 2.37 \ln n)\} Z_t \end{aligned}$$

and

$$b_2 = 2.13/(1 - 2.37 \ln n) + b_1$$

If  $Z_c < -1$  set  $Z = Z_c$ ; else if  $Z_c < Z_t$  set  $Z = a_1 + b_1 Z_c$ ; else set  $Z = a_2 + b_2 Z_c$ . Define  $P = 1 - \Phi(Z)$ . Then,  $K^2 = -2 \ln P$  is approximately distributed  $\chi^2$  with 2 degrees of freedom.

The relative merits of the skewness and kurtosis test versus the Shapiro–Wilk and Shapiro–Francia tests have been a subject of debate. Our recommendation is to use the Shapiro–Francia test whenever possible, that is, whenever dealing with nonaggregated or ungrouped data (Gould and Rogers 1991; Gould 1992); see [R] [swilk](#). If normality is rejected, use `sktest` to determine the source of the problem.

As both D’Agostino, Belanger, and D’Agostino (1990) and Royston (1991d) mention, researchers should also examine the normal quantile plot to determine normality rather than blindly relying on a few test statistics. See the `qnorm` command documented in [R] [Diagnostic plots](#) for more information on normal quantile plots.

`sktest` is similar in spirit to the Jarque–Bera (1987) test of normality. The Jarque–Bera test statistic is also calculated from the sample skewness and kurtosis, though it is based on asymptotic standard errors with no corrections for sample size. In effect, `sktest` offers two adjustments for sample size, that of Royston (1991c) and that of D’Agostino, Belanger, and D’Agostino (1990).

## Acknowledgments

`sktest` has benefited greatly by the comments and work of Patrick Royston of the MRC Clinical Trials Unit, London, and coauthor of the Stata Press book *Flexible Parametric Survival Analysis Using Stata: Beyond the Cox Model*. At this point, the program should be viewed as due as much to Royston as to us, except, of course, for any errors. We are also indebted to Nicholas J. Cox of the Department of Geography at Durham University, UK, and coeditor of the *Stata Journal* and author of *Speaking Stata Graphics* for his helpful comments.

## Description

`slogit` fits Anderson's (1984) maximum-likelihood stereotype logistic regression model for categorical dependent variables. Stereotype logistic models can be used when the relevance of the ordering is unclear. These models do not impose the proportional-odds assumption.

## Quick start

One-dimensional model of  $y$  as a function of  $x_1$  and  $x_2$

```
slogit y x1 x2
```

Add [indicators](#) for categorical variable  $a$  and set  $y = 1$  as the base category

```
slogit y x1 x2 i.a, baseoutcome(1)
```

Multidimensional model reparameterizing a multinomial logit when  $y$  has 4 categories

```
slogit y x1 x2 i.a, dimensions(3) baseoutcome(1)
```

*indepvars* may contain factor variables; see [U] 11.4.3 **Factor variables**.

`bayesboot`, `bootstrap`, `by`, `collect`, `fp`, `jackknife`, `rolling`, `statsby`, and `svy` are allowed; see [U] 11.1.10 **Prefix commands**.

Weights are not allowed with the `bootstrap` prefix; see [R] **bootstrap**.

`vce()` and weights are not allowed with the `svy` prefix; see [SVY] **svy**.

`fweights`, `iweights`, and `pweights` are allowed; see [U] 11.1.6 **weight**.

`collinear` and `coeflegend` do not appear in the dialog box.

See [U] 20 **Estimation and postestimation commands** for more capabilities of estimation commands.

## Options

### Model

`dimension(#)` specifies the dimension of the model, which is the number of equations required to describe the relationship between the dependent variable and the independent variables. The maximum dimension is  $\min(m - 1, p)$ , where  $m$  is the number of categories of the dependent variable and  $p$  is the number of independent variables in the model. The stereotype model with maximum dimension is a reparameterization of the multinomial logistic model.

`baseoutcome(#|lbl)` specifies the outcome level whose scale parameters and intercept are constrained to be zero. The base outcome may be specified as a number or a label. By default, `slogit` assumes that the outcome levels are ordered and uses the largest level of the dependent variable as the base outcome.

`constraints(numlist)`; see [R] [Estimation options](#).

By default, the linear equality constraints suggested by [Anderson \(1984\)](#), termed the corner constraints, are generated for you. You can add constraints to these as needed, or you can turn off the corner constraints by specifying `nocorner`. These constraints are in addition to the constraints placed on the  $\phi$  parameters corresponding to `baseoutcome(#)`.

`nocorner` specifies that `slogit` not generate the corner constraints. If you specify `nocorner`, you must specify at least `dimension() × dimension()` constraints for the model to be identified.

#### SE/Robust

`vce(vctype)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory (`oim`, `opg`), that are robust to some kinds of misspecification (`robust`), that allow for intragroup correlation (`cluster clustvar`), and that use bootstrap or jackknife methods (`bootstrap`, `jackknife`); see [R] [vce\\_option](#).

If specifying `vce(bootstrap)` or `vce(jackknife)`, you must also specify `baseoutcome()`.

#### Reporting

`level(#)`, `nocnsreport`; see [R] [Estimation options](#).

`display_options`: `nocl`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `nolstretch`; see [R] [Estimation options](#).

#### Maximization

`maximize_options`: `difficult`, `technique(algorithm_spec)`, `iterate(#)`, `[no]log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `ltolerance(#)`, `nrtolerance(#)`, `nonrtolerance`, and `from(init_specs)`; see [R] [Maximize](#). These options are seldom used.

Setting the optimization type to `technique(bhhh)` resets the default `vctype` to `vce(opg)`.

`initialize(constant|random|svd)` specifies how initial estimates are computed. The default, `initialize(constant)`, is to set the scale parameters to the constant  $\min(1/2, 1/d)$ , where  $d$  is the dimension specified in `dimension()`.

`initialize(random)` requests that uniformly distributed random numbers between 0 and 1 be used as initial values for the scale parameters. If you specify this option, you should also use `set seed` to ensure that you can replicate your results; see [R] [set seed](#).

`initialize(svd)` requests that a singular value decomposition (SVD) be performed on the matrix of regression estimates from `mlogit` to reduce its rank to the dimension specified in `dimension()`. `slogit` uses the reduced-rank components of the SVD as initial estimates for the scale and regression coefficients. For details, see [Methods and formulas](#).

`nonnormalize` specifies that the numeric variables not be normalized. Normalization of the numeric variables improves numerical stability but consumes more memory in generating temporary double-precision variables. Variables that are of type `byte` are not normalized, and if initial estimates are specified using the `from()` option, normalization of variables is not performed. See [Methods and formulas](#) for more information.

The following options are available with `slogit` but are not shown in the dialog box:

`collinear`, `coeflegend`; see [\[R\] Estimation options](#).

[One-dimensional model](#)

[Higher-dimension models](#)

### Introduction

Like multinomial logistic and ordered logistic models, stereotype logistic models are used with categorical dependent variables. They are often used when subjects are requested to assess or judge something. In a multinomial logistic model, the categories cannot be ranked. By contrast, in an ordered logistic model, the categories follow a natural ranking scheme and are subject to the proportional-odds assumption. Stereotype logistic regression can be viewed as a compromise between these two models and is primarily used when you are unsure of the relevance of the ordering of the outcome.

A common case is when subjects are asked to assess or judge something. For example, consider a survey in which consumers are asked to rate the quality of a product on a scale from 1 to 5, with 1 indicating poor quality and 5 indicating excellent quality. If the categories are monotonically related to one underlying latent variable, the ordered logistic model is appropriate. However, suppose that consumers weigh two or three latent factors when assessing quality. The stereotype logistic model is preferred to the ordered logistic model in this case because it allows you to specify multiple equations to capture the effects of the latent variables. Unlike multinomial logit models, the number of equations you specify could be fewer than  $m - 1$ , where  $m$  is the number of categories of the dependent variable. Stereotype logistic models are also used when categories may be indistinguishable. Suppose that a consumer must choose among A, B, C, or D. Multinomial logistic modeling assumes that the four choices are distinct in the sense that a consumer choosing one of the goods can distinguish its characteristics from the others. If goods A and B are in fact similar, consumers may be randomly picking between the two. One alternative is to combine the two categories and fit a three-category multinomial logistic model. A more flexible alternative is to use a stereotype logistic model.

In the multinomial logistic model, you estimate  $m - 1$  parameter vectors  $\tilde{\beta}_k$ ,  $k = 1, \dots, m - 1$ , where  $m$  is the number of categories of the dependent variable. The stereotype logistic model is a restriction on the multinomial model in the sense that there are  $d$  parameter vectors, where  $d$  is between one and  $\min(m - 1, p)$ , and  $p$  is the number of regressors. The relationship between the stereotype model's coefficients  $\beta_j$ ,  $j = 1, \dots, d$ , and the multinomial model's coefficients is  $\tilde{\beta}_k = -\sum_{j=1}^d \phi_{jk} \beta_j$ . The  $\phi$ s are scale parameters to be estimated along with the  $\beta_j$ s.

Given a row vector of covariates  $\mathbf{x}$ , let  $\eta_k = \theta_k - \sum_{j=1}^d \phi_{jk} \mathbf{x} \beta_j$ . The probability of observing outcome  $k$  is

$$\Pr(Y_i = k) = \begin{cases} \frac{\exp(\eta_k)}{1 + \sum_{l=1}^{m-1} \exp(\eta_l)} & k < m \\ \frac{1}{1 + \sum_{l=1}^{m-1} \exp(\eta_l)} & k = m \end{cases}$$

This model includes a set of  $\theta$  parameters so that each equation has an unrestricted constant term. If  $d = m - 1$ , the stereotype model is just a reparameterization of the multinomial logistic model. To identify the  $\phi$ s and the  $\beta$ s, you must place at least  $d^2$  restrictions on the parameters. By default, `slomit` uses the “corner constraints”  $\phi_{jj} = 1$  and  $\phi_{jk} = 0$  for  $j \neq k$ ,  $k \leq d$ , and  $j \leq d$ .

For a discussion of the stereotype logistic model, see [Lunt \(2005\)](#).

## One-dimensional model

### ▷ Example 1

We have 2 years of repair rating data on the make, price, mileage rating, and gear ratio of 104 foreign and 44 domestic automobiles (with 13 missing values on repair rating). We wish to fit a stereotype logistic model to discriminate between the levels of repair rating using mileage, price, gear ratio, and origin of the manufacturer. Here is an overview of our data:

```
. use https://www.stata-press.com/data/r19/auto2yr
(Automobile models)
. tabulate repair
```

| Repair rating | Freq. | Percent | Cum.   |
|---------------|-------|---------|--------|
| Poor          | 5     | 3.70    | 3.70   |
| Fair          | 19    | 14.07   | 17.78  |
| Average       | 57    | 42.22   | 60.00  |
| Good          | 38    | 28.15   | 88.15  |
| Excellent     | 16    | 11.85   | 100.00 |
| Total         | 135   | 100.00  |        |

The variable `repair` can take five values, 1, ..., 5, which represent the subjective rating of the car model’s repair record as *Poor*, *Fair*, *Average*, *Good*, and *Excellent*.

We wish to fit the one-dimensional stereotype logistic model

$$\eta_k = \theta_k - \phi_k (\beta_1 \text{foreign} + \beta_2 \text{mpg} + \beta_3 \text{price} + \beta_4 \text{gratio})$$

for  $k < 5$  and  $\eta_5 = 0$ . To fit this model, we type

```
. slomit repair foreign mpg price gratio
Iteration 0: Log likelihood = -237.99802 (not concave)
Iteration 1: Log likelihood = -204.98644 (not concave)
Iteration 2: Log likelihood = -169.79473 (not concave)
Iteration 3: Log likelihood = -167.53649
Iteration 4: Log likelihood = -164.63477
Iteration 5: Log likelihood = -163.20867 (not concave)
Iteration 6: Log likelihood = -160.67522
Iteration 7: Log likelihood = -159.69646
Iteration 8: Log likelihood = -159.35057
Iteration 9: Log likelihood = -159.28495
Iteration 10: Log likelihood = -159.25748
Iteration 11: Log likelihood = -159.25691
Iteration 12: Log likelihood = -159.25691

Stereotype logistic regression Number of obs = 135
 Wald chi2(4) = 9.33
Log likelihood = -159.25691 Prob > chi2 = 0.0535

(1) [phi1_1]_cons = 1
```

| repair  | Coefficient      | Std. err. | z     | P> z  | [95% conf. interval] |           |

| /theta4 | -3.85724         | 3.824132  | -1.01 | 0.313 | -11.3524             | 3.637922  |
| /theta5 | 0 (base outcome) |           |       |       |                      |           |

(repair=Excellent is the base outcome)

The coefficient associated with the first scale parameter,  $\phi_{11}$ , is 1, and its standard error and other statistics are missing. This is the corner constraint applied to the one-dimensional model; in the header, this constraint is listed as `[phi1_1]_cons = 1`. Also, the  $\phi$  and  $\theta$  parameters that are associated with the base outcome are identified. Keep in mind, though, that there are no coefficient estimates for `[phi1_5]_cons` or `[theta5]_cons` in the `ereturn` matrix `e(b)`. The Wald statistic is for a test of the joint significance of the regression coefficients on `foreign`, `mpg`, `price`, and `gratio`.

The one-dimensional stereotype model restricts the multinomial logistic regression coefficients  $\tilde{\beta}_k$ ,  $k = 1, \dots, m - 1$  to be parallel; that is,  $\tilde{\beta}_k = -\phi_k \beta$ . As Lunt (2001) discusses, in the one-dimensional stereotype model, one linear combination  $\mathbf{x}_i \beta$  best discriminates the outcomes of the dependent variable, and the scale parameters  $\phi_k$  measure the distance between the outcome levels and the linear predictor. If  $\phi_1 \geq \phi_2 \geq \dots \geq \phi_{m-1} \geq \phi_m \equiv 0$ , the model suggests that the subjective assessment of the dependent variable is indeed ordered. Here the maximum likelihood estimates of the  $\phi$ 's are not monotonic, as would be assumed in an ordered logit model.

We test that  $\phi_1 = \phi_2$  by typing

```
. test [phi1_2]_cons = [phi1_1]_cons
(1) - [phi1_1]_cons + [phi1_2]_cons = 0
 chi2(1) = 0.55
 Prob > chi2 = 0.4576
```

Because the two parameters are not statistically different, we decide to add a constraint to force  $\phi_1 = \phi_2$ :

```
. constraint define 1 [phi1_2]_cons = [phi1_1]_cons
. slogit repair foreign mpg price gratio, constraint(1) nolog
Stereotype logistic regression Number of obs = 135
 Wald chi2(4) = 21.28
 Prob > chi2 = 0.0003
Log likelihood = -159.65769
(1) [phi1_1]_cons = 1
(2) - [phi1_1]_cons + [phi1_2]_cons = 0
```

(repair=Excellent is the base outcome)

The  $\phi$  estimates are now monotonically decreasing and the standard errors of the  $\phi$ 's are small relative to the size of the estimates, so we conclude that, with the exception of outcomes *Poor* and *Fair*, the groups are distinguishable for the one-dimensional model and that the quality assessment can be ordered. ◀

## Higher-dimension models

The stereotype logistic model is not limited to ordered categorical dependent variables; you can use it on nominal data to reduce the dimension of the regressions. Recall that a multinomial model fit to a categorical dependent variable with  $m$  levels will have  $m - 1$  sets of regression coefficients. However, a model with fewer dimensions may fit the data equally well, suggesting that some of the categories are indistinguishable.

### ▶ Example 2

As discussed in [R] **mlogit**, we have data on the type of health insurance available to 616 psychologically depressed subjects in the United States (Tarlov et al. 1989; Wells et al. 1989). Patients may have either an indemnity (fee-for-service) plan or a prepaid plan, such as an HMO, or may be uninsured. Demographic variables include age, gender, race, and site.

First, we fit the saturated, two-dimensional model that is equivalent to a multinomial logistic model. We choose the base outcome to be 1 (indemnity insurance) because that is the default for mlogit.

```

| 3              | -.2078123   | .3662926  | -0.57 | 0.570 | -.9257327            | .510108   |
| _cons          | -1.286943   | .5923219  | -2.17 | 0.030 | -2.447872            | -.1260134 |

Apart from having opposite signs, the coefficients from the stereotype logistic model are identical to those from the multinomial logit model. Recall the [definition](#) of  $\eta_k$  given in the *Remarks and examples*, particularly the minus sign in front of the summation. One other difference in the output is that the constant estimates labeled `/theta` in the `slogit` output are the constants labeled `_cons` in the `mlogit` output.

Next, we examine the one-dimensional model.

```
. slogit insure age male nonwhite i.site, dim(1) base(1) nolog
Stereotype logistic regression Number of obs = 615
 Wald chi2(5) = 28.20
Log likelihood = -539.75205 Prob > chi2 = 0.0000
(1) [phi1_2]_cons = 1
```

(insure=Indemnity is the base outcome)

We have reduced a two-dimensional multinomial model to one dimension, reducing the number of estimated parameters by four and decreasing the model likelihood by  $\approx 5.4$ .

slogit does not report a model likelihood-ratio test. The test of  $d = 1$  (a one-dimensional model) versus  $d = 0$  (the null model) does not have an asymptotic  $\chi^2$  distribution because the unconstrained  $\phi$  parameters (/phi1\_3 in this example) cannot be identified if  $\beta = \mathbf{0}$ . More generally, this problem precludes testing any hierarchical model of dimension  $d$  versus  $d - 1$ . Of course, the likelihood-ratio test of a full-dimension model versus  $d = 0$  is valid because the full model is just multinomial logistic, and all the  $\phi$  parameters are fixed at 0 or 1.

## □ Technical note

The stereotype model is a special case of the reduced-rank vector generalized linear model discussed by Yee and Hastie (2003). If we define  $\eta_{ik} = \theta_k - \sum_{j=1}^d \phi_{jk} \mathbf{x}_i \beta_j$ , for  $k = 1, \dots, m-1$ , we can write the expression in matrix notation as

$$\boldsymbol{\eta}_i = \boldsymbol{\theta} + \boldsymbol{\Phi} (\mathbf{x}_i \mathbf{B})'$$

where  $\boldsymbol{\Phi}$  is a  $(m-1) \times d$  matrix containing the  $\phi_{jk}$  parameters and  $\mathbf{B}$  is a  $p \times d$  matrix with columns containing the  $\beta_j$  parameters,  $j = 1, \dots, d$ . The factorization  $\boldsymbol{\Phi} \mathbf{B}'$  is not unique because  $\boldsymbol{\Phi} \mathbf{B}' = \boldsymbol{\Phi} \mathbf{M} \mathbf{M}^{-1} \mathbf{B}'$  for any nonsingular  $d \times d$  matrix  $\mathbf{M}$ . To avoid this identifiability problem, we choose  $\mathbf{M} = \boldsymbol{\Phi}_1^{-1}$ , where

$$\boldsymbol{\Phi} = \begin{pmatrix} \boldsymbol{\Phi}_1 \\ \boldsymbol{\Phi}_2 \end{pmatrix}$$

and  $\boldsymbol{\Phi}_1$  is  $d \times d$  of rank  $d$  so that

$$\boldsymbol{\Phi} \mathbf{M} = \begin{pmatrix} \mathbf{I}_d \\ \boldsymbol{\Phi}_2 \boldsymbol{\Phi}_1^{-1} \end{pmatrix}$$

and  $\mathbf{I}_d$  is a  $d \times d$  identity matrix. Thus, the corner constraints used by `slogit` are  $\phi_{jj} \equiv 1$  and  $\phi_{jk} \equiv 0$  for  $j \neq k$  and  $k, j \leq d$ . □

## Stored results

`slogit` stores the following in `e()`:

Matrices

|                 |                                              |
|-----------------|----------------------------------------------|
| e(b)            | coefficient vector                           |
| e(outcomes)     | outcome values                               |
| e(Cns)          | constraints matrix                           |
| e(iilog)        | iteration log (up to 20 iterations)          |
| e(gradient)     | gradient vector                              |
| e(V)            | variance–covariance matrix of the estimators |
| e(V_modelbased) | model-based variance                         |

Functions

|           |                         |
|-----------|-------------------------|
| e(sample) | marks estimation sample |
|-----------|-------------------------|

In addition to the above, the following is stored in `r()`:

Matrices

|          |                                                                                                                            |
|----------|----------------------------------------------------------------------------------------------------------------------------|
| r(table) | matrix containing the coefficients with their standard errors, test statistics, <i>p</i> -values, and confidence intervals |
|----------|----------------------------------------------------------------------------------------------------------------------------|

Note that results stored in `r()` are updated when the command is replayed and will be replaced when any `r-class` command is run after the estimation command.

## Methods and formulas

`slogit` obtains the maximum likelihood estimates for the stereotype logistic model by using `ml`; see [R] `ml`. Each set of regression estimates, one set of  $\beta_j$ s for each dimension, constitutes one `ml model` equation. The  $d \times (m - 1)$   $\phi$ s and the  $(m - 1)$   $\theta$ s are `ml ancillary` parameters.

Without loss of generality, let the base outcome level be the  $m$ th level of the dependent variable. Define the row vector  $\phi_k = (\phi_{1k}, \dots, \phi_{dk})$  for  $k = 1, \dots, m - 1$ , and define the  $p \times d$  matrix  $\mathbf{B} = (\beta_1, \dots, \beta_d)$ . For observation  $i$ , the log odds of outcome level  $k$  relative to level  $m$ ,  $k = 1, \dots, m - 1$  is the index

$$\begin{aligned} \ln \left\{ \frac{\Pr(Y_i = k)}{\Pr(Y_i = m)} \right\} &= \eta_{ik} = \theta_k - \phi_k (\mathbf{x}_i \mathbf{B})' \\ &= \theta_k - \phi_k \nu_i' \end{aligned}$$

The row vector  $\nu_i$  can be interpreted as a latent variable reducing the  $p$ -dimensional vector of covariates to a more interpretable  $d < p$  dimension.

The probability of the  $i$ th observation having outcome level  $k$  is then

$$\Pr(Y_i = k) = p_{ik} = \begin{cases} \frac{e^{\eta_{ik}}}{m-1} & , \text{ if } k < m \\ 1 + \sum_{j=1}^{m-1} e^{\eta_{ij}} & \\ \frac{1}{m-1} & , \text{ if } k = m \\ 1 + \sum_{j=1}^{m-1} e^{\eta_{ij}} & \end{cases}$$

from which the log-likelihood function is computed as

$$L = \sum_{i=1}^n w_i \sum_{k=1}^m I_k(y_i) \ln(p_{ik}) \tag{1}$$

Here  $w_i$  is the weight for observation  $i$  and

$$I_k(y_i) = \begin{cases} 1 & , \text{ if observation } y_i \text{ has outcome } k \\ 0 & , \text{ otherwise} \end{cases}$$

Numeric variables are normalized for numerical stability during optimization where a new double-precision variable  $\tilde{x}_j$  is created from variable  $x_j$ ,  $j = 1, \dots, p$ , such that  $\tilde{x}_j = (x_j - \bar{x}_j)/s_j$ . This feature is turned off if you specify `nonnormalize`, or if you use the `from()` option for initial estimates. Normalization is not performed on byte variables, including the indicator variables generated by `[R] xi`. The linear equality constraints for regression parameters, if specified, must be scaled also. Assume that a constraint is applied to the regression parameter associated with variable  $j$  and dimension  $i$ ,  $\beta_{ji}$ , and the corresponding element of the constraint matrix (see `[P] makecons`) is divided by  $s_j$ .

After convergence, the parameter estimates for variable  $j$  and dimension  $i$ — $\tilde{\beta}_{ji}$ , say—are transformed back to their original scale,  $\beta_{ji} = \tilde{\beta}_{ji}/s_j$ . For the intercepts, you compute

$$\theta_k = \tilde{\theta}_k + \sum_{i=1}^d \phi_{ik} \sum_{j=1}^p \frac{\tilde{\beta}_{ji} \bar{x}_j}{s_j}$$

Initial values are computed using estimates obtained using `mlogit` to fit a multinomial logistic model. Let the  $p \times (m - 1)$  matrix  $\tilde{\mathbf{B}}$  contain the multinomial logistic regression parameters less the  $m - 1$  intercepts. Each  $\phi$  is initialized with constant values  $\min(1/2, 1/d)$ , the `initialize(constant)` option (the default), or, with uniform random numbers, the `initialize(random)` option. Constraints are then applied to the starting values so that the structure of the  $(m - 1) \times d$  matrix  $\Phi$  is

$$\Phi = \begin{pmatrix} \phi_1 \\ \phi_2 \\ \vdots \\ \phi_{m-1} \end{pmatrix} = \begin{pmatrix} \mathbf{I}_d \\ \tilde{\Phi} \end{pmatrix}$$

where  $\mathbf{I}_d$  is a  $d \times d$  identity matrix. Assume that only the corner constraints are used, but any constraints you place on the scale parameters are also applied to the initial scale estimates, so the structure of  $\Phi$  will change accordingly. The  $\phi$  parameters are invariant to the scale of the covariates, so initial estimates in  $[0, 1]$  are reasonable. The constraints guarantee that the rank of  $\Phi$  is at least  $d$ , so the initial estimates for the stereotype regression parameters are obtained from  $\mathbf{B} = \tilde{\mathbf{B}}\Phi(\Phi'\Phi)^{-1}$ .

One other approach for initial estimates is provided: `initialize(svd)`. It starts with the `mlogit` estimates and computes  $\tilde{\mathbf{B}}' = \mathbf{U}\mathbf{D}\mathbf{V}'$ , where  $\mathbf{U}_{m-1 \times p}$  and  $\mathbf{V}_{p \times p}$  are orthonormal matrices and  $\mathbf{D}_{p \times p}$  is a diagonal matrix containing the singular values of  $\tilde{\mathbf{B}}$ . The estimates for  $\Phi$  and  $\mathbf{B}$  are the first  $d$  columns of  $\mathbf{U}$  and  $\mathbf{V}\mathbf{D}$ , respectively (Yee and Hastie 2003).

The score for regression coefficients is

$$\mathbf{u}_i(\beta_j) = \frac{\partial L_{ik}}{\partial \beta_j} = \mathbf{x}_i \left( \sum_{l=1}^{m-1} \phi_{jl} p_{il} - \phi_{jk} \right)$$

the score for the scale parameters is

$$u_i(\phi_{jl}) = \frac{\partial L_{ik}}{\partial \phi_{jl}} = \begin{cases} \mathbf{x}_i \beta_j (p_{ik} - 1), & \text{if } l = k \\ \mathbf{x}_i \beta_j p_{il}, & \text{if } l \neq k \end{cases}$$

for  $l = 1, \dots, m - 1$ ; and the score for the intercepts is

$$u_i(\theta_l) = \frac{\partial L_{ik}}{\partial \theta_l} = \begin{cases} 1 - p_{ik}, & \text{if } l = k \\ -p_{il}, & \text{if } l \neq k \end{cases}$$

This command supports the Huber/White/sandwich estimator of the variance and its clustered version using `vce(robust)` and `vce(cluster clustvar)`, respectively. See [P] [\\_robust](#), particularly *Maximum likelihood estimators* and *Methods and formulas*.

`slomit` also supports estimation with survey data. For details on VCEs with survey data, see [SVY] [Variance estimation](#).

## Postestimation commands

The following postestimation commands are available after `slogit`:

| Command                      | Description                                                                                                                             |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <code>contrast</code>        | contrasts and ANOVA-style joint tests of parameters                                                                                     |
| <code>estat ic</code>        | Akaike's, consistent Akaike's, corrected Akaike's, and Schwarz's Bayesian information criteria (AIC, CAIC, AICc, and BIC, respectively) |
| <code>estat summarize</code> | summary statistics for the estimation sample                                                                                            |
| <code>estat vce</code>       | variance–covariance matrix of the estimators (VCE)                                                                                      |
| <code>estat (svy)</code>     | postestimation statistics for survey data                                                                                               |
| <code>estimates</code>       | cataloging estimation results                                                                                                           |
| <code>etable</code>          | table of estimation results                                                                                                             |
| * <code>hausman</code>       | Hausman's specification test                                                                                                            |
| <code>lincom</code>          | point estimates, standard errors, testing, and inference for linear combinations of parameters                                          |
| * <code>lrtest</code>        | likelihood-ratio test                                                                                                                   |
| <code>margins</code>         | marginal means, predictive margins, marginal effects, and average marginal effects                                                      |
| <code>marginsplot</code>     | graph the results from margins (profile plots, interaction plots, etc.)                                                                 |
| <code>nlcom</code>           | point estimates, standard errors, testing, and inference for nonlinear combinations of parameters                                       |
| <code>predict</code>         | probabilities, linear predictions and their SEs, etc.                                                                                   |
| <code>predictnl</code>       | point estimates, standard errors, testing, and inference for generalized predictions                                                    |
| <code>pwcompare</code>       | pairwise comparisons of parameters                                                                                                      |
| <code>suest</code>           | seemingly unrelated estimation                                                                                                          |
| <code>test</code>            | Wald tests of simple and composite linear hypotheses                                                                                    |
| <code>testnl</code>          | Wald tests of nonlinear hypotheses                                                                                                      |

\*`hausman` and `lrtest` are not appropriate with `svy` estimation results.

# predict

## Description for predict

`predict` creates a new variable containing predictions such as probabilities, indexes for the  $k$ th outcome, and standard errors.

## Menu for predict

Statistics > Postestimation

## Syntax for predict

```
predict [type] { stub* | newvar | newvarlist } [if] [in] [, statistic outcome(outcome)]
```

```
predict [type] stub* [if] [in], scores
```

| <i>statistic</i> | Description |
|------------------|-------------|
|------------------|-------------|

Main

|                   |                                                                           |
|-------------------|---------------------------------------------------------------------------|
| <code>pr</code>   | probability of one of or all the dependent variable outcomes; the default |
| <code>xb</code>   | index for the $k$ th outcome                                              |
| <code>stdp</code> | standard error of the index for the $k$ th outcome                        |

You specify one or  $k$  new variables with `pr`, where  $k$  is the number of outcomes. If you specify one new variable and you do not specify `outcome()`, then `outcome(#1)` is assumed.

You specify one new variable with `xb` and `stdp`. If you do not specify `outcome()`, then `outcome(#1)` is assumed.

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

## Options for predict

Main

`pr`, the default, computes the predicted probabilities for all outcomes or for a specific outcome. To compute probabilities for all outcomes, you specify  $k$  new variables, where  $k$  is the number of categories of the dependent variable. Alternatively, you can specify `stub*`; in which case, `pr` will store predicted probabilities in variables `stub1`, `stub2`, ..., `stubk`. To compute the probability for a specific outcome, you specify one new variable and, optionally, the outcome value in option `outcome()`; if you omit `outcome()`, the first outcome value, `outcome(#1)`, is assumed.

Say that you fit a model by typing `estimation_cmd y x1 x2`, and `y` takes on four values. Then, you could type `predict p1 p2 p3 p4` to obtain all four predicted probabilities; alternatively, you could type `predict p*` to generate the four predicted probabilities. To compute specific probabilities one at a time, you can type `predict p1, outcome(#1)` (or simply `predict p1`), `predict p2, outcome(#2)`, and so on. See option `outcome()` for other ways to refer to outcome values.

`xb` calculates the index,  $\theta_k - \sum_{j=1}^d \phi_{jk} \mathbf{x}_i \beta_j$ , for outcome level  $k \neq e(i\_base)$  and dimension  $d = e(k\_dim)$ . It returns a vector of zeros if  $k = e(i\_base)$ . A synonym for `xb` is `index`. If `outcome()` is not specified, `outcome(#1)` is assumed.

`stdp` calculates the standard error of the index. A synonym for `stdp` is `seindex`. If `outcome()` is not specified, `outcome(#1)` is assumed.

`outcome(outcome)` specifies for which outcome the predicted probabilities are to be calculated. `outcome()` should contain either one value of the dependent variable or one of #1, #2, ..., with #1 meaning the first category of the dependent variable, #2 meaning the second category, etc. `outcome()` is not allowed with `scores`.

`scores` calculates the equation-level score variables. For models with  $d$  dimensions and  $m$  levels,  $d + (d + 1)(m - 1)$  new variables are created. Assume  $j = 1, \dots, d$  and  $k = 1, \dots, m$  in the following.

The first  $d$  new variables will contain  $\partial \ln L / \partial (\mathbf{x} \boldsymbol{\beta}_j)$ .

The next  $d(m - 1)$  new variables will contain  $\partial \ln L / \partial \phi_{jk}$ .

The last  $m - 1$  new variables will contain  $\partial \ln L / \partial \theta_k$ .

## margins

### Description for margins

`margins` estimates margins of response for probabilities and indexes for the  $k$ th outcome.

### Menu for margins

Statistics > Postestimation

### Syntax for margins

```
margins [marginlist] [, options]
```

```
margins [marginlist] , predict(statistic ...) [predict(statistic ...) ...] [options]
```

| <i>statistic</i> | Description                                                  |
|------------------|--------------------------------------------------------------|
| default          | probabilities for each outcome                               |
| pr               | probability of one of or all the dependent variable outcomes |
| xb               | index for the $k$ th outcome                                 |
| stdp             | not allowed with <code>margins</code>                        |

`pr` and `xb` default to the first outcome.

Statistics not allowed with `margins` are functions of stochastic quantities other than `e(b)`.

For the full syntax, see [\[R\] margins](#).

## Remarks and examples

Once you have fit a stereotype logistic model, you can obtain the predicted probabilities by using the `predict` command for both the estimation sample and other samples; see [U] 20 Estimation and postestimation commands and [R] `predict`.

`predict` without arguments (or with the `pr` option) calculates the predicted probability of each outcome of the dependent variable. You must therefore give a new variable name for each of the outcomes. To compute the estimated probability of one outcome, you use the `outcome(outcome)` option where `outcome` is the level encoding the outcome. If the dependent variable's levels are labeled, the outcomes can also be identified by the label values (see [D] `label`).

The `xb` option in conjunction with `outcome(outcome)` specifies that the index be computed for the outcome encoded by level `outcome`. Its approximate standard error is computed if the `stdp` option is specified. Only one of the `pr`, `xb`, or `stdp` options can be specified with a call to `predict`.

### ▷ Example 1

In example 2 of [R] `slogit`, we fit the one-dimensional stereotype model, where the `depvar` is `insure` with levels  $k = 1$  for outcome *Indemnity*,  $k = 2$  for *Prepaid*, and  $k = 3$  for *Uninsure*. The base outcome for the model is *Indemnity*, so for  $k \neq 1$  the vector of indices for the  $k$ th level is

$$\eta_k = \theta_k - \phi_k (\beta_1 \text{age} + \beta_2 \text{male} + \beta_3 \text{nonwhite} + \beta_4 2.\text{site} + \beta_5 3.\text{site})$$

We estimate the group probabilities by calling `predict` after `slogit`.

```
. use https://www.stata-press.com/data/r19/sysdsn1
(Health insurance data)
. slogit insure age male nonwhite i.site, dim(1) base(1) nolog
(output omitted)
. predict pIndemnity pPrepaid pUninsure, p
. list pIndemnity pPrepaid pUninsure insure in 1/10
```

|     | pIndem-y | pPrepaid | pUnins-e | insure    |
|-----|----------|----------|----------|-----------|
| 1.  | .5419344 | .3754875 | .0825782 | Indemnity |
| 2.  | .4359638 | .496328  | .0677081 | Prepaid   |
| 3.  | .5111583 | .4105107 | .0783309 | Indemnity |
| 4.  | .3941132 | .5442234 | .0616633 | Prepaid   |
| 5.  | .4655651 | .4625064 | .0719285 | .         |
| 6.  | .4401779 | .4915102 | .0683118 | Prepaid   |
| 7.  | .4632122 | .4651931 | .0715948 | Prepaid   |
| 8.  | .3772302 | .5635696 | .0592002 | .         |
| 9.  | .4867758 | .4383018 | .0749225 | Uninsure  |
| 10. | .5823668 | .3295802 | .0880531 | Prepaid   |

Observations 5 and 8 are not used to fit the model because `insure` is missing at these points, but `predict` estimates the probabilities for these observations because none of the independent variables is missing. You can use `if e(sample)` in the call to `predict` to use only those observations that are used to fit the model.

## Methods and formulas

### predict

Let level  $b$  be the base outcome that is used to fit the stereotype logistic regression model of dimension  $d$ . The index for observation  $i$  and level  $k \neq b$  is  $\eta_{ik} = \theta_k - \sum_{j=1}^d \phi_{jk} \mathbf{x}_i \boldsymbol{\beta}_j$ . This is the log odds of outcome encoded as level  $k$  relative to that of  $b$  so that we define  $\eta_{ib} \equiv 0$ . The outcome probabilities for this model are defined as  $\Pr(Y_i = k) = e^{\eta_{ik}} / \sum_{j=1}^m e^{\eta_{ij}}$ . Unlike in `mlogit`, `ologit`, and `oprobit`, the index is no longer a linear function of the parameters. The standard error of index  $\eta_{ik}$  is thus computed using the delta method (see also [\[R\] predictnl](#)).

The equation-level score for regression coefficients is

$$\frac{\partial \ln L_{ik}}{\partial \mathbf{x}_i \boldsymbol{\beta}_j} = \left( \sum_{l=1}^{m-1} \phi_{jl} p_{il} - \phi_{jk} \right)$$

the equation-level score for the scale parameters is

$$\frac{\partial \ln L_{ik}}{\partial \phi_{jl}} = \begin{cases} \mathbf{x}_i \boldsymbol{\beta}_j (p_{ik} - 1), & \text{if } l = k \\ \mathbf{x}_i \boldsymbol{\beta}_j p_{il}, & \text{if } l \neq k \end{cases}$$

for  $l = 1, \dots, m - 1$ ; and the equation-level score for the intercepts is

$$\frac{\partial \ln L_{ik}}{\partial \theta_l} = \begin{cases} 1 - p_{ik}, & \text{if } l = k \\ -p_{il}, & \text{if } l \neq k \end{cases}$$

## Description

`smooth` applies the specified resistant, nonlinear smoother to *varname* and stores the smoothed series in *newvar*.

## Quick start

Running median smoother of span 3 for *v*, placing smoothed values in the new variable *newv*  
`smooth 3 v, generate(newv)`

Same as above, but with a compound smoother of running medians, first of span 3, then span 5  
`smooth 35 v, generate(newv)`

Same as above, but repeating the span-5 running median until convergence  
`smooth 35R v, generate(newv)`

Same as above, splitting any repeated values after the span-3 running median  
`smooth 3S5R v, generate(newv)`

Same as above, but apply the compound smoother to the resulting rough  
`smooth 3S5R, twice v, generate(newv)`

## Menu

Statistics > Nonparametric analysis > Robust nonlinear smoother

## Syntax

```
smooth smoother[, twice] varname [if] [in], generate(newvar)
```

where *smoother* is specified as  $Sm[Sm[\dots]]$  and *Sm* is one of

```
{ 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 } [R]
3[R]S[S|R][S|R]...
E
H
```

Letters may be specified in lowercase if preferred. Examples of *smoother*[, twice] include

```
3RSSH 3RSSH,twice 4253H 4253H,twice 43RSR2H,twice
3rssh 3rssh,twice 4253h 4253h,twice 43rsr2h,twice
```

## Option

`generate(newvar)` is required; it specifies the name of the new variable that will contain the smoothed values.

## Remarks and examples

Smoothing is an exploratory data-analysis technique for making the general shape of a series apparent. In this approach (Tukey 1977), the observed data series is assumed to be the sum of an underlying process that evolves smoothly (the smooth) and of an unsystematic noise component (the rough); that is,

$$\text{data} = \text{smooth} + \text{rough}$$

Smoothed values  $z_t$  are obtained by taking medians (or some other location estimate) of each point in the original data  $y_t$  and a few of the points around it. The number of points used is called the span of the smoother. Thus, a span-3 smoother produces  $z_t$  by taking the median of  $y_{t-1}$ ,  $y_t$ , and  $y_{t+1}$ . `smooth` provides running median smoothers of spans 1 to 9—indicated by the digit that specifies their span. Median smoothers are resistant to isolated outliers, so they provide robustness to spikes in the data. Because the median is also a nonlinear operator, such smoothers are known as robust (or resistant) nonlinear smoothers.

`smooth` also provides the Hanning linear, nonrobust smoother, indicated by the letter H. Hanning is a span-3 smoother with binomial weights. Repeated applications of H—HH, HHH, etc.—provide binomial smoothers of span 5, 7, etc. See Cox (1997, 2004) for a graphical application of this fact.

Because one smoother usually cannot adequately separate the smooth from the rough, compound smoothers—multiple smoothers applied in sequence—are used. The smoother 35H, for instance, then smooths the data with a span-3 median smoother, smooths the result with a span-5 median smoother, and finally smooths that result with the Hanning smoother. `smooth` allows you to specify any number of smoothers in any sequence.

Three refinements can be combined with the running median and Hanning smoothers. First, the endpoints of a smooth can be given special treatment. This is specified by the E operator. Second, smoothing by 3, the span-3 running median, tends to produce flat-topped hills and valleys. The splitting operator, S, “splits” these repeated values, applies the endpoint operator to them, and then “rejoins” the series. Finally, it is sometimes useful to repeat an odd-span median smoother or the splitting operator until the smooth no longer changes. Following a digit or an S with an R specifies this type of repetition.

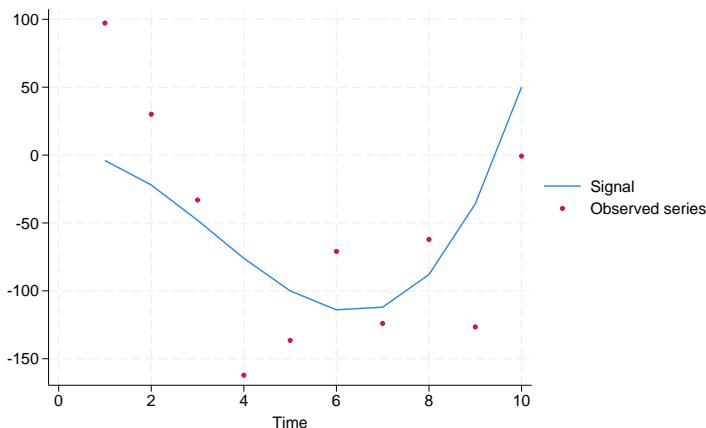

Even the best smoother may fail to separate the smooth from the rough adequately. To guard against losing any systematic components of the data series, after smoothing, the smoother can be reapplied to the resulting rough, and any recovered signal can be added back to the original smooth. The twice operator specifies this procedure. More generally, an arbitrary smoother can be applied to the rough (using a second `smooth` command), and the recovered signal can be added back to the smooth. This more general procedure is called reroughing (Tukey 1977).

The details of each of the smoothers and operators are explained in *Methods and formulas* below.

### ▷ Example 1

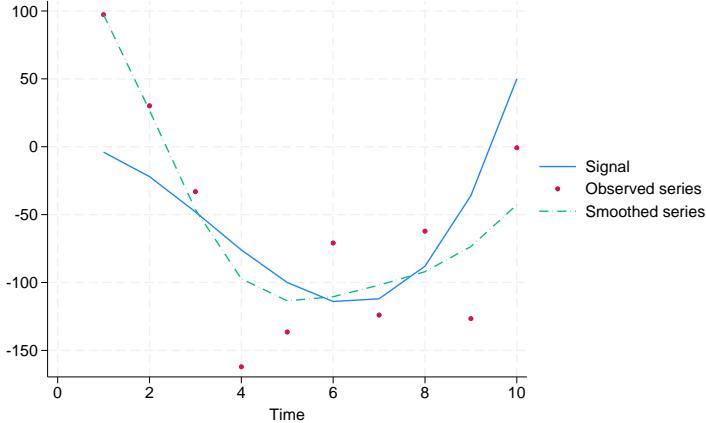

`smooth` is designed to recover the general features of a series that has been contaminated with noise. To demonstrate this, we construct a series, add noise to it, and then `smooth` the noisy version to recover an estimate of the original data. First, we construct and display the data:

```
. drop _all
. set obs 10
. set seed 123456789
. generate time = _n
. label variable time "Time"
. generate x = _n^3 - 10*_n^2 + 5*_n
. label variable x "Signal"
. generate z = x + 50*rnormal()
. label variable z "Observed series"
. scatter x z time, c(l .) m(i o) ytitle("")
```

Now we smooth the noisy series,  $z$ , assumed to be the only data we would observe:

```
. smooth 4253eh,twice z, gen(sz)
. label variable sz "Smoothed series"
. scatter x z time, c(1 . 1) m(i o i) ytitle("") || scatter sz time,
> c(1 . 1) m(i o i) ytitle("") clpattern(dash_dot)
```

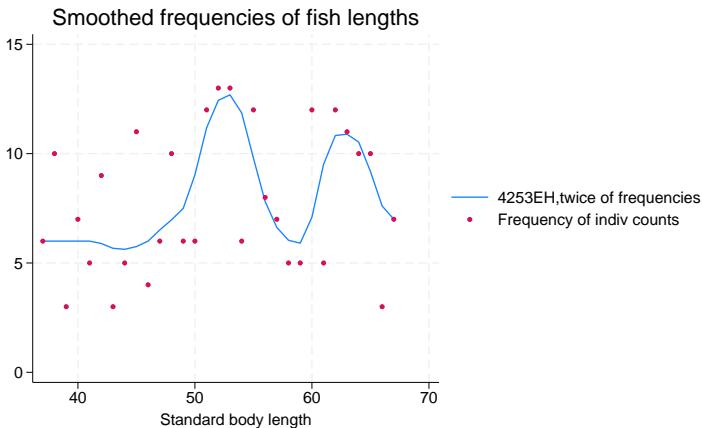

◀

## ► Example 2

Salgado-Ugarte and Curts-García (1993) provide data on the frequencies of observed fish lengths. In this example, the series to be smoothed—the frequencies—is ordered by fish length rather than by time.

```
. use https://www.stata-press.com/data/r19/fishdata, clear
. smooth 4253eh,twice freq, gen(sfreq)
. scatter sfreq freq length, c(1 .) m(i o)
> title("Smoothed frequencies of fish lengths") ytitle("") xlabel(#4)
```

◀

## □ Technical note

`smooth` allows missing values at the beginning and end of the series, but missing values in the middle are not allowed. Leading and trailing missing values are ignored. If you wish to ignore missing values in the middle of the series, you must drop the missing observations before using `smooth`. Doing so, of course, would violate `smooth`'s assumption that observations are equally spaced—each observation represents a year, a quarter, or a month (or a 1-year birth-rate category). In practice, `smooth` produces good results as long as the spaces between adjacent observations do not vary too much.

Smoothing is usually applied to time series, but any variable with a natural order can be smoothed. For example, a smoother might be applied to the birth rate recorded by the age of the mothers (birthrate for 17-year-olds, birthrate for 18-year-olds, and so on).

□

## Methods and formulas

Methods and formulas are presented under the following headings:

*Running median smoothers of odd span*  
*Running median smoothers of even span*  
*Repeat operator*  
*Endpoint rule*  
*Splitting operator*  
*Hanning smoother*  
*Twicing*

## Running median smoothers of odd span

The smoother 3 defines

$$z_t = \text{median}(y_{t-1}, y_t, y_{t+1})$$

The smoother 5 defines

$$z_t = \text{median}(y_{t-2}, y_{t-1}, y_t, y_{t+1}, y_{t+2})$$

and so on. The smoother 1 defines  $z_t = \text{median}(y_t)$ , so it does nothing.

Endpoints are handled by using smoothers of shorter, odd span. Thus, for 3,

$$\begin{aligned} z_1 &= y_1 \\ z_2 &= \text{median}(y_1, y_2, y_3) \\ &\vdots \\ z_{N-1} &= \text{median}(y_{N-2}, y_{N-1}, y_N) \\ Z_N &= y_N \end{aligned}$$

For 5,

$$\begin{aligned}
 z_1 &= y_1 \\
 z_2 &= \text{median}(y_1, y_2, y_3) \\
 z_3 &= \text{median}(y_1, y_2, y_3, y_4, y_5) \\
 z_4 &= \text{median}(y_2, y_3, y_4, y_5, y_6) \\
 &\vdots \\
 z_{N-2} &= \text{median}(y_{N-4}, y_{N-3}, y_{N-2}, y_{N-1}, y_N) \\
 z_{N-1} &= \text{median}(y_{N-2}, y_{N-1}, y_N) \\
 Z_N &= y_N
 \end{aligned}$$

and so on.

### Running median smoothers of even span

Define the  $\text{median}()$  function as returning the linearly interpolated value when given an even number of arguments. Thus, the smoother 2 defines

$$z_{t+0.5} = (y_t + y_{t+1})/2$$

The smoother 4 defines  $z_{t+0.5}$  as the linearly interpolated median of  $(y_{t-1}, y_t, y_{t+1}, y_{t+2})$ , and so on. Endpoints are always handled using smoothers of shorter, even span. Thus, for 4,

$$\begin{aligned}
 z_{0.5} &= y_1 \\
 z_{1.5} &= \text{median}(y_1, y_2) = (y_1 + y_2)/2 \\
 z_{2.5} &= \text{median}(y_1, y_2, y_3, y_4) \\
 &\vdots \\
 z_{N-2.5} &= \text{median}(y_{N-4}, y_{N-3}, y_{N-2}, y_N) \\
 z_{N-1.5} &= \text{median}(y_{N-2}, y_{N-1}) \\
 z_{N-0.5} &= \text{median}(y_{N-1}, y_N) \\
 z_{N+0.5} &= y_N
 \end{aligned}$$

As defined above, an even-span smoother increases the length of the series by 1 observation. However, the series can be recentered on the original observation numbers, and the “extra” observation can be eliminated by smoothing the series again with another even-span smoother. For instance, the smooth of 4 illustrated above could be followed by a smooth of 2 to obtain

$$\begin{aligned} z_1^* &= (z_{0.5} + z_{1.5})/2 \\ z_2^* &= (z_{1.5} + z_{2.5})/2 \\ z_3^* &= (z_{2.5} + z_{3.5})/2 \\ &\vdots \\ z_{N-2}^* &= (z_{N-2.5} + z_{N-1.5})/2 \\ z_{N-1}^* &= (z_{N-1.5} + z_{N-0.5})/2 \\ z_N^* &= (z_{N-0.5} + z_{N+0.5})/2 \end{aligned}$$

smooth keeps track of the number of even smoothers applied to the data and expands and shrinks the length of the series accordingly. To ensure that the final smooth has the same number of observations as *varname*, smooth requires you to specify an even number of even-span smoothers. However, the pairs of even-span smoothers need not be contiguous; for instance, 4253 and 4523 are both allowed.

## Repeat operator

R indicates that a smoother is to be repeated until convergence, that is, until repeated applications of the smoother produce the same series. Thus, 3 applies the smoother of running medians of span 3. 33 applies the smoother twice. 3R produces the result of repeating 3 an infinite number of times. R should be used only with odd-span smoothers because even-span smoothers are not guaranteed to converge.

The smoother 453R2 applies a span-4 smoother, followed by a span-5 smoother, followed by repeated applications of a span-3 smoother, followed by a span-2 smoother.

## Endpoint rule

The endpoint rule E modifies the values  $z_1$  and  $z_N$  according to the following formulas:

$$\begin{aligned} z_1 &= \text{median}(3z_2 - 2z_3, z_1, z_2) \\ z_N &= \text{median}(3z_{N-2} - 2z_{N-1}, z_N, z_{N-1}) \end{aligned}$$

When the endpoint rule is not applied, endpoints are typically “copied in”; that is,  $z_1 = y_1$  and  $z_N = y_N$ .

## Splitting operator

The smoothers `3` and `3R` can produce flat-topped hills and valleys. The split operator attempts to eliminate such hills and valleys by splitting the sequence, applying the endpoint rule `E`, rejoining the series, and then resmoothing by `3R`.

The `S` operator may be applied only after `3`, `3R`, or `S`.

We recommend that the `S` operator be repeated once (`SS`) or until no further changes take place (`SR`).

## Hanning smoother

`H` is the Hanning linear smoother:

$$z_t = (y_{t-1} + 2y_t + y_{t+1})/4$$

Endpoints are copied in:  $z_1 = y_1$  and  $z_N = y_N$ . `H` should be applied only after all nonlinear smoothers.

## Twicing

A smoother divides the data into a smooth and a rough:

$$\text{data} = \text{smooth} + \text{rough}$$

If the smoothing is successful, the rough should exhibit no pattern. Twicing refers to applying the smoother to the observed, calculating the rough, and then applying the smoother to the rough. The resulting “smoothed rough” is then added back to the smooth from the first step.

## Acknowledgments

`smooth` was originally written by William Gould (1992)—at which time it was named `nlsm`—and was inspired by Salgado-Ugarte and Curts-García (1992). Salgado-Ugarte and Curts-García (1993) subsequently reported anomalies in `nlsm`’s treatment of even-span median smoothers. `smooth` corrects these problems and incorporates other improvements but otherwise is essentially the same as originally published.

## Description

`spearman` displays Spearman's rank correlation coefficients for all pairs of variables in *varlist* or, if *varlist* is not specified, for all the variables in the dataset. When there are two variables, an exact *p*-value can be calculated optionally using permutations.

`ktau` displays Kendall's rank correlation coefficients between the variables in *varlist* or, if *varlist* is not specified, for all the variables in the dataset. `ktau` is intended for use on small- and moderate-sized datasets; it requires considerable computation time for larger datasets.

## Quick start

Spearman's rank correlation coefficient with approximate *p*-value for *v1* and *v2*

```
spearman v1 v2
```

Same as above, but report an exact *p*-value calculated using Monte Carlo permutations

```
spearman v1 v2, exact
```

Same as above, but perform 100,000 Monte Carlo permutations rather than the default of 10,000, and set the random-number seed for reproducibility

```
spearman v1 v2, exact(montecarlo, reps(100000) rseed(1234))
```

Display Spearman's rank correlation coefficients in a matrix for all pairs of *v1*, *v2*, and *v3*

```
spearman v1 v2 v3
```

Display *p*-values as well as correlation coefficients

```
spearman v1 v2 v3, stats(rho p)
```

Same as above, but perform Bonferroni's adjustment to *p*-values

```
spearman v1 v2 v3, stats(rho p) bonferroni
```

Kendall's rank correlation coefficients, scores, and standard errors of the scores for pairs of *v1*, *v2*, and *v3*

```
ktau v1 v2 v3, stats(taua taub score se)
```

Same as above, but use pairwise instead of casewise deletion

```
ktau v1 v2 v3, stats(taua taub score se) pw
```

| p     | <i>p</i> -value                  |

## Options for spearman

Main

`stats(spearman_list)` specifies the statistics to be displayed in the matrix of output. `stats(rho)` is the default. Up to three statistics may be specified; `stats(rho obs p)` would display the correlation coefficient, number of observations, and  $p$ -value. If *varlist* contains only two variables, all statistics are shown in tabular form, and `stats()`, `print()`, and `star()` have no effect unless the `matrix` option is specified.

`print(#)` specifies the  $p$ -value cutoff for correlation coefficients to be printed. Correlation coefficients with larger  $p$ -values are left blank in the matrix. Typing `spearman, print(.10)` would display only those correlation coefficients that have  $p$ -values less than or equal to 0.10.

`star(#)` specifies the  $p$ -value cutoff for correlation coefficients to be marked with a star. Typing `spearman, star(.05)` would star all correlation coefficients that have  $p$ -values less than or equal to 0.05.

`bonferroni` makes the Bonferroni adjustment to  $p$ -values. This adjustment affects displayed  $p$ -values and the `print()` and `star()` options. Thus, `spearman, print(.05) bonferroni` prints coefficients with Bonferroni-adjusted  $p$ -values of 0.05 or less.

`sidak` makes the Šidák adjustment to  $p$ -values. This adjustment affects displayed  $p$ -values and the `print()` and `star()` options. Thus, `spearman, print(.05) sidak` prints coefficients with Šidák-adjusted  $p$ -values of 0.05 or less.

`pw` specifies that correlations be calculated using pairwise deletion of observations with missing values. By default, `spearman` uses casewise deletion, where observations are ignored if any of the variables in *varlist* are missing.

`matrix` forces `spearman` to display the statistics as a matrix, even if *varlist* contains only two variables. `matrix` is implied if more than two variables are specified.

`exact` and `exact(exact_specs)` specify that an exact  $p$ -value be reported. This option is available only when *varlist* contains only two variables.

`exact` specifies that an exact  $p$ -value from a Monte Carlo permutation test be reported. `exact` is a synonym for `exact(montecarlo)`.

`exact(montecarlo[ , options] | enumerate[ , options])` specifies that an exact  $p$ -value be reported in addition to the approximate  $p$ -value. Specifying `exact(montecarlo)` does a Monte Carlo permutation test. Specifying `exact(enumerate)` does an enumeration of all possible permutations. Because the number of all possible permutations is typically extremely large, enumeration is feasible only for very small datasets. The number of permutations will be displayed, and you can click on *Break* to stop the computation. The exact  $p$ -value is computed by `permute`.

`exact(montecarlo[ , options])` allows *options* `show`, `reps(#)`, `rseed(#)`, `saving(filename[ , sav_options])`, `level(#)`, `dots(#)`, `nodots`, and `eps(#)`. The `show` option specifies that the table produced by `permute` also be displayed. By default, 10,000 Monte Carlo permutations are done. That is, the default is the same as specifying `exact(montecarlo, reps(10000))`. The default for `dots()` is `dots(100)` when `reps()` is  $\geq 10,000$ ; otherwise, it is `dots(1)`. See *Options* in [R] `permute`.

`exact(enumerate[ , options])` allows *options* `show`, `saving(filename[ , sav_options])`, `dots(#)`, `nodots`, and `eps(#)`. The `show` option specifies that the table produced by `permute` also be displayed. The default for `dots()` is `dots(100)`. See *Options* in [R] `permute`.

## Options for ktau

Main

`stats(ktau_list)` specifies the statistics to be displayed in the matrix of output. `stats(taua)` is the default. Up to six statistics may be specified; `stats(taua taub score se obs p)` would display the correlation coefficients  $\tau_a$  and  $\tau_b$ , score, standard error of score, number of observations, and  $p$ -value. If *varlist* contains only two variables, all statistics are shown in tabular form and `stats()`, `print()`, and `star()` have no effect unless the `matrix` option is specified.

`print(#)` specifies the  $p$ -value cutoff for correlation coefficients to be printed. Correlation coefficients with larger  $p$ -values are left blank in the matrix. Typing `ktau, print(.10)` would display only those correlation coefficients that have  $p$ -values less than or equal to 0.10.

`star(#)` specifies the  $p$ -value cutoff for correlation coefficients to be marked with a star. Typing `ktau, star(.05)` would star all correlation coefficients that have  $p$ -values less than or equal to 0.05.

`bonferroni` makes the Bonferroni adjustment to  $p$ -values. This adjustment affects displayed  $p$ -values and the `print()` and `star()` options. Thus, `ktau, print(.05) bonferroni` prints coefficients with Bonferroni-adjusted  $p$ -values of 0.05 or less.

`sidak` makes the Šidák adjustment to  $p$ -values. This adjustment affects displayed  $p$ -values and the `print()` and `star()` options. Thus, `ktau, print(.05) sidak` prints coefficients with Šidák-adjusted  $p$ -values of 0.05 or less.

`pw` specifies that correlations be calculated using pairwise deletion of observations with missing values. By default, `ktau` uses casewise deletion, where observations are ignored if any of the variables in *varlist* are missing.

`matrix` forces `ktau` to display the statistics as a matrix, even if *varlist* contains only two variables. `matrix` is implied if more than two variables are specified.

## Remarks and examples

### ▷ Example 1

We wish to calculate the correlation coefficients among marriage rate (`mrgrate`), divorce rate (`divorce_rate`), and median age (`medage`) in state data. We can calculate the standard Pearson correlation coefficients and  $p$ -values by typing

```
. use https://www.stata-press.com/data/r19/states2
(State data)
```

```
. pwcorr mrgrate divorce_rate medage, sig
```

|              | mrgrate          | divorc-e          | medage |
|--------------|------------------|-------------------|--------|
| mrgrate      | 1.0000           |                   |        |
| divorce_rate | 0.7895<br>0.0000 | 1.0000            |        |
| medage       | 0.0011<br>0.9941 | -0.1526<br>0.2900 | 1.0000 |

We can calculate Spearman's rank correlation coefficients by typing

```
. spearman mrgrate divorce_rate medage, stats(rho p)
```

```
Number of observations = 50
```

| Key            |
|----------------|
| <i>rho</i>     |
| <i>p-value</i> |

|              | mrgrate           | divorc-e          | medage |
|--------------|-------------------|-------------------|--------|
| mrgrate      | 1.0000            | .                 | .      |
| divorce_rate | 0.6933<br>0.0000  | 1.0000            | .      |
| medage       | -0.4869<br>0.0004 | -0.2455<br>0.0857 | 1.0000 |

The large difference in the results is caused by one observation. Nevada's marriage rate is almost 10 times higher than the state with the next-highest marriage rate. An important feature of the Spearman rank correlation is its reduced sensitivity to extreme values compared with the Pearson correlation.

We can calculate Kendall's rank correlations by typing

```
. ktau mrgrate divorce_rate medage, stats(taua taub p)
Number of observations = 50
```

| Key     |
|---------|
| tau_a   |
| tau_b   |
| p-value |

|              | mrgrate                      | divorc-e                     | medage                |
|--------------|------------------------------|------------------------------|-----------------------|
| mrgrate      | 0.9829<br>1.0000<br>.        |                              |                       |
| divorce_rate | 0.5110<br>0.5206<br>0.0000   | 0.9804<br>1.0000<br>.        |                       |
| medage       | -0.3486<br>-0.3544<br>0.0004 | -0.1698<br>-0.1728<br>0.0828 | 0.9845<br>1.0000<br>. |

There are tied values for variables `mrgrate`, `divorce_rate`, and `medage`, so average ranks are used for the tied values. As a result,  $\tau_a < 1$  on the diagonal (see [Methods and formulas](#) for the definition of  $\tau_a$ ). ◀

According to [Conover \(1999, 323\)](#), “Spearman's  $\rho$  tends to be larger than Kendall's  $\tau$  in absolute value. However, as a test of significance, there is no strong reason to prefer one over the other because both will produce nearly identical results in most cases.”

[Newson \(2000a, 2000b, 2000c, 2001, 2003, 2005, 2006\)](#) introduces confidence intervals for Kendall's  $\tau_a$ . The community-contributed `somersd` command provides these confidence intervals along with additional rank statistics such as Somers'  $D$  and Harrell's  $C$  and their corresponding confidence intervals.

See [Seed \(2001\)](#) for confidence intervals for Spearman's rank correlation.

## ▷ Example 2

We illustrate `spearman` and `ktau` with the `auto` data, which contains some missing values.

```
. use https://www.stata-press.com/data/r19/auto
(1978 automobile data)
. spearman mpg rep78
Number of observations = 69
Spearman's rho = 0.3098
Test of H0: mpg and rep78 are independent
Prob = 0.0098
```

Because we specified two variables, spearman displayed the sample size, correlation, and *p*-value in tabular form. To obtain just the correlation coefficient displayed in matrix form, we type

```
. spearman mpg rep78, stats(rho) matrix
Number of observations = 69
```

|       | mpg    | rep78  |
|-------|--------|--------|
| mpg   | 1.0000 |        |
| rep78 | 0.3098 | 1.0000 |

We can specify the *pw* option with *spearman* and *ktau* so that all nonmissing observations between a pair of variables when calculating their correlation coefficient are used. In the output below, some correlations are based on 74 observations, whereas others are based on 69 because 5 observations contain a missing value for *rep78*.

```
. spearman mpg price rep78, pw stats(rho obs p) star(0.01)
Number of observations:
 min = 69
 avg = 71
 max = 74
```

| Key             |
|-----------------|
| <i>rho</i>      |
| Number of obs   |
| <i>p</i> -value |

|       | mpg                      | price                  | rep78             |
|-------|--------------------------|------------------------|-------------------|
| mpg   | 1.0000<br>74<br>.        |                        |                   |
| price | -0.5419*<br>74<br>0.0000 | 1.0000<br>74           |                   |
| rep78 | 0.3098*<br>69<br>0.0098  | 0.1028<br>69<br>0.4000 | 1.0000<br>69<br>. |

The bonferroni and sidak options provide adjusted  $p$ -values:

```
. ktau mpg price rep78, stats(taua taub score se p) bonferroni
Number of observations = 69
```

| Key         |
|-------------|
| tau_a       |
| tau_b       |
| score       |
| se of score |
| p-value     |

|       | mpg                                                   | price                                              | rep78                                          |
|-------|-------------------------------------------------------|----------------------------------------------------|------------------------------------------------|
| mpg   | 0.9471<br>1.0000<br>2222.0000<br>191.8600<br>.        |                                                    |                                                |
| price | -0.3973<br>-0.4082<br>-932.0000<br>192.4561<br>0.0000 | 1.0000<br>1.0000<br>2346.0000<br>193.0682<br>.     |                                                |
| rep78 | 0.2076<br>0.2525<br>487.0000<br>181.7024<br>0.0224    | 0.0648<br>0.0767<br>152.0000<br>182.2233<br>1.0000 | 0.7136<br>1.0000<br>1674.0000<br>172.2161<br>. |

◀

### ▷ Example 3

We continue with the auto data and show an example of `spearman` with the `exact` option.

```
. set seed 1234
. spearman mpg gear_ratio if foreign == 1, exact
Permutations (10,000):1,000.....2,000.....3,000.....4,000.
>5,000.....6,000.....7,000.....8,000.....9,000.....
> 10,000 done
Number of observations = 22
Spearman's rho = 0.4881
Test of H0: mpg and gear_ratio are independent
Prob = 0.0222
Exact prob = 0.0214 (10,000 Monte Carlo permutations)
```

By default, `exact` does a Monte Carlo permutation test with 10,000 permutations. Because it is a Monte Carlo test, we set the random-number generator seed before running `spearman` for reproducibility.

The exact  $p$ -value from the Monte Carlo permutation test is 0.0214, which is close to the approximate  $p$ -value of 0.0222. Note that the approximate  $p$ -value is not based on the normal distribution or the  $t$  distribution. It is calculated using a beta distribution fit to the first four moments of the null distribution of Spearman's rank correlation, and these four moments are calculated exactly for any value of  $N$ , the number of observations. See [Methods and formulas](#) below.

Let's increase the number of Monte Carlo permutations to 1,000,000 to see how close the approximate  $p$ -value is to the exact  $p$ -value. We specify `dots(10000)` to see a dot every 10,000th permutation, rather than the default of every 1,000th permutation. This time we set the random-number generator seed using a suboption. The exact  $p$ -value is computed by `permute`, and we can see `permute`'s output by specifying the `show` suboption.

```
. spearman mpg gear_ratio if foreign == 1,
> exact(montecarlo, reps(1000000) dots(10000) rseed(1234) show)
Permutations (1,000,000):100,000.....200,000.....300,000.....
> ...400,000.....500,000.....600,000.....700,000.....800,000....
>900,000.....1,000,000 done
Monte Carlo permutation results Number of observations = 22
Permutation variable: mpg Number of permutations = 1,000,000
```

| T   | T(obs)   | Test      | c      | n       | p     | Monte Carlo error |             |       |
|-----|----------|-----------|--------|---------|-------|-------------------|-------------|-------|
|     |          |           |        |         |       | SE(p)             | [95% CI(p)] |       |
| rho | .4880642 | lower     | 988530 | 1000000 | .9885 | .0001             | .9883       | .9887 |
|     |          | upper     | 11510  | 1000000 | .0115 | .0001             | .0113       | .0117 |
|     |          | two-sided |        |         | .0230 | .0001             | .0227       | .0233 |

Notes: For lower one-sided test,  $c = \#\{T \leq T(\text{obs})\}$  and  $p = p_{\text{lower}} = c/n$ .  
 For upper one-sided test,  $c = \#\{T \geq T(\text{obs})\}$  and  $p = p_{\text{upper}} = c/n$ .  
 For two-sided test,  $p = 2 \cdot \min(p_{\text{lower}}, p_{\text{upper}})$ ; SE and CI approximate.

```
Number of observations = 22
Spearman's rho = 0.4881
```

```
Test of H0: mpg and gear_ratio are independent
Prob = 0.0222
Exact prob = 0.0230 (1,000,000 Monte Carlo permutations)
```

With this increase in the number of permutations, the exact  $p$ -value is now calculated as 0.0230. From the table produced by `permute`, we see that this  $p$ -value has a confidence interval of [0.0227, 0.0233], accounting for the Monte Carlo error. The approximate  $p$ -value of 0.0222 falls outside this confidence interval, but it is still very close. Not bad for  $N = 22$ .

◀

#### ▷ Example 4

For very small sample sizes, an exact  $p$ -value can be computed by enumerating the full permutation distribution. Here is an example using the auto data with sample size  $N = 11$ .

```
. spearman mpg gear_ratio if foreign == 1 & mpg <= 24,
> exact(enumerate, dots(10000))
(enumerating all 831,600 possible permutations)
Permutations (831,600):100,000.....200,000.....300,000.....
> .400,000.....500,000.....600,000.....700,000.....800,000.... d
> one
Number of observations = 11
Spearman's rho = 0.5636
Test of H0: mpg and gear_ratio are independent
Prob = 0.0722
Exact prob = 0.0747 (enumerated all 831,600 permutations)
```

The exact  $p$ -value is 0.0747. The approximate  $p$ -value is 0.0722, which is quite close to the exact  $p$ -value in this case, even with only 11 observations.

For  $N = 11$ , the permutation distribution consists of  $11! = 39,916,800$  permutations. However, the output above says that there are only 831,600 permutations. This is because the values of mpg in this sample are not all unique.

```
. tabulate mpg if foreign == 1 & mpg <= 24
```

| Mileage<br>(mpg) | Freq. | Percent | Cum.   |
|------------------|-------|---------|--------|
| 14               | 1     | 9.09    | 9.09   |
| 17               | 2     | 18.18   | 27.27  |
| 18               | 2     | 18.18   | 45.45  |
| 21               | 2     | 18.18   | 63.64  |
| 23               | 3     | 27.27   | 90.91  |
| 24               | 1     | 9.09    | 100.00 |
| Total            | 11    | 100.00  |        |

The multiplicities in the values of mpg yield permutations that give identical results, and we need to enumerate only the permutations that are distinct. From the values of mpg, we see that each distinct permutation has a multiplicity of  $2! 2! 2! 3! = 48$ , and  $39,916,800/48 = 831,600$ , which reduces considerably the number of permutations that need to be computed.

`permute`, which computes the permutations, permutes the first variable of the two in the `spearman varlist` command. So to best exploit this, the variable that produces the most multiplicities in the permutations should be placed first in `varlist` when doing an enumeration.

◀

Charles Edward Spearman (1863–1945) was a British psychologist who made contributions to correlation, factor analysis, test reliability, and psychometrics. After several years' military service, he obtained a PhD in experimental psychology at Leipzig and became a professor at University College London, where he sustained a long program of work on the interpretation of intelligence tests. Ironically, the rank correlation version bearing his name is not the formula he advocated.

Maurice George Kendall (1907–1983) was a British statistician who contributed to rank correlation, time series, multivariate analysis, among other topics, and wrote many statistical texts. Most notably, perhaps, his advanced survey of the theory of statistics went through several editions, later ones with Alan Stuart; the baton has since passed to others. Kendall was employed in turn as a government and business statistician, as a professor at the London School of Economics, as a consultant, and as director of the World Fertility Survey. He was knighted in 1974.

## Stored results

spearman stores the following in `r()`:

### Scalars

|                           |                                                 |
|---------------------------|-------------------------------------------------|
| <code>r(N)</code>         | number of observations (last variable pair)     |

## Methods and formulas

Methods and formulas are presented under the following headings:

[Spearman's rank correlation](#)  
[Exact  \$p\$ -values](#)  
[Kendall's tau](#)

## Spearman's rank correlation

Spearman's (1904) rank correlation is calculated as Pearson's correlation computed on the ranks (averaged for ties) (Conover 1999, 314–315). Ranks are as calculated by `egen`; see [\[D\] egen](#).

If  $x_i$  and  $y_i$ , where  $i = 1, 2, \dots, n$ , are the ranks of one variable pair, and  $n$  is the number of observations, then Spearman's rank correlation is

$$\rho = \frac{\sum_i (x_i - \bar{x})(y_i - \bar{y})}{\sqrt{\sum_i (x_i - \bar{x})^2} \sqrt{\sum_i (y_i - \bar{y})^2}}$$

where  $\bar{x} = (\sum_i x_i)/n$  is the mean of  $x$  and  $\bar{y}$  is defined similarly.

Under the null hypothesis of independence (or, more generally, exchangeability), the distribution of  $\rho$  is given by all the possible permutations of  $x_i$  with  $y_i$  fixed. For the permutation distribution, an equivalent statistic to  $\rho$  is

$$T = \sum_i x_i y_i$$

The moments of  $T$  for the permutation distribution can be computed exactly. Its mean is

$$E(T) = \frac{1}{n} \{ \sum_i x_i \} \{ \sum_i y_i \}$$

Assume now that the ranks,  $x_i$  and  $y_i$ , are adjusted so that their means are zero. With this assumption, we have (Stuart, Ord, and Arnold 1999, eqs. 27.42 and 27.43)

$$E(T^2) = \frac{1}{n-1} \{ \sum_i x_i^2 \} \{ \sum_i y_i^2 \}$$

$$\begin{aligned} E(T^3) &= \frac{1}{n} \{ \sum_i x_i^3 \} \{ \sum_i y_i^3 \} \\ &\quad + \frac{3}{n(n-1)} \{ \sum_{i \neq j} x_i^2 x_j \} \{ \sum_{i \neq j} y_i^2 y_j \} \\ &\quad + \frac{36}{n(n-1)(n-2)} \{ \sum_{i < j < k} x_i x_j x_k \} \{ \sum_{i < j < k} y_i y_j y_k \} \end{aligned}$$

$$\begin{aligned} E(T^4) &= \frac{1}{n} \{ \sum_i x_i^4 \} \{ \sum_i y_i^4 \} \\ &\quad + \frac{4}{n(n-1)} \{ \sum_{i \neq j} x_i^3 x_j \} \{ \sum_{i \neq j} y_i^3 y_j \} \\ &\quad + \frac{12}{n(n-1)} \{ \sum_{i < j} x_i^2 x_j^2 \} \{ \sum_{i < j} y_i^2 y_j^2 \} \\ &\quad + \frac{24}{n(n-1)(n-2)} \{ \sum_{i \neq j, k; j < k} x_i^2 x_j x_k \} \{ \sum_{i \neq j, k; j < k} y_i^2 y_j y_k \} \\ &\quad + \frac{576}{n(n-1)(n-2)(n-3)} \{ \sum_{i < j < k < l} x_i x_j x_k x_l \} \{ \sum_{i < j < k < l} y_i y_j y_k y_l \} \end{aligned}$$

Note that Stuart, Ord, and Arnold (1999, eq. 27.43) express  $E(T^3)$  and  $E(T^4)$  in terms of  $k$  statistics, but that formulation is exactly equivalent to the equations given above.

An approximate  $p$ -value for Spearman's rank correlation is calculated by fitting a four-parameter beta distribution to the first four moments of  $T$ . (See Lord [1965] and Hanson [1991] for a description of the technique of fitting a four-parameter beta distribution to moments of another distribution.) The four-parameter beta distribution with domain  $[l, u]$  is

$$f(x) = \frac{(-l+x)^{\alpha-1}(u-x)^{\beta-1}}{(u-l)^{\alpha+\beta-1}B(\alpha, \beta)}$$

where  $0 \leq l < u \leq 1$  and  $B(\alpha, \beta)$  is the beta function with  $\alpha > 0$  and  $\beta > 0$ .

The parameters for the beta distribution are calculated as follows. Let  $m$  be the mean of  $T$ ,  $v$  its variance,  $g_3$  its skewness, and  $g_4$  its kurtosis (see *Methods and formulas* in [R] **summarize**). Define

$$r = \frac{6(g_4 - g_3^2 - 1)}{6 + 3g_3^2 - 2g_4}$$

and

$$d = 1 - \frac{24(r+1)}{(r+2)(r+3)g_4 - 3(r-6)(r+1)}$$

Let

$$a = \frac{r(1 - \sqrt{d})}{2}$$

$$b = \frac{r(1 + \sqrt{d})}{2}$$

If  $g_3 > 0$ , then  $\alpha = a$  and  $\beta = b$ ; otherwise,  $\alpha = b$  and  $\beta = a$ . The domain boundaries are given by

$$l = m - \alpha \sqrt{\frac{v(\alpha + \beta + 1)}{\alpha\beta}}$$

$$u = m + \beta \sqrt{\frac{v(\alpha + \beta + 1)}{\alpha\beta}}$$

To calculate the  $p$ -values, we first scale the observed value of  $T$  to the domain of beta:

$$s = \frac{T_{\text{obs}} - l}{u - l}$$

Then the lower and upper one-sided  $p$ -values are given by

$$p_{\text{lower}} = \text{ibeta}(\alpha, \beta, s)$$

$$p_{\text{upper}} = \text{ibetatail}(\alpha, \beta, s)$$

where `ibeta` is Stata's two-parameter cumulative beta distribution and `ibetatail` is the function for its upper tail; see [FN] **Statistical functions**. The two-sided  $p$ -value is given by

$$p = \min\{1, 2 \min(p_{\text{lower}}, p_{\text{upper}})\}$$

## Exact p-values

Exact  $p$ -values for Spearman's rank correlation are computed by permute. For details on the permutation computation, see [R] [permute](#).

## Kendall's tau

Kendall's  $\tau$  is calculated in the following manner. For any two pairs of ranks  $(x_i, y_i)$  and  $(x_j, y_j)$ ,  $1 \leq i, j \leq n$ , define them as concordant if

$$(x_i - x_j)(y_i - y_j) > 0$$

and discordant if this product is less than zero.

Kendall's (1938; also see [Kendall and Gibbons \[1990\]](#) or [Bland \[2015\]](#), 187–188) score  $S$  is defined as  $C - D$ , where  $C$  ( $D$ ) is the number of concordant (discordant) pairs. Let  $N = n(n - 1)/2$  be the total number of pairs, so  $\tau_a$  is given by

$$\tau_a = \frac{S}{N}$$

and  $\tau_b$  is given by

$$\tau_b = \frac{S}{\sqrt{N - U}\sqrt{N - V}}$$

where

$$U = \sum_{i=1}^{N_1} u_i(u_i - 1)/2$$

$$V = \sum_{j=1}^{N_2} v_j(v_j - 1)/2$$

and where  $N_1$  is the number of sets of tied  $x$  values,  $u_i$  is the number of tied  $x$  values in the  $i$ th set,  $N_2$  is the number of sets of tied  $y$  values, and  $v_j$  is the number of tied  $y$  values in the  $j$ th set.

Under the null hypothesis of independence, the variance of  $S$  is exactly ([Kendall and Gibbons 1990](#), 66)

$$\begin{aligned} \text{Var}(S) = & \frac{1}{18} \left\{ n(n-1)(2n+5) - \sum_{i=1}^{N_1} u_i(u_i-1)(2u_i+5) - \sum_{j=1}^{N_2} v_j(v_j-1)(2v_j+5) \right\} \\ & + \frac{1}{9n(n-1)(n-2)} \left\{ \sum_{i=1}^{N_1} u_i(u_i-1)(u_i-2) \right\} \left\{ \sum_{j=1}^{N_2} v_j(v_j-1)(v_j-2) \right\} \\ & + \frac{1}{2n(n-1)} \left\{ \sum_{i=1}^{N_1} u_i(u_i-1) \right\} \left\{ \sum_{j=1}^{N_2} v_j(v_j-1) \right\} \end{aligned}$$

Using a normal approximation with a continuity correction,

$$z = \frac{|S| - 1}{\sqrt{\text{Var}(S)}}$$

For the hypothesis of independence, the statistics  $S$ ,  $\tau_a$ , and  $\tau_b$  produce equivalent tests and give the same  $p$ -value.

For Kendall's  $\tau$ , the normal approximation is surprisingly accurate for sample sizes as small as 8, at least for calculating  $p$ -values under the null hypothesis for continuous variables. See [Kendall and Gibbons \[1990, chap. 4\]](#), who also present some tables for calculating exact  $p$ -values for  $n < 10$ .

Let  $v$  be the number of variables specified so that  $k = v(v - 1)/2$  correlation coefficients are to be estimated. If `bonferroni` is specified, the adjusted  $p$ -value is  $p' = \min(1, kp)$ . If `sidak` is specified,  $p' = \min\{1, 1 - (1 - p)^n\}$ . See [Methods and formulas](#) in [\[R\] oneway](#) for a more complete description of the logic behind these adjustments.

Early work on rank correlation is surveyed by [Kruskal \(1958\)](#).

## Description

`spikeplot` produces a frequency plot for a variable in which the frequencies are depicted as vertical lines from zero. The frequency may be a count, a fraction, or the square root of the count (Tukey's rootogram, circa 1965). The vertical lines may also originate from a baseline other than zero at the user's option.

## Quick start

Spike plot of `v1`

```
spikeplot v1
```

Same as above, but apply frequency weights `wvar`

```
spikeplot v1 [fweight = wvar]
```

Plot proportions of the total number of observations instead of frequencies

```
spikeplot v1, fraction
```

Tukey's rootogram of `v2`

```
spikeplot v2, root
```

## Menu

Graphics > Distributional graphs > Spike plot and rootogram

## Syntax

```
spikeplot varname [if] [in] [weight] [, options]
```

| <i>options</i>                                     | Description                                                                |
|----------------------------------------------------|----------------------------------------------------------------------------|

| <code>twoway_options</code>                        | any options documented in [G-3] <a href="#">twoway_options</a>             |

fweights, awweights, and iweights are allowed; see [U] 11.1.6 [weight](#).

## Options

### Main

`round(#)` rounds the values of *varname* to the nearest multiple of #. This action effectively specifies the bin width.

`fraction` specifies that the vertical scale be the proportion of total values (percentage) rather than the count.

`root` specifies that the vertical scale show square roots. This option may not be specified if `fraction` is specified.

### Plot

`spike_options` affect the rendition of the plotted spikes; see [G-2] [graph twoway spike](#).

### Add plots

`addplot(plot)` provides a way to add other plots to the generated graph. See [G-3] [addplot\\_option](#).

### Y axis, X axis, Titles, Legend, Overall, By

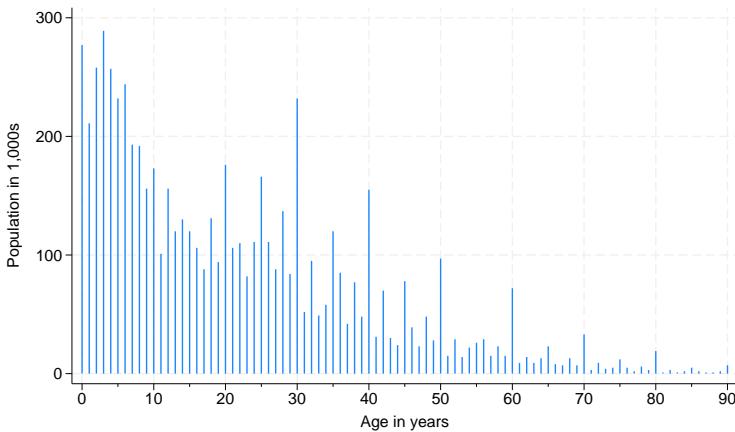

`twoway_options` are any of the options documented in [G-3] [twoway\\_options](#). These include options for titling the graph (see [G-3] [title\\_options](#)), options for saving the graph to disk (see [G-3] [saving\\_option](#)), and the `by()` option (see [G-3] [by\\_option](#)).

## Remarks and examples

### ▷ Example 1

Cox and Brady (1997a) present an illustrative example using the age structure of the population of Ghana from the 1960 census (rounded to the nearest 1,000). The dataset has ages from 0 (less than 1 year) to 90. To view the distribution of ages, we would like to use each integer from 0 to 90 as the bins for the dataset.

```
. use https://www.stata-press.com/data/r19/ghanaage
(Age structure of population of Ghana)
. spikeplot age [fw=pop], ytitle("Population in 1,000s") xlab(0(10)90)
> xmtick(5(10)85)
```

The resulting graph shows a “heaping” of ages at the multiples of 5. Also, ages ending in even numbers are more frequent than ages ending in odd numbers (except for 5). This preference for reporting ages is well known in demography and other social sciences.

Note also that we used the `ytitle()` option to override the default title of “Frequency” and that we used the `xlab()` and `xmtick()` options with *numlists* to further customize the resulting graph. See [U] 11.1.8 *numlist* for details on specifying *numlists*.

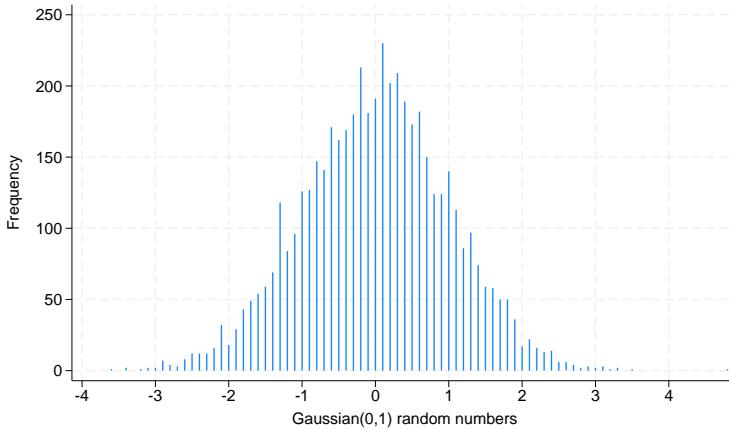

### ▷ Example 2

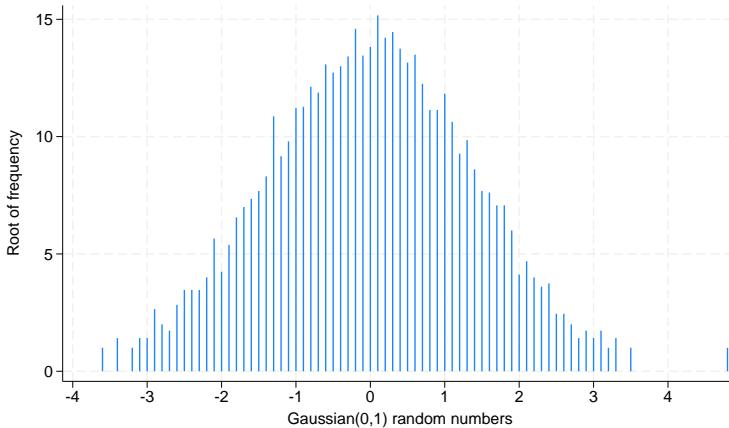

The rootogram is a plot of the square-root transformation of the frequency counts. The square root of a normal distribution is a multiple of another normal distribution.

```
. clear
. set seed 1234567
. set obs 5000
Number of observations (_N) was 0, now 5,000.
. generate normal = rnormal()
. label variable normal "Gaussian(0,1) random numbers"
```

```
. spikeplot normal, round(.10) xlab(-4(1)4)
```

```
. spikeplot normal, round(.10) xlab(-4(1)4) root
```

Interpreting a histogram in terms of normality is thus similar to interpreting the rootogram for normality.

This example also shows how the `round()` option is used to bin the values for a spike plot of a continuous variable.

### ▷ Example 3

`spikeplot` can also be used to produce time-series plots. `varname` should be the time variable, and weights should be specified as the values for those times. To get a plot of daily rainfalls, we type

```
. spikeplot day [fw=rain] if rain, ytitle("Daily rainfall in mm")
```

The `base()` option of `graph twoway spike` may be used to set a different baseline, such as when we want to show variations relative to an average or to some other measure of level.

## Acknowledgments

The original version of `spikeplot` was written by Nicholas J. Cox of the Department of Geography at Durham University, UK, who is coeditor of the *Stata Journal* and author of *Speaking Stata Graphics* and by Anthony R. Brady founder of Sealed Envelope, London (1997a, 1997b).

## Description

`ssc` works with packages (and files) from the Statistical Software Components (SSC) Archive, which is often called the Boston College Archive and is provided by <http://repec.org>.

The SSC has become the premier Stata download site for community-contributed software on the web. `ssc` provides a convenient interface to the resources available there. For example, on Statalist (see <https://www.statalist.org/>), users will often write

```
The program can be found by typing ssc install newprogramname.
```

Typing that would load everything associated with `newprogramname`, including the help files.

If you are searching for what is available, type `ssc new` and `ssc hot`, and see [R] [search](#). `search` searches the SSC and other places, too. `search` provides a GUI interface from which programs can be installed, including the programs at the SSC Archive.

You can uninstall particular packages by using `ssc uninstall`. For the packages that you keep, see [R] [ado update](#) for an automated way of keeping those packages up to date.

## Command overview

`ssc new` summarizes the packages made available or updated recently. Output is presented in the Stata Viewer, and from there you may click to find out more about individual packages or to install them.

`ssc hot` lists the most popular packages—popular based on a moving average of the number of downloads in the past three months. By default, 10 packages are listed.

`ssc describe pkgname` describes, but does not install, the specified package. Use `search` to find packages; see [R] [search](#). If you know the package name but do not know the exact spelling, type `ssc describe` followed by one letter, a–z or \_ (underscore), to list all the packages starting with that letter.

`ssc install pkgname` installs the specified package. You do not have to describe a package before installing it. (You may also install a package by using `net install`; see [R] [net](#).)

`ssc uninstall pkgname` removes the previously installed package from your computer. It does not matter how the package was installed. (`ssc uninstall` is a synonym for `ado uninstall`, so either may be used to installed any package.)

`ssc type filename` types a specific file stored at SSC. `ssc cat` is a synonym for `ssc type`, which may appeal to those familiar with Unix.

`ssc copy filename` copies a specific file stored at SSC to your computer. By default, the file is copied to the current directory, but you can use options to change this. `ssc copy` is a rarely used alternative to `ssc install ... , all`. `ssc cp` is a synonym for `ssc copy`.

## Quick start

Describe mycommand at SSC

```
ssc describe mycommand
```

Install mycommand from SSC

```
ssc install mycommand
```

Same as above, but replace previously installed version of mycommand

```
ssc install mycommand, replace
```

See a summary of all new and recently updated packages on SSC

```
ssc new
```

See a summary of the 10 most popular SSC packages

```
ssc hot
```

Same as above, but see the top 25 packages

```
ssc hot, n(25)
```

## Syntax

*Summary of packages most recently added or updated at SSC*

```
ssc new [, saving(filename[, replace]) type]
```

*Summary of most popular packages at SSC*

```
ssc hot [, n(#) author(name)]
```

*Describe a specified package at SSC*

```
ssc describe { pkgname | letter } [, saving(filename[, replace])]
```

*Install a specified package from SSC*

```
ssc install pkgname [, all replace]
```

*Uninstall from your computer a previously installed package from SSC*

```
ssc uninstall pkgname
```

*Type a specific file stored at SSC*

```
ssc type filename [, asis]
```

*Copy a specific file from SSC to your computer*

```
ssc copy filename [, plus personal replace public binary]
```

where *letter* in ssc describe is a–z or \_.

## Options

Options are presented under the following headings:

*Options for use with ssc new*  
*Options for use with ssc hot*  
*Option for use with ssc describe*  
*Options for use with ssc install*  
*Option for use with ssc type*  
*Options for use with ssc copy*

### Options for use with ssc new

`saving(filename[, replace])` specifies that the “what’s new” summary be saved in *filename*. If *filename* is specified without a suffix, *filename.smcl* is assumed. If `saving()` is not specified, `saving(ssc_results.smcl)` is assumed.

`type` specifies that the “what’s new” results be displayed in the Results window rather than in the Viewer.

### Options for use with ssc hot

`n(#)` specifies the number of packages to list; `n(10)` is the default. Specify `n(.)` to list all packages in order of popularity.

`author(name)` lists the 10 most popular packages by the specified author. If `n(#)` is also specified, the top # packages are listed.

### Option for use with ssc describe

`saving(filename[, replace])` specifies that, in addition to the description’s being displayed on your screen, it be saved in the specified file.

If *filename* is specified without an extension, `.smcl` will be assumed, and the file will be saved as a SMCL file.

If *filename* is specified with an extension, no default extension is added. If the extension is `.log`, the file will be stored as a text file.

If `replace` is specified, *filename* is replaced if it already exists.

### Options for use with ssc install

`all` specifies that any ancillary files associated with the package be downloaded to your current directory, in addition to the program and help files being installed. Ancillary files are files that do not end in `.ado` or `.sthlp` and typically contain datasets or examples of the use of the new command.

You can find out which files are associated with the package by typing `ssc describe pkgname` before or after installing. If you install without using the `all` option and then want the ancillary files, you can `ssc install` again.

`replace` specifies that any files being downloaded that already exist on your computer be replaced by the downloaded files. If `replace` is not specified and any files already exist, none of the files from the package is downloaded or installed.

It is better not to specify the `replace` option and wait to see if there is a problem. If there is a problem, it is usually better to uninstall the old package by using `ssc uninstall` or `ado uninstall` (which are, in fact, the same command).

## Option for use with `ssc type`

`asis` affects how files with the suffixes `.smcl` and `.sthlp` are displayed. The default is to interpret SMCL directives the file might contain. `asis` specifies that the file be displayed in raw, uninterpreted form.

## Options for use with `ssc copy`

`plus` specifies that the file be copied to the PLUS directory, the directory where community-contributed additions are installed. Typing `sysdir` will display the identity of the PLUS directory on your computer; see [P] [sysdir](#).

`personal` specifies that the file be copied to your PERSONAL directory as reported by `sysdir`; see [P] [sysdir](#).

If neither `plus` nor `personal` is specified, the default is to copy the file to the current directory.

`replace` specifies that, if the file already exists on your computer, the new file replace it.

`public` specifies that the new file be made readable by everyone; otherwise, the file will be created according to the default permission you have set with your operating system.

`binary` specifies that the file being copied is a binary file and that it is to be copied as is. The default is to assume that the file is a text file and change the end-of-line characters to those appropriate for your computer/operating system.

## Remarks and examples

Users can add new features to Stata, and some users choose to make new features that they have written available to others via the web. The files that comprise a new feature are called a package, and a package usually consists of one or more `ado`-files and help files. The `net` command (see [R] [net](#)) makes it reasonably easy to install and uninstall packages regardless of where they are on the web. One site, the SSC, has become particularly popular as a repository for additions to Stata. Command `ssc` is an easier to use version of `net` designed especially for the SSC.

Many packages are available at the SSC. Packages have names, such as `oaxaca`, `estout`, or `egenmore`. At SSC, capitalization is not significant, so `Oaxaca`, `ESTOUT`, and `EGENmore` are ways of writing the same package names.

When you type

```
. ssc install oaxaca
```

the files associated with the package are downloaded and installed on your computer. Package names usually correspond to the names of the command being added to Stata, so one would expect that installing the package `oaxaca` will add command `oaxaca` to Stata on your computer, and expect that typing `help oaxaca` will provide the documentation. That is the situation here, but that is not always so. Before or after installing a package, type `ssc describe pkgname` to obtain the details.

▷ Example 1

ssc new summarizes the packages most recently made available or updated. Output is presented in the Viewer, from which you may click on a package name to find out more or install it. Try it for yourself! Type ssc new in the Command window.

ssc hot provides a list of the most popular packages at SSC.

```
. ssc hot
```

(Click on package name for description)

The author (*name*) option allows you to list the most popular packages by a specific person:

```
. ssc hot, author(baum)
```

**Top 10 packages at SSC by author Baum**

| Rank | Feb 2025<br># hits | Package  | Author(s)                                               |
|------|--------------------|----------|---------------------------------------------------------|
| 7    | 33506.2            | ivreg210 | Christopher F Baum, Mark E Schaffer,<br>Steven Stillman |
| 8    | 31413.5            | ivreg2   | Christopher F Baum, Steven Stillman,<br>Mark E Schaffer |

(output omitted)

(Click on package name for description)

ssc describe *pkgname* describes, but does not install, the specified package. You must already know the name of the package. See [R] [search](#) for assistance in searching for packages. Sometimes you know the package name, but you do not know the exact spelling. Then, you can type ssc describe followed by one letter, a–z or `_`, to list all the packages starting with that letter; even so, using search is better.

```
. ssc describe i
```

---

```
http://fmwww.bc.edu/repec/bocode/i/
(no title)
```

---

PACKAGES you could **-not describe-**:

(output omitted)

|            |                                                                                                                                                                   |
|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ivreg2     | module for extended instrumental variables/2SLS and GMM estimation                                                                                                |
| ivreg210   | module for extended instrumental variables/2SLS and GMM estimation (v10)                                                                                          |
| ivreg28    | module for extended instrumental variables/2SLS and GMM estimation (v8)                                                                                           |
| ivreg29    | module for extended instrumental variables/2SLS and GMM estimation (v9)                                                                                           |
| ivreg2h    | module to perform instrumental variables estimation using heteroskedasticity-based instruments                                                                    |
| ivreg2hdfe | module to estimate an Instrumental Variable Linear Regression Model with two High Dimensional Fixed Effects                                                       |
| ivreg2m    | module to identify treatment-effects estimates with potentially misreported and endogenous program participation                                                  |
| ivreg_ss   | module to compute confidence intervals, standard errors, and p-values in an IV regression in which the excluded instrumental variable has a shift-share structure |
| ivreghdfe  | module for extended instrumental variable regressions with multiple levels of fixed effects                                                                       |
| ivregress2 | module to export first and second-stage results similar to ivregress                                                                                              |

(output omitted)

---

(type **ssc describe** *pkgname* for more information on *pkgname*)

The default setting for the `saving()` option is for the output to be saved with the `.smc1` extension. You could also save the file with a `log` extension, and in this case, the file would be stored as a text file. For example, we could type

```
. ssc describe i, saving(i.index)
```

or the following:

```
. ssc describe ivreg2, saving(ivreg2.log)
```

`ssc install pkgname` installs the specified package. You do not have to describe a package before installing it. There are ways of installing packages other than `ssc install`, such as `net`; see [R] [net](#). It does not matter how a package is installed. For instance, a package can be installed using `net` and still be uninstalled using `ssc`.

```
. ssc install ivreg2
checking ivreg2 consistency and verifying not already installed...
installing into C:\ado\plus\...
installation complete.
```

`ssc uninstall pkgname` removes the specified, previously installed package from your computer. You can uninstall immediately after installation or at any time in the future. (Technical note: `ssc uninstall` is a synonym for `ado uninstall`, so it can uninstall any installed package, not just packages obtained from the SSC.)

```
. ssc uninstall ivreg2
package ivreg2 from http://fmwww.bc.edu/repec/bocode/i
'IVREG2': module for extended instrumental variables/2SLS and GMM
estimation
(package uninstalled)
```

`ssc type filename` types a specific file stored at the SSC. Although not shown in the syntax diagram, `ssc cat` is a synonym for `ssc type`, which may appeal to those familiar with Unix. To view only the `ivreg2` help file from the `ivreg2` package, you would type

```
. ssc type ivreg2.sthlp
```

---

```
help for ivreg2
```

---

**Extended instrumental variables/2SLS, GMM and AC/HAC, LIML and k-class regression**

```
Full syntax
(output omitted)
```

`ssc copy filename` copies a specific file stored at the SSC to your computer. By default, the file is copied to the current directory, but you can use options to change this. `ssc copy` is a rarely used alternative to `ssc install ...`, `all`. `ssc cp` is a synonym for `ssc copy`.

```
. ssc copy ivreg2.ado
(file ivreg2.ado copied to current directory)
```

For more details on the SSC Archive and for information on how to submit your own programs to the SSC, see <http://repec.org/bocode/s/sscsubmit.html>.

## Acknowledgments

ssc is based on `archutil` by Nicholas J. Cox of the Department of Geography at Durham University, UK, who is coeditor of the *Stata Journal* and author of *Speaking Stata Graphics* and by Christopher F. Baum of the Department of Economics at Boston College and author of the Stata Press books *An Introduction to Modern Econometrics Using Stata* and *An Introduction to Stata Programming* and coauthor of the Stata Press book *Environmental Econometrics Using Stata*. The reworking of the original was done with their blessing and their participation.

Baum maintains the Stata-related files stored at the SSC Archive. We thank him for this contribution to the Stata community.

## Description

`stem` displays stem-and-leaf plots.

## Quick start

Stem-and-leaf plot for `v1`

```
stem v1
```

Same as above, with 2 lines per interval of 10

```
stem v1, lines(2)
```

Specify that each stem has a width of 5 (equivalent to above)

```
stem v1, width(5)
```

Stem-and-leaf plot for `v2` with an interval of 100

```
stem v2, digits(2)
```

Same as above, with 4 lines per interval of 100

```
stem v2, digits(2) lines(4)
```

Display `v2` rounded to the nearest hundred

```
stem v2, round(100)
```

Do not display empty stems

```
stem v2, prune
```

## Menu

## Syntax

```
stem varname [if] [in] [, options]
```

| <i>options</i>           | Description                                                |
|--------------------------|------------------------------------------------------------|
| <code>prune</code>       | do not print stems that have no leaves                     |
| <code>round(#)</code>    | round data to this value; default is <code>round(1)</code> |
| <code>truncate(#)</code> | truncate data to this value                                |
| <code>digits(#)</code>   | digits per leaf; default is <code>digits(1)</code>         |
| <code>lines(#)</code>    | number of stems per interval of $10^{\text{digits}}$       |
| <code>width(#)</code>    | stem width; equal to $10^{\text{digits}}/\text{width}$     |

by and collect are allowed; see [\[U\] 11.1.10 Prefix commands](#).

## Options

Main

`prune` prevents printing any stems that have no leaves.

`round(#)` rounds the data to this value and displays the plot in these units. If `round()` is not specified, noninteger data will be rounded automatically.

`truncate(#)` truncates the data to this value and displays the plot in these units.

`digits(#)` sets the number of digits per leaf. The default is 1.

`lines(#)` sets the number of stems per every data interval of  $10^{\text{digits}}$ . The value of `lines()` must divide  $10^{\text{digits}}$ ; that is, if `digits(1)` is specified, then `lines()` must divide 10. If `digits(2)` is specified, then `lines()` must divide 100, etc. Only one of `lines()` or `width()` may be specified. If neither is specified, an appropriate value will be set automatically.

`width(#)` sets the width of a stem. `lines()` is equal to  $10^{\text{digits}}/\text{width}$ , and this option is merely an alternative way of setting `lines()`. The value of `width()` must divide  $10^{\text{digits}}$ . Only one of `width()` or `lines()` may be specified. If neither is specified, an appropriate value will be set automatically.

Note: If `lines()` or `width()` is not specified, `digits()` may be decreased in some circumstances to make a better-looking plot. If `lines()` or `width()` is set, the user-specified value of `digits()` will not be altered.

## Remarks and examples

### ▷ Example 1

Stem-and-leaf displays are a compact way to present considerable information about a batch of data. For instance, using our automobile data (described in [U] 1.2.2 Example datasets):

```
. use https://www.stata-press.com/data/r19/auto
(1978 automobile data)

. stem mpg
Stem-and-leaf plot for mpg (Mileage (mpg))

1t | 22
1f | 44444455
1s | 66667777
1. | 888888888899999999
2* | 00011111
2t | 22222333
2f | 444455555
2s | 666
2. | 8889
3* | 001
3t |
3f | 455
3s |
3. |
4* | 1
```

The stem-and-leaf display provides a way to list our data. The expression to the left of the vertical bar is called the stem; the digits to the right are called the leaves. All the stems that begin with the same digit and the corresponding leaves, written beside each other, reconstruct an observation of the data. Thus, if we look at the four stems that begin with the digit 1 and their corresponding leaves, we see that we have two cars rated at 12 mpg, 6 cars at 14, 2 at 15, and so on. The car with the highest mileage rating in our data is rated at 41 mpg.

The above plot is a five-line plot with `lines()` equal to 5 (five lines per interval of 10) and `width()` equal to 2 (two leaves per stem).

Instead, we could specify `lines(2)`:

```
. stem mpg, lines(2)
Stem-and-leaf plot for mpg (Mileage (mpg))

1* | 22444444
1. | 5566667777888888888899999999
2* | 00011111222223334444
2. | 555556668889
3* | 0014
3. | 55
4* | 1
```

`stem mpg, width(5)` would produce the same plot as above.

The stem-and-leaf display provides a crude histogram of our data, one not so pretty as that produced by `histogram` (see [R] [histogram](#)), but one that is nonetheless informative.

## ▷ Example 2

The miles per gallon rating fits easily into a stem-and-leaf display because, in our data, it has two digits. However, `stem` does not require two digits.

```
. stem price, lines(1) digits(3)
Stem-and-leaf plot for price (Price)
 3*** | 291,299,667,748,798,799,829,895,955,984,995
 4*** | 010,060,082,099,172,181,187,195,296,389,424,425,453,482,499, ... (26)
 5*** | 079,104,172,189,222,379,397,705,719,788,798,799,886,899
 6*** | 165,229,295,303,342,486,850
 7*** | 140,827
 8*** | 129,814
 9*** | 690,735
10*** | 371,372
11*** | 385,497,995
12*** | 990
13*** | 466,594
14*** | 500
15*** | 906
```

The (26) at the right of the second stem shows that there were 26 leaves on this stem—too many to display on one line.

We can make a more compact stem-and-leaf plot by rounding. To display `stem` in units of 100, we could type

```
. stem price, round(100)
Stem-and-leaf plot for price (Price)
price rounded to nearest multiple of 100
plot in units of 100
 3* | 33778889
 4* | 00001112222344455555667777899
 5* | 11222447788899
 6* | 2233359
 7* | 18
 8* | 18
 9* | 77
10* | 44
11* | 45
12* | 0
13* | 056
14* | 5
15* | 9
```

`price`, in our data, has four or five digits. `stem` presented the display in terms of units of 100, so a car that cost \$3,291 was treated for display purposes as \$3,300.

◀

## □ Technical note

Stem-and-leaf diagrams have been used in Japanese railway timetables, as shown in [Tufte \(1990, 46–47\)](#).

□

## Stored results

stem stores the following in `r()`:

### Scalars

|                        |                                         |
|------------------------|-----------------------------------------|
| <code>r(width)</code>  | width of a stem                         |
| <code>r(digits)</code> | number of digits per leaf; default is 1 |

### Macros

|                          |                                             |
|--------------------------|---------------------------------------------|
| <code>r(round)</code>    | number specified in <code>round()</code>    |
| <code>r(truncate)</code> | number specified in <code>truncate()</code> |

## Description

`stepwise` performs stepwise estimation. Typing

```
. stepwise, pr(#): command
```

performs backward-selection estimation for *command*. The stepwise selection method is determined by the following option combinations:

| <i>options</i>      | Description                     |
|---------------------|---------------------------------|
| pr(#)               | backward selection              |
| pr(#) hierarchical  | backward hierarchical selection |
| pr(#) pe(#)         | backward stepwise               |
| pe(#)               | forward selection               |
| pe(#) hierarchical  | forward hierarchical selection  |
| pr(#) pe(#) forward | forward stepwise                |

*command* defines the estimation command to be executed. The following Stata commands are supported by `stepwise`:

```
betareg, clogit, cloglog, glm, intreg, logistic, logit, nbreg,
ologit, oprobit, poisson, probit, qreg, regress, scobit, stcox,
stcrreg, stintreg, streg, tobit
```

`stepwise` expects *command* to have the following form:

```
command_name [depvar] term [term . . .] [if] [in] [weight] [, command_options]
```

where *term* is either *varname* or (*varlist*) (*varlist* in parentheses indicates that this group of variables is to be included or excluded together). *depvar* is not present when *command\_name* is `stcox`, `stcrreg`, `stintreg`, or `streg`; otherwise, *depvar* is assumed to be present. For `intreg`, *depvar* is actually two dependent variable names (*depvar*<sub>1</sub> and *depvar*<sub>2</sub>).

`sw` is a synonym for `stepwise`.

For model selection and estimation using lasso, see the [Stata Lasso Reference Manual](#).

## Quick start

Backward selection, removing terms with  $p \geq 0.2$

```
stepwise, pr(.2): regress y x1 x2 x3 x4
```

Same as above, and select from the indicators for categorical variable a

```
stepwise, pr(.2): regress y x1 x2 x3 x4 i.a
```

Same as above, but force x1 to be included in model

```
stepwise, pr(.2) lockterm1: regress y x1 x2 x3 x4 i.a
```

Consider the indicators for a as a group for inclusion in model

```
stepwise, pr(.2): regress y x1 x2 x3 x4 (i.a)
```

Add d1, d2, and d3, and force them to be included in model

```
stepwise, pr(.2) lockterm1: regress y (d1 d2 d3) x1 x2 x3 x4 (i.a)
```

Forward selection, adding terms with  $p < 0.1$

```
stepwise, pe(.1): regress y x1 x2 x3 x4
```

Backward stepwise selection, removing terms with  $p \geq 0.2$  and adding those with  $p < 0.1$

```
stepwise, pr(.2) pe(.1): regress y x1 x2 x3 x4
```

Forward stepwise selection, adding terms with  $p < 0.1$  and removing those with  $p \geq 0.2$

```
stepwise, pr(.2) pe(.1) forward: regress y x1 x2 x3 x4
```

Backward hierarchical selection

```
stepwise, pr(.2) hierarchical: regress y x1 x2 x3 x4
```

Forward hierarchical selection

```
stepwise, pe(.1) hierarchical: regress y x1 x2 x3 x4
```

Note: In the above examples, regress could be replaced with any estimation command allowing the stepwise prefix.

| <code>lr</code>              | perform likelihood-ratio test instead of Wald test |
| <b>Reporting</b>             |                                                    |
| <code>display_options</code> | control columns and column formats and line width  |

\*At least one of `pr(#)` or `pe(#)` must be specified.

`by` is allowed; see [U] 11.1.10 Prefix commands.

Weights are allowed if *command* allows them; see [U] 11.1.6 weight.

All postestimation commands behave as they would after *command* without the `stepwise` prefix; see the postestimation manual entry for *command*.

## Options

### Model

`pr(#)` specifies the significance level for removal from the model; terms with  $p \geq \text{pr}()$  are eligible for removal.

`pe(#)` specifies the significance level for addition to the model; terms with  $p < \text{pe}()$  are eligible for addition.

### Model 2

`forward` specifies the forward-stepwise method and may be specified only when both `pr()` and `pe()` are also specified. Specifying both `pr()` and `pe()` without `forward` results in backward-stepwise selection. Specifying only `pr()` results in backward selection, and specifying only `pe()` results in forward selection.

`hierarchical` specifies hierarchical selection.

`lockterm1` specifies that the first term be included in the model and not be subjected to the selection criteria.

`lr` specifies that the test of term significance be the likelihood-ratio test. The default is the less computationally expensive Wald test; that is, the test is based on the estimated variance–covariance matrix of the estimators.

### Reporting

`display_options`: `nocl`, `nopvalues`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `no1stretch`; see [R] Estimation options.

## Remarks and examples

Remarks are presented under the following headings:

*Introduction*  
*Search logic for a step*  
*Full search logic*  
*Examples*  
*Estimation sample considerations*  
*Messages*  
*Programming for stepwise*

### Introduction

#### Typing

```
. stepwise, pr(.10): regress y1 x1 x2 d1 d2 d3 x4 x5
```

performs a backward-selection search for the regression model  $y_1$  on  $x_1$ ,  $x_2$ ,  $d_1$ ,  $d_2$ ,  $d_3$ ,  $x_4$ , and  $x_5$ . In this search, each explanatory variable is said to be a term. Typing

```
. stepwise, pr(.10): regress y1 x1 x2 (d1 d2 d3) (x4 x5)
```

performs a similar backward-selection search, but the variables  $d_1$ ,  $d_2$ , and  $d_3$  are treated as one term, as are  $x_4$  and  $x_5$ . That is,  $d_1$ ,  $d_2$ , and  $d_3$  may or may not appear in the final model, but they appear or do not appear together.

#### ▷ Example 1

Using the automobile dataset, we fit a backward-selection model of mpg:

```
. use https://www.stata-press.com/data/r19/auto
(1978 automobile data)
. stepwise, pr(.2): regress mpg c.weight#c.weight displ gear turn headroom
> i.foreign price
note: 0b.foreign omitted because of estimability.
Wald test, begin with full model:
p = 0.7116 >= 0.2000, removing headroom
p = 0.6138 >= 0.2000, removing displacement
p = 0.3278 >= 0.2000, removing price
```

| Source   | SS         | df | MS         | Number of obs | = | 74     |
|----------|------------|----|------------|---------------|---|--------|
| Model    | 1736.31455 | 5  | 347.262911 | F(5, 68)      | = | 33.39  |

| Total    | 2443.45946 | 73 | 33.4720474 | Root MSE      | = | 3.2248 |

| mpg                   | Coefficient | Std. err. | t     | P> t  | [95% conf. interval] |           |
|-----------------------|-------------|-----------|-------|-------|----------------------|-----------|
| weight                | -.0158002   | .0039169  | -4.03 | 0.000 | -.0236162            | -.0079842 |
| c.weight#<br>c.weight | 1.77e-06    | 6.20e-07  | 2.86  | 0.006 | 5.37e-07             | 3.01e-06  |
| foreign<br>Foreign    | -3.615107   | 1.260844  | -2.87 | 0.006 | -6.131082            | -1.099131 |
| gear_ratio            | 2.011674    | 1.468831  | 1.37  | 0.175 | -.9193321            | 4.94268   |
| turn                  | -.3087038   | .1763099  | -1.75 | 0.084 | -.6605248            | .0431172  |
| _cons                 | 59.02133    | 9.3903    | 6.29  | 0.000 | 40.28327             | 77.75938  |

This estimation treated each variable as its own term and thus considered each one separately. The engine displacement and gear ratio should really be considered together:

```
. stepwise, pr(.2): regress mpg c.weight#c.weight (displ gear) turn headroom
> i.foreign price
note: 0b.foreign omitted because of estimability.
```

Wald test, begin with full model:

p = 0.7116 >= 0.2000, removing headroom

p = 0.3944 >= 0.2000, removing displacement gear\_ratio

p = 0.2798 >= 0.2000, removing price

◀

## Search logic for a step

Before discussing the complete search logic, consider the logic for a step—the first step—in detail. The other steps follow the same logic. If you type

```
. stepwise, pr(.20): regress y1 x1 x2 (d1 d2 d3) (x4 x5)
```

the logic is

1. Fit the model  $y$  on  $x_1 x_2 d_1 d_2 d_3 x_4 x_5$ .
2. Consider dropping  $x_1$ .
3. Consider dropping  $x_2$ .
4. Consider dropping  $d_1 d_2 d_3$ .
5. Consider dropping  $x_4 x_5$ .
6. Find the term above that is least significant. If its significance level is  $\geq 0.20$ , remove that term.

If you type

```
. stepwise, pr(.20) hierarchical: regress y1 x1 x2 (d1 d2 d3) (x4 x5)
```

the logic would be different because the `hierarchical` option states that the terms are ordered. The initial logic would become

1. Fit the model  $y$  on  $x_1$   $x_2$   $d_1$   $d_2$   $d_3$   $x_4$   $x_5$ .
2. Consider dropping  $x_4$   $x_5$ —the last term.
3. If the significance of this last term is  $\geq 0.20$ , remove the term.

The process would then stop or continue. It would stop if  $x_4$   $x_5$  were not omitted, and otherwise, `stepwise` would continue to consider the significance of the next-to-last term,  $d_1$   $d_2$   $d_3$ .

Specifying `pe()` rather than `pr()` switches to forward estimation. If you type

```
. stepwise, pe(.20): regress y1 x1 x2 (d1 d2 d3) (x4 x5)
```

`stepwise` performs forward-selection search. The logic for the first step is

1. Fit a model of  $y$  on nothing (meaning a constant).
2. Consider adding  $x_1$ .
3. Consider adding  $x_2$ .
4. Consider adding  $d_1$   $d_2$   $d_3$ .
5. Consider adding  $x_4$   $x_5$ .
6. Find the term above that is most significant. If its significance level is  $< 0.20$ , add that term.

As with backward estimation, if you specify `hierarchical`,

```
. stepwise, pe(.20) hierarchical: regress y1 x1 x2 (d1 d2 d3) (x4 x5)
```

the search for the most significant term is restricted to the next term:

1. Fit a model of  $y$  on nothing (meaning a constant).
2. Consider adding  $x_1$ —the first term.
3. If the significance is  $< 0.20$ , add the term.

If  $x_1$  were added, `stepwise` would next consider  $x_2$ ; otherwise, the search process would stop.

`stepwise` can also use a stepwise selection logic that alternates between adding and removing terms. The full logic for all the possibilities is given below.

## Full search logic

| Option                                                              | Logic                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|---------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>pr()</code><br>(backward selection)                           | Fit the full model on all explanatory variables.<br>While the least-significant term is “insignificant”, remove it and reestimate.                                                                                                                                                                                                                                                                                                                                                 |

| <code>pe() hierarchical</code><br>(forward hierarchical selection)  | Fit “empty” model.<br>While the next term is “significant”, add it and reestimate.                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>pr() pe() forward</code><br>(forward stepwise)                | Fit “empty” model.<br>If the most-significant excluded term is “significant”, add it and reestimate; otherwise, stop.<br>Do that again: if the most-significant excluded term is “significant”, add it and reestimate; otherwise, stop.<br>Repeatedly,<br>if the least-significant included term is “insignificant”, remove it and reestimate;<br>if the most-significant excluded term is “significant”, add it and reestimate;<br>until neither is possible.                     |

## Examples

The following two statements are equivalent; both include solely single-variable terms:

```
. stepwise, pr(.2): regress price mpg weight displ
. stepwise, pr(.2): regress price (mpg) (weight) (displ)
```

The following two statements are equivalent; the last term in each is  $r_1, \dots, r_4$ :

```
. stepwise, pr(.2) hierarchical: regress price mpg weight displ (r1-r4)
. stepwise, pr(.2) hierarchical: regress price (mpg) (weight) (displ) (r1-r4)
```

To group variables `weight` and `displ` into one term, type

```
. stepwise, pr(.2) hierarchical: regress price mpg (weight displ) (r1-r4)
```

`stepwise` can be used with commands other than `regress`; for instance,

```
. stepwise, pr(.2): logit outcome (sex weight) treated1 treated2
. stepwise, pr(.2): logistic outcome (sex weight) treated1 treated2
```

Either statement would fit the same model because `logistic` and `logit` both perform logistic regression; they differ only in how they report results; see [\[R\] logit](#) and [\[R\] logistic](#).

We use the `lockterm1` option to force the first term to be included in the model. To keep `treated1` and `treated2` in the model no matter what, we type

```
. stepwise, pr(.2) lockterm1: logistic outcome (treated1 treated2) ...
```

After `stepwise` estimation, we can type `stepwise` without arguments to redisplay results,

```
. stepwise
 (output from logistic appears)
```

or type the underlying estimation command:

```
. logistic
 (output from logistic appears)
```

At estimation time, we can specify options unique to the command being stepped:

```
. stepwise, pr(.2): logit outcome (sex weight) treated1 treated2, or
```

or is `logit`'s option to report odds ratios rather than coefficients; see [\[R\] logit](#).

## Estimation sample considerations

Whether you use backward or forward estimation, `stepwise` forms an estimation sample by taking observations with nonmissing values of all the variables specified (except for  $depvar_1$  and  $depvar_2$  for `intreg`). The estimation sample is held constant throughout the stepping. Thus, if you type

```
. stepwise, pr(.2) hierarchical: regress amount sk edul sval
```

and variable `sval` is missing in half the data, that half of the data will not be used in the reported model, even if `sval` is not included in the final model.

The function `e(sample)` identifies the sample that was used. `e(sample)` contains 1 for observations used and 0 otherwise. For instance, if you type

```
. stepwise, pr(.2) pe(.10): logistic outcome x1 x2 (x3 x4) (x5 x6 x7)
```

and the final model is outcome on x1, x5, x6, and x7, you could re-create the final regression by typing

```
. logistic outcome x1 x5 x6 x7 if e(sample)
```

You could obtain summary statistics within the estimation sample of the independent variables by typing

```
. summarize x1 x5 x6 x7 if e(sample)
```

If you fit another model, `e(sample)` will automatically be redefined. Typing

```
. stepwise, lock pr(.2): logistic outcome (x1 x2) (x3 x4) (x5 x6 x7)
```

would automatically drop `e(sample)` and re-create it.

## Messages

**note: \_\_\_\_\_ omitted because of estimability.**

This indicates that a variable was omitted because its coefficient could not be estimated. This message is most commonly issued because the variable is collinear with other variables in the model. For instance, say that you type

```
. stepwise, pr(.2): regress y x1 x2 x3 x4
```

and x2 is collinear with x3, one of these variables will automatically be omitted. If you type

```
. stepwise, pr(.2): regress y x1 x2 i.a
```

and include indicators for factor variable a in your model, the set of indicators for a are perfectly collinear, and one will be omitted with the note indicating that it was omitted because of estimability.

**note: \_\_\_\_\_ omitted because of estimability.**

**note: \_\_\_\_\_ obs omitted because of estimability.**

You probably received this message in fitting a logistic or probit model. Regardless of estimation strategy, `stepwise` checks that the full model can be fit. The indicated variable had a 0 or infinite standard error.

For logistic, logit, and probit, this message is typically caused by one-way causation. Assume that you type

```
. stepwise, pr(.2): logistic outcome (x1 x2 x3) d1
```

and assume that variable d1 is an indicator (dummy) variable. Further assume that whenever  $d1 = 1$ ,  $outcome = 1$  in the data. Then the coefficient on d1 is infinite. One (conservative) solution to this problem is to drop the d1 variable and the  $d1=1$  observations. The underlying estimation commands `probit`, `logit`, and `logistic` report the details of the difficulty and solution; `stepwise` simply accumulates such problems and reports the above summary messages. Thus, if you see this message, you could type

```
. logistic outcome x1 x2 x3 d1
```

to see the details. Although you should think carefully about such situations, Stata's solution of dropping the offending variables and observations is, in general, appropriate.

## Programming for stepwise

stepwise requires that *command\_name* follow standard Stata syntax and allow the `if` qualifier; see [U] **11 Language syntax**. Furthermore, *command\_name* must have `sw` or `swml` as a program property; see [P] **program properties**. If *command\_name* has `swml` as a property, *command\_name* must store the log-likelihood value in `e(ll)` and model degrees of freedom in `e(df_m)`.

## Stored results

stepwise stores whatever is stored by the underlying estimation command.

Also, stepwise stores stepwise in `e(stepwise)`.

## Methods and formulas

Some statisticians do not recommend stepwise procedures; see [Sribney \(1998\)](#) for a summary.

## Description

Results of calculations are stored by many Stata commands so that they can be easily accessed and substituted into later commands.

`return list` lists results stored in `r()`.

`ereturn list` lists results stored in `e()`.

`sreturn list` lists results stored in `s()`.

This entry discusses using stored results. Programmers wishing to store results should see [\[P\] return](#) and [\[P\] ereturn](#).

## Syntax

*List results from general commands, stored in r()*

```
return list [, all]
```

*List results from estimation commands, stored in e()*

```
ereturn list [, all]
```

*List results from parsing commands, stored in s()*

```
sreturn list
```

## Option

`all` is for use with `return list` and `ereturn list`. `all` specifies that hidden and historical stored results be listed along with the usual stored results. This option is seldom used. See [Using hidden and historical stored results](#) and [Programming hidden and historical stored results](#) under [Remarks and examples](#) of [\[P\] return](#) for more information. These sections are written in terms of `return list`, but everything said there applies equally to `ereturn list`.

`all` is not allowed with `sreturn list` because `s()` does not allow hidden or historical results.

## Remarks and examples

Stata commands are classified as being

|         |                                                                                         |
|---------|-----------------------------------------------------------------------------------------|
| r-class | general commands that store results in <code>r()</code>                                 |
| e-class | estimation commands that store results in <code>e()</code>                              |
| s-class | parsing commands that store results in <code>s()</code>                                 |
| n-class | commands that do not store in <code>r()</code> , <code>e()</code> , or <code>s()</code> |

There is also a `c`-class, `c()`, containing the values of system parameters and settings, along with certain constants, such as the value of `pi`; see [P] [creturn](#). A program, however, cannot be `c`-class.

You can look at the *Stored results* section of the manual entry of a command to determine whether it is `r`-, `e`-, `s`-, or `n`-class, but it is easy enough to guess.

Commands producing statistical results are either `r`-class or `e`-class. They are `e`-class if they present estimation results and `r`-class otherwise. `s`-class is a class used by programmers and is primarily used in subprograms performing parsing. `n`-class commands explicitly state where the result is to go. For instance, `generate` and `replace` are `n`-class because their syntax is `generate varname = ...` and `replace varname = ....`

After executing a command, you can type `return list`, `ereturn list`, or `sreturn list` to see what has been stored.

### ▷ Example 1

```
. use https://www.stata-press.com/data/r19/auto4
(1978 automobile data)
. describe
Contains data from https://www.stata-press.com/data/r19/auto4.dta
Observations: 74 1978 automobile data
Variables: 6 6 Apr 2024 00:20
```

| Variable name | Storage type | Display format | Value label | Variable label     |
|---------------|--------------|----------------|-------------|--------------------|
| price         | int          | %8.0gc         |             | Price              |
| weight        | int          | %8.0gc         |             | Weight (lbs.)      |
| mpg           | byte         | %8.0g          |             | Mileage (mpg)      |
| make          | str17        | %-17s          |             | Make and model     |
| length        | int          | %8.0g          |             | Length (in.)       |
| rep78         | byte         | %8.0g          |             | Repair record 1978 |

Sorted by:

```
. return list
```

scalars:

```
 r(changed) = 0
 r(width) = 25
 r(k) = 6
 r(N) = 74
```

macros:

```
 r(datalabel) : "1978 automobile data"
```

To view all stored results, including those that are historical or hidden, specify the `all` option.

```
. return list, all
scalars:
 r(changed) = 0
 r(width) = 25
 r(k) = 6
 r(N) = 74

macros:
 r(datalabel) : "1978 automobile data"
Historical; used before Stata 12, may exist only under version control
scalars:
 r(widthmax) = 1048576
 r(k_max) = 5000
 r(N_max) = 2147483619
```

`r(widthmax)`, `r(k_max)`, and `r(N_max)` are historical stored results. They are no longer relevant because Stata dynamically adjusts memory beginning with Stata 12.

### □ Technical note

In the above example, we stated that `r(widthmax)` and `r(N_max)` are no longer relevant. In fact, they are not useful. Stata no longer has a fixed memory size, so the methods used to calculate `r(widthmax)` and `r(N_max)` are no longer appropriate.

### ▷ Example 2

You can use stored results in expressions.

```
. summarize mpg
 Variable | Obs Mean Std. dev. Min Max
-----|-----
 mpg | 74 21.2973 5.785503 12 41

. return list
scalars:
 r(N) = 74
 r(sum_w) = 74
 r(mean) = 21.2972972972973
 r(Var) = 33.47204738985561
 r(sd) = 5.785503209735141
 r(min) = 12
 r(max) = 41
 r(sum) = 1576

. generate double mpgstd = (mpg-r(mean))/r(sd)
. summarize mpgstd
 Variable | Obs Mean Std. dev. Min Max
-----|-----
 mpgstd | 74 -1.64e-16 1 -1.606999 3.40553
```

Be careful to use results stored in `r()` soon because they will be replaced the next time you execute another `r-class` command. For instance, although `r(mean)` was 21.3 (approximately) after `summarize mpg`, it is  $-1.64e-16$  now because you just ran `summarize` with `mpgstd`.

### ▶ Example 3

`e-class` is really no different from `r-class`, except for where results are stored and that, when an estimation command stores results, it tends to store a lot of them:

```
. regress mpg weight length
 (output omitted)
. ereturn list
scalars:
 e(N) = 74
e(sum_w) = 74
 e(df_m) = 2
 e(df_r) = 71
 e(F) = 69.34050004300227
 e(r2) = .6613903979336323
 e(rmse) = 3.413681741382589
 e(mss) = 1616.08062422659
 e(rss) = 827.3788352328695
 e(r2_a) = .6518520992838754
 e(ll) = -194.3267619410807
 e(ll_0) = -234.3943376482347
 e(rank) = 3

macros:

 e(estat_cmd) : "regress_estat"

matrices:
 e(b) : 1 x 3
 e(V) : 3 x 3
 e(beta) : 1 x 2

functions:
 e(sample)
```

These `e-class` results will stick around until you run another estimation command. Typing `return list` and `ereturn list` is the easy way to find out what a command stores.

Both `r-` and `e-class` results come in four types: scalars, macros, matrices, and functions. (`s-class` results come in only one type—macros—and as earlier noted, `s-class` is used solely by programmers, so ignore it.)

Scalars are just that—numbers by any other name. You can subsequently refer to `r(mean)` or `e(rmse)` in numeric expressions and obtain the result to full precision.

Macros are strings. For instance, `e(depvar)` contains “mpg”. You can refer to it, too, in subsequent expressions, but really that would be of most use to programmers, who will refer to it using constructs like “`e(depvar)`”. In any case, macros are macros, and you obtain their contents just as you would a local macro, by enclosing their name in single quotes. The name here is the full name, so ‘`e(depvar)`’ is `mpg`.

Matrices are matrices, and all estimation commands store `e(b)` and `e(V)` containing the coefficient vector and variance–covariance matrix of the estimates (VCE).

Functions are stored by e-class commands only, and the only function existing is `e(sample)`. `e(sample)` evaluates to 1 (meaning true) if the observation was used in the previous estimation and to 0 (meaning false) otherwise.

## □ Technical note

Say that some command set `r(scalar)` and `r(macro)`, the first being stored as a scalar and the second as a macro. In theory, in subsequent use you are supposed to refer to `r(scalar)` and `'r(macro)'`. In fact, however, you can refer to either one with or without quotes, so you could refer to `'r(scalar)'` and `r(macro)`. Programmers sometimes do this.

When you refer to `r(scalar)`, you are referring to the full double-precision stored result. Think of `r(scalar)` without quotes as a function returning the value of the stored result `scalar`. When you refer to `r(scalar)` in quotes, Stata understands `'r(scalar)'` to mean “substitute the printed result of evaluating `r(scalar)`”. Pretend that `r(scalar)` equals the number 23. Then, `'r(scalar)'` is 23, the character 2 followed by 3.

Referring to `r(scalar)` in quotes is sometimes useful. Say that you want to use the immediate command `cii` with `r(scalar)`. The immediate command `cii` requires its arguments to be numeric—numeric literals in programmer’s jargon—and it will not take an expression. Thus, you could not type `'cii r(scalar) ...'`. You could, however, type `'cii 'r(scalar)' ...'` because `'r(scalar)'` is just a numeric literal.

For `r(macro)`, you are supposed to refer to it in quotes: `'r(macro)'`. If, however, you omit the quotes in an expression context, Stata evaluates the macro and then pretends that it is the result of function-returning-string. There are side effects of this, the most important being that the result is trimmed to 80 characters.

Referring to `r(macro)` without quotes is never a good idea; the feature was included merely for completeness.

You can even refer to `r(matrix)` in quotes (assume that `r(matrix)` is a matrix). `'r(matrix)'` does not result in the matrix being substituted; it returns the word `matrix`. Programmers sometimes find that useful.

## Description

`suest` is a postestimation command; see [\[U\] 20 Estimation and postestimation commands](#).

`suest` combines the estimation results—parameter estimates and associated (co)variance matrices—stored under *namelist* into one parameter vector and *simultaneous* (co)variance matrix of the sandwich/robust type. This (co)variance matrix is appropriate even if the estimates were obtained on the same or on overlapping data.

Typical applications of `suest` are tests for intramodel and cross-model hypotheses using `test` or `testnl`, for example, a generalized Hausman specification test. `lincom` and `nlcom` may be used after `suest` to estimate linear combinations and nonlinear functions of coefficients. `suest` may also be used to adjust a standard VCE for clustering or survey design effects.

Different estimators are allowed, for example, a `regress` model and a `probit` model; the only requirement is that `predict` produce equation-level scores with the `score` option after an estimation command. The models may be estimated on different samples, due either to explicit `if` or `in` selection or to missing values. If weights are applied, the same weights (type and values) should be applied to all models in *namelist*. The estimators should be estimated without `vce(robust)` or `vce(cluster clustvar)` options. `suest` returns the robust VCE, allows the `vce(cluster clustvar)` option, and automatically works with results from the `svy` prefix command (only for `vce(linearized)`). See [example 8](#) in [\[SVY\] svy postestimation](#) for an example using `suest` with `svy: ologit`.

Because `suest` posts its results like a proper estimation command, its results can be stored via [estimates store](#). Moreover, like other estimation commands, `suest` typed without arguments replays the results.

## Quick start

Combined results for stored estimates `m1` and `m2`

```
suest m1 m2
```

Same as above, but report exponentiated coefficients and label them “Odds ratio”

```
suest m1 m2, eform(Odds ratio)
```

With cluster–robust standard errors adjusting for clustering by levels of `cvar`

```
suest m1 m2, vce(cluster cvar)
```

Use `svyset` data after specifying command prefix `svy:` to estimate `m1` and `m2`

```
suest m1 m2
```

## Menu

Statistics > Postestimation

## Syntax

```
suest namelist [, options]
```

where *namelist* is a list of one or more names under which estimation results were stored via `estimates store`; see [R] [estimates store](#). Wildcards may be used. \* and `_all` refer to all stored results. A period (.) may be used to refer to the last estimation results, even if they have not (yet) been stored.

| <code>dir</code>                  | display a table describing the models                                                                                                            |
| <code>eform(<i>string</i>)</code> | report exponentiated coefficients and label as <i>string</i>                                                                                     |
| <code>display_options</code>      | control columns and column formats, row spacing, line width, display of omitted variables and base and empty cells, and factor-variable labeling |
| <code>coeflegend</code>           | display legend instead of statistics                                                                                                             |

`collect` is allowed; see [U] [11.1.10 Prefix commands](#).

`coeflegend` does not appear in the dialog box.

## Options

### SE/Robust

`svy` specifies that estimation results should be modified to reflect the survey design effects according to the `svyset` specifications, see [SVY] [svyset](#).

The `svy` option is implied when `suest` encounters survey estimation results from the `svy` prefix; see [SVY] [svy](#). Poststratification is allowed only with survey estimation results from the `svy` prefix.

`vce(vcetype)` specifies the type of standard error reported, which includes types that are robust to some kinds of misspecification (`robust`) and that allow for intragroup correlation (`cluster clustvar`); see [R] [vce\\_option](#).

The `vce()` option may not be combined with the `svy` option or estimation results from the `svy` prefix.

### Reporting

`level(#)` specifies the confidence level, as a percentage, for confidence intervals of the coefficients; see [R] [level](#).

`dir` displays a table describing the models in *namelist* just like `estimates dir namelist`.

`eform(string)` displays the coefficient table in exponentiated form: for each coefficient,  $\exp(b)$  rather than  $b$  is displayed, and standard errors and confidence intervals are transformed. *string* is the table header that will be displayed above the transformed coefficients and must be 11 characters or fewer, for example, `eform("Odds ratio")`.

*display\_options*: `nocl`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fwrap(#)`, `fwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `no1stretch`; see [R] [Estimation options](#).

The following option is available with `suest` but is not shown in the dialog box:  
`coeflegend`; see [R] [Estimation options](#).

## Remarks and examples

Remarks are presented under the following headings:

*Using suest*

*Remarks on regress*

*Testing the assumption of the independence of irrelevant alternatives*

*Testing proportionality*

*Testing cross-model hypotheses*

## Using suest

If you plan to use `suest`, you must take precautions when fitting the original models. These restrictions are relaxed when using `svy` commands; see [SVY] [svy postestimation](#).

1. `suest` works with estimation commands that allow `predict` to generate equation-level score variables when supplied with the `score` (or `scores`) option. For example, equation-level score variables are generated after running `mlogit` by typing

```
. predict sc*, scores
```

To ensure that `suest` generates the appropriate scores and therefore an appropriate VCE, you should not modify the values of the variables used in the models in between fitting the models and using `suest`.

2. Estimation should take place *without* the `vce(robust)` or `vce(cluster clustvar)` option. `suest` always computes the robust estimator of the (co)variance, and `suest` has a `vce(cluster clustvar)` option.

The within-model covariance matrices computed by `suest` are identical to those obtained by specifying a `vce(robust)` or `vce(cluster clustvar)` option during estimation. `suest`, however, also estimates the between-model covariances of parameter estimates.

3. Finally, the estimation results to be combined should be stored by `estimates store`; see [R] [estimates store](#).

After estimating and storing a series of estimation results, you are ready to combine the estimation results with `suest`,

```
. suest name1 [name2 ...] [, vce(cluster clustvar)]
```

and you can subsequently use postestimation commands, such as `test`, to test hypotheses. Here an important issue is how `suest` assigns names to the equations. If you specify one model *name*, the original equation names are left unchanged; otherwise, `suest` constructs new equation names. The coefficients of a single-equation model (such as `logit` and `poisson`) that was `estimate` stored under name *X* are collected under equation *X*. With a multiequation model stored under name *X*, `suest` prefixes *X\_* to an original equation name *eq*, forming equation name, *X\_eq*.

### □ Technical note

Earlier we said that standard errors from `suest` are identical to those obtained by specifying the `vce(robust)` option with each command individually. Thus if you fit a logistic model using `logit` with the `vce(robust)` option, you will get the same standard errors when you type

```
. suest .
```

directly after `logit` using the same data without the `vce(robust)` option.

This is not true for multiple estimation results when the estimation samples are not all the same. The standard errors from `suest` will be slightly smaller than those from individual model fits using the `vce(robust)` option because `suest` uses a larger number of observations to estimate the simultaneous (co)variance matrix. □

### □ Technical note

In rare circumstances, `suest` may have to truncate equation names to 32 characters. When equation names are not unique because of truncation, `suest` numbers the equations within models, using equations named *X\_#*. □

## Remarks on `regress`

`regress` (see [R] `regress`) does not include its ancillary parameter, the residual variance, in its coefficient vector and (co)variance matrix. Moreover, while the `score` option is allowed with `predict` after `regress`, a score variable is generated for the mean but not for the variance parameter. `suest` contains special code that assigns the equation name `mean` to the coefficients for the mean, adds the equation `lnvar` for the log variance, and computes the appropriate two score variables itself.

## Testing the assumption of the independence of irrelevant alternatives

The multinomial logit model and the closely related conditional logit model satisfy a probabilistic version of the assumption of the independence of irrelevant alternatives (IIA), implying that the ratio of the probabilities for two alternatives does not depend on what other alternatives are available. [Hausman and McFadden \(1984\)](#) proposed a test for this assumption that is implemented in the `hausman` command. The standard Hausman test has several limitations. First, the test statistic may be undefined because the estimated VCE does not satisfy the required asymptotic properties of the test. Second, the classic Hausman test applies only to the test of the equality of two estimators. Third, the test requires access to a fully efficient estimator; such an estimator may not be available, for example, if you are analyzing complex survey data. Using `suest` can overcome these three limitations.

### ▷ Example 1

In our first example, we follow the analysis of the type of health insurance reported in [\[R\] mlogit](#) and demonstrate the `hausman` command with the `suest/test` combination. We fit the full multinomial logit model for all three alternatives and two restricted multinomial models in which one alternative is excluded. After fitting each of these models, we give them a title with the `estimates title` command and then store them with the `estimates store` command.

```
. use https://www.stata-press.com/data/r19/sysdsn4
(Health insurance data)
. mlogit insure age male

Iteration 0: Log likelihood = -555.85446
Iteration 1: Log likelihood = -551.32973
Iteration 2: Log likelihood = -551.32802
Iteration 3: Log likelihood = -551.32802

Multinomial logistic regression Number of obs = 615
LR chi2(4) = 9.05
Prob > chi2 = 0.0598
Pseudo R2 = 0.0081

Log likelihood = -551.32802
```

| insure    | Coefficient    | Std. err. | z     | P> z  | [95% conf. interval] |           |

Legend: \* p<0.05; \*\* p<0.01; \*\*\* p<0.001

Comparing the coefficients between models does not suggest substantial differences. We can formally test that coefficients are the same for the full model m1 and the restricted models m2 and m3 by using the `hausman` command. `hausman` expects the models to be specified in the order “always consistent” first and “efficient under  $H_0$ ” second.

```
. hausman m2 m1, alleqs constant
```

|       | Coefficients |           | (b-B)<br>Difference | sqrt(diag(V_b-V_B))<br>Std. err. |
|-------|--------------|-----------|---------------------|----------------------------------|
|       | (b)<br>m2    | (B)<br>m1 |                     |                                  |
| age   | -.0101521    | -.0100251 | -.0001269           | .                                |
| male  | .5144003     | .5095747  | .0048256            | .0123338                         |
| _cons | .2678043     | .2633838  | .0044205            | .                                |

b = Consistent under  $H_0$  and  $H_a$ ; obtained from `mlogit`.

B = Inconsistent under  $H_a$ , efficient under  $H_0$ ; obtained from `mlogit`.

Test of  $H_0$ : Difference in coefficients not systematic

$$\text{chi2}(3) = (b-B)' [(V_b-V_B)^{-1}] (b-B) = 0.08$$

Prob > chi2 = 0.9944

(V\_b-V\_B is not positive definite)

```
. hausman m3 m1, alleqs constant
```

|       | Coefficients |           | (b-B)<br>Difference | sqrt(diag(V_b-V_B))<br>Std. err. |
|-------|--------------|-----------|---------------------|----------------------------------|
|       | (b)<br>m3    | (B)<br>m1 |                     |                                  |
| age   | -.0041055    | -.0051925 | .001087             | .0021355                         |

| _cons | -1.801774    | -1.756843 | -.0449311           | .1333421                         |

b = Consistent under H0 and Ha; obtained from **mlogit**.  
 B = Inconsistent under Ha, efficient under H0; obtained from **mlogit**.

Test of H0: Difference in coefficients not systematic

$$\text{chi2}(3) = (b-B)' [(V_b-V_B)^{-1}] (b-B) = -0.18$$

Warning: chi2 < 0 ==> model fitted on these data fails to meet the asymptotic assumptions of the Hausman test; see **suest** for a generalized test.

According to the test of m1 against m2, we cannot reject the hypothesis that the coefficients of m1 and m2 are the same. The second Hausman test is not well defined—something that happens fairly often. The problem is due to the estimator of the variance  $V(b-B)$  as  $V(b)-V(B)$ , which is a feasible estimator only asymptotically. Here it simply is not a proper variance matrix, and the Hausman test becomes undefined.

**suest** m1 m2 estimates the simultaneous (co)variance of the coefficients of models m1 and m2. Although **suest** is technically a postestimation command, it acts like an estimation command in that it stores the simultaneous coefficients in  $e(b)$  and the full (co)variance matrix in  $e(V)$ . We could have used the **estat vce** command to display the full (co)variance matrix to show that the cross-model covariances were indeed estimated. Typically, we would not have a direct interest in  $e(V)$ .

```
. suest m1 m2, noomitted
```

suest created equation names by combining the name under which we stored the results using estimates store with the original equation names. Thus, in the simultaneous estimation result, equation Prepaid originating in model m1 is named m1\_Prepaid. According to the McFadden–Hausman specification of a test for IIA, the coefficients of the equations m1\_PrePaid and m2\_PrePaid should be equal. This equality can be tested easily with the test command. The cons option specifies that the intercept \_cons be included in the test.

```
. test [m1_Prepaid = m2_Prepaid], cons
(1) [m1_Prepaid]age - [m2_Prepaid]age = 0
(2) [m1_Prepaid]male - [m2_Prepaid]male = 0
(3) [m1_Prepaid]_cons - [m2_Prepaid]_cons = 0
 chi2(3) = 0.89
 Prob > chi2 = 0.8266
```

The Hausman test via suest is comparable with that computed by hausman, but they use different estimators of the variance of the difference of the estimates. The hausman command estimates  $V(b - B)$  by  $V(b) - V(B)$ , whereas suest estimates  $V(b - B)$  by  $V(b) - \text{cov}(b, B) - \text{cov}(B, b) + V(B)$ . One advantage of the second estimator is that it is always admissible, so the resulting test is always well defined. This quality is illustrated in the Hausman-type test of IIA comparing models m1 and m3.

```

Although the classic Hausman test computed by hausman is not defined here, the suest-based test is just fine. We cannot reject the equality of the common coefficients across m1 and m3.

A second advantage of the `suest` approach is that we can estimate the (co)variance matrix of the multivariate normal distribution of the estimators of the three models `m1`, `m2`, and `m3` and test that the common coefficients are equal.

Again, we do not find evidence against the correct specification of the multinomial logit for type of insurance. The classic Hausman test assumes that one of the estimators (named `B` in `hausman`) is efficient, that is, it has minimal (asymptotic) variance. This assumption ensures that  $V(b) - V(B)$  is an admissible, viable estimator for  $V(b - B)$ . The assumption that we have an efficient estimator is a restrictive one. It is violated, for instance, if our data are clustered. We want to adjust for clustering via a `vce(cluster clustvar)` option by requesting the cluster-adjusted sandwich estimator of variance. Consequently, in such a case, `hausman` cannot be used. This problem does not exist with the `suest`

version of the Hausman test. To illustrate this feature, we suppose that the data are clustered by city—we constructed an imaginary variable `cityid` for this illustration. If we plan to apply `suest`, we would not specify the `vce(cluster clustvar)` option at the time of estimation. `suest` has a `vce(cluster clustvar)` option. Thus, we do not need to refit the models; we can call `suest` and `test` right away.

```
. suest m1 m2, vce(cluster cityid) noomitted

(2) [m1_Prepaid]male - [m2_Prepaid]male = 0
(3) [m1_Prepaid]_cons - [m2_Prepaid]_cons = 0
 chi2(3) = 0.79
 Prob > chi2 = 0.8529
```

`suest` provides some descriptive information about the clustering on `cityid`. Like any other estimation command, `suest` informs us that the standard errors are adjusted for clustering. The Hausman-type test obtained from the `test` command uses a simultaneous (co)variance of `m1` and `m2` appropriately adjusted for clustering. In this example, we still do not have reason to conclude that the multinomial logit model in this application is misspecified, that is, that IIA is violated.

◀

The multinomial logistic regression model is a special case of the conditional logistic regression model; see [R] [clogit](#). Like the multinomial logistic regression model, the conditional logistic regression model also makes the IIA assumption. Consider an example, introduced in [CM] [cmclogit](#), in which the demand for American, Japanese, and European cars is modeled in terms of the number of local dealers of the respective brands and of some individual attributes incorporated in interaction with the nationality of cars. We want to perform a Hausman-type test for IIA comparing the decision between all nationalities with the decision between non-American cars. The following code fragment demonstrates how to conduct a Hausman test for IIA via `suest` in this case.

```

. clogit choice japan europe maleJap maleEur incJap incEur dealer, group(id)
. estimates store allcars
. clogit choice japan maleJap incJap dealer if car!=1 , group(id)
. estimates store foreign
. suest allcars foreign
. test [allcars_choice=foreign_choice], common

```

## Testing proportionality

The applications of `suest` that we have discussed so far concern Hausman-type tests for misspecification. To test such a hypothesis, we compared two estimators that have the same probability limit if the hypothesis holds true, but otherwise have different limits. We may also want to compare the coefficients of models (estimators) for other substantive reasons. Although we most often want to test whether coefficients differ between models or estimators, we may occasionally want to test other constraints (see [Hausman and Ruud \[1987\]](#)).

### ► Example 2

In this example, using simulated labor market data for siblings, we consider two dependent variables, income (`inc`) and whether a person was promoted in the last year (`promo`). We apply familiar economic arguments regarding human capital, according to which employees have a higher income and a higher probability of being promoted, by having more human capital. Human capital is acquired through formal education (`edu`) and on-the-job training experience (`exp`). We study whether income and promotion are “two sides of the same coin”, that is, whether they reflect a common latent variable, “human capital”. Accordingly, we want to compare the effects of different aspects of human capital on different outcome variables.

We estimate fairly simple labor market equations. The income model is estimated with `regress`, and the estimation results are stored under the name `Inc`.

```

. use https://www.stata-press.com/data/r19/income
. regress inc edu exp male

```

| Source   | SS         | df  | MS         | Number of obs | = | 277    |
|----------|------------|-----|------------|---------------|---|--------|
| Model    | 2058.44672 | 3   | 686.148908 | F(3, 273)     | = | 42.34  |
| Residual | 4424.05183 | 273 | 16.2053181 | Prob > F      | = | 0.0000 |
|          |            |     |            | R-squared     | = | 0.3175 |
|          |            |     |            | Adj R-squared | = | 0.3100 |
| Total    | 6482.49855 | 276 | 23.4873136 | Root MSE      | = | 4.0256 |

| inc   | Coefficient | Std. err. | t    | P> t  | [95% conf. interval] |
|-------|-------------|-----------|------|-------|----------------------|
| edu   | 2.213707    | .243247   | 9.10 | 0.000 | 1.734828 2.692585    |
| exp   | 1.47293     | .231044   | 6.38 | 0.000 | 1.018076 1.927785    |
| male  | .5381153    | .4949466  | 1.09 | 0.278 | -.436282 1.512513    |
| _cons | 1.255497    | .3115808  | 4.03 | 0.000 | .642091 1.868904     |

```

. est store Inc

```

Being sibling data, the observations are clustered on family of origin, `famid`. In the estimation of the regression parameters, we did not specify a `vce(cluster famid)` option to adjust standard errors for clustering on family (`famid`). Thus, the standard errors reported by `regress` are potentially flawed. This problem will, however, be corrected by specifying a `vce(cluster clustvar)` option with `suest`.

Next, we estimate the promotion equation with probit and again store the results under an appropriate name.

```
. probit promo edu exp male, nolog
Probit regression
Log likelihood = -158.43888
Number of obs = 277
LR chi2(3) = 49.76
Prob > chi2 = 0.0000
Pseudo R2 = 0.1357
```

| promo | Coefficient | Std. err. | z     | P> z  | [95% conf. interval] |           |
|-------|-------------|-----------|-------|-------|----------------------|-----------|
| edu   | .4593002    | .0898537  | 5.11  | 0.000 | .2831901             | .6354102  |
| exp   | .3593023    | .0805774  | 4.46  | 0.000 | .2013735             | .5172312  |
| male  | .2079983    | .1656413  | 1.26  | 0.209 | -.1166527            | .5326494  |
| _cons | -.464622    | .1088166  | -4.27 | 0.000 | -.6778985            | -.2513454 |

```
. est store Promo
```

The coefficients in the income and promotion equations definitely seem to be different. However, because the scales of the two variables are different, we would not expect the coefficients to be equal. The correct hypothesis here is that the proportionality of the coefficients of the two models, apart from the constant, are equal. This formulation would still reflect that the relative effects of the different aspects of human capital do not differ between the dependent variables. We can obtain a nonlinear Wald test for the hypothesis of proportionality by using the `testnl` command on the combined estimation results of the two estimators. Thus, we first have to form the combined estimation results. At this point, we specify the `vce(cluster famid)` option to adjust for the clustering of observations on `famid`.

```
. suest Inc Promo, vce(cluster famid)
Simultaneous results for Inc, Promo
(Std. err. adjusted for 135 clusters in famid)
Number of obs = 277
```

|             | Coefficient | Robust std. err. | z     | P> z  | [95% conf. interval] |           |
|-------------|-------------|------------------|-------|-------|----------------------|-----------|
| Inc_mean    |             |                  |       |       |                      |           |
| edu         | 2.213707    | .2483907         | 8.91  | 0.000 | 1.72687              | 2.700543  |
| exp         | 1.47293     | .1890583         | 7.79  | 0.000 | 1.102383             | 1.843478  |
| male        | .5381153    | .4979227         | 1.08  | 0.280 | -.4377952            | 1.514026  |
| _cons       | 1.255497    | .3374977         | 3.72  | 0.000 | .594014              | 1.916981  |
| Inc_lvar    |             |                  |       |       |                      |           |
| _cons       | 2.785339    | .079597          | 34.99 | 0.000 | 2.629332             | 2.941347  |
| Promo_promo |             |                  |       |       |                      |           |
| edu         | .4593002    | .0886982         | 5.18  | 0.000 | .2854549             | .6331454  |
| exp         | .3593023    | .079772          | 4.50  | 0.000 | .2029522             | .5156525  |
| male        | .2079983    | .1691053         | 1.23  | 0.219 | -.1234419            | .5394386  |
| _cons       | -.464622    | .1042169         | -4.46 | 0.000 | -.6688833            | -.2603607 |

The standard errors reported by `suest` are identical to those reported by the respective estimation commands when invoked with the `vce(cluster famid)` option. We are now ready to test for proportionality:

$$H_0 : \frac{\beta_{\text{edu}}^{\text{Income}}}{\beta_{\text{edu}}^{\text{Promotion}}} = \frac{\beta_{\text{exp}}^{\text{Income}}}{\beta_{\text{exp}}^{\text{Promotion}}} = \frac{\beta_{\text{male}}^{\text{Income}}}{\beta_{\text{male}}^{\text{Promotion}}}$$

It is straightforward to translate this into syntax suitable for `testnl`, recalling that the coefficient of variable  $v$  in equation  $eq$  is denoted by  $[eq]v$ .

```
. testnl [Inc_mean]edu/[Promo_promo]edu =
> [Inc_mean]exp/[Promo_promo]exp =
> [Inc_mean]male/[Promo_promo]male
(1) [Inc_mean]edu/[Promo_promo]edu = [Inc_mean]exp/[Promo_promo]exp
(2) [Inc_mean]edu/[Promo_promo]edu = [Inc_mean]male/[Promo_promo]male
 chi2(2) = 0.61
 Prob > chi2 = 0.7385
```

From the evidence, we fail to reject the hypotheses that the coefficients of the income and promotion equations are proportional. Thus, it is not unreasonable to assume that income and promotion can be explained by the same latent variable, “labor market success”.

A disadvantage of the nonlinear Wald test is that it is not invariant with respect to representation: a Wald test for a mathematically equivalent formulation of the nonlinear constraint usually leads to a different test result. An equivalent formulation of the proportionality hypothesis is

$$H_0 : \begin{aligned} \beta_{\text{edu}}^{\text{Income}} \beta_{\text{exp}}^{\text{Promotion}} &= \beta_{\text{edu}}^{\text{Promotion}} \beta_{\text{exp}}^{\text{Income}} & \text{and} \\ \beta_{\text{edu}}^{\text{Income}} \beta_{\text{male}}^{\text{Promotion}} &= \beta_{\text{edu}}^{\text{Promotion}} \beta_{\text{male}}^{\text{Income}} \end{aligned}$$

This formulation is “more linear” in the coefficients. The asymptotic  $\chi^2$  distribution of the nonlinear Wald statistic can be expected to be more accurate for this representation.

```
. testnl ([Inc_mean]edu*[Promo_promo]exp = [Inc_mean]exp*[Promo_promo]edu)
> ([Inc_mean]edu*[Promo_promo]male = [Inc_mean]male*[Promo_promo]edu)
(1) [Inc_mean]edu*[Promo_promo]exp = [Inc_mean]exp*[Promo_promo]edu
(2) [Inc_mean]edu*[Promo_promo]male = [Inc_mean]male*[Promo_promo]edu
 chi2(2) = 0.46
 Prob > chi2 = 0.7936
```

Here the two representations lead to similar test statistics and  $p$ -values. As before, we fail to reject the hypothesis of proportionality of the coefficients of the two models.

◀

## Testing cross-model hypotheses

### ▷ Example 3

In this example, we demonstrate how some cross-model hypotheses can be tested using the facilities already available in most estimation commands. This demonstration will explain the intricate relationship between the cluster adjustment of the robust estimator of variance and the `suest` command. It will also be made clear that a new facility is required to perform more general cross-model testing.

We want to test whether the effect of  $x_1$  on the binary variable  $y_1$  is the same as the effect of  $x_2$  on the binary  $y_2$ ; see [Clogg, Petkova, and Haritou \(1995\)](#). In this setting,  $x_1$  may equal  $x_2$ , and  $y_1$  may equal  $y_2$ . We assume that logistic regression models can be used to model the responses, and for simplicity, we ignore further predictor variables in these models. If the two logit models are fit on independent samples so that the estimators are (stochastically) independent, a Wald test for `_b[x1] = _b[x2]` rejects the null hypothesis if

$$\frac{\hat{b}(x_1) - \hat{b}(x_2)}{\left[ \hat{\sigma}^2 \{ \hat{b}(x_1) \} + \hat{\sigma}^2 \{ \hat{b}(x_2) \} \right]^{1/2}}$$

is larger than the appropriate  $\chi_1^2$  threshold. If the models are fit on the *same* sample (or on dependent samples), so that the estimators are stochastically dependent, the above test that ignores the covariance between the estimators is not appropriate.

It is instructive to see how this problem can be tackled by “stacking” data. In the stacked format, we doubled the number of observations. The dependent variable is  $y_1$  in the first half of the data and is  $y_2$  in the second half of the data. The predictor variable  $z_1$  is set to  $x_1$  in the first half of the expanded data and to 0 in the rest. Similarly,  $z_2$  is 0 in the first half and  $x_2$  in the second half. The following diagram illustrates the transformation, in the terminology of the `reshape` command, from wide to long format.

$$\left( \begin{array}{ccccc} \text{id} & y_1 & y_2 & x_1 & x_2 \\ 1 & y_{11} & y_{21} & x_{11} & x_{21} \\ 2 & y_{12} & y_{22} & x_{12} & x_{22} \\ 3 & y_{13} & y_{23} & x_{13} & x_{23} \end{array} \right) \Rightarrow \left( \begin{array}{ccccc} \text{id} & y & z_1 & z_2 & \text{model} \\ 1 & y_{11} & x_{11} & 0 & 1 \\ 2 & y_{12} & x_{12} & 0 & 1 \\ 3 & y_{13} & x_{13} & 0 & 1 \\ 1 & y_{21} & 0 & x_{21} & 2 \\ 2 & y_{22} & 0 & x_{22} & 2 \\ 3 & y_{23} & 0 & x_{23} & 2 \end{array} \right)$$

The observations in the long-format data organization are *clustered* on the original subjects and are identified with the identifier `id`. The clustering on `id` has to be accounted for when fitting a simultaneous model. The simplest way to deal with clustering is to use the cluster adjustment of the robust or sandwich estimator; see [\[P\] `\_robust`](#). The data manipulation can be accomplished easily with the `stack` command; see [\[D\] `stack`](#). Subsequently, we fit a simultaneous logit model and perform a Wald test for the hypothesis that the coefficients of `z1` and `z2` are the same. A full setup to obtain the cross-model Wald test could then be as follows:

```
. generate zero = 0 // a variable that is always 0
. generate one = 1 // a variable that is always 1
. generate two = 2 // a variable that is always 2
. stack id y1 x1 zero one id y2 zero x2 two, into(id y z1 z2 model)
. generate model2 = (model==2)
. logit y model2 z1 z2, vce(cluster id)
. test _b[z1] = _b[z2]
```

The coefficient of `z1` represents the effect of `x1` on `y1`, and similarly, `z2` for the effect of `x2` on `y2`. The variable `model2` is a dummy for the “second model”, which is included to allow the intercept in the second model to differ from that in the first model. The estimates of the coefficient of `z1` and its standard error in the combined model are the same as the estimates of the coefficient of `z1` and its standard error if we fit the model on the unstacked data.

```
. logit y1 x1, vce(robust)
```

The `vce(cluster clustvar)` option specified with the `logit` command for the stacked data ensures that the covariances of `_b[z1]` and `_b[z2]` are indeed estimated. This estimation ensures that the Wald test for the equality of the coefficients is correct. If we had not specified the `vce(cluster clustvar)` option, the (co)variance matrix of the coefficients would have been block-diagonal; that is, the covariances of `_b[z1]` and `_b[z2]` would have been 0. Then, `test` would have effectively used the invalid formula for the Wald test for two independent samples.

In this example, the two logit models were fit on the same data. The same setup would apply, without modification, when the two logit models were fit on overlapping data that resulted, for instance, if the `y` or `x` variables were missing in some observations.

The `suest` command allows us to obtain the above Wald test more efficiently by avoiding the data manipulation, obviating the need to fit a model with twice the number of coefficients. The test statistic produced by the above code fragment is *identical* to that obtained via `suest` on the original (unstacked) data:

```
. logit y1 x1
. estimates store M1
. logit y2 x2
. estimates store M2
. suest M1 M2
. test [M1]x1=[M2]x2
```

The stacking method can be applied not only to the testing of cross-model hypotheses for `logit` models but also to any estimation command that supports the `vce(cluster clustvar)` option. The stacking approach clearly generalizes to stacking more than two logit or other models, testing more general linear hypotheses, and testing nonlinear cross-model hypotheses (see [R] [testnl](#)). In all of these cases, `suest` would yield identical statistical results but at smaller costs in terms of data management, computer storage, and computer time.

Is `suest` nothing but a convenience command? No, there are two disadvantages to the stacking method, both of which are resolved via `suest`. First, if the models include ancillary parameters (in a regression model, the residual variance; in an ordinal response model, the cutpoints; and in lognormal survival-time regression, the time scale parameter), these parameters are constrained to be equal between the stacked models. In `suest`, this constraint is relaxed. Second, the stacking method does not generalize to compare different statistical models, such as a probit model and a regression model. As demonstrated in the previous section, `suest` can deal with this situation.

## Stored results

suest stores the following in `e()`:

### Scalars

## Methods and formulas

The estimation of the simultaneous (co)variance of a series of  $k$  estimators is a nonstandard application of the sandwich estimator, as implemented by the command `[P] _robust`. You may want to read this manual entry before reading further.

The starting point is that we have fit  $k$  different models on the *same* data—partially overlapping or nonoverlapping data are special cases. We want to derive the *simultaneous* distribution of these  $k$  estimators, for instance, to test a cross-estimator hypothesis  $H_0$ . As in the framework of Hausman testing,  $H_0$  will often be of the form that different estimators have the same probability limit under some hypothesis, while the estimators have different limits if the hypothesis is violated.

We consider (vector) estimators  $\widehat{\beta}_i$  to be defined as “the” solution of the estimation equations  $\mathbf{G}_i$ ,

$$\mathbf{G}_i(\mathbf{b}_i) = \sum_j w_{ij} \mathbf{u}_{ij}(\mathbf{b}_i) = \mathbf{0}, \quad i = 1, \dots, k$$

We refer to the  $\mathbf{u}_{ij}$  as the “scores”. Specifying some weights  $w_{ij} = 0$  trivially accommodates for partially overlapping or even disjointed data. Under “suitable regularity conditions” (see White [1982; 1996] for details), the  $\widehat{\beta}_i$  are asymptotically normally distributed, with the variance estimated consistently by the sandwich estimator

$$V_i = \text{Var}(\widehat{\beta}_i) = \mathbf{D}_i^{-1} \sum_j w_{ij} \mathbf{u}_{ij} \mathbf{u}'_{ij} \mathbf{D}_i^{-1}$$

where  $\mathbf{D}_i$  is the Jacobian of  $\mathbf{G}_i$  evaluated at  $\widehat{\beta}_i$ . In the context of maximum likelihood estimation,  $\mathbf{D}_i$  can be estimated consistently by (minus) the Hessian of the log likelihood or by the Fisher information matrix. If the model is also well specified, the sandwiched term  $(\sum_j w_{ij} \mathbf{u}_{ij} \mathbf{u}'_{ij})$  converges in probability to  $\mathbf{D}_i$ , so  $V_i$  may be consistently estimated by  $\mathbf{D}_i^{-1}$ .

To derive the simultaneous distribution of the estimators, we consider the “stacked” estimation equation,

$$\mathbf{G}(\widehat{\boldsymbol{\beta}}) = \left\{ \mathbf{G}_1(\widehat{\boldsymbol{\beta}}_1)' \quad \mathbf{G}_1(\widehat{\boldsymbol{\beta}}_2)' \quad \dots \quad \mathbf{G}_k(\widehat{\boldsymbol{\beta}}_k)' \right\}' = \mathbf{0}$$

Under “suitable regularity conditions” (see White [1996] for details),  $\widehat{\boldsymbol{\beta}}$  is asymptotically *jointly* normally distributed. The Jacobian and scores of the simultaneous equation are easily expressed in the Jacobian and scores of the separate equations. The Jacobian of  $\mathbf{G}$ ,

$$\mathbf{D}(\widehat{\boldsymbol{\beta}}) = \left. \frac{d\mathbf{G}(\boldsymbol{\beta})}{d\boldsymbol{\beta}} \right|_{\boldsymbol{\beta}=\widehat{\boldsymbol{\beta}}}$$

is block diagonal with blocks  $\mathbf{D}_1, \dots, \mathbf{D}_k$ . The inverse of  $\mathbf{D}(\widehat{\boldsymbol{\beta}})$  is again block diagonal, with the inverses of  $\mathbf{D}_i$  on the diagonal. The scores  $\mathbf{u}$  of  $\mathbf{G}$  are simply obtained as the *concatenated* scores of the separate equations:

$$\mathbf{u}_j = (\mathbf{u}'_{1j} \quad \mathbf{u}'_{2j} \quad \dots \quad \mathbf{u}'_{kj})'$$

Out-of-sample (that is, where  $w_{ij} = 0$ ) values of the score variables are defined as 0 (thus we drop the  $i$  subscript from the common weight variable). The sandwich estimator for the asymptotic variance of  $\widehat{\boldsymbol{\beta}}$  reads

$$V = \text{Var}(\widehat{\boldsymbol{\beta}}) = \mathbf{D}(\widehat{\boldsymbol{\beta}})^{-1} \left( \sum_j w_j \mathbf{u}_j \mathbf{u}'_j \right) \mathbf{D}(\widehat{\boldsymbol{\beta}})^{-1}$$

Taking a “partitioned” look at this expression, we see that  $V(\widehat{\boldsymbol{\beta}}_i)$  is estimated by

$$\mathbf{D}_i^{-1} \left( \sum_j w_j \mathbf{u}_{ij} \mathbf{u}'_{ij} \right) \mathbf{D}_i^{-1}$$

which is, yet again, the familiar sandwich estimator for  $\widehat{\boldsymbol{\beta}}_i$  based on the separate estimation equation  $\mathbf{G}_i$ . Thus, considering several estimators simultaneously in this way does not affect the estimators of the asymptotic variances of these estimators. However, as a bonus of stacking, we obtained a sandwich-type estimate of the *covariance*  $V_{ih}$  of estimators  $\widehat{\boldsymbol{\beta}}_i$  and  $\widehat{\boldsymbol{\beta}}_h$ ,

$$V_{ih} = \text{Cov}(\widehat{\boldsymbol{\beta}}_i, \widehat{\boldsymbol{\beta}}_h) = \mathbf{D}_i^{-1} \left( \sum_j w_j \mathbf{u}_{ij} \mathbf{u}'_{hj} \right) \mathbf{D}_h^{-1}$$

which is also obtained by White (1982).

This estimator for the covariance of estimators is an application of the cluster modification of the sandwich estimator proposed by Rogers (1993). Consider the stacked data format as discussed in the logit example, and assume that Stata would be able to estimate a “stacked model” in which different models apply to different observations, for example, a probit model for the first half, a regression model for the second half, and a one-to-one cluster relation between the first and second half. If there are no common parameters to both models, the score statistics of parameters for the stacked models are zero in the half of the data in which they do not occur. In Rogers’s method, we have to sum the score statistics over the observations within a cluster. This step boils down to concatenating the score statistics at the level of the cluster.

We compare the sandwich estimator of the (co)variance  $V_{12}$  of two estimators with the estimator of variance  $\tilde{V}_{12}$  applied in the classic Hausman test. Hausman (1978) showed that if  $\widehat{\beta}_1$  is consistent under  $H_0$  and  $\widehat{\beta}_2$  is efficient under  $H_0$ , then asymptotically

$$\text{Cov}(\widehat{\beta}_1, \widehat{\beta}_2) = \text{Var}(\widehat{\beta}_2)$$

and so  $\text{var}(\widehat{\beta}_1 - \widehat{\beta}_2)$  is consistently estimated by  $V_1 - V_2$ .

## Acknowledgment

suest was written by Jeroen Weesie of the Department of Sociology at Utrecht University, The Netherlands. This research is supported by grant PGS 50-370 by The Netherlands Organization for Scientific Research.

An earlier version of suest was published in the *Stata Technical Bulletin* (1999). The current version of suest is not backward compatible with the 1999 version because of the introduction of new ways to manage estimation results via the `estimates` command.

## Description

`summarize` calculates and displays a variety of univariate summary statistics. If no *varlist* is specified, summary statistics are calculated for all the variables in the dataset.

## Quick start

Basic summary statistics for continuous variable `v1`

```
summarize v1
```

Same as above, and include `v2` and `v3`

```
summarize v1-v3
```

Same as above, and provide additional detail about the distribution

```
summarize v1-v3, detail
```

Summary statistics reported separately for each level of `catvar`

```
by catvar: summarize v1
```

With frequency weight `wvar`

```
summarize v1 [fweight=wvar]
```

## Menu

Statistics > Summaries, tables, and tests > Summary and descriptive statistics > Summary statistics

## Syntax

```
summarize [varlist] [if] [in] [weight] [, options]
```

| <i>options</i> | Description |
|----------------|-------------|
|----------------|-------------|

Main

|                              |                                                                      |
|------------------------------|----------------------------------------------------------------------|
| <code>detail</code>          | display additional statistics                                        |
| <code>meanonly</code>        | suppress the display; calculate only the mean; programmer's option   |
| <code>format</code>          | use variable's display format                                        |
| <code>separator(#)</code>    | draw separator line after every # variables; default is separator(5) |
| <code>display_options</code> | control spacing, line width, and base and empty cells                |

*varlist* may contain factor variables; see [\[U\] 11.4.3 Factor variables](#).

*varlist* may contain time-series operators; see [\[U\] 11.4.4 Time-series varlists](#).

`by`, `collect`, `rolling`, and `statsby` are allowed; see [\[U\] 11.1.10 Prefix commands](#).

`aweight`s, `fweight`s, and `iweight`s are allowed. However, `iweight`s may not be used with the `detail` option; see [\[U\] 11.1.6 weight](#).

## Options

Main

`detail` produces additional statistics, including skewness, kurtosis, the four smallest and four largest values, and various percentiles.

`meanonly`, which is allowed only when `detail` is not specified, suppresses the display of results and calculation of the variance. Ado-file writers will find this useful for fast calls.

`format` requests that the summary statistics be displayed using the display formats associated with the variables rather than the default `g` display format; see [\[U\] 12.5 Formats: Controlling how data are displayed](#).

`separator(#)` specifies how often to insert separation lines into the output. The default is `separator(5)`, meaning that a line is drawn after every five variables. `separator(10)` would draw a line after every 10 variables. `separator(0)` suppresses the separation line.

`display_options`: `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap(#)`, and `fvwrapon(style)`; see [\[R\] Estimation options](#).

## Remarks and examples

`summarize` can produce two different sets of summary statistics. Without the `detail` option, the number of nonmissing observations, the mean and standard deviation, and the minimum and maximum values are presented. With `detail`, the same information is presented along with the variance, skewness, and kurtosis; the four smallest and four largest values; and the 1st, 5th, 10th, 25th, 50th (median), 75th, 90th, 95th, and 99th percentiles.

Also see [\[R\] ci](#) for calculating the standard error and confidence intervals of the mean.

### ▷ Example 1: summarize with the separator() option

We have data containing information on various automobiles, among which is the variable `mpg`, the mileage rating. We can obtain a quick summary of the `mpg` variable by typing

```
. use https://www.stata-press.com/data/r19/auto2
(1978 automobile data)
. summarize mpg
```

| Variable | Obs | Mean    | Std. dev. | Min | Max |
|----------|-----|---------|-----------|-----|-----|
| mpg      | 74  | 21.2973 | 5.785503  | 12  | 41  |

We see that we have 74 observations. The mean of `mpg` is 21.3 miles per gallon, and the standard deviation is 5.79. The minimum is 12, and the maximum is 41.

If we had not specified the variable (or variables) we wanted to summarize, we would have obtained summary statistics on all the variables in the dataset:

```
. summarize, separator(4)
```

| Variable     | Obs | Mean     | Std. dev. | Min  | Max   |
|--------------|-----|----------|-----------|------|-------|
| make         | 0   |          |           |      |       |
| price        | 74  | 6165.257 | 2949.496  | 3291 | 15906 |
| mpg          | 74  | 21.2973  | 5.785503  | 12   | 41    |
| rep78        | 69  | 3.405797 | .9899323  | 1    | 5     |
| headroom     | 74  | 2.993243 | .8459948  | 1.5  | 5     |
| trunk        | 74  | 13.75676 | 4.277404  | 5    | 23    |
| weight       | 74  | 3019.459 | 777.1936  | 1760 | 4840  |
| length       | 74  | 187.9324 | 22.26634  | 142  | 233   |
| turn         | 74  | 39.64865 | 4.399354  | 31   | 51    |
| displacement | 74  | 197.2973 | 91.83722  | 79   | 425   |
| gear_ratio   | 74  | 3.014865 | .4562871  | 2.19 | 3.89  |
| foreign      | 74  | .2972973 | .4601885  | 0    | 1     |

There are only 69 observations on `rep78`, so some of the observations are missing. There are no observations on `make` because it is a string variable.

The idea of the mean is quite old (Plackett 1958), but its extension to a scheme of moment-based measures was not done until the end of the 19th century. Between 1893 and 1905, Pearson discussed and named the standard deviation, skewness, and kurtosis, but he was not the first to use any of these. Thiele (1889), in contrast, had earlier firmly grasped the notion that the  $m_r$  provide a systematic basis for discussing distributions. However, even earlier anticipations can also be found. For example, Euler in 1778 used  $m_2$  and  $m_3$  in passing in a treatment of estimation (Hald 1998, 87), but seemingly did not build on that.

Similarly, the idea of the median is quite old. The history of the interquartile range is tangled up with that of the probable error, a long-popular measure. Extending this in various ways to a more general approach based on quantiles (to use a later term) occurred to several people in the nineteenth century. Galton (1875) is a nice example, particularly because he seems so close to the key idea of the quantiles as a function, which took another century to reemerge strongly.

Thorvald Nicolai Thiele (1838–1910) was a Danish scientist who worked in astronomy, mathematics, actuarial science, and statistics. He made many pioneering contributions to statistics, several of which were overlooked until recently. Thiele advocated graphical analysis of residuals checking for trends, symmetry of distributions, and changes of sign, and he even warned against overinterpreting such graphs.

### ▷ Example 2: summarize with the detail option

The `detail` option provides all the information of a normal `summarize` and more. The format of the output also differs, as shown here:

```
. summarize mpg, detail
```

| Mileage (mpg) |    |          |             |          |
|---------------|----|----------|-------------|----------|
| Percentiles   |    | Smallest |             |          |
| 1%            | 12 | 12       |             |          |
| 5%            | 14 | 12       |             |          |
| 10%           | 14 | 14       | Obs         | 74       |
| 25%           | 18 | 14       | Sum of wgt. | 74       |
| 50%           | 20 |          | Mean        | 21.2973  |
|               |    | Largest  | Std. dev.   | 5.785503 |
| 75%           | 25 | 34       |             |          |
| 90%           | 29 | 35       | Variance    | 33.47205 |
| 95%           | 34 | 35       | Skewness    | .9487176 |
| 99%           | 41 | 41       | Kurtosis    | 3.975005 |

As in the [previous example](#), we see that the mean of `mpg` is 21.3 miles per gallon and that the standard deviation is 5.79. We also see the various percentiles. The median of `mpg` (the 50th percentile) is 20 miles per gallon. The 25th percentile is 18, and the 75th percentile is 25.

When we performed `summarize`, we learned that the minimum and maximum were 12 and 41, respectively. We now see that the four smallest values in our dataset are 12, 12, 14, and 14. The four largest values are 34, 35, 35, and 41. The skewness of the distribution is 0.95, and the kurtosis is 3.98. (A normal distribution would have a skewness of 0 and a kurtosis of 3.)

*Skewness* is a measure of the lack of symmetry of a distribution. If the distribution is symmetric, the coefficient of skewness is 0. If the coefficient is negative, the median is usually greater than the mean and the distribution is said to be skewed left. If the coefficient is positive, the median is usually less than the mean and the distribution is said to be skewed right. *Kurtosis* (from the Greek *kyrtosis*, meaning curvature) is a measure of peakedness of a distribution. The smaller the coefficient of kurtosis, the flatter the distribution. The normal distribution has a coefficient of kurtosis of 3 and provides a convenient benchmark.

## □ Technical note

The convention of calculating the median of an even number of values by averaging the central two order statistics is of long standing. (That is, given 8 values, average the 4th and 5th smallest values, or given 42, average the 21st and 22nd smallest.) [Stigler \(1977\)](#) filled a much-needed gap in the literature by naming such paired central order statistics as “comedians”, although it remains unclear how far he was joking.

## ▷ Example 3: summarize with the by prefix

`summarize` can usefully be combined with the `by varlist:` prefix. In our dataset, we have a variable, `foreign`, that distinguishes foreign and domestic cars. We can obtain summaries of `mpg` and `weight` within each subgroup by typing

```
. by foreign: summarize mpg weight
```

```
-> foreign = Domestic
```

| Variable | Obs | Mean     | Std. dev. | Min  | Max  |
|----------|-----|----------|-----------|------|------|
| mpg      | 52  | 19.82692 | 4.743297  | 12   | 34   |
| weight   | 52  | 3317.115 | 695.3637  | 1800 | 4840 |

```
-> foreign = Foreign
```

| Variable | Obs | Mean     | Std. dev. | Min  | Max  |
|----------|-----|----------|-----------|------|------|
| mpg      | 22  | 24.77273 | 6.611187  | 14   | 41   |
| weight   | 22  | 2315.909 | 433.0035  | 1760 | 3420 |

Domestic cars in our dataset average 19.8 miles per gallon, whereas foreign cars average 24.8.

Because *by varlist*: can be combined with summarize, it can also be combined with summarize, detail:

```
. by foreign: summarize mpg, detail
```

```
-> foreign = Domestic
```

| Mileage (mpg) |      |          |             |          |
|---------------|------|----------|-------------|----------|
| Percentiles   |      | Smallest |             |          |
| 1%            | 12   | 12       |             |          |
| 5%            | 14   | 12       |             |          |
| 10%           | 14   | 14       | Obs         | 52       |
| 25%           | 16.5 | 14       | Sum of wgt. | 52       |
| 50%           | 19   |          | Mean        | 19.82692 |
|               |      | Largest  | Std. dev.   | 4.743297 |
| 75%           | 22   | 28       |             |          |
| 90%           | 26   | 29       | Variance    | 22.49887 |
| 95%           | 29   | 30       | Skewness    | .7712432 |
| 99%           | 34   | 34       | Kurtosis    | 3.441459 |

```
-> foreign = Foreign
```

| Mileage (mpg) |      |          |             |          |
|---------------|------|----------|-------------|----------|
| Percentiles   |      | Smallest |             |          |
| 1%            | 14   | 14       |             |          |
| 5%            | 17   | 17       |             |          |
| 10%           | 17   | 17       | Obs         | 22       |
| 25%           | 21   | 18       | Sum of wgt. | 22       |
| 50%           | 24.5 |          | Mean        | 24.77273 |
|               |      | Largest  | Std. dev.   | 6.611187 |
| 75%           | 28   | 31       |             |          |
| 90%           | 35   | 35       | Variance    | 43.70779 |
| 95%           | 35   | 35       | Skewness    | .657329  |
| 99%           | 41   | 41       | Kurtosis    | 3.10734  |

## □ Technical note

`summarize` respects display formats if we specify the `format` option. When we type `summarize price weight`, we obtain

```
. summarize price weight
```

| Variable | Obs | Mean     | Std. dev. | Min  | Max   |
|----------|-----|----------|-----------|------|-------|
| price    | 74  | 6165.257 | 2949.496  | 3291 | 15906 |
| weight   | 74  | 3019.459 | 777.1936  | 1760 | 4840  |

The display is accurate but is not as aesthetically pleasing as we may wish, particularly if we plan to use the output directly in published work. By placing formats on the variables, we can control how the table appears:

```
. format price weight %9.2fc
. summarize price weight, format
```

| Variable | Obs | Mean     | Std. dev. | Min      | Max       |
|----------|-----|----------|-----------|----------|-----------|
| price    | 74  | 6,165.26 | 2,949.50  | 3,291.00 | 15,906.00 |
| weight   | 74  | 3,019.46 | 777.19    | 1,760.00 | 4,840.00  |

□

If you specify a weight (see [U] 11.1.6 **weight**), each observation is multiplied by the value of the weighting expression before the summary statistics are calculated so that the weighting expression is interpreted as the discrete density of each observation.

## ▷ Example 4: summarize with factor variables

You can also use `summarize` to obtain summary statistics for factor variables. For example, if you type

```
. summarize i.rep78
```

| Variable  | Obs | Mean     | Std. dev. | Min | Max |
|-----------|-----|----------|-----------|-----|-----|
| rep78     |     |          |           |     |     |
| Poor      | 69  | .0289855 | .1689948  | 0   | 1   |
| Fair      | 69  | .115942  | .3225009  | 0   | 1   |
| Average   | 69  | .4347826 | .4993602  | 0   | 1   |
| Good      | 69  | .2608696 | .4423259  | 0   | 1   |
| Excellent | 69  | .1594203 | .3687494  | 0   | 1   |

you obtain the sample proportions for the five levels of the `rep78` variable. For example, 11.6% of the 69 cars with nonmissing values of `rep78` have a fair repair record.

We could have used `tabulate oneway rep78` to obtain the sample proportions along with the cumulative proportions. Alternatively, we could have used `proportions rep78` to obtain the sample proportions along with the standard errors of the proportions instead of the standard deviations of the proportions.

◀

### ▷ Example 5: summarize with weights

We have 1980 census data on each of the 50 states. Included in our variables is `medage`, the median age of the population of each state. If we type `summarize medage`, we obtain unweighted statistics:

```
. use https://www.stata-press.com/data/r19/census, clear
(1980 Census data by state)
. summarize medage
```

| Variable | Obs | Mean  | Std. dev. | Min  | Max  |
|----------|-----|-------|-----------|------|------|
| medage   | 50  | 29.54 | 1.693445  | 24.2 | 34.7 |

Also among our variables is `pop`, the population in each state. Typing `summarize medage [w=pop]` produces population-weighted statistics:

```
. summarize medage [w=pop]
(analytic weights assumed)
```

| Variable | Obs | Weight    | Mean     | Std. Dev. | Min  | Max  |
|----------|-----|-----------|----------|-----------|------|------|
| medage   | 50  | 225907472 | 30.11047 | 1.66933   | 24.2 | 34.7 |

The number listed under `Weight` is the sum of the weighting variable, `pop`, indicating that there are roughly 226 million people in the United States. The `pop`-weighted mean of `medage` is 30.11 (compared with 29.54 for the unweighted statistic), and the weighted standard deviation is 1.67 (compared with 1.69).

### ▷ Example 6: summarize with weights and the detail option

We can obtain detailed summaries of weighted data as well. When we do this, *all* the statistics are weighted, including the percentiles.

```
. summarize medage [w=pop], detail
(analytic weights assumed)
```

| Median age  |      |          |             |           |  |
|-------------|------|----------|-------------|-----------|--|
| Percentiles |      | Smallest |             |           |  |
| 1%          | 27.1 | 24.2     |             |           |  |
| 5%          | 27.7 | 26.1     |             |           |  |
| 10%         | 28.2 | 27.1     | Obs         | 50        |  |
| 25%         | 29.2 | 27.4     | Sum of wgt. | 225907472 |  |
| 50%         | 29.9 |          | Mean        | 30.11047  |  |
|             |      | Largest  | Std. dev.   | 1.66933   |  |
| 75%         | 30.9 | 32       |             |           |  |
| 90%         | 32.1 | 32.1     | Variance    | 2.786661  |  |
| 95%         | 32.2 | 32.2     | Skewness    | .5281972  |  |
| 99%         | 34.7 | 34.7     | Kurtosis    | 4.494223  |  |

## □ Technical note

If you are writing a program and need to access the mean of a variable, the `meanonly` option provides for fast calls. For example, suppose that your program reads as follows:

```
program mean
 summarize '1', meanonly
 display " mean = " r(mean)
end
```

The result of executing this is

```
. use https://www.stata-press.com/data/r19/auto2
(1978 automobile data)

. mean price
mean = 6165.2568
```

□

## Video example

[Descriptive statistics in Stata](#)

## Stored results

`summarize` stores the following in `r()`:

### Scalars

|                          |                               |                          |                               |

| <code>r(p25)</code>      | 25th percentile (detail only) |                          |                               |

## Methods and formulas

Let  $x$  denote the variable on which we want to calculate summary statistics, and let  $x_i, i = 1, \dots, n$ , denote an individual observation on  $x$ . Let  $v_i$  be the weight, and if no weight is specified, define  $v_i = 1$  for all  $i$ .

Define the total number of observations as  $N = n$  if  $v_i$  is an `aweight` and as

$$N = \sum_{i=1}^n v_i$$

otherwise.

Additionally, define the normalized weight as

$$w_i = \frac{nv_i}{\sum_{i=1}^n v_i}$$

if  $v_i$  is an `aweight` and as  $w_i = v_i$  otherwise.

The mean,  $\bar{x}$ , is defined as

$$\bar{x} = \frac{1}{N} \sum_{i=1}^n w_i x_i$$

The variance,  $s^2$ , is defined as

$$s^2 = \frac{1}{N-1} \sum_{i=1}^n w_i (x_i - \bar{x})^2$$

The standard deviation,  $s$ , is defined as  $\sqrt{s^2}$ .

Define  $m_r$  as the  $r$ th moment about the mean  $\bar{x}$ :

$$m_r = \frac{1}{N} \sum_{i=1}^n w_i (x_i - \bar{x})^r$$

The coefficient of skewness is then defined as  $m_3 m_2^{-3/2}$ . The coefficient of kurtosis is defined as  $m_4 m_2^{-2}$ .

Let  $x_{(i)}$  refer to the  $x$  in ascending order, and let  $w_{(i)}$  refer to the corresponding weights of  $x_{(i)}$ . The four smallest values are  $x_{(1)}$ ,  $x_{(2)}$ ,  $x_{(3)}$ , and  $x_{(4)}$ . The four largest values are  $x_{(n)}$ ,  $x_{(n-1)}$ ,  $x_{(n-2)}$ , and  $x_{(n-3)}$ .

To obtain the  $p$ th percentile, which we will denote as  $x_{[p]}$ , let  $P = Np/100$ . Let

$$W_{(i)} = \sum_{j=1}^i w_{(j)}$$

Find the first index  $i$  such that  $W_{(i)} > P$ . The  $p$ th percentile is then

$$x_{[p]} = \begin{cases} \frac{x_{(i-1)} + x_{(i)}}{2} & \text{if } W_{(i-1)} = P \\ x_{(i)} & \text{otherwise} \end{cases}$$

## Description

`sunflower` draws density-distribution sunflower plots (Plummer and Dupont 2003). Dark sunflowers, light sunflowers, and marker symbols represent high-, medium-, and low-density regions of the data, respectively. These plots are useful for displaying bivariate data whose density is too great for conventional scatterplots to be effective.

## Quick start

Density-distribution sunflower plot showing the relationship between  $x$  and  $y$

```
sunflower y x
```

Set the center of the reference bin to  $x = 5$  and  $y = 8$

```
sunflower y x, xcenter(5) ycenter(8)
```

Same as above, but specify the width of the hexagonal bins to be 1.5

```
sunflower y x, xcenter(5) ycenter(8) binwidth(1.5)
```

Same as above, but set the minimum number of observations needed for a bin to be represented by a light sunflower to 4

```
sunflower y x, xcenter(5) ycenter(8) binwidth(1.5) light(4)
```

Use the `s1color` scheme

```
sunflower y x, scheme(s1color)
```

Specify that only the petals are shown and the hexegons are omitted

```
sunflower y x, floweronly
```

Suppress display of the table

```
sunflower y x, notable
```

## Menu

Graphics > Smoothing and densities > Density-distribution sunflower plot

## Syntax

```
sunflower yvar xvar [if] [in] [weight] [, options]
```

All options are *rightmost*; see [G-4] **Concept: repeated options**.

`fweights` are allowed; see [U] 11.1.6 **weight**.

## Options

### Main

`nograph` prevents the graph from being generated.

`notable` prevents the summary table from being displayed. This option is implied when the `by()` option is specified.

`marker_options` affect the rendition of markers drawn at the plotted points, including their shape, size, color, and outline; see [G-3] [marker\\_options](#).

### Bins/Petals

`binwidth(#)` specifies the horizontal width of the hexagonal bins in the same units as `xvar`. By default,

$$\text{binwidth} = \max(\text{rbw}, \text{nbw})$$

where

$$\text{rbw} = \text{range of } xvar / 40$$

$$\text{nbw} = \text{range of } xvar / \max(1, \text{nb})$$

and

$$\text{nb} = \text{int}(\min(\sqrt{n}, 10 * \log_{10}(n)))$$

where

$$n = \text{the number of observations in the dataset}$$

`binar(#)` specifies the aspect ratio for the hexagonal bins. The height of the bins is given by

$$\text{binheight} = \text{binwidth} \times \# \times 2 / \sqrt{3}$$

where `binheight` and `binwidth` are specified in the units of `yvar` and `xvar`, respectively. The default is `binar(r)`, where `r` results in the rendering of regular hexagons.

`bin_options` affect how the hexagonal bins are rendered.

`lstyle(areastyle)` and `dbstyle(areastyle)` specify the look of the light and dark hexagonal bins, respectively. The options listed below allow you to change each attribute, but `lstyle()` and `dbstyle()` provide the starting points. See [G-4] [areastyle](#) for a list of available area styles.

`lbcolor(colorstyle)` and `dbcOLOR(colorstyle)` specify one color to be used both to outline the shape and to fill the interior of the light and dark hexagonal bins, respectively. See [G-4] [colorstyle](#) for a list of color choices.

`lbfcolor(colorstyle)` and `dbfcolor(colorstyle)` specify the color to be used to fill the interior of the light and dark hexagonal bins, respectively. See [G-4] [colorstyle](#) for a list of color choices.

`lstyle(linestyle)` and `dbstyle(linestyle)` specify the overall style of the line used to outline the area, which includes its pattern (solid, dashed, etc.), thickness, and color. The other options listed below allow you to change the line's attributes, but `lstyle()` and `dbstyle()` are the starting points. See [G-4] [linestyle](#) for a list of choices.

`lbcolor(colorstyle)` and `dblcolor(colorstyle)` specify the color to be used to outline the light and dark hexagonal bins, respectively. See [G-4] [colorstyle](#) for a list of color choices.

`lblwidth(linewidthstyle)` and `dblwidth(linewidthstyle)` specify the thickness of the line to be used to outline the light and dark hexagonal bins, respectively. See [G-4] [linewidthstyle](#) for a list of choices.

`light(#)` specifies the minimum number of observations needed for a bin to be represented by a light sunflower. The default is `light(3)`.

`dark(#)` specifies the minimum number of observations needed for a bin to be represented by a dark sunflower. The default is `dark(13)`.

`xcenter(#)` and `ycenter(#)` specify the center of the reference bin. The default values are the median values of *xvar* and *yvar*, respectively. The centers of the other bins are implicitly defined by the location of the reference bin together with the common bin width and height.

`petalweight(#)` specifies the number of observations represented by each petal of a dark sunflower. The default value is chosen so that the maximum number of petals on a dark sunflower is 14.

`petalength(#)` specifies the length of petals in the sunflowers. The value specified is interpreted as a percentage of half the bin width. The default is 100%.

*petal\_options* affect how the sunflower petals are rendered.

`lflstyle(linestyle)` and `dflstyle(linestyle)` specify the overall style of the light and dark sunflower petals, respectively.

`lflcolor(colorstyle)` and `dflcolor(colorstyle)` specify the color of the light and dark sunflower petals, respectively.

`lflwidth(linewidthstyle)` and `dflwidth(linewidthstyle)` specify the width of the light and dark sunflower petals, respectively.

`floweronly` suppresses rendering of the bins. This option is equivalent to specifying `lbcolor(none)` and `dbcold(none)`.

`nosinglepetal` suppresses flowers from being drawn in light bins that contain only 1 observation and dark bins that contain as many observations as the petal weight (see the `petalweight()` option).

#### Add plots

`addplot(plot)` provides a way to add other plots to the generated graph; see [G-3] [addplot\\_option](#).

#### Y axis, X axis, Titles, Legend, Overall, By

*twoway\_options* are any of the options documented in [G-3] [twoway\\_options](#). These include options for titling the graph (see [G-3] [title\\_options](#)), options for saving the graph to disk (see [G-3] [saving\\_option](#)), and the `by()` option (see [G-3] [by\\_option](#)).

## Remarks and examples

A sunflower is several line segments of equal length, called petals, that radiate from a central point. There are two varieties of sunflowers: light and dark. Each petal of a light sunflower represents 1 observation. Each petal of a dark sunflower represents several observations. Dark and light sunflowers represent high- and medium-density regions of the data, and marker symbols represent individual observations in low-density regions.

`sunflower` divides the plane defined by the variables `yvar` and `xvar` into contiguous hexagonal bins. The number of observations contained within a bin determines how the bin will be represented.

- When there are fewer than `light(#)` observations in a bin, each point is plotted using the usual marker symbols in a scatterplot.
- Bins with at least `light(#)` but fewer than `dark(#)` observations are represented by a light sunflower. Each petal of a light sunflower represents one observation in the bin.
- Bins with at least `dark(#)` observations are represented by a dark sunflower. Each petal of a dark sunflower represents multiple observations.

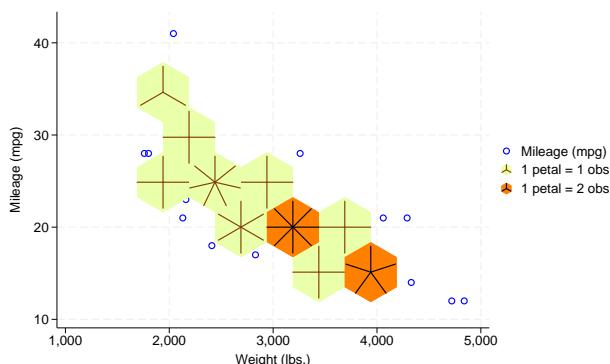

See Dupont (2009, 87–92) for a discussion of sunflower plots and how to create them using Stata.

### ▷ Example 1

Using the `auto` dataset, we want to examine the relationship between `weight` and `mpg`. To do that, we type

```
. use https://www.stata-press.com/data/r19/auto
(1978 automobile data)
. sunflower mpg weight, binwid(500) petalw(2) dark(8) scheme(stcolor)
Bin width = 500
Bin height = 6.50422
Bin aspect ratio = .0112656
Max obs in a bin = 15
Light = 3
Dark = 8
X-center = 3190
Y-center = 20
Petal weight = 2
```

| Flower type | Petal weight | No. of petals | No. of flowers | Estimated obs | Actual obs |
|-------------|--------------|---------------|----------------|---------------|------------|
| none        |              |               |                | 13            | 13         |
| light       | 1            | 3             | 1              | 3             | 3          |
| light       | 1            | 4             | 5              | 20            | 20         |
| light       | 1            | 6             | 1              | 6             | 6          |
| light       | 1            | 7             | 1              | 7             | 7          |
| dark        | 2            | 5             | 1              | 10            | 10         |
| dark        | 2            | 8             | 1              | 16            | 15         |
|             |              |               |                | 75            | 74         |

The two darkly shaded sunflowers immediately catch our eyes, indicating a group of 10 cars that are heavy (nearly 4,000 pounds) and fuel inefficient and a group 16 of cars that get about 20 miles per gallon and weight in the neighborhood of 3,000 pounds. The lighter sunflowers each indicate groups of three to seven cars that share similar weight and fuel economy characteristics. To obtain the number of cars in each group, we count the number of petals in each flower and consult the graph legend to see how many observations each petal represents.

## Description

`sureg` fits seemingly unrelated regression models (Zellner 1962; Zellner and Huang 1962; Zellner 1963). The acronyms SURE and SUR are often used for the estimator.

## Quick start

Model of  $y_1$  and  $y_2$  as a function of  $x_1$ ,  $x_2$ , and  $x_3$

```
sureg (y1 x1 x2 x3) (y2 x1 x2 x3)
```

Same as above

```
sureg (y1 y2 = x1 x2 x3)
```

Same as above, but obtain small-sample statistics and use small-sample adjustment

```
sureg (y1 y2 = x1 x2 x3), small dfk
```

Also perform Breusch–Pagan test

```
sureg (y1 y2 = x1 x2 x3), small dfk corr
```

Model of  $y_1$  as a function of  $x_1$  and  $x_2$  and  $y_2$  as a function of  $x_2$  and lag of  $x_2$  using `tsset` data

```
sureg (y1 x1 x2) (y2 x2 L.x2)
```

## Menu

Statistics > Linear models and related > Multiple-equation models > Seemingly unrelated regression

## Syntax

### Basic syntax

```
sureg (depvar1 varlist1) (depvar2 varlist2) ... (depvarN varlistN)
 [if] [in] [weight]
```

### Full syntax

```
sureg ([eqname1:]depvar1a [depvar1b ... =]varlist1 [, noconstant])
 ([eqname2:]depvar2a [depvar2b ... =]varlist2 [, noconstant])
 ...
 ([eqnameN:]depvarNa [depvarNb ... =]varlistN [, noconstant])
 [if] [in] [weight] [, options]
```

Explicit equation naming (*eqname*:) cannot be combined with multiple dependent variables in an equation specification.

| <u>c</u> oeflegend                        | display legend instead of statistics                                                                                                             |

*varlist*<sub>1</sub>, . . . , *varlist*<sub>*N*</sub> may contain factor variables; see [U] 11.4.3 Factor variables. You must have the same levels of factor variables in all equations that have factor variables.

*deprvars* and the *varlists* may contain time-series operators; see [U] 11.4.4 Time-series varlists.

*bootstrap*, *by*, *collect*, *fp*, *jackknife*, *rolling*, and *statsby* are allowed; see [U] 11.1.10 Prefix commands.

Weights are not allowed with the *bootstrap* prefix; see [R] *bootstrap*.

*aweight*s are not allowed with the *jackknife* prefix; see [R] *jackknife*.

*aweight*s and *fweight*s are allowed; see [U] 11.1.6 weight.

*noheader*, *notable*, and *coeflegend* do not appear in the dialog box.

See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

## Options

### Model

*isure* specifies that *sureg* iterate over the estimated disturbance covariance matrix and parameter estimates until the parameter estimates converge. Under seemingly unrelated regression, this iteration converges to the maximum likelihood results. If this option is not specified, *sureg* produces two-step estimates.

*constraints* (*constraints*); see [R] Estimation options.

### SE/Robust

*vce* (*vcetype*) specifies the type of standard error reported, which includes types that are derived from asymptotic theory (*unadjusted*), that are robust to some kinds of misspecification (*robust*), and that allow for intragroup correlation (*cluster clustvar*); see [R] *vce\_option*.

*vce*(*unadjusted*), the default, specifies that an unadjusted (nonrobust) VCE matrix be used; this results in efficient estimates when assuming homoskedasticity.

### df adj.

*small* specifies that small-sample statistics be computed. It shifts the test statistics from  $\chi^2$  and *z* statistics to *F* statistics and *t* statistics. Although the standard errors from each equation are computed using the degrees of freedom for the equation, the degrees of freedom for the *t* statistics are all taken to be those for the first equation.

*dfk* specifies the use of an alternative divisor in computing the covariance matrix for the equation residuals. As an asymptotically justified estimator, *sureg* by default uses the number of sample observations (*n*) as a divisor. When the *dfk* option is set, a small-sample adjustment is made and the divisor is taken to be  $\sqrt{(n - k_i)(n - k_j)}$ , where *k<sub>i</sub>* and *k<sub>j</sub>* are the number of parameters in equations *i* and *j*, respectively.

*dfk2* specifies the use of an alternative divisor in computing the covariance matrix for the equation residuals. When the *dfk2* option is set, the divisor is taken to be the mean of the residual degrees of freedom from the individual equations.

### Reporting

*level*(#); see [R] Estimation options.

*corr* displays the correlation matrix of the residuals between equations and performs a Breusch–Pagan test for independent equations; that is, the disturbance covariance matrix is diagonal.

nocnsreport; see [R] [Estimation options](#).

*display\_options*: `nocl`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `no1stretch`; see [R] [Estimation options](#).

### Optimization

*optimization\_options* control the iterative process that minimizes the sum of squared errors when `isure` is specified. These options are seldom used.

`iterate(#)` specifies the maximum number of iterations. When the number of iterations equals `#`, the optimizer stops and presents the current results, even if the convergence tolerance has not been reached. The default is the number set using `set maxiter`, which is 300 by default.

`trace` adds to the iteration log a display of the current parameter vector.

`log` and `nolog` specify whether to display the iteration log. The iteration log is displayed by default unless you used `set iterlog off` to suppress it; see `set iterlog` in [R] [set iter](#).

`tolerance(#)` specifies the tolerance for the coefficient vector. When the relative change in the coefficient vector from one iteration to the next is less than or equal to `#`, the optimization process is stopped. `tolerance(1e-6)` is the default.

The following options are available with `sureg` but are not shown in the dialog box:

`noheader` suppresses display of the header reporting  $F$  statistics,  $R^2$ , and root mean squared error above the coefficient table.

`notable` suppresses display of the coefficient table.

`coeflegend`; see [R] [Estimation options](#).

## Remarks and examples

Seemingly unrelated regression models are so called because they appear to be joint estimates from several regression models, each with its own error term. The regressions are related because the (contemporaneous) errors associated with the dependent variables may be correlated. Chapter 6 of [Cameron and Trivedi \(2022\)](#) contains a discussion of the seemingly unrelated regression model and the feasible generalized least-squares estimator underlying it.

### ▷ Example 1

When we fit models with the same set of right-hand-side variables, the seemingly unrelated regression results (in terms of coefficients and standard errors) are the same as fitting the models separately (using, say, `regress`). The same is true when the models are nested. Even in such cases, `sureg` is useful when we want to perform joint tests. For instance, let us assume that we think

$$\begin{aligned}\text{price} &= \beta_0 + \beta_1 \text{foreign} + \beta_2 \text{length} + u_1 \\ \text{weight} &= \gamma_0 + \gamma_1 \text{foreign} + \gamma_2 \text{length} + u_2\end{aligned}$$

Because the models have the same set of explanatory variables, we could estimate the two equations separately. Yet, we might still choose to estimate them with `sureg` because we want to perform the joint test  $\beta_1 = \gamma_1 = 0$ .

We use the small and dfk options to obtain small-sample statistics comparable with regress or mvreg.

```
. use https://www.stata-press.com/data/r19/auto
(1978 automobile data)
. sureg (price foreign length) (weight foreign length), small dfk
Seemingly unrelated regression
```

| Equation | Obs | Params | RMSE     | "R-squared" | F      | P>F    |
|----------|-----|--------|----------|-------------|--------|--------|
| price    | 74  | 2      | 2474.593 | 0.3154      | 16.35  | 0.0000 |
| weight   | 74  | 2      | 250.2515 | 0.8992      | 316.54 | 0.0000 |

|         | Coefficient | Std. err. | t     | P> t  | [95% conf. interval] |           |
|---------|-------------|-----------|-------|-------|----------------------|-----------|
| price   |             |           |       |       |                      |           |
| foreign | 2801.143    | 766.117   | 3.66  | 0.000 | 1286.674             | 4315.611  |
| length  | 90.21239    | 15.83368  | 5.70  | 0.000 | 58.91219             | 121.5126  |
| _cons   | -11621.35   | 3124.436  | -3.72 | 0.000 | -17797.77            | -5444.93  |
| weight  |             |           |       |       |                      |           |
| foreign | -133.6775   | 77.47615  | -1.73 | 0.087 | -286.8332            | 19.4782   |
| length  | 31.44455    | 1.601234  | 19.64 | 0.000 | 28.27921             | 34.60989  |
| _cons   | -2850.25    | 315.9691  | -9.02 | 0.000 | -3474.861            | -2225.639 |

Note: Small-sample degrees-of-freedom adjustment applied when estimating covariance matrix of residuals.

These two equations have a common set of regressors, and we could have used a shorthand syntax to specify the equations:

```
. sureg (price weight = foreign length), small dfk
```

Here the results presented by sureg are the same as if we had estimated the equations separately:

```
. regress price foreign length
(output omitted)
. regress weight foreign length
(output omitted)
```

There is, however, a difference. We have allowed  $u_1$  and  $u_2$  to be correlated and have estimated the full variance–covariance matrix of the coefficients. sureg has estimated the correlations, but it does not report them unless we specify the corr option. We did not remember to specify corr when we fit the model, but we can redisplay the results:

```
. sureg, notable noheader corr
```

Note: Small-sample degrees-of-freedom adjustment applied when estimating covariance matrix of residuals.

Correlation matrix of residuals:

```
 price weight
price 1.0000
weight 0.5840 1.0000
```

```
Breusch-Pagan test of independence: chi2(1) = 25.237, Pr = 0.0000
```

The notable and noheader options prevented sureg from redisplaying the header and coefficient tables. We find that, for the same cars, the correlation of the residuals in the price and weight equations is 0.5840 and that we can reject the hypothesis that this correlation is zero.

We can test that the coefficients on `foreign` are jointly zero in both equations—as we set out to do—by typing `test foreign`; see [R] [test](#). When we type a variable without specifying the equation, that variable is tested for zero in all equations in which it appears:

```
. test foreign
(1) [price]foreign = 0
(2) [weight]foreign = 0
 F(2, 142) = 17.99
 Prob > F = 0.0000
```

◀

## ▶ Example 2

When the models do not have the same set of explanatory variables and are not nested, `sureg` may lead to more efficient estimates than running the models separately as well as allowing joint tests. This time, let us assume that we believe

$$\begin{aligned} \text{price} &= \beta_0 + \beta_1 \text{foreign} + \beta_2 \text{mpg} + \beta_3 \text{displ} + u_1 \\ \text{weight} &= \gamma_0 + \gamma_1 \text{foreign} + \gamma_2 \text{length} + u_2 \end{aligned}$$

To fit this model, we type

```
. sureg (price foreign mpg displ) (weight foreign length), corr
Seemingly unrelated regression
```

| Equation | Obs | Params | RMSE     | "R-squared" | chi2   | P>chi2 |
|----------|-----|--------|----------|-------------|--------|--------|
| price    | 74  | 3      | 2165.321 | 0.4537      | 49.64  | 0.0000 |
| weight   | 74  | 2      | 245.2916 | 0.8990      | 661.84 | 0.0000 |

|              | Coefficient | Std. err. | z     | P> z  | [95% conf. interval] |           |
|--------------|-------------|-----------|-------|-------|----------------------|-----------|
| price        |             |           |       |       |                      |           |
| foreign      | 3058.25     | 685.7357  | 4.46  | 0.000 | 1714.233             | 4402.267  |
| mpg          | -104.9591   | 58.47209  | -1.80 | 0.073 | -219.5623            | 9.644042  |
| displacement | 18.18098    | 4.286372  | 4.24  | 0.000 | 9.779842             | 26.58211  |
| _cons        | 3904.336    | 1966.521  | 1.99  | 0.047 | 50.0263              | 7758.645  |
| weight       |             |           |       |       |                      |           |
| foreign      | -147.3481   | 75.44314  | -1.95 | 0.051 | -295.2139            | .517755   |
| length       | 30.94905    | 1.539895  | 20.10 | 0.000 | 27.93091             | 33.96718  |
| _cons        | -2753.064   | 303.9336  | -9.06 | 0.000 | -3348.763            | -2157.365 |

Correlation matrix of residuals:

```
 price weight
price 1.0000
weight 0.3285 1.0000
```

Breusch-Pagan test of independence: `chi2(1) = 7.984, Pr = 0.0047`

In comparison, if we had fit the price model separately,

```
. regress price foreign mpg displ
```

| Source   | SS        | df | MS         | Number of obs | = | 74     |
|----------|-----------|----|------------|---------------|---|--------|
| Model    | 294104790 | 3  | 98034929.9 | F(3, 70)      | = | 20.13  |
| Residual | 340960606 | 70 | 4870865.81 | Prob > F      | = | 0.0000 |
|          |           |    |            | R-squared     | = | 0.4631 |
|          |           |    |            | Adj R-squared | = | 0.4401 |
| Total    | 635065396 | 73 | 8699525.97 | Root MSE      | = | 2207   |

| price        | Coefficient | Std. err. | t     | P> t  | [95% conf. interval] |          |
|--------------|-------------|-----------|-------|-------|----------------------|----------|
| foreign      | 3545.484    | 712.7763  | 4.97  | 0.000 | 2123.897             | 4967.072 |
| mpg          | -98.88559   | 63.17063  | -1.57 | 0.122 | -224.8754            | 27.10426 |
| displacement | 22.40416    | 4.634239  | 4.83  | 0.000 | 13.16146             | 31.64686 |
| _cons        | 2796.91     | 2137.873  | 1.31  | 0.195 | -1466.943            | 7060.763 |

The coefficients are slightly different, but the standard errors are uniformly larger. This would still be true if we specified the `dfk` option to make a small-sample adjustment to the estimated covariance of the disturbances.

◀

## □ Technical note

Constraints can be applied to SURE models using Stata's standard syntax for constraints. For a general discussion of constraints, see [R] [constraint](#); for examples similar to seemingly unrelated regression models, see [R] [reg3](#).

□

## Stored results

sureg stores the following in `e()`:

### Scalars

|                          |                                                        |
|--------------------------|--------------------------------------------------------|
| <code>e(N)</code>        | number of observations                                 |
| <code>e(k)</code>        | number of parameters                                   |
| <code>e(k_eq)</code>     | number of equations in <code>e(b)</code>               |
| <code>e(mss_#)</code>    | model sum of squares for equation #                    |
| <code>e(df_m#)</code>    | model degrees of freedom for equation #                |
| <code>e(rss_#)</code>    | residual sum of squares for equation #                 |
| <code>e(df_r)</code>     | residual degrees of freedom                            |
| <code>e(r2_#)</code>     | $R^2$ for equation #                                   |
| <code>e(F_#)</code>      | $F$ statistic for equation # (small only)              |
| <code>e(rmse_#)</code>   | root mean squared error for equation #                 |
| <code>e(dfk2_adj)</code> | divisor used with VCE when <code>dfk2</code> specified |
| <code>e(ll)</code>       | log likelihood                                         |
| <code>e(N_clust)</code>  | number of clusters                                     |
| <code>e(chi2_#)</code>   | $\chi^2$ for equation #                                |
| <code>e(p_#)</code>      | $p$ -value for equation #                              |
| <code>e(cons_#)</code>   | 1 if equation # has a constant, 0 otherwise            |
| <code>e(chi2_bp)</code>  | Breusch–Pagan $\chi^2$                                 |
| <code>e(df_bp)</code>    | degrees of freedom for Breusch–Pagan $\chi^2$ test     |
| <code>e(rank)</code>     | rank of <code>e(V)</code>                              |
| <code>e(ic)</code>       | number of iterations                                   |

## Macros

|                   |                                                    |

| e(corr)           | correlation structure                              |
| e(small)          | small, if specified                                |
| e(dfk)            | dfk or dfk2, if specified                          |
| e(clustvar)       | name of cluster variable                           |
| e(vce)            | <i>vcetype</i> specified in <i>vce()</i>           |
| e(vcetype)        | title used to label Std. err.                      |
| e(properties)     | b V                                                |
| e(predict)        | program used to implement predict                  |
| e(marginsok)      | predictions allowed by margins                     |
| e(marginsnotok)   | predictions disallowed by margins                  |
| e(marginsdefault) | default <i>predict()</i> specification for margins |
| e(asbalanced)     | factor variables <i>fvset</i> as <i>asbalanced</i> |
| e(asobserved)     | factor variables <i>fvset</i> as <i>asobserved</i> |

## Matrices

|          |                                                 |
|----------|-------------------------------------------------|
| e(b)     | coefficient vector                              |
| e(Cns)   | constraints matrix                              |
| e(Sigma) | $\hat{\Sigma}$ , covariance matrix of residuals |
| e(V)     | variance–covariance matrix of the estimators    |

## Functions

|           |                         |
|-----------|-------------------------|
| e(sample) | marks estimation sample |
|-----------|-------------------------|

In addition to the above, the following is stored in *r()*:

## Matrices

|          |                                                                                                                            |
|----------|----------------------------------------------------------------------------------------------------------------------------|
| r(table) | matrix containing the coefficients with their standard errors, test statistics, <i>p</i> -values, and confidence intervals |
|----------|----------------------------------------------------------------------------------------------------------------------------|

Note that results stored in *r()* are updated when the command is replayed and will be replaced when any *r*-class command is run after the estimation command.

## Methods and formulas

sureg uses the asymptotically efficient, feasible, generalized least-squares algorithm described in Greene (2018, 328–339). The computing formulas are given on page 328–335.

The  $R^2$  reported is the percent of variance explained by the predictors. It may be used for descriptive purposes, but  $R^2$  is not a well-defined concept when GLS is used.

sureg will refuse to compute the estimators if the same equation is named more than once or the covariance matrix of the residuals is singular.

The Breusch and Pagan (1980)  $\chi^2$  statistic—a Lagrange multiplier statistic—is given by

$$\lambda = T \sum_{m=2}^M \sum_{n=1}^{m-1} r_{mn}^2$$

where  $r_{mn}$  is the estimated correlation between the residuals of the  $M$  equations and  $T$  is the number of observations. It is distributed as  $\chi^2$  with  $M(M - 1)/2$  degrees of freedom.

This command supports the Huber/White/sandwich estimator of the variance and its clustered version using `vce(robust)` and `vce(cluster clustvar)`, respectively. See [P] [\\_robust](#), particularly *Introduction* and *Methods and formulas*.

**Arnold Zellner** (1927–2010) was born in New York. He studied physics at Harvard and economics at Berkeley, and then he taught economics at the Universities of Washington and Wisconsin before settling in Chicago in 1966. Among his many major contributions to econometrics and statistics are his work on seemingly unrelated regression, three-stage least squares, and Bayesian econometrics.

## Postestimation commands

The following postestimation commands are available after `sureg`:

| Command                      | Description                                                                                                                             |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <code>contrast</code>        | contrasts and ANOVA-style joint tests of parameters                                                                                     |
| <code>estat ic</code>        | Akaike's, consistent Akaike's, corrected Akaike's, and Schwarz's Bayesian information criteria (AIC, CAIC, AICc, and BIC, respectively) |
| <code>estat summarize</code> | summary statistics for the estimation sample                                                                                            |
| <code>estat vce</code>       | variance–covariance matrix of the estimators (VCE)                                                                                      |
| <code>estimates</code>       | cataloging estimation results                                                                                                           |
| <code>etable</code>          | table of estimation results                                                                                                             |
| <code>forecast</code>        | dynamic forecasts and simulations                                                                                                       |
| <code>hausman</code>         | Hausman's specification test                                                                                                            |
| <code>lincom</code>          | point estimates, standard errors, testing, and inference for linear combinations of parameters                                          |
| <code>margins</code>         | marginal means, predictive margins, marginal effects, and average marginal effects                                                      |
| <code>marginsplot</code>     | graph the results from margins (profile plots, interaction plots, etc.)                                                                 |
| <code>nlcom</code>           | point estimates, standard errors, testing, and inference for nonlinear combinations of parameters                                       |
| <code>predict</code>         | predictions and their SEs, residuals, etc.                                                                                              |
| <code>predictnl</code>       | point estimates, standard errors, testing, and inference for generalized predictions                                                    |

| <code>test</code>            | Wald tests of simple and composite linear hypotheses                                                                                    |
| <code>testnl</code>          | Wald tests of nonlinear hypotheses                                                                                                      |

# predict

## Description for predict

`predict` creates a new variable containing predictions such as linear predictions, standard errors, residuals, and differences between the linear predictions.

## Menu for predict

Statistics > Postestimation

## Syntax for predict

```
predict [type] newvar [if] [in] [, equation(eqno[,eqno]) statistic]
```

| <i>statistic</i>        | Description                                                |
|-------------------------|------------------------------------------------------------|
| Main                    |                                                            |
| <code>xb</code>         | linear prediction; the default                             |
| <code>stdp</code>       | standard error of the linear prediction                    |
| <code>residuals</code>  | residuals                                                  |
| <code>difference</code> | difference between the linear predictions of two equations |
| <code>stddp</code>      | standard error of the difference in linear predictions     |

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

## Options for predict

Main

`equation(eqno[ ,eqno])` specifies to which equation(s) you are referring.

`equation()` is filled in with one `eqno` for the `xb`, `stdp`, and `residuals` options. `equation(#1)` would mean that the calculation is to be made for the first equation, `equation(#2)` would mean the second, and so on. You could also refer to the equations by their names. `equation(income)` would refer to the equation named `income` and `equation(hours)` to the equation named `hours`.

If you do not specify `equation()`, the results are the same as if you specified `equation(#1)`.

`difference` and `stddp` refer to between-equation concepts. To use these options, you must specify two equations, for example, `equation(#1,#2)` or `equation(income,hours)`. When two equations must be specified, `equation()` is required.

`xb`, the default, calculates the linear prediction (fitted values)—the prediction of  $\mathbf{x}_j\mathbf{b}$  for the specified equation.

`stdp` calculates the standard error of the prediction for the specified equation. It can be thought of as the standard error of the predicted expected value or mean for the observation's covariate pattern. The standard error of the prediction is also referred to as the standard error of the fitted value.

`residuals` calculates the residuals.

`difference` calculates the difference between the linear predictions of two equations in the system. With `equation(#1,#2)`, `difference` computes the prediction of equation(#1) minus the prediction of equation(#2).

`stdp` is allowed only after you have previously fit a multiple-equation model. The standard error of the difference in linear predictions ( $\mathbf{x}_{1j}\mathbf{b} - \mathbf{x}_{2j}\mathbf{b}$ ) between equations 1 and 2 is calculated.

For more information on using `predict` after multiple-equation estimation commands, see [R] [predict](#).

## margins

### Description for margins

`margins` estimates margins of response for linear predictions and differences between the linear predictions.

### Menu for margins

Statistics > Postestimation

### Syntax for margins

```
margins [marginlist] [, options]
```

```
margins [marginlist] , predict(statistic ...) [predict(statistic ...) ...] [options]
```

| <i>statistic</i>        | Description                                                |
|-------------------------|------------------------------------------------------------|
| <code>default</code>    | linear predictions for each equation                       |
| <code>xb</code>         | linear prediction for a specified equation                 |
| <code>difference</code> | difference between the linear predictions of two equations |
| <code>stdp</code>       | not allowed with <code>margins</code>                      |
| <code>residuals</code>  | not allowed with <code>margins</code>                      |
| <code>stddp</code>      | not allowed with <code>margins</code>                      |

`xb` defaults to the first equation.

Statistics not allowed with `margins` are functions of stochastic quantities other than  $e(b)$ .

For the full syntax, see [R] [margins](#).

## Remarks and examples

For an example of cross-equation testing of parameters using the `test` command, see [example 1](#) in [\[R\] sureg](#).

### ▷ Example 1

In [example 1](#) of [\[R\] sureg](#), we fit a seemingly unrelated regressions model of price and weight. Here we obtain the fitted values.

```
. use https://www.stata-press.com/data/r19/auto
(1978 automobile data)
. sureg (price foreign length) (weight foreign length), small dfk
(output omitted)
. predict phat, equation(price)
(option xb assumed; fitted values)
. predict what, equation(weight)
(option xb assumed; fitted values)
. summarize price phat weight what
```

| Variable | Obs | Mean     | Std. dev. | Min      | Max      |
|----------|-----|----------|-----------|----------|----------|
| price    | 74  | 6165.257 | 2949.496  | 3291     | 15906    |
| phat     | 74  | 6165.257 | 1656.407  | 1639.872 | 9398.138 |
| weight   | 74  | 3019.459 | 777.1936  | 1760     | 4840     |
| what     | 74  | 3019.459 | 736.9666  | 1481.199 | 4476.331 |

Just as in single-equation OLS regression, in a SURE model the sample mean of the fitted values for an equation equals the sample mean of the dependent variable.

◀

### ▷ Example 2

Suppose that for whatever reason we were interested in the difference between the predicted values of price and weight. `predict` has an option to compute this difference in one step:

```
. predict diff, equation(price, weight) difference
```

`diff` is the same as `phat - what`:

```
. generate mydiff = phat - what
. summarize diff mydiff
```

| Variable | Obs | Mean     | Std. dev. | Min       | Max      |
|----------|-----|----------|-----------|-----------|----------|
| diff     | 74  | 3145.797 | 1233.26   | -132.2275 | 5505.914 |
| mydiff   | 74  | 3145.797 | 1233.26   | -132.2275 | 5505.914 |

## Description

`swilk` performs the Shapiro–Wilk  $W$  test for normality for each variable in the specified varlist. Likewise, `sfrancia` performs the Shapiro–Francia  $W'$  test for normality. See [\[MV\] mvtest normality](#) for multivariate tests of normality.

## Quick start

*Shapiro–Wilk test of normality*

Shapiro–Wilk test for `v1`

```
swilk v1
```

Separate tests of normality for `v1` and `v2`

```
swilk v1 v2
```

Generate new variable `w` containing  $W$  test coefficients

```
swilk v1, generate(w)
```

Specify that average ranks should not be used for tied values

```
swilk v1 v2, noties
```

Test that `v3` is distributed lognormally

```
generate lnv3 = ln(v3)
swilk lnv3
```

*Shapiro–Francia test of normality*

Shapiro–Francia test for `v1`

```
sfrancia v1
```

Separate tests of normality for `v1` and `v2`

```
sfrancia v1 v2
```

Same as above, but use the Box–Cox transformation

```
sfrancia v1 v2, boxcox
```

Specify that average ranks should not be used for tied values

```
sfrancia v1 v2, noties
```

## Menu

### swilk

Statistics > Summaries, tables, and tests > Distributional plots and tests > Shapiro-Wilk normality test

### sfrancia

Statistics > Summaries, tables, and tests > Distributional plots and tests > Shapiro-Francia normality test

## Syntax

*Shapiro–Wilk normality test*

```
swilk varlist [if] [in] [, swilk_options]
```

*Shapiro–Francia normality test*

```
sfrancia varlist [if] [in][, sfrancia_options]
```

*swilk\_options*

Description

Main

|                                      |                                                       |
|--------------------------------------|-------------------------------------------------------|
| <code>generate(<i>newvar</i>)</code> | create <i>newvar</i> containing $W$ test coefficients |
| <code>lnnormal</code>                | test for three-parameter lognormality                 |
| <code>noties</code>                  | do not use average ranks for tied values              |

*sfrancia\_options*

Description

Main

|                     |                                                                                        |
|---------------------|----------------------------------------------------------------------------------------|
| <code>boxcox</code> | use the Box–Cox transformation for $W'$ ; the default is to use the log transformation |
| <code>noties</code> | do not use average ranks for tied values                                               |

`by` and `collect` are allowed with `swilk` and `sfrancia`; see [\[U\] 11.1.10 Prefix commands](#).

## Options for swilk

Main

`generate(newvar)` creates new variable *newvar* containing the  $W$  test coefficients.

`lnnormal` specifies that the test be for three-parameter lognormality, meaning that  $\ln(X - k)$  is tested for normality, where  $k$  is calculated from the data as the value that makes the skewness coefficient zero. When simply testing  $\ln(X)$  for normality, do not specify this option. See [\[R\] lnskew0](#) for estimation of  $k$ .

`noties` suppresses use of averaged ranks for tied values when calculating the  $W$  test coefficients.

## Options for sfrancia

Main

`boxcox` specifies that the Box–Cox transformation of [Royston \(1983\)](#) for calculating  $W'$  test coefficients be used instead of the default log transformation ([Royston 1993a](#)). Under the Box–Cox transformation, the normal approximation to the sampling distribution of  $W'$ , used by `sfrancia`, is valid for  $5 \leq n \leq 1000$ . Under the log transformation, it is valid for  $10 \leq n \leq 5000$ .

`noties` suppresses use of averaged ranks for tied values when calculating the  $W'$  test coefficients.

## Remarks and examples

`swilk` can be used with  $4 \leq n \leq 2000$  observations. `sfrancia` can be used with  $10 \leq n \leq 5000$  observations; however, if the `boxcox` option is specified, it can be used with  $5 \leq n \leq 1000$  observations.

Also see [\[R\] sktest](#) for the skewness and kurtosis test described by [D'Agostino, Belanger, and D'Agostino \(1990\)](#) with the empirical correction developed by [Royston \(1991b\)](#). While the Shapiro–Wilk and Shapiro–Francia tests for normality are, in general, preferred for nonaggregated data ([Gould and Rogers 1991](#); [Gould 1992b](#); [Royston 1991b](#)), the skewness and kurtosis test will permit more observations. Moreover, a normal quantile plot should be used with any test for normality; see [\[R\] Diagnostic plots](#) for more information.

### ▷ Example 1

Using our automobile dataset, we will test whether the variables `mpg` and `trunk` are normally distributed:

```
. use https://www.stata-press.com/data/r19/auto
(1978 automobile data)
. swilk mpg trunk
```

| Shapiro–Wilk W test for normal data |     |         |       |       |         |
|-------------------------------------|-----|---------|-------|-------|---------|
| Variable                            | Obs | W       | V     | z     | Prob>z  |
| mpg                                 | 74  | 0.94821 | 3.335 | 2.627 | 0.00430 |
| trunk                               | 74  | 0.97921 | 1.339 | 0.637 | 0.26215 |

```
. sfrancia mpg trunk
```

| Shapiro–Francia W' test for normal data |     |         |       |       |         |
|-----------------------------------------|-----|---------|-------|-------|---------|
| Variable                                | Obs | W'      | V'    | z     | Prob>z  |
| mpg                                     | 74  | 0.94872 | 3.650 | 2.510 | 0.00604 |
| trunk                                   | 74  | 0.98446 | 1.106 | 0.195 | 0.42271 |

We can reject the hypothesis that `mpg` is normally distributed, but we cannot reject that `trunk` is normally distributed.

The values reported under  $W$  and  $W'$  are the Shapiro–Wilk and Shapiro–Francia test statistics. The tests also report  $V$  and  $V'$  ([Royston 1991d](#)), which are more appealing indexes for departure from normality. The median values of  $V$  and  $V'$  are 1 for samples from normal populations. Large values indicate nonnormality. There is no more information in  $V(V')$  than in  $W(W')$ —one is just the transform of the other.

## ▷ Example 2

We have data on a variable called `studytime`, which we suspect is distributed lognormally:

```
. use https://www.stata-press.com/data/r19/cancer
(Patient survival in drug trial)
. generate lnstudytime = ln(studytime)
. swilk lnstudytime
```

| Shapiro–Wilk W test for normal data |     |         |       |       |         |
|-------------------------------------|-----|---------|-------|-------|---------|
| Variable                            | Obs | W       | V     | z     | Prob>z  |
| lnstudytime                         | 48  | 0.92731 | 3.311 | 2.547 | 0.00543 |

We can reject the lognormal assumption. We do *not* specify the `lnnormal` option when testing for lognormality. The `lnnormal` option is for three-parameter lognormality.

◀

## ▷ Example 3

Having discovered that  $\ln(\text{studytime})$  is not distributed normally, we now test that  $\ln(\text{studytime} - k)$  is normally distributed, where  $k$  is chosen so that the resulting skewness is zero. We obtain the estimate for  $k$  from `lnskew0`; see [R] [lnskew0](#):

```
. lnskew0 lnstudytimek = studytime, level(95)
```

| Transform       | k         | [95% conf. interval] | Skewness  |
|-----------------|-----------|----------------------|-----------|
| ln(studytime-k) | -11.01181 | -infinity - .9477328 | -.0000173 |

```
. swilk lnstudytimek, lnnormal
```

| Shapiro–Wilk W test for 3-parameter lognormal data |     |         |       |       |         |
|----------------------------------------------------|-----|---------|-------|-------|---------|
| Variable                                           | Obs | W       | V     | z     | Prob>z  |
| lnstudytimek                                       | 48  | 0.97064 | 1.337 | 1.261 | 0.10363 |

We cannot reject the hypothesis that  $\ln(\text{studytime} + 11.01181)$  is distributed normally. We do specify the `lnnormal` option when using an estimated value of  $k$ .

◀

## Stored results

`swilk` and `sfrancia` store the following in `r()`:

Scalars

|                   |                        |                   |             |
|-------------------|------------------------|-------------------|-------------|
| <code>r(N)</code> | number of observations | <code>r(W)</code> | $W$ or $W'$ |
| <code>r(p)</code> | $p$ -value             | <code>r(V)</code> | $V$ or $V'$ |
| <code>r(z)</code> | $z$ statistic          |                   |             |

## Methods and formulas

The Shapiro–Wilk test is based on Shapiro and Wilk (1965) with a new approximation accurate for  $4 \leq n \leq 2000$  (Royston 1992). The calculations made by `swilk` are based on Royston (1982, 1992, 1993b).

The Shapiro–Francia test (Shapiro and Francia 1972; Royston 1983; Royston 1993a) is an approximate test that is similar to the Shapiro–Wilk test for very large samples.

The relative merits of the Shapiro–Wilk and Shapiro–Francia tests versus skewness and kurtosis test have been a subject of debate. The interested reader is directed to the articles in the *Stata Technical Bulletin*. Our recommendation is to use the Shapiro–Francia test whenever possible, that is, whenever dealing with nonaggregated or ungrouped data (Gould and Rogers 1991; Gould 1992b); see [R] `swilk`. If normality is rejected, use `sktest` to determine the source of the problem. As both D’Agostino, Belanger, and D’Agostino (1990) and Royston (1991c) mention, researchers should also examine the normal quantile plot to determine normality rather than blindly relying on a few test statistics. See the `qnorm` command documented in [R] **Diagnostic plots** for more information on normal quantile plots.

Samuel Sanford Shapiro (1930–2023) earned degrees in statistics and engineering from City College of New York, Columbia, and Rutgers. After employment in the US Army and industry, he joined the faculty at Florida International University in 1972. Shapiro has coauthored various texts in statistics and published several papers on distributional testing and other statistical topics.

## Acknowledgment

`swilk` and `sfrancia` were written by Patrick Royston of the MRC Clinical Trials Unit, London and coauthor of the Stata Press book *Flexible Parametric Survival Analysis Using Stata: Beyond the Cox Model*.

## Description

`symmetry` performs asymptotic symmetry and marginal homogeneity tests, as well as an exact symmetry test on  $K \times K$  tables where there is a 1-to-1 matching of cases and controls (nonindependence). This testing is used to analyze matched-pair case–control data with multiple discrete levels of the exposure (outcome) variable. In genetics, the test is known as the transmission/disequilibrium test (TDT) and is used to test the association between transmitted and nontransmitted parental marker alleles to an affected child (Spieldman, McGinnis, and Ewens 1993). For  $2 \times 2$  tables, the asymptotic test statistics reduce to the McNemar test statistic, and the exact symmetry test produces an exact McNemar test; see [R] [Epitab](#). For many exposure variables, `symmetry` can optionally perform a test for linear trend in the log relative risk.

`symmetry` expects the data to be in the wide format; that is, each observation contains the matched case and control values in variables *casevar* and *controlvar*. Variables can be numeric or string.

`symmi` is the immediate form of `symmetry`. The `symmi` command uses the values specified on the command line; rows are separated by ‘\’, and options are the same as for `symmetry`. See [U] [19 Immediate commands](#) for a general introduction to immediate commands.

## Quick start

Symmetry and marginal homogeneity tests for 1-to-1 matched case–control studies

| <u>trend</u>   | perform a test for linear trend in the (log) relative risk (RR)  |
| <u>cc</u>      | use continuity correction when calculating test for linear trend |

collect is allowed with symmetry; see [U] 11.1.10 Prefix commands.

fweights are allowed; see [U] 11.1.6 weight.

## Options

Main

**notable** suppresses the output of the contingency table. By default, `symmetry` displays the  $n \times n$  contingency table at the top of the output.

**contrib** reports the contribution of each off-diagonal cell pair to the overall symmetry  $\chi^2$ .

**exact** performs an exact test of table symmetry. This option is recommended for sparse tables. CAUTION: The exact test requires substantial amounts of time and memory for large tables.

**mh** performs two marginal homogeneity tests that do not require the inversion of the variance–covariance matrix.

By default, `symmetry` produces the Stuart–Maxwell test statistic, which requires the inversion of the nondiagonal variance–covariance matrix,  $\mathbf{V}$ . When the table is sparse, the matrix may not be of full rank, and then the command substitutes a generalized inverse  $\mathbf{V}^*$  for  $\mathbf{V}^{-1}$ . `mh` calculates optional marginal homogeneity statistics that do not require the inversion of the variance–covariance matrix. These tests may be preferred in certain situations. See *Methods and formulas* and *Bickeböllner and Clerget-Darpoux (1995)* for details on these test statistics.

`trend` performs a test for linear trend in the (log) relative risk (RR). This option is allowed only for numeric exposure (outcome) variables, and its use should be restricted to measurements on the ordinal or the interval scales.

`cc` specifies that the continuity correction be used when calculating the test for linear trend. This correction should be specified only when the levels of the exposure variable are equally spaced.

## Remarks and examples

`symmetry` and `symmi` may be used to analyze 1-to-1 matched case–control data with multiple discrete levels of the exposure (outcome) variable.

### ▷ Example 1

Consider a survey of 344 individuals (BMDP 1990, 267–270) who were asked in October 1986 whether they agreed with President Reagan’s handling of foreign affairs. In January 1987, after the Iran-Contra affair became public, these same individuals were surveyed again and asked the same question. We would like to know if public opinion changed over this period.

We first describe the dataset and list a few observations.

```
. use https://www.stata-press.com/data/r19/iran
. describe
Contains data from https://www.stata-press.com/data/r19/iran.dta
Observations: 344
Variables: 2 29 Jan 2024 02:37
```

| Variable name | Storage type | Display format | Value label | Variable label           |
|---------------|--------------|----------------|-------------|--------------------------|
| before        | byte         | %8.0g          | vlab        | Public opinion before IC |
| after         | byte         | %8.0g          | vlab        | Public opinion after IC  |

Sorted by:

```
. list in 1/5
```

|    | before   | after    |
|----|----------|----------|
| 1. | Agree    | Agree    |
| 2. | Agree    | Disagree |
| 3. | Agree    | Unsure   |
| 4. | Disagree | Agree    |
| 5. | Disagree | Disagree |

Each observation corresponds to one of the 344 individuals. The data are in wide form so that each observation has a before and an after measurement. We now perform the test without options.

```
. symmetry before after
```

| Public opinion before IC              | Public opinion after IC |          |        | Total | chi2  | df | Prob>chi2 |
|---------------------------------------|-------------------------|----------|--------|-------|-------|----|-----------|
|                                       | Agree                   | Disagree | Unsure |       |       |    |           |
| Agree                                 | 47                      | 56       | 38     | 141   |       |    |           |
| Disagree                              | 28                      | 61       | 31     | 120   |       |    |           |
| Unsure                                | 26                      | 47       | 10     | 83    |       |    |           |
| Total                                 | 101                     | 164      | 79     | 344   |       |    |           |
| Symmetry (asymptotic)                 |                         |          |        |       | 14.87 | 3  | 0.0019    |
| Marginal homogeneity (Stuart-Maxwell) |                         |          |        |       | 14.78 | 2  | 0.0006    |

The test first tabulates the data in a  $K \times K$  table and then performs Bowker's (1948) test for table symmetry and the Stuart–Maxwell (Stuart 1955; Maxwell 1970) test for marginal homogeneity.

Both the symmetry test and the marginal homogeneity test are highly significant, thus indicating a shift in public opinion.

An exact test of symmetry is provided for use on sparse tables. This test is computationally intensive, so it should not be used on large tables. Because we are working on a fast computer, we will run the symmetry test again and this time include the exact option. We will suppress the output of the contingency table by specifying `notable` and include the `contrib` option so that we may further examine the cells responsible for the significant result.

|                                           |                                      | 14.87 | 3  | 0.0019    |
|                                           |                                      | 14.78 | 2  | 0.0006    |
|                                           |                                      | 13.53 | 2  | 0.0012    |
|                                           |                                      | 15.25 | 2  | 0.0005    |
| Symmetry (exact significance probability) |                                      |       |    |           |
|                                           |                                      |       |    | 0.0018    |

The largest contribution to the symmetry  $\chi^2$  is due to cells  $n_{12}$  and  $n_{21}$ . These correspond to changes between the agree and disagree categories. Of the 344 individuals, 56 (16.3%) changed from the agree to the disagree response, whereas only 28 (8.1%) changed in the opposite direction.

For these data, the results from the exact test are similar to those from the asymptotic test.

▷ Example 2

Breslow and Day (1980, 163) reprinted data from Mack et al. (1976) from a case–control study of the effect of exogenous estrogen on the risk of endometrial cancer. The data consist of 59 elderly women diagnosed with endometrial cancer and 59 disease-free control subjects living in the same community as the cases. Cases and controls were matched on age, marital status, and time living in the community. The data collected included information on the daily dose of conjugated estrogen therapy. Breslow and Day analyzed these data by creating four levels of the dose variable. Here are the data as entered into a Stata dataset:

```
. use https://www.stata-press.com/data/r19/bd163
. list, noobs divider
```

| case      | control   | count |
|-----------|-----------|-------|
| 0         | 0         | 6     |
| 0         | 0.1-0.299 | 2     |
| 0         | 0.3-0.625 | 3     |
| 0         | 0.626+    | 1     |
| 0.1-0.299 | 0         | 9     |
| 0.1-0.299 | 0.1-0.299 | 4     |
| 0.1-0.299 | 0.3-0.625 | 2     |
| 0.1-0.299 | 0.626+    | 1     |
| 0.3-0.625 | 0         | 9     |
| 0.3-0.625 | 0.1-0.299 | 2     |
| 0.3-0.625 | 0.3-0.625 | 3     |
| 0.3-0.625 | 0.626+    | 1     |
| 0.626+    | 0         | 12    |
| 0.626+    | 0.1-0.299 | 1     |
| 0.626+    | 0.3-0.625 | 2     |
| 0.626+    | 0.626+    | 1     |

This dataset is in a different format from that of the [previous example](#). Instead of each observation representing one matched pair, each observation represents possibly multiple pairs indicated by the count variable. For instance, the first observation corresponds to six matched pairs where neither the case nor the control was on estrogen, the second observation corresponds to two matched pairs where the case was not on estrogen and the control was on 0.1 to 0.299 mg/day, etc.

To use `symmetry` to analyze this dataset, we must specify `fweight` to indicate that in our data there are observations corresponding to more than one matched pair.

```
. symmetry case control [fweight=count]
```

| Dosage level for case | Dosage level for control |           |           |        | Total |
|-----------------------|--------------------------|-----------|-----------|--------|-------|
|                       | 0                        | 0.1-0.299 | 0.3-0.625 | 0.626+ |       |
| 0                     | 6                        | 2         | 3         | 1      | 12    |
| 0.1-0.299             | 9                        | 4         | 2         | 1      | 16    |
| 0.3-0.625             | 9                        | 2         | 3         | 1      | 15    |
| 0.626+                | 12                       | 1         | 2         | 1      | 16    |
| Total                 | 36                       | 9         | 10        | 4      | 59    |

|                                       | chi2  | df | Prob>chi2 |
|---------------------------------------|-------|----|-----------|
| Symmetry (asymptotic)                 | 17.10 | 6  | 0.0089    |
| Marginal homogeneity (Stuart-Maxwell) | 16.96 | 3  | 0.0007    |

Both the test of symmetry and the test of marginal homogeneity are highly significant, thus leading us to reject the null hypothesis that there is no effect of exposure to estrogen on the risk of endometrial cancer.

Breslow and Day perform a test for trend assuming that the estrogen exposure levels were equally spaced by recoding the exposure levels as 1, 2, 3, and 4.

We can easily reproduce their results by recoding our data in this way and by specifying the trend option. Two new numeric variables were created, ca and co, corresponding to the variables case and control, respectively. Below, we list some of the data and our results from symmetry:

```
. encode case, gen(ca)
. encode control, gen(co)
. label values ca
. label values co
. list in 1/4
```

|    | case | control   | count | ca | co |
|----|------|-----------|-------|----|----|
| 1. | 0    | 0         | 6     | 1  | 1  |
| 2. | 0    | 0.1-0.299 | 2     | 1  | 2  |
| 3. | 0    | 0.3-0.625 | 3     | 1  | 3  |
| 4. | 0    | 0.626+    | 1     | 1  | 4  |

```
. symmetry ca co [fw=count], notable trend cc
```

|                                       | chi2  | df | Prob>chi2 |
|---------------------------------------|-------|----|-----------|
| Symmetry (asymptotic)                 | 17.10 | 6  | 0.0089    |
| Marginal homogeneity (Stuart-Maxwell) | 16.96 | 3  | 0.0007    |
| Linear trend in the (log) RR          | 14.43 | 1  | 0.0001    |

We requested the continuity correction by specifying cc. Doing so is appropriate because our coded exposure levels are equally spaced.

The test for trend was highly significant, indicating an increased risk of endometrial cancer with increased dosage of conjugated estrogen.

You must be cautious: the way in which you code the exposure variable affects the linear trend statistic. If instead of coding the levels as 1, 2, 3, and 4, we had instead used 0, 0.2, 0.46, and 0.7 (roughly the midpoint in the range of each level), we would have obtained a  $\chi^2$  statistic of 11.19 for these data. ◀

## Stored results

symmetry stores the following in `r()`:

Scalars

|                         |                                        |

## Methods and formulas

Methods and formulas are presented under the following headings:

*Asymptotic tests*  
*Exact symmetry test*

### Asymptotic tests

Consider a square table with  $K$  exposure categories, that is,  $K$  rows and  $K$  columns. Let  $n_{ij}$  be the count corresponding to row  $i$  and column  $j$  of the table,  $N_{ij} = n_{ij} + n_{ji}$ , for  $i, j = 1, 2, \dots, K$ , and  $n_{i\cdot}$ , and let  $n_{\cdot j}$  be the marginal totals for row  $i$  and column  $j$ , respectively. Asymptotic tests for symmetry and marginal homogeneity for this  $K \times K$  table are calculated as follows:

The null hypothesis of complete symmetry  $p_{ij} = p_{ji}$ ,  $i \neq j$ , is tested by calculating the test statistic (Bowker 1948)

$$T_{cs} = \sum_{i < j} \frac{(n_{ij} - n_{ji})^2}{n_{ij} + n_{ji}}$$

which is asymptotically distributed as  $\chi^2$  with  $K(K - 1)/2 - R$  degrees of freedom, where  $R$  is the number of off-diagonal cells with  $N_{ij} = 0$  as discussed in Hoenig, Morgan, and Brown (1995).

The null hypothesis of marginal homogeneity,  $p_{i.} = p_{.i}$ , is tested by calculating the Stuart–Maxwell test statistic (Stuart 1955; Maxwell 1970),

$$T_{\text{sm}} = \mathbf{d}'\mathbf{V}^{-1}\mathbf{d}$$

where  $\mathbf{d}$  is a column vector with elements equal to the differences  $d_i = n_{i.} - n_{.i}$  for  $i = 1, 2, \dots, K$ , and  $\mathbf{V}$  is the variance–covariance matrix with elements

$$\begin{aligned} v_{ii} &= n_{i.} + n_{.i} - 2n_{ii} \\ v_{ij} &= -(n_{ij} + n_{ji}), \quad i \neq j \end{aligned}$$

$T_{\text{sm}}$  is asymptotically  $\chi^2$  with  $K - 1$  degrees of freedom.

This test statistic properly accounts for the dependence between the table’s rows and columns. When the matrix  $\mathbf{V}$  is not of full rank, a generalized inverse  $\mathbf{V}^*$  is substituted for  $\mathbf{V}^{-1}$ .

The Bickeböllner and Clerget-Darpoux (1995) marginal homogeneity test statistic is calculated by

$$T_{\text{mh}} = \sum_i \frac{(n_{i.} - n_{.i})^2}{n_{i.} + n_{.i}}$$

This statistic is asymptotically distributed, under the assumption of marginal independence, as  $\chi^2$  with  $K - 1$  degrees of freedom.

The marginal homogeneity (no diagonals) test statistic  $T_{\text{mh}}^0$  is calculated in the same way as  $T_{\text{mh}}$ , except that the diagonal elements do not enter into the calculation of the marginal totals. Unlike the previous test statistic,  $T_{\text{mh}}^0$  reduces to a McNemar test statistic for  $2 \times 2$  tables. The test statistic  $\{(K - 1)/2\}T_{\text{mh}}^0$  is asymptotically distributed as  $\chi^2$  with  $K - 1$  degrees of freedom (Cleves, Olson, and Jacobs 1997; Spielman and Ewens 1996).

Breslow and Day’s test statistic for linear trend in the (log) of RR is

$$\frac{\left\{ \sum_{i < j} (n_{ij} - n_{ji})(X_j - X_i) - cc \right\}^2}{\sum_{i < j} (n_{ij} + n_{ji})(X_j - X_i)^2}$$

where the  $X_j$  are the doses associated with the various levels of exposure and  $cc$  is the continuity correction; it is asymptotically distributed as  $\chi^2$  with 1 degree of freedom.

The continuity correction option is applicable only when the levels of the exposure variable are equally spaced.

### Exact symmetry test

The exact test is based on a permutation algorithm applied to the null distribution. The distribution of the off-diagonal elements  $n_{ij}$ ,  $i \neq j$ , conditional on the sum of the complementary off-diagonal cells,  $N_{ij} = n_{ij} + n_{ji}$ , can be written as the product of  $K(K - 1)/2$  binomial random variables,

$$P(\mathbf{n}) = \prod_{i < j} \binom{N_{ij}}{n_{ij}} \pi_{ij}^{n_{ij}} (1 - \pi_{ij})^{n_{ji}}$$

where  $\mathbf{n}$  is a vector with elements  $n_{ij}$  and  $\pi_{ij} = E(n_{ij}/N_{ij}|N_{ij})$ . Under the null hypothesis of complete symmetry,  $\pi_{ij} = \pi_{ji} = 1/2$ , and thus the permutation distribution is given by

$$P_0(\mathbf{n}) = \prod_{i < j} \binom{N_{ij}}{n_{ij}} \left(\frac{1}{2}\right)^{N_{ij}}$$

The exact significance test is performed by evaluating

$$P_{cs} = \sum_{\mathbf{n} \in p} P_0(\mathbf{n})$$

where  $p = \{n : P_0(\mathbf{n}) < P_0(\mathbf{n}^*)\}$  and  $\mathbf{n}^*$  is the observed contingency table data vector. The algorithm evaluates  $p_{cs}$  exactly. For information about permutation tests, see Good (2005, 2006).

## Description

Tables allow us to effectively communicate information about our data and results from our analyses. The `table` command is a flexible tool for creating tables. It allows you to create tabulations, tables of summary statistics, tables of results from hypothesis tests, tables of regression results, and more. `table` also allows you to customize the table so that it effectively communicates the results.

## Remarks and examples

Remarks are presented under the following headings:

[Overview](#)

[Tabulations](#)

[Tables of summary statistics](#)

[Tables of results from other commands](#)

[Flexible tables combining results](#)

[Formatting, customizing, and exporting tables](#)

## Overview

The `table` command allows you to create various types of tables.

1. Tabulations of one, two, or more categorical variables, reporting frequencies, percentages, or proportions.
2. Tables of summary statistics such as means, standard deviations, medians, and the like—perhaps computed across levels of one or more categorical variables.
3. Tables of results from other Stata commands, such as regression results or results of classic hypothesis tests.
4. Tables combining summary statistics and results from other Stata commands.

`table` obtains the statistics it reports in two ways. The `table` command itself can compute summary statistics. `table` also provides a `command()` option that allows you to run any Stata command and include its results in the table.

`table` also provides much flexibility for you to arrange the results in your table in a meaningful way. You can control how the rows, columns, and potentially even separate tables are defined. For instance, you might type

```
. table (var1) (var2) ...
```

to place the levels of `var1` on the rows and the levels of `var2` on the columns. The first set of parentheses is used to define the rows, and the second set is used to define the columns. The parentheses could be omitted in this case, but for clarity we will use them in our discussion here.

We could use the levels of both `var1` and `var2` to define the rows.

```
. table (var1 var2) ...
```

If we have an additional variable, `var3`, we can define rows by both `var1` and `var2` and the columns by `var3` by typing

```
. table (var1 var2) (var3) ...
```

or we can place the levels of `var2` and `var3` on the columns,

```
. table (var1) (var2 var3) ...
```

We could even create separate tables for the levels of `var3`,

```
. table (var1) (var2) (var3) ...
```

The third set of parentheses defines the separate tables.

If our table reports multiple statistics, say, means and standard deviations, we can use the keyword `result` to specify how they are included in the table layout. To place the statistics on separate rows, we could type

```
. table (var1 result) (var2) ...
```

The flexibility of the table layout goes beyond these examples. You can add additional variables to define rows, columns, and tables as is appropriate for the table you wish to create.

In addition to controlling the layout of your table, you can customize the results by specifying formats, including stars representing significance, and selecting from styles that determine how the headers of the table are displayed.

## Tabulations

Tabulations allow you to examine the distribution of your data across the levels of one or more categorical variables. Tabulations often report frequencies, percentages, and proportions.

With `table`, you can easily create one-way tabulations, two-way tabulations, three-way tabulations, and even more complex tabulations. For example, we could create a two-way tabulation of `region` and `diabetes`, reporting frequencies,

```
. table (region) (diabetes)
```

|        | Diabetes status |          | Total  |
|--------|-----------------|----------|--------|
|        | Not diabetic    | Diabetic |        |
| Region |                 |          |        |
| NE     | 1,997           | 98       | 2,095  |
| MW     | 2,648           | 125      | 2,773  |
| S      | 2,692           | 161      | 2,853  |
| W      | 2,513           | 115      | 2,628  |
| Total  | 9,850           | 499      | 10,349 |

or we can report percentages,

```
. table (region) (diabetes), statistic(percent)
```

|        | Diabetes status |          | Total  |
|--------|-----------------|----------|--------|
|        | Not diabetic    | Diabetic |        |
| Region |                 |          |        |
| NE     | 19.30           | 0.95     | 20.24  |
| MW     | 25.59           | 1.21     | 26.79  |
| S      | 26.01           | 1.56     | 27.57  |
| W      | 24.28           | 1.11     | 25.39  |
| Total  | 95.18           | 4.82     | 100.00 |

To learn how to create tabulations, see

- [R] [table oneway](#) One-way tabulation
- [R] [table twoway](#) Two-way tabulation
- [R] [table multiway](#) Multiway tables

In these entries, we provide simplified syntax for creating the specific type of tabulation you are interested in, and we provide a number of examples demonstrating how to build these tables and customize the results.

## Tables of summary statistics

`table` can compute summary statistics such as minimums, maximums, means, standard deviations, medians, and interquartile ranges. Summary statistics can be computed for one or more variables. Summary statistics can also be computed separately for groups of data. For example, we can create a table reporting the means of age, height, and bmi,

```
. table, statistic(mean age height bmi)
```

|                       |          |
|-----------------------|----------|
| Age (years)           | 47.57965 |
| Height (cm)           | 167.6509 |
| Body mass index (BMI) | 25.5376  |

or we can compute these means separately for males and females,

```
. table () (sex), statistic(mean age height bmi)
```

|                       | Sex      |          | Total    |
|-----------------------|----------|----------|----------|
|                       | Male     | Female   |          |
| Age (years)           | 47.4238  | 47.72057 | 47.57965 |
| Height (cm)           | 174.7421 | 161.2393 | 167.6509 |
| Body mass index (BMI) | 25.50999 | 25.56256 | 25.5376  |

To learn how to create tables of summary statistics, including the simplified `table` syntax and worked examples, see

[R] [table summary](#)

Table of summary statistics

You can also create a table of summary statistics with `dtable`. The advantage of using `dtable` is that you can create a table with a title and notes and export it to a variety of file types, all in a single step. Unlike `table`, however, `dtable` has a predefined layout, and you will not be able to specify how the results should be arranged in the table.

## Tables of results from other commands

With `table`'s `command()` option, you can run any Stata command and place statistics reported by that command in your table. For instance, you might use `test` to test for differences in means or use `regress` to fit a linear regression model. You can include any stored results from these commands in your table. For example, we can create a table to compare coefficients from linear regressions of `bpsysol` on age and weight fit separately for males and females.

```
. table (colname) (sex result), command(regress bpsystol age weight)
```

|             | Sex      |          | Total    |
|-------------|----------|----------|----------|
|             | Male     | Female   |          |
| Age (years) | .4789361 | .7735499 | .6379892 |
| Weight (kg) | .3346106 | .4586108 | .4069041 |
| Intercept   | 84.08037 | 61.70456 | 71.27096 |

To learn how to create tables with results from other commands, including simplified `table` syntax and worked examples, see

|                                            |                             |
|--------------------------------------------|-----------------------------|
| [R] <a href="#">table hypothesis tests</a> | Table of hypothesis tests   |
| [R] <a href="#">table regression</a>       | Table of regression results |

## Flexible tables combining results

`table` can create tables with combinations of frequencies, other summary statistics, and results from other table commands. To see the full syntax and discussion of how `table` automates the table layout, see

|                           |                                                      |
|---------------------------|------------------------------------------------------|
| [R] <a href="#">table</a> | Table of frequencies, summaries, and command results |
|---------------------------|------------------------------------------------------|

## Formatting, customizing, and exporting tables

`table` allows you to customize your results by specifying the layout and with options that change the numeric formatting, add characters such as percent signs or parentheses to specific types of statistics, add stars representing significance levels, and modify the look of confidence intervals. In addition, Stata provides predefined styles that you may select from using the `style()` option. These styles control which labels are displayed in the headers of the tables, how the labels are aligned, how the statistics are aligned within the cells, and more. To learn about the predefined styles that you can select from, see [TABLES] [Predefined styles](#). Examples of using the `style()` and other formatting options are provided in the entries for specific types of tables listed in the previous sections.

The results from `table` can be customized even beyond what its formatting options allow. `table` is unique in that it stores its results in a format that we refer to as a “collection”. Stata’s `collect` suite of commands can be used to produce highly customized tables from results in a collection and to export those tables to presentation-ready formats such as HTML, Word,  $\LaTeX$ , PDF, Excel, and more. Examples of using `collect` to modify labels and table layout are also provided in the entries for the specific types of tables listed in the previous sections. To learn more about the `collect` commands, see [TABLES] [Intro](#) and the entries discussed therein.

## Description

`table` is a flexible command for creating tables of many types—tabulations, tables of summary statistics, tables of regression results, and more. `table` can calculate summary statistics to display in the table. `table` can also include results from other Stata commands.

## Quick start

Two-way tabulation of `a1` and `a2`

```
table a1 a2
```

Table of means for `v1` and `v2` across the levels of `a1`

```
table a1, statistic(mean v1 v2)
```

Two-way table with `a1` defining rows and `a2` defining columns, with frequencies and pairwise correlation coefficients between `v3` and `v4` computed for every cell

```
table a1 a2, command(pwcorr v3 v4)
```

Table of regression coefficients with means of the covariates; rows correspond to covariates and columns correspond to the statistics

```
table (colname) (statcmd result),
command(regress y x1 x2)
statistic(mean x1 x2)
```

Same as above, and include standard deviations for the covariates

```
table (colname) (statcmd result),
command(regress y x1 x2)
statistic(mean x1 x2)
statistic(sd x1 x2)
```

## Menu

Statistics > Summaries, tables, and tests > Tables of frequencies, summaries, and command results

## Syntax

*Basic syntax for a one-way table*

```
table rowvar
table () colvar
```

*Basic syntax for a two-way table*

```
table rowvar colvar
```

*Basic syntax for an  $n$ -way table*

```
table rowvars colvar
table rowvar (colvars)
table (rowvars) (colvars)
```

*Basic syntax for multiple  $n$ -way tables*

```
table (rowvars) (colvars) (tabvars)
```

*Full syntax*

```
table (rowspec) (colspec) [(tabspec)] [if] [in] [weight] [, options]
```

*rowspec*, *colspec*, and *tabspec* may be empty or may include variable names or any of the following keywords:

| <i>keyword</i> | Description                                                       |
|----------------|-------------------------------------------------------------------|
| result         | requested statistics                                              |
| stars          | stars denoting statistical significance                           |
| var            | variables from <code>statistic()</code> option                    |

*fontfamily* specifies a valid font family.

*unit* may be in (inch), pt (point), or cm (centimeter). An inch is equivalent to 72 points and 2.54 centimeters. The default is pt.

*variant* may be allcaps, smallcaps, or normal.

*variant* (allcaps) changes the text to all uppercase letters; applicable when publishing items from a collection to Microsoft Word, PDF, L<sup>A</sup>T<sub>E</sub>X, and HTML files.

*variant* (smallcaps) changes the text to use large capitals for uppercase letters and smaller capitals for lowercase letters; applicable when publishing items from a collection to Microsoft Word, L<sup>A</sup>T<sub>E</sub>X, and HTML files.

*variant* (normal) changes the font variant back to normal and leaves the capitalization unchanged from the original text; applicable when publishing items from a collection to Microsoft Word, PDF, L<sup>A</sup>T<sub>E</sub>X, and HTML files.

*smcl* specifies the name of the SMCL directive to render text for SMCL output. The supported SMCL directives are `input`, `error`, `result`, and `text`.

*latex* specifies the name of a L<sup>A</sup>T<sub>E</sub>X macro to render text for L<sup>A</sup>T<sub>E</sub>X output. Example L<sup>A</sup>T<sub>E</sub>X macro names are `textbf`, `textsf`, `textrm`, and `texttt`. Custom L<sup>A</sup>T<sub>E</sub>X macros are also allowed. If *text* is to be rendered in a cell, title, or note, then *latex* is translated to the following when you export to L<sup>A</sup>T<sub>E</sub>X:

```
\latex {text}
```

*sspec* is

```
[background(bgcolor) foreground(fgcolor) pattern(fpattern)]
```

*bgcolor* specifies the background color.

*fgcolor* specifies the foreground color.

*fpattern* specifies the fill pattern. A complete list of fill patterns is shown in the [Appendix](#).

*bgcolor*, *fgcolor*, and *color* may be one of the colors listed in the [Appendix](#); a valid RGB value in the form `### ## #`, for example, `171 248 103`; or a valid RRGGBB hex value in the form `#####`, for example, `ABF867`.

## Options

### Main

`totals` (*totals*) and `nototals` control which totals are to be displayed in the table. By default, all totals are reported.

`totals` (*totals*) specifies which margin totals to display in the reported table. *totals* can contain variables in *rowspec*, *colspec*, *tabspec*, and their interaction. Interactions can be specified by using the # operator.

`nototals` prevents table from displaying any totals.

### Statistics

`statistic` (*statspec*) specifies the statistic to be displayed. Frequency statistics, summary statistics, and ratio statistics are available by specifying `statistic` (*freqstat*), `statistic` (*sumstat varlist*), and `statistic` (*ratiostat [varlist] [ , ratio\_options ]*), respectively.

`statistic()` may be repeated to request multiple statistics.

`statistic` (*freqstat*) specifies that frequencies be computed.

| <i>freqstat</i>        | Definition     |
|------------------------|----------------|
| <code>frequency</code> | frequency      |
| <code>sumw</code>      | sum of weights |

`statistic(sumstat varlist)` specifies that summary statistic *sumstat* be computed for the variables in *varlist*.

| <i>sumstat</i>         | Definition                                              |
|------------------------|---------------------------------------------------------|
| mean                   | mean                                                    |
| semean                 | standard error of the mean                              |
| sebinomial             | standard error of the mean, binomial                    |
| sepoisson              | standard error of the mean, Poisson                     |
| variance               | variance                                                |
| sd                     | standard deviation                                      |
| skewness               | skewness                                                |
| kurtosis               | kurtosis                                                |
| cv                     | coefficient of variation                                |
| svy cv                 | coefficient of variation (svy)                          |
| geomean                | geometric mean                                          |
| geosd                  | geometric standard deviation                            |
| count                  | number of nonmissing values                             |
| median                 | median                                                  |
| p#                     | #th percentile                                          |
| q1                     | first quartile                                          |
| q2                     | second quartile                                         |
| q3                     | third quartile                                          |
| iqr                    | interquartile range                                     |
| min                    | minimum value                                           |
| max                    | maximum value                                           |
| range                  | range                                                   |
| first                  | first value                                             |
| last                   | last value                                              |
| firstnm                | first nonmissing value                                  |
| lastnm                 | last nonmissing value                                   |
| total                  | total                                                   |
| rawtotal               | unweighted total                                        |
| <u>fvfrequency</u>     | frequency of each factor-variable level                 |
| <u>fvrawfrequency</u>  | unweighted frequency of each factor-variable level      |
| <u>fvproportion</u>    | proportion within each factor-variable level            |
| <u>fvrawproportion</u> | unweighted proportion within each factor-variable level |
| <u>fvpercent</u>       | percentage within each factor-variable level            |
| <u>fvrawpercent</u>    | unweighted percentage within each factor-variable level |

`statistic(ratiostat [varlist] [ , ratio_options ])` specifies that ratio statistic *ratiostat* be computed. If *varlist* is specified, ratios are computed based on the totals of the specified variables. If *varlist* is not specified, ratios are computed based on frequencies.

| <i>ratiostat</i>     | Definition                                       |
|----------------------|--------------------------------------------------|
| <u>proportion</u>    | proportion                                       |
| <u>percent</u>       | percentage                                       |
| <u>rawproportion</u> | proportion ignoring optionally specified weights |
| <u>rawpercent</u>    | percentage ignoring optionally specified weights |

| <i>ratio_options</i>           | Definition                                                            |
|--------------------------------|-----------------------------------------------------------------------|
| <u>across(<i>cellspec</i>)</u> | percentages or proportions across levels of variables or interactions |
| <u>total</u>                   | compute overall percentages or proportions                            |

*cellspec* may contain *rowvars*, *colvars*, *tabvars*, or an interaction between any of these variables. Interactions can be specified by using the # operator.

#### Commands

`command(cmdsspec)` specifies the Stata commands from which to collect results. `command()` may be repeated to collect results from multiple commands.

*cmds*spec is [*explist*: ] *command* [*arguments*] [ , *cmdoptions* ]

*explist* specifies which results to collect and report in the table. *explist* may include *result identifiers* and *named expressions*.

*result identifiers* are results stored in `r()` and `e()` by the *command*. For instance, *result identifiers* could be `r(mean)`, `r(C)`, or `e(chi2)`. After estimation commands, *result identifiers* also include the following:

| Identifier            | Result                                                              |
|-----------------------|---------------------------------------------------------------------|
| <code>_r_b</code>     | coefficients or transformed coefficients reported by <i>command</i> |
| <code>_r_se</code>    | standard errors of <code>_r_b</code>                                |
| <code>_r_z</code>     | test statistics for <code>_r_b</code>                               |
| <code>_r_z_abs</code> | absolute value of <code>_r_z</code>                                 |
| <code>_r_p</code>     | <i>p</i> -values for <code>_r_b</code>                              |
| <code>_r_lb</code>    | lower bounds of confidence intervals for <code>_r_b</code>          |
| <code>_r_ub</code>    | upper bounds of confidence intervals for <code>_r_b</code>          |
| <code>_r_ci</code>    | confidence intervals for <code>_r_b</code>                          |
| <code>_r_cr1b</code>  | lower bounds of credible intervals for <code>_r_b</code>            |
| <code>_r_crub</code>  | upper bounds of credible intervals for <code>_r_b</code>            |
| <code>_r_cri</code>   | credible intervals for <code>_r_b</code>                            |
| <code>_r_df</code>    | degrees of freedom for <code>_r_b</code>                            |

*named expressions* are specified as *name* = *exp*, where *name* may be any valid Stata name and *exp* is an expression, typically an expression that involves one or more *result identifiers*. An example of a named expression is `sd = sqrt(r(variance))`.

For r-class commands, the default is to include all numeric scalars posted to `r()` in the table results. For e-class commands, the default is to include `_r_b` in the table results.

*command* is any command that follows standard Stata syntax.

*arguments* may be anything so long as they do not include an `if` clause, `in range`, or weight specification.

Any `if` or `in` qualifier and weights should be specified directly with `table`, not within the `command()` option.

*cmdoptions* may be anything supported by *command*.

#### Formats

`nformat(%fmt [results][, basestyle])` changes the numeric format, such as the number of decimal places, for specified results. If *results* are not specified, the numeric format is changed for all results.

*results* may be any statistic named in option `statistic()` (that is, any *freqstat*, *sumstat*, or *ratiostat*) or may be any name in the `e()` or `r()` results produced by commands specified in option `command()`.

This option is repeatable, and when multiple formats apply to one result, the rightmost specification is applied.

This option does not affect the format of numeric layout variables (*rowspec*, *colspec*, and *tabspec*) or the format of factor variables specified in the `statistic()` option. The default format of these variables is taken from the dataset.

*basestyle* indicates that the format be applied to results that do not already have their own format instead of overriding the format for all results.

`sformat(sfmt [results])` changes the string format for specified results. You can, for instance, add symbols or text to the values reported in the table by modifying the string format.

*sfmt* may contain a mix of text and `%s`. Here `%s` refers to the numeric value that is formatted as specified using `nformat()`. The text will be placed around the numeric values in your table as it is placed around `%s` in this option. For instance, to place parentheses around the percent statistics, you can specify `sformat("(%s) percent)`.

*results* may be any statistic named in option `statistic()` (that is, any *freqstat*, *sumstat*, or *ratiostat*) or may be any name in the `e()` or `r()` results produced by commands specified in option `command()`.

Two text characters must be specified using a special character sequence if you want them to be displayed in your table. To include `%`, type `%%`. To include `\`, type `\\`. For instance, to place a percent sign following percent statistics, you can specify `sformat("%s%" percent)`.

This option is repeatable, and when multiple formats apply to one result, the rightmost specification is applied.

`cidelimiter(char)` changes the delimiter between confidence interval limits to *char*. The default is `cidelimiter(" ")`, that is, two spaces.

`cridelimiter(char)` changes the delimiter between credible interval limits to *char*. The default is `cridelimiter(" ")`, that is, two spaces.

## Stars

`stars(starspec)` specifies that stars representing statistical significance be included in the table. *starspec* identifies the result whose values determine significance, which characters should represent each significance level, and where these characters should be displayed in the table. *starspec* is

```
starres [#1 "label1" [#2 "label2" [#3 "label3" [#4 "label4" [#5 "label5"]]]]]
[, attach(attachres) result dimension starsnoteopts]
```

*starres* is the name of the result whose values determine which characters, typically which number of stars, are to be displayed.

*label1* specifies the characters to be displayed when *starres* < #1.

*label2* specifies the characters to be displayed when *starres* < #2.

*label3* specifies the characters to be displayed when *starres* < #3.

*label4* specifies the characters to be displayed when *starres* < #4.

*label5* specifies the characters to be displayed when *starres* < #5.

`attach(attachres)` specifies the name of the result to which the characters defined by *label1*, ..., *label5* are to be attached. If `attach()` is not specified, a new result named `stars` is created and is automatically added to the table.

`result` and `dimension` control how `collect stars` adds items when labeling significant results. These options are mutually exclusive.

`result` specifies the default behavior, and this option is necessary only if the following `dimension` behavior is in effect and you want to change back to the `result` behavior.

`dimension` specifies that dimension `stars` be added to the collection. Items will be tagged with `stars[value]`, and the labels will be tagged with `stars[label]`. Use this option for layouts where results are to be stacked within columns, and use new dimension `stars` in the column specification of the layout.

*starsnoteopts* control the display and composition of the stars note.

`noshownote` and `shownote` control whether to display the stars note.

`increasing` and `decreasing` control the order of *p*-values in the stars note.

`pvname(string)` specifies a name for the *p*-value in the stars note. The default is `pvname(p)`.

`delimiter(string)` specifies the delimiter between labels in the stars note. The default is `delimiter(",")`.

`nformat(%fmt)` specifies the numeric format for the cutoff values in the stars note. The default is `nformat(%9.0g)`.

`prefix(string)` specifies the prefix for the stars note. The prefix is empty by default.

`suffix(string)` specifies the suffix for the stars note. The suffix is empty by default.

For example, `stars(_r_p 0.01 "***" 0.05 "***" 0.1 "*", attach(_r_b))` could be added to a table of regression results to specify that stars be defined based on the *p*-values in `_r_p` and be attached to the reported coefficients (`_r_b`).

Title

`title(string)` adds the text *string* as a title to the table.

`titlestyles(text_styles)` changes the style for the table title. *text\_styles* are the following:

`font([fontfamily] [, size(# [unit]) color(color) variant(variant) [no]bold [no]italic [no]strikeout [no]underline])` specifies the font style. These font style properties are applicable when exporting the table to Microsoft Word, Microsoft Excel, PDF, HTML, and  $\LaTeX$  files, unless otherwise specified.

*fontfamily* specifies a valid font family. This font style property is applicable when publishing items from a collection to Microsoft Word, Microsoft Excel, PDF, and HTML files.

`size(# [unit])` specifies the font size as a number optionally followed by units. This font style property is applicable when publishing items from a collection to Microsoft Word, Microsoft Excel, PDF, and HTML files.

`color(color)` specifies the text color.

`variant(variant)` specifies the font variant and capitalization.

`bold` and `nobold` specify the font weight. `bold` changes the font weight to bold; `nobold` changes the font weight back to normal.

`italic` and `noitalic` specify the font style. `italic` changes the font style to italic; `noitalic` changes the font style back to normal.

`strikeout` and `nostrikeout` specify whether to add a strikeout mark to the title. `strikeout` adds a strikeout mark to the title; `nostrikeout` changes the title back to normal.

`underline` and `nounderline` specify whether to underline the table title. `underline` adds a single line under the title; `nounderline` removes the underline.

Only one of `strikeout` or `underline` is allowed when publishing to HTML files.

`smcl(smcl)` specifies how to render the table title for SMCL output. This style property is applicable only when publishing items from a collection to a SMCL file.

`latex(latex)` specifies how to render the table title for  $\LaTeX$  output. This style property is applicable only when publishing items from a collection to a  $\LaTeX$  file.

`shading(sspec)` sets the background color, foreground color, and fill pattern. The background color is applicable when exporting the table to Microsoft Word, Microsoft Excel, PDF, HTML, and  $\LaTeX$  files. The foreground color and fill pattern are applicable when exporting the table to Microsoft Word and Microsoft Excel.

`note(string)` adds the text *string* as a note to the table. `note()` may be specified multiple times to add multiple notes. Each note is placed on a new line.

`notestyles(text_styles)` changes the style for the table notes. *text\_styles* are the following:

`font([fontfamily] [, size(# [unit]) color(color) variant(variant) [no]bold [no]italic [no]strikeout [no]underline])` specifies the font style. These font style properties are applicable when exporting the table to Microsoft Word, Microsoft Excel, PDF, HTML, and  $\LaTeX$  files, unless otherwise specified.

*fontfamily* specifies a valid font family. This font style property is applicable when publishing items from a collection to Microsoft Word, Microsoft Excel, PDF, and HTML files.

`size(# [unit])` specifies the font size as a number optionally followed by units. This font style property is applicable when publishing items from a collection to Microsoft Word, Microsoft Excel, PDF, and HTML files.

`color(color)` specifies the text color.

`variant(variant)` specifies the font variant and capitalization.

`bold` and `nobold` specify the font weight. `bold` changes the font weight to bold; `nobold` changes the font weight back to normal.

`italic` and `noitalic` specify the font style. `italic` changes the font style to italic; `noitalic` changes the font style back to normal.

`strikeout` and `nostrikeout` specify whether to add a strikeout mark to the notes. `strikeout` adds a strikeout mark to the note; `nostrikeout` changes the note back to normal.

`underline` and `nounderline` specify whether to underline the table notes. `underline` adds a single line under the notes; `nounderline` removes the underline.

Only one of `strikeout` or `underline` is allowed when publishing to HTML files.

`smcl(smcl)` specifies how to render the table notes for SMCL output. This style property is applicable only when publishing items from a collection to a SMCL file.

`latex(latex)` specifies how to render the table notes for  $\LaTeX$  output. This style property is applicable only when publishing items from a collection to a  $\LaTeX$  file.

`shading(sspec)` sets the background color, foreground color, and fill pattern. The background color is applicable when exporting the table to Microsoft Word, Microsoft Excel, PDF, HTML, and  $\LaTeX$  files. The foreground color and fill pattern are applicable when exporting the table to Microsoft Word and Microsoft Excel.

## Export

`export(filename.suffix[, export_opts])` exports the table to the specified file. *export\_opts* are the following:

`as(fileformat)` specifies the file format to which the table is to be exported. This option is rarely specified because, by default, `table` determines the format from the suffix of the file being created.

`replace` permits `table` to overwrite an existing file.

`noisily` specifies that `table` show the commands used to export the table to Microsoft Word, Microsoft Excel, and PDF files. The `putdocx`, `putexcel`, or `putpdf` command used to export the table will be displayed.

`dofile(filename[, replace])` specifies that `table` save to *filename* the commands used to export the table to Microsoft Word, Microsoft Excel, and PDF files.

If *filename* already exists, it can be overwritten by specifying `replace`. If *filename* is specified without an extension, `.do` is assumed.

`append` specifies that `table` append the table to an existing file.

This option is applicable when you export the table to an HTML, a  $\LaTeX$ , a SMCL, a `txt`, or a Markdown file. When you export to HTML and  $\LaTeX$  files, the `append` option implies the `tableonly` option. Furthermore, when you export to HTML files, if the target CSS file already exists, `table` will also append to it.

`tableonly` specifies that only the table be exported to the specified HTML or  $\LaTeX$  document. With this option, the produced file may be included in other HTML or  $\LaTeX$  documents. By default, `table` produces complete HTML and  $\LaTeX$  documents.

When you export to an HTML file, if the `cssfile()` option is not specified, a CSS filename is constructed from *filename*, with the extension replaced with `.css`.

`cssfile(cssfile)` specifies that `table` define the styles in *cssfile* instead of *filename* when you export to HTML.

`prefix(prefix)` specifies that `table` use *prefix* to identify style classes when you export to HTML.

`sheet(sheetname [, replace])` saves to the worksheet named *sheetname*. For more information about this option, see [RPT] [putexcel](#).

`cell(cell)` specifies an Excel upper-left cell as the starting position to publish the table. The default is `cell(A1)`.

`modify` permits `putexcel` set to modify an Excel file. For more information about this option, see [RPT] [putexcel](#).

`noopen` prevents `putexcel` from opening the Excel file in memory for modification. It does not appear in the dialog box. For more information about this option, see [RPT] [putexcel](#).

## Options

`listwise` handles missing values through listwise deletion, meaning that the entire observation is omitted from the sample if any variable specified in a `statistic()` option is missing for that observation. By default, `table` will omit an observation only if all variables specified in all `statistic()` options are missing for that observation.

`missing` specifies that numeric missing values of any variables specified in `rowspec`, `colspec`, or `tabspec` be treated as valid categories. By default, observations with a numeric missing value in any of these variables are omitted.

This option does not apply to factor variables specified with statistics `fvfrequency`, `fvrawfrequency`, `fvproportion`, `fvrawproportion`, `fvpercent`, or `fvrawpercent`.

`showcounts` specifies that `table` report the sample size for each variable specified in option `statistic()`.

`zerocounts` specifies that `table` report a 0 in empty cells for results `count`, `frequency`, `fvfrequency`, and `fvrawfrequency`.

`name(cname)` specifies that a collection named *cname* be associated with the collected statistics and results. The default is `name(Table)`.

`append` specifies that `table` append its collection information into the collection named in `name()`.

`replace` permits `table` to overwrite an existing collection. This option is implied for `name(Table)` when `append` is not specified.

`label(filename)` specifies the *filename* containing the collection labels to use for your table. Labels in *filename* will be loaded for the table, and any labels not specified in *filename* will be taken from the labels defined in `c(collect_label)`. The default is to use only the collection labels set in `c(collect_label)`; see [TABLES] [set collect\\_label](#).

`style(filename [, override])` specifies the *filename* containing the collection styles to use for your table. The default collection styles will be discarded, and only the collection styles in *filename* will be applied.

If you prefer the default collection styles but also want to apply any styles in *filename*, specify `override`. If there are conflicts between the default collection styles and those in *filename*, the ones in *filename* will take precedence.

The default is to use only the collection styles set in `c(table_style)`; see [TABLES] [set table\\_style](#).

The following options are available with `table` but are not shown in the dialog box:

`markvar(newvar)` generates an indicator variable that identifies the observations used in the tabulation.

`noisily` specifies that output from the commands specified in `command()` options be displayed. By default, output from commands is suppressed.

## Remarks and examples

Remarks are presented under the following headings:

[Introduction](#)

[Specifying the table layout](#)

[Advanced table customization](#)

### Introduction

The `table` command can create many customized tables, ranging from simple one-way tabulations to multiple *n*-way tables with summary statistics and estimation results. `table` can compute and report frequencies, proportions, percentiles, and other summary statistics. It can also run other Stata commands and include their results in the table. This means you can combine the summary statistics computed

by `table` with test statistics, correlations, regression coefficients, and other results collected from Stata commands. In addition to building tables with the desired statistics, you can customize them by formatting the values in the table and applying predefined styles and labels that affect how the row headers, column headers, and values are displayed in the table.

`table` can accommodate a variety of layouts. You can define the rows, columns, and even separate tables by levels of categorical variables, statistics, or Stata commands.

If your goal is simply to create a table of estimation results or descriptive statistics, you can use the `etable` and `dtable` commands, respectively. These commands allow you to create these tables and export them to a variety of file types in a single step. However, unlike `table`, these commands create tables with a predefined layout. Therefore, if you want control over the layout or you wish to include a combination of summary statistics, estimation results, and results from other Stata commands, you should use the `table` command.

In the following entries, we provide simplified syntax, examples, and discussion for specialized types of tables that can be created using `table`. If you are interested in creating one of these types of tables, we suggest reading the corresponding entry.

|                                   |                             |
|-----------------------------------|-----------------------------|
| [R] <b>table oneway</b>           | One-way tabulation          |
| [R] <b>table twoway</b>           | Two-way tabulation          |
| [R] <b>table multiway</b>         | Multiway tables             |
| [R] <b>table summary</b>          | Table of summary statistics |
| [R] <b>table hypothesis tests</b> | Table of hypothesis tests   |
| [R] <b>table regression</b>       | Table of regression results |

All the concepts demonstrated in the entries above can be combined to create tables including combinations of tabulations, summary statistics, hypothesis tests, and regression results.

In this entry, we provide additional information on specifying the table layout and which portions of the layout `table` will automate for you. In addition, we provide resources for customizing the table and exporting the results to your preferred format.

## Specifying the table layout

A table's layout is determined by our row, column, and table dimension specifications. For example, we specify variable names to define the rows and place statistics in the columns, or vice versa. Because we can include so many different statistics, we can specify keywords that we use to identify the results we have collected from commands and the statistics that `table` has calculated.

The syntax for specifying the table layout is

```
table ([rowspec]) ([colspec]) ([tabspec])
```

We refer to *rowsec*, *colspec*, and *tabspec* collectively as the “layout”. For some tables, **keywords** are required in the layout to uniquely identify the values that we want to include in our table. If you omit a necessary keyword from the layout, `table` will fill one in for you.

The rules determining whether a keyword is necessary to uniquely identify values in the table are as follows:

1. If more than one statistic is specified, then `result` is needed in the layout.
2. If more than one variable is specified in option `statistic()` and option `command()` is not specified, then `var` is needed in the layout.

3. If more than one `across()` specification is used for ratio statistics, then `across` is needed in the layout.
4. If option `command()` is specified, then `colname` is needed in the layout. If, in addition, more than one variable is specified in option `statistic()`, then `colname` is needed instead of `var`, which was required in 2.
5. If multiple `command()` options are specified and option `statistic()` is not specified, then `command` is needed in the layout.
6. If both options `command()` and `statistic()` are specified, then `statcmd` is needed in the layout.

If we do not directly specify a necessary keyword in one of `rowspec`, `colspec`, or `tabspec`, the missing keywords will be automatically added to the layout as follows:

1. If the row specification is empty, then put the missing keywords in `rowspec`.
2. If the row specification is not empty but the column specification is empty, then put the missing keywords in `colspec`.
3. If the row and column specifications are not empty but the table specification is empty and if `result` is the only missing keyword and there is only one statistic (`result`), then put `result` in `tabspec`.
4. Otherwise, append the missing keywords to `rowvars`.

Below, we demonstrate how missing keywords are added to the *layout*.

Using `auto.dta`, we create a table with the minimum and maximum mpg for each level of `rep78`. The keyword `result` identifies the statistics we computed. By listing an empty set of parentheses followed by `rep78`, we request that the levels of `rep78` be placed on the columns.

```
. use https://www.stata-press.com/data/r19/auto
(1978 automobile data)
. table () rep78, statistic(min mpg) statistic(max mpg)
```

|               | Repair record 1978 |    |    |    |    | Total |
|---------------|--------------------|----|----|----|----|-------|
|               | 1                  | 2  | 3  | 4  | 5  |       |
| Minimum value | 18                 | 14 | 12 | 14 | 17 | 12    |
| Maximum value | 24                 | 24 | 29 | 30 | 41 | 41    |

Based on [rule 1](#), if we request more than one statistic, `result` must be in the layout. Based on [situation 1](#), if the row specification is empty, then the missing keyword will be placed in the row specification. We could have created the same table by typing

```
. table (result) (rep78), statistic(min mpg) statistic(max mpg)
```

Now, let's include multiple variables in our `statistic()` option. We also type `rep78` immediately after `table` to specify that the levels of `rep78` be placed on the rows.

```
. table rep78, statistic(mean mpg price)
```

|                    | Mileage (mpg) | Price    |
|--------------------|---------------|----------|
| Repair record 1978 |               |          |
| 1                  | 21            | 4564.5   |
| 2                  | 19.125        | 5967.625 |
| 3                  | 19.43333      | 6429.233 |
| 4                  | 21.66667      | 6071.5   |
| 5                  | 27.36364      | 5913     |
| Total              | 21.28986      | 6146.043 |

Because we have more than one variable in the `statistic()` option, then keyword `var` must be in the layout ([rule 2](#)). If we include a row specification but leave the column specification empty, `table` will treat `var` as the column identifier. We could have equivalently typed

```
. table (rep78) (var), statistic(mean mpg price)
```

Next, let's include both a `command()` option and a `statistic()` option with multiple variables in the same table. We want a table with coefficients and means of the independent variables. We use the `command()` option to fit the regression and obtain the means with the `statistic()` option. Now, we need both `colname` and `statcmd` to uniquely identify the values in the table. Let's omit `statcmd` from our command.

```
. table (colname) (result[_r_b mean]),
> command(regress mpg turn trunk) statistic(mean turn trunk)
```

|                        | Coefficient | Mean     |
|------------------------|-------------|----------|
| Turn circle (ft.)      |             |          |
| regress mpg turn trunk | -.7610113   |          |
| Mean                   |             | 39.64865 |
| Trunk space (cu. ft.)  |             |          |
| regress mpg turn trunk | -.3161825   |          |
| Mean                   |             | 13.75676 |
| Intercept              |             |          |
| regress mpg turn trunk | 55.82001    |          |

But based on [situation 4](#), `table` will add `statcmd` to the row specification if we leave it out. So we could have also typed the following to create the same table:

```
. table (colname statcmd) (result[_r_b mean]),
 command(regress mpg turn trunk) statistic(mean turn trunk)
```

This table displays each of the statistics that we requested. If we simply wanted to compute some statistics quickly, it has served its purpose. However, if we wish to share these results with others or include a table in a report, we will want to make some modifications.

## Advanced table customization

`table` allows you to customize the results of your table using the `stars()`, `nformat()`, `sformat()`, `cidelimiter()`, `label()`, and `style()` options. With these, you can add significance stars, change the numeric format, and attach characters such as percent signs or parentheses to values in the table, use a stored set of labels, or use a predefined style. If these options provide all the customizations you need, you can export your finalized table directly with the `export()` option. See [TABLES] [Predefined styles](#) for more information on selecting a style that adjusts elements of the table such as row header alignment, alignment of values within the cells, and which labels are included in the headers.

Customization can also go beyond the predefined styles and options available to you in the `table` command. `table` stores all of its results in a collection named `Table`. This means that you can use the specialized tools available in the `collect` suite of commands to further customize your table. With `collect`, you can modify specific labels, add borders, change the style of the headers, and the like. Once you have a publication-ready table, you can use `collect export` to export your table to HTML, Word, L<sup>A</sup>T<sub>E</sub>X, PDF, Excel, or another format appropriate for your report.

## Stored results

`table` stores the following in `r()`:

Scalars

`r(N)`    number of observations

## Methods and formulas

Variables specified in `rowspec`, `colspec`, and `tabspec` identify groups of observations within the dataset. These groups are represented in the table by cells and cell margins (totals). For a given cell or cell margin, let  $n$  denote the number of observations (frequency). Let  $x$  denote the variable on which we want to calculate summary statistics, and let  $x_i$ ,  $i = 1, \dots, n$ , denote an individual observation on  $x$ . `count` is the number of nonmissing values of  $x$ . `first` is  $x_1$  and `last` is  $x_n$ . Let  $a$  be the smallest  $i$  such that  $x_i$  is not missing, and then `firstnm` is  $x_a$ . Let  $b$  be the largest  $i$  such that  $x_i$  is not missing, and then `lastnm` is  $x_b$ .

Let  $v_i$  be the weight, and if no weight is specified, define  $v_i = 1$  for all  $i$ . Let  $v$  denote the sum of the weights (`sumw`):

$$v = \sum_{i=1}^n v_i$$

When `aweights` or `pweights` are specified, the normalized weights are given by  $w_i = v_i(n/v)$  with  $w = n$ ; otherwise,  $w_i = v_i$  and  $w = v$ .

The remaining summary statistics are computed according to the following formulas:

total

$$x. = \begin{cases} \sum_{i=1}^n v_i x_i & \text{if pweights} \\ \sum_{i=1}^n w_i x_i & \text{otherwise} \end{cases}$$

rawtotal

$$\sum_{i=1}^n x_i$$

mean

$$\bar{x} = \frac{1}{w.} \sum_{i=1}^n w_i x_i$$

Define  $m_r$  as the  $r$ th moment about the mean:

$$m_r = \frac{1}{w.} \sum_{i=1}^n w_i (x_i - \bar{x})^r$$

variance

$$s^2 = \frac{w.}{w. - 1} m_2 = \frac{1}{w. - 1} \sum_{i=1}^n w_i (x_i - \bar{x})^2$$

sd (standard deviation)

$$s = \sqrt{s^2}$$

semean (standard error of the mean)

$$\text{se}(\bar{x}) = \frac{s}{\sqrt{w.}}$$

sebinomial (standard error of the mean, binomial distribution)

$$\sqrt{\frac{\bar{x}(1 - \bar{x})}{w.}}$$

sepoisson (standard error of the mean, Poisson distribution)

$$\sqrt{\frac{\bar{x}}{w.}}$$

When pweights are specified, `semean`, `sebinomial`, and `sepoisson` are all computed as

$$\text{se}_{\text{pw}}(\bar{x}) = \sqrt{\frac{n}{n-1} \sum_{i=1}^n \left\{ \frac{v_i}{v.} (x_i - \bar{x}) \right\}^2}$$

skewness

$$m_3 m_2^{-3/2}$$

kurtosis

$$m_4 m_2^{-2}$$

cv (coefficient of variation)

$$\frac{s}{\bar{x}}$$

svycv (coefficient of variation, survey literature)

$$100 \frac{\text{se}(\bar{x})}{|\bar{x}|}$$

svycv with pweights

$$100 \frac{\text{se}_{\text{pw}}(\bar{x})}{|\bar{x}|}$$

geomean (geometric mean)

$$\bar{x}_g = \exp \left( \frac{1}{w.} \sum_{i=1}^n w_i \ln x_i \right)$$

geosd (geometric standard deviation)

$$\exp \left( \sqrt{\frac{1}{w. - 1} \sum_{i=1}^n w_i (\ln x_i - \ln \bar{x}_g)^2} \right)$$

Let  $x_{(i)}$  refer to the  $x$  in ascending order, and let  $w_{(i)}$  refer to the corresponding weights of  $x_{(i)}$ .

minimum

$$x_{(1)}$$

maximum

$$x_{(n)}$$

range

$$x_{(n)} - x_{(1)}$$

To obtain the  $p$ th percentile, which we will denote as  $x_{[p]}$ , let  $P = np/100$  and

$$W_{(i)} = \frac{n}{w} \sum_{j=1}^i w_{(j)}$$

Find the first index  $i$  such that  $W_{(i)} > P$ . The  $p$ th percentile is then

$$x_{[p]} = \begin{cases} \frac{x_{(i-1)} + x_{(i)}}{2} & \text{if } W_{(i-1)} = P \\ x_{(i)} & \text{otherwise} \end{cases}$$

q1 (first quartile)

$$x_{[25]}$$

q2 (second quartile)

$$x_{[50]}$$

q3 (third quartile)

$$x_{[75]}$$

iqr (interquartile range)

$$x_{[75]} - x_{[25]}$$

Let  $f$  be an indicator for a specific level of a factor variable and  $f_i$  denote an individual observation on  $f$ .

fvf frequency (frequency of the factor variable's level)

$$\sum_{i=1}^n w_i f_i$$

fvrawfrequency (unweighted frequency of the factor variable's level)

$$\sum_{i=1}^n f_i$$

fvproportion (proportion of the factor variable's level)

$$\frac{1}{w} \sum_{i=1}^n w_i f_i$$

fvrawproportion (unweighted proportion of the factor variable's level)

$$\frac{1}{n} \sum_{i=1}^n f_i$$

`fvpercent` (percentage of the factor variable's level)

$$\frac{100}{w_i} \sum_{i=1}^n w_i f_i$$

`fvrawpercent` (unweighted percentage of the factor variable's level)

$$\frac{100}{n} \sum_{i=1}^n f_i$$

`proportion` is computed from ratios of totals. The numerator is taken from the total for the given cell or cell margin, and the denominator is taken from the total for a cell margin that contains the given cell or cell margin. `percent` is `proportion` multiplied by 100.

`rawproportion` and `rawpercent` are similarly computed using unweighted totals.

## Description

In this entry, we discuss how to use `table` to create a one-way tabulation, including frequencies, percentages, and proportions.

## Quick start

One-way table of frequencies, with rows corresponding to the levels of `a1`

```
table a1
```

Same as above, but with columns corresponding to the levels of `a1`

```
table () a1
```

Same as above, but treat missing values like other values of `a1`

```
table () a1, missing
```

One-way table of frequencies, using the collection style `mystyle`

```
table a1, style(mystyle)
```

One-way table of frequencies and percentages

```
table a1, statistic(frequency) statistic(percent)
```

## Menu

Statistics > Summaries, tables, and tests > Tables of frequencies, summaries, and command results

## Syntax

### Basic one-way tabulation

```
table varname [if] [in] [weight] [, options]
```

### Customized one-way tabulation

```
table [(rowspec)] [(colspec)] [if] [in] [weight] [, options]
```

*rowspec* and *colspec* may be empty or may include *varname*, *result*, or *varname* and *result*, where *result* refers to the requested statistics.

| <i>options</i>                                                          | Description                                                                                                                                     |
|-------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Main</b>                                                             |                                                                                                                                                 |
| <code>nototals</code>                                                   | suppress the marginal totals                                                                                                                    |
| <b>Statistics</b>                                                       |                                                                                                                                                 |
| <code>statistic(<i>stat</i>)</code>                                     | statistic to be reported; default is <code>statistic(frequency)</code> when no weights are specified and <code>statistic(sumw)</code> otherwise |
| <b>Formats</b>                                                          |                                                                                                                                                 |
| <code>nformat(<i>%fmt</i> [<i>results</i>] [, <i>basestyle</i>])</code> | specify numeric format                                                                                                                          |
| <code>sformat(<i>sfmt</i> [<i>results</i>])</code>                      | specify string format                                                                                                                           |
| <b>Title</b>                                                            |                                                                                                                                                 |
| <code>title(<i>string</i>)</code>                                       | add table title                                                                                                                                 |
| <code>titlestyles(<i>text_styles</i>)</code>                            | change table title styles                                                                                                                       |
| <b>Notes</b>                                                            |                                                                                                                                                 |
| <code>note(<i>string</i>)</code>                                        | add table note                                                                                                                                  |
| <code>notestyles(<i>text_styles</i>)</code>                             | change table note styles                                                                                                                        |
| <b>Export</b>                                                           |                                                                                                                                                 |
| <code>export(<i>filename.suffix</i> [, <i>export_opts</i>])</code>      | export table                                                                                                                                    |
| <b>Options</b>                                                          |                                                                                                                                                 |
| <code>missing</code>                                                    | treat numeric missing values of <i>varname</i> like other values                                                                                |
| <code>name(<i>cname</i>)</code>                                         | collect results into a collection named <i>cname</i>                                                                                            |
| <code>append</code>                                                     | append results to an existing collection                                                                                                        |
| <code>replace</code>                                                    | replace results of an existing collection                                                                                                       |
| <code>label(<i>filename</i>)</code>                                     | specify the collection labels                                                                                                                   |
| <code>style(<i>filename</i> [, <i>override</i>])</code>                 | specify the collection style                                                                                                                    |
| <code>markvar(<i>newvar</i>)</code>                                     | create <i>newvar</i> that identifies observations used in the tabulation                                                                        |

*fweights*, *awweights*, *iweights*, and *pweights* are allowed; see [\[U\] 11.1.6 weight](#).

*strL* variables are not allowed; see [\[U\] 12.4.8 strL](#).

`markvar()` does not appear in the dialog box.

| <i>text_styles</i>                           | Description                                              |
|----------------------------------------------|----------------------------------------------------------|
| <code>font([fontfamily][, font_opts])</code> | specify font style                                       |
| <code>smcl(smcl)</code>                      | specify formatting for SMCL files                        |
| <code>latex(latex)</code>                    | specify L <sup>A</sup> T <sub>E</sub> X macro            |

| sheet( <i>sheetname</i> [, replace]) | specify the worksheet to use; the default sheet name is Sheet1                                          |
| cell( <i>cell</i> )                  | specify the Excel upper-left cell as the starting position to export the table; the default is cell(A1) |
| modify                               | modify Excel file                                                                                       |
| noopen                               | do not open Excel file in memory                                                                        |

noopen does not appear in the dialog box.

| <i>tex_options</i> | Description                                 |
|--------------------|---------------------------------------------|
| append             | append to an existing file                  |
| tableonly          | export only the table to the specified file |

| <i>smcl_option</i> | Description                |
|--------------------|----------------------------|
| append             | append to an existing file |

| <i>txt_option</i> | Description                |
|-------------------|----------------------------|
| append            | append to an existing file |

| <i>md_option</i> | Description                |
|------------------|----------------------------|
| append           | append to an existing file |

*fontfamily* specifies a valid font family.

*unit* may be in (inch), pt (point), or cm (centimeter). An inch is equivalent to 72 points and 2.54 centimeters. The default is pt.

*variant* may be allcaps, smallcaps, or normal.

*variant* (allcaps) changes the text to all uppercase letters; applicable when publishing items from a collection to Microsoft Word, PDF, L<sup>A</sup>T<sub>E</sub>X, and HTML files.

*variant* (smallcaps) changes the text to use large capitals for uppercase letters and smaller capitals for lowercase letters; applicable when publishing items from a collection to Microsoft Word, L<sup>A</sup>T<sub>E</sub>X, and HTML files.

*variant* (normal) changes the font variant back to normal and leaves the capitalization unchanged from the original text; applicable when publishing items from a collection to Microsoft Word, PDF, L<sup>A</sup>T<sub>E</sub>X, and HTML files.

*smcl* specifies the name of the SMCL directive to render text for SMCL output. The supported SMCL directives are `input`, `error`, `result`, and `text`.

*latex* specifies the name of a L<sup>A</sup>T<sub>E</sub>X macro to render text for L<sup>A</sup>T<sub>E</sub>X output. Example L<sup>A</sup>T<sub>E</sub>X macro names are `textbf`, `textsf`, `textrm`, and `texttt`. Custom L<sup>A</sup>T<sub>E</sub>X macros are also allowed. If *text* is to be rendered in a cell, title, or note, then *latex* is translated to the following when you export to L<sup>A</sup>T<sub>E</sub>X:

```
\latex {text}
```

*sspec* is

```
[background(bgcolor) foreground(fgcolor) pattern(fpattern)]
```

*bgcolor* specifies the background color.

*fgcolor* specifies the foreground color.

*fpattern* specifies the fill pattern. A complete list of fill patterns is shown in the [Appendix](#).

*bgcolor*, *fgcolor*, and *color* may be one of the colors listed in the [Appendix](#); a valid RGB value in the form `### ## #`, for example, `171 248 103`; or a valid RRGGBB hex value in the form `#####`, for example, `ABF867`.

## Options

### Main

`nototals` prevents `table` from displaying the row or column totals.

### Statistics

`statistic(stat)` specifies the statistic to be displayed. `statistic()` may be repeated to request multiple statistics.

Available statistics are

| <i>stat</i>                | Definition                                       |
|----------------------------|--------------------------------------------------|
| <code>frequency</code>     | frequency                                        |
| <code>sumw</code>          | sum of weights                                   |
| <code>proportion</code>    | proportion                                       |
| <code>percent</code>       | percentage                                       |
| <code>rawproportion</code> | proportion ignoring optionally specified weights |
| <code>rawpercent</code>    | percentage ignoring optionally specified weights |

### Formats

`nformat(%fmt [results] [, basestyle])` changes the numeric format, such as the number of decimal places, for specified results. If `results` are not specified, the numeric format is changed for all results.

`results` may be any statistic named in option `statistic()` (that is, any `stat`).

This option is repeatable, and when multiple formats apply to one result, the rightmost specification is applied.

This option does not affect the format of numeric layout variables (`rowspec` and `colspec`). The default format of these variables is taken from the dataset.

`basestyle` indicates that the format be applied to results that do not already have their own format instead of overriding the format for all results.

`sformat(sfmt [results])` changes the string format for specified results. You can, for instance, add symbols or text to the values reported in the table by modifying the string format.

`sfmt` may contain a mix of text and `%s`. Here `%s` refers to the numeric value that is formatted as specified using `nformat()`. The text will be placed around the numeric values in your table as it is placed around `%s` in this option. For instance, to place parentheses around the percent statistics, you can specify `sformat("(%s) percent)`.

`results` may be any statistic named in option `statistic()` (that is, any `stat`).

Two text characters must be specified using a special character sequence if you want them to be displayed in your table. To include `%`, type `%%`. To include `\`, type `\\`. For instance, to place a percent sign following percent statistics, you can specify `sformat("%s%%" percent)`.

This option is repeatable, and when multiple formats apply to one result, the rightmost specification is applied.

Title

`title(string)` adds the text *string* as a title to the table.

`titlestyles(text_styles)` changes the style for the table title. *text\_styles* are the following:

`font([fontfamily] [, size(# [unit]) color(color) variant(variant) [no]bold [no]italic [no]strikeout [no]underline)` specifies the font style. These font style properties are applicable when exporting the table to Microsoft Word, Microsoft Excel, PDF, HTML, and  $\LaTeX$  files, unless otherwise specified.

*fontfamily* specifies a valid font family. This font style property is applicable when publishing items from a collection to Microsoft Word, Microsoft Excel, PDF, and HTML files.

*size*(# [*unit*]) specifies the font size as a number optionally followed by units. This font style property is applicable when publishing items from a collection to Microsoft Word, Microsoft Excel, PDF, and HTML files.

*color*(*color*) specifies the text color.

*variant*(*variant*) specifies the font variant and capitalization.

`bold` and `nobold` specify the font weight. `bold` changes the font weight to bold; `nobold` changes the font weight back to normal.

`italic` and `noitalic` specify the font style. `italic` changes the font style to italic; `noitalic` changes the font style back to normal.

`strikeout` and `nostrikeout` specify whether to add a strikeout mark to the title. `strikeout` adds a strikeout mark to the title; `nostrikeout` changes the title back to normal.

`underline` and `nounderline` specify whether to underline the table title. `underline` adds a single line under the title; `nounderline` removes the underline.

Only one of `strikeout` or `underline` is allowed when publishing to HTML files.

`smcl(smcl)` specifies how to render the table title for SMCL output. This style property is applicable only when publishing items from a collection to a SMCL file.

`latex(latex)` specifies how to render the table title for  $\LaTeX$  output. This style property is applicable only when publishing items from a collection to a  $\LaTeX$  file.

`shading(sspec)` sets the background color, foreground color, and fill pattern. The background color is applicable when exporting the table to Microsoft Word, Microsoft Excel, PDF, HTML, and  $\LaTeX$  files. The foreground color and fill pattern are applicable when exporting the table to Microsoft Word and Microsoft Excel.

## Notes

`note(string)` adds the text *string* as a note to the table. `note()` may be specified multiple times to add multiple notes. Each note is placed on a new line.

`notestyles(text_styles)` changes the style for the table notes. *text\_styles* are the following:

`font([fontfamily] [, size(# [unit]) color(color) variant(variant) [no]bold [no]italic [no]strikeout [no]underline])` specifies the font style. These font style properties are applicable when exporting the table to Microsoft Word, Microsoft Excel, PDF, HTML, and  $\LaTeX$  files, unless otherwise specified.

*fontfamily* specifies a valid font family. This font style property is applicable when publishing items from a collection to Microsoft Word, Microsoft Excel, PDF, and HTML files.

`size(# [unit])` specifies the font size as a number optionally followed by units. This font style property is applicable when publishing items from a collection to Microsoft Word, Microsoft Excel, PDF, and HTML files.

`color(color)` specifies the text color.

`variant(variant)` specifies the font variant and capitalization.

`bold` and `nobold` specify the font weight. `bold` changes the font weight to bold; `nobold` changes the font weight back to normal.

`italic` and `noitalic` specify the font style. `italic` changes the font style to italic; `noitalic` changes the font style back to normal.

`strikeout` and `nostrikeout` specify whether to add a strikeout mark to the notes. `strikeout` adds a strikeout mark to the note; `nostrikeout` changes the note back to normal.

`underline` and `nounderline` specify whether to underline the table notes. `underline` adds a single line under the notes; `nounderline` removes the underline.

Only one of `strikeout` or `underline` is allowed when publishing to HTML files.

`smcl(smcl)` specifies how to render the table notes for SMCL output. This style property is applicable only when publishing items from a collection to a SMCL file.

`latex(latex)` specifies how to render the table notes for  $\LaTeX$  output. This style property is applicable only when publishing items from a collection to a  $\LaTeX$  file.

`shading(sspec)` sets the background color, foreground color, and fill pattern. The background color is applicable when exporting the table to Microsoft Word, Microsoft Excel, PDF, HTML, and  $\LaTeX$  files. The foreground color and fill pattern are applicable when exporting the table to Microsoft Word and Microsoft Excel.

Export

`export(filename.suffix[ , export_opts])` exports the table to the specified file. *export\_opts* are the following:

`as(fileformat)` specifies the file format to which the table is to be exported. This option is rarely specified because, by default, `table` determines the format from the suffix of the file being created.

`replace` permits `table` to overwrite an existing file.

`noisily` specifies that `table` show the commands used to export the table to Microsoft Word, Microsoft Excel, and PDF files. The `putdocx`, `putexcel`, or `putpdf` command used to export the table will be displayed.

`dofile(filename[ , replace])` specifies that `table` save to *filename* the commands used to export the table to Microsoft Word, Microsoft Excel, and PDF files.

If *filename* already exists, it can be overwritten by specifying `replace`. If *filename* is specified without an extension, `.do` is assumed.

`append` specifies that `table` append the table to an existing file.

This option is applicable when you export the table to an HTML, a  $\LaTeX$ , a SMCL, a `txt`, or a Markdown file. When you export to HTML and  $\LaTeX$  files, the `append` option implies the `tableonly` option. Furthermore, when you export to HTML files, if the target CSS file already exists, `table` will also append to it.

`tableonly` specifies that only the table be exported to the specified HTML or  $\LaTeX$  document. By default, `table` produces complete HTML and  $\LaTeX$  documents.

When you export to an HTML file, if the `cssfile()` option is not specified, a CSS filename is constructed from *filename*, with the extension replaced with `.css`.

`cssfile(cssfile)` specifies that `table` define the styles in *cssfile* instead of *filename* when you export to HTML.

`prefix(prefix)` specifies that `table` use *prefix* to identify style classes when you export to HTML.

`sheet(sheetname [ , replace])` saves to the worksheet named *sheetname*. For more information about this option, see [RPT] [putexcel](#).

`cell(cell)` specifies an Excel upper-left cell as the starting position to publish the table. The default is `cell(A1)`.

`modify` permits `putexcel` set to modify an Excel file. For more information about this option, see [RPT] [putexcel](#).

`noopen` prevents `putexcel` from opening the Excel file in memory for modification. It does not appear in the dialog box. For more information about this option, see [RPT] [putexcel](#).

## Options

`missing` specifies that numeric missing values of *varname* be treated as valid categories. By default, observations with a numeric missing value in *varname* are omitted.

`name(cname)` specifies that a collection named *cname* be associated with the collected statistics and results. The default is `name(Table)`.

`append` specifies that `table` append its collection information into the collection named in `name()`.

`replace` permits `table` to overwrite an existing collection. This option is implied for `name(Table)` when `append` is not specified.

`label(filename)` specifies the *filename* containing the collection labels to use for your table. Labels in *filename* will be loaded for the table, and any labels not specified in *filename* will be taken from the labels defined in `c(collect_label)`. The default is to use only the collection labels set in `c(collect_label)`; see [TABLES] [set collect\\_label](#).

`style(filename [, override])` specifies the *filename* containing the collection styles to use for your table. The default collection styles will be discarded, and only the collection styles in *filename* will be applied.

If you prefer the default collection styles but also want to apply any styles in *filename*, specify `override`. If there are conflicts between the default collection styles and those in *filename*, the ones in *filename* will take precedence.

The default is to use only the collection styles set in `c(table_style)`; see [TABLES] [set table\\_style](#).

The following option is available with `table` but is not shown in the dialog box:

`markvar(newvar)` generates an indicator variable that identifies the observations used in the tabulation.

## Remarks and examples

Remarks are presented under the following headings:

- [Tabulation of one variable](#)
- [Tabulation, including percentages](#)
- [Customizing results](#)
- [Advanced customization](#)

## Tabulation of one variable

To obtain a one-way tabulation that reports the number of observations for each level of a categorical variable, we need specify only the name of the categorical variable following `table`.

To demonstrate, we use data from the Second National Health and Nutrition Examination Survey (NHANES II) (McDowell et al. 1981). We tabulate the `hlthstat` variable, which contains individuals' self-reported health status categories.

```
. use https://www.stata-press.com/data/r19/nhanes21
(Second National Health and Nutrition Examination Survey)
. table hlthstat
```

|               | Frequency |
|---------------|-----------|
| Health status |           |
| Excellent     | 2,407     |
| Very good     | 2,591     |
| Good          | 2,938     |
| Fair          | 1,670     |
| Poor          | 729       |
| Total         | 10,335    |

We see that more people self-reported having excellent, very good, or good health status than reported having fair or poor health status.

Above, we see frequencies for those who reported a health status. This information is not available for some individuals in the dataset. We can determine how many missing values we have for this variable by adding the `missing` option

```
. table hlthstat, missing
```

|                      | Frequency |
|----------------------|-----------|
| Health status        |           |
| Excellent            | 2,407     |
| Very good            | 2,591     |
| Good                 | 2,938     |
| Fair                 | 1,670     |
| Poor                 | 729       |
| .                    | 2         |
| Blank but applicable | 14        |
| Total                | 10,351    |

We find that there is missing health status data for 16 individuals—2 with a generic missing value and 14 whose responses were labeled “Blank but applicable”.

## Tabulation, including percentages

In addition to frequencies, we can report the proportion or percentage of observations in each health status category. By default, `table` reports frequencies, which is equivalent to including the `statistic(frequency)` option. Here we include that option along with the `statistic(percent)` option to report both frequencies and percentages.

```
. table hlthstat, statistic(frequency) statistic(percent)
```

|               | Frequency | Percent |
|---------------|-----------|---------|
| Health status |           |         |
| Excellent     | 2,407     | 23.29   |
| Very good     | 2,591     | 25.07   |
| Good          | 2,938     | 28.43   |
| Fair          | 1,670     | 16.16   |
| Poor          | 729       | 7.05    |
| Total         | 10,335    | 100.00  |

Now, it is clear that 28.43% of respondents reported having good health.

## Customizing results

There are a number of ways that you can customize the results in your table.

In some cases, you may prefer to place frequencies and percentages on the rows and the levels of the variable being tabulated on the columns. To do this, you can include both the row and column specifications in parentheses following `table`. Here we use `result` in the first set of parentheses to request that the statistics be placed on rows and the variable `hlthstat` in the second set of parentheses to request that the levels of this variable be placed on the columns.

```
. table (result) (hlthstat), statistic(frequency) statistic(percent)
```

|           | Health status |           |       |       |      |        |
|-----------|---------------|-----------|-------|-------|------|--------|
|           | Excellent     | Very good | Good  | Fair  | Poor | Total  |
| Frequency | 2,407         | 2,591     | 2,938 | 1,670 | 729  | 10,335 |
| Percent   | 23.29         | 25.07     | 28.43 | 16.16 | 7.05 | 100.00 |

Alternatively, we could have omitted `result` and typed

```
. table () (hlthstat), statistic(freq) statistic(percent)
```

Because we requested that `hlthstat` be moved to the columns by specifying it in the second set of parentheses, `table` automatically moves the requested statistics to the rows.

If instead of a short and wide table, you prefer a tall and narrow table, you can specify that both the levels of `hlthstat` and the statistics be used to define the rows by including the variable name and result in the first set of parentheses.

```
. table (hlthstat result), statistic(frequency) statistic(percent)
```

|               |        |
|---------------|--------|
| Health status |        |
| Excellent     |        |
| Frequency     | 2,407  |
| Percent       | 23.29  |
| Very good     |        |
| Frequency     | 2,591  |
| Percent       | 25.07  |
| Good          |        |
| Frequency     | 2,938  |
| Percent       | 28.43  |
| Fair          |        |
| Frequency     | 1,670  |
| Percent       | 16.16  |
| Poor          |        |
| Frequency     | 729    |
| Percent       | 7.05   |
| Total         |        |
| Frequency     | 10,335 |
| Percent       | 100.00 |

In addition to modifying the layout of the table, we may want to customize the results reported within the cells of the table. For instance, we can specify that the percentages be reported using only one decimal place by using the `nformat()` option. Here we return to the two-column table layout.

```
. table hlthstat, statistic(frequency) statistic(percent)
> nformat(%5.1f percent)
```

|               | Frequency | Percent |
|---------------|-----------|---------|
| Health status |           |         |
| Excellent     | 2,407     | 23.3    |
| Very good     | 2,591     | 25.1    |
| Good          | 2,938     | 28.4    |
| Fair          | 1,670     | 16.2    |
| Poor          | 729       | 7.1     |
| Total         | 10,335    | 100.0   |

The `table` command produces its output using a default set of styles, typically those defined in the `table` style but could be any other style that you have set as the default by using `set table_style`. When customizing our tables, we can take advantage of one of the styles described in [TABLES] **Predefined styles**. For instance, for tables with only one or two row variables, row labels that are right-aligned may be preferred. Here we use the `table-right` style.

```
. table hlthstat, statistic(frequency) statistic(percent)
> nformat(%5.1f percent) style(table-right)
```

|               | Frequency | Percent |
|---------------|-----------|---------|
| Health status |           |         |
| Excellent     | 2,407     | 23.3    |
| Very good     | 2,591     | 25.1    |
| Good          | 2,938     | 28.4    |
| Fair          | 1,670     | 16.2    |
| Poor          | 729       | 7.1     |
| Total         | 10,335    | 100.0   |

## Advanced customization

Customization can go beyond the predefined styles and options available to you in the `table` command. `table` creates a collection of results that can be used in combination with the `collect` suite of commands to produce highly customized tables and to export those tables to presentation-ready formats such as HTML, Word, L<sup>A</sup>T<sub>E</sub>X, PDF, Excel, and more.

Continuing with our example above, if we want to shorten the labels on the column headings, we could use the `collect label levels` command to define our new labels. After a change using `collect`, we can use `collect preview` to see the results.

```
. collect label levels result frequency "Freq" percent "%", modify
. collect preview
```

|               | Freq   | %     |
|---------------|--------|-------|
| Health status |        |       |
| Excellent     | 2,407  | 23.3  |
| Very good     | 2,591  | 25.1  |
| Good          | 2,938  | 28.4  |
| Fair          | 1,670  | 16.2  |
| Poor          | 729    | 7.1   |
| Total         | 10,335 | 100.0 |

We could continue making style edits to this table. When we are happy with the result, we can then export it to the format of our choice using `collect export`.

See [TABLES] **collect label** for details on the `collect label` command we used here, and for an overview of the `collect` suite, see [TABLES] **Intro**.

## Stored results

table stores the following in `r()`:

Scalars

`r(N)` number of observations

## Description

In this entry, we discuss how to use `table` to create a two-way tabulation, including frequencies, percentages, and proportions.

## Quick start

Table of frequencies, with rows defined by categories of `a1` and columns defined by categories of `a2`

```
table a1 a2
```

Same as above, but treat missing values like other values

```
table a1 a2, missing
```

Table with the percentage of observations in each cell

```
table a1 a2, statistic(percent)
```

For each category of `a1`, report the percentage of observations across levels of `a2`

```
table a1 a2, statistic(percent, across(a2))
```

Report frequencies and the proportion of observations across categories of `a1`, enclosed within parentheses

```
table a1 a2, statistic(frequency) ///
 statistic(proportion, across(a1)) sformat("%s)" proportion)
```

## Menu

Statistics > Summaries, tables, and tests > Tables of frequencies, summaries, and command results

## Syntax

### Basic two-way tabulation

```
table rowvar colvar [if] [in] [weight] [, options]
```

### Customized two-way tabulation

```
table [(rowspec)] [(colspec)] [if] [in] [weight] [, options]
```

*rowspec* may be empty or may include *rowvar*, *result*, or *rowvar* and *result*, where *result* refers to the requested statistics.

*colspec* may be empty or may include *colvar*, *result*, or *colvar* and *result*, where *result* refers to the requested statistics.

| <i>options</i>                                                          | Description                                                                                                                                     |
|-------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Main</b>                                                             |                                                                                                                                                 |
| <code>totals(<i>totals</i>)</code>                                      | report only the specified totals                                                                                                                |
| <code>nototals</code>                                                   | suppress the marginal totals                                                                                                                    |
| <b>Statistics</b>                                                       |                                                                                                                                                 |
| <code><u>statistic</u>(<i>stat</i> [, <i>statopts</i>])</code>          | statistic to be reported; default is <code>statistic(frequency)</code> when no weights are specified and <code>statistic(sumw)</code> otherwise |

| <code>sheet(sheetname[, replace])</code> | specify the worksheet to use; the default sheet name is Sheet1                                          |
| <code>cell(cell)</code>                  | specify the Excel upper-left cell as the starting position to export the table; the default is cell(A1) |
| <code>modify</code>                      | modify Excel file                                                                                       |
| <code>noopen</code>                      | do not open Excel file in memory                                                                        |

`noopen` does not appear in the dialog box.

| <i>tex_options</i>     | Description                                 |
|------------------------|---------------------------------------------|
| <code>append</code>    | append to an existing file                  |
| <code>tableonly</code> | export only the table to the specified file |

| <i>smcl_option</i>  | Description                |
|---------------------|----------------------------|
| <code>append</code> | append to an existing file |

| <i>txt_option</i>   | Description                |
|---------------------|----------------------------|
| <code>append</code> | append to an existing file |

| <i>md_option</i>    | Description                |
|---------------------|----------------------------|
| <code>append</code> | append to an existing file |

*fontfamily* specifies a valid font family.

*unit* may be in (inch), pt (point), or cm (centimeter). An inch is equivalent to 72 points and 2.54 centimeters. The default is pt.

*variant* may be allcaps, smallcaps, or normal.

*variant* (allcaps) changes the text to all uppercase letters; applicable when publishing items from a collection to Microsoft Word, PDF, L<sup>A</sup>T<sub>E</sub>X, and HTML files.

*variant* (smallcaps) changes the text to use large capitals for uppercase letters and smaller capitals for lowercase letters; applicable when publishing items from a collection to Microsoft Word, L<sup>A</sup>T<sub>E</sub>X, and HTML files.

*variant* (normal) changes the font variant back to normal and leaves the capitalization unchanged from the original text; applicable when publishing items from a collection to Microsoft Word, PDF, L<sup>A</sup>T<sub>E</sub>X, and HTML files.

*smcl* specifies the name of the SMCL directive to render text for SMCL output. The supported SMCL directives are `input`, `error`, `result`, and `text`.

*latex* specifies the name of a L<sup>A</sup>T<sub>E</sub>X macro to render text for L<sup>A</sup>T<sub>E</sub>X output. Example L<sup>A</sup>T<sub>E</sub>X macro names are `textbf`, `textsf`, `textrm`, and `texttt`. Custom L<sup>A</sup>T<sub>E</sub>X macros are also allowed. If *text* is to be rendered in a cell, title, or note, then *latex* is translated to the following when you export to L<sup>A</sup>T<sub>E</sub>X:

```
\latex {text}
```

*sspec* is

```
[background(bcolor) foreground(fgcolor) pattern(fpattern)]
```

*bcolor* specifies the background color.

*fgcolor* specifies the foreground color.

*fpattern* specifies the fill pattern. A complete list of fill patterns is shown in the [Appendix](#).

*bcolor*, *fgcolor*, and *color* may be one of the colors listed in the [Appendix](#); a valid RGB value in the form `### ## #`, for example, `171 248 103`; or a valid RRGGBB hex value in the form `#####`, for example, `ABF867`.

## Options

### Main

`totals` (*totals*) and `nototals` control which totals are to be displayed in the table. By default, all totals are reported.

`totals` (*totals*) specifies which margin totals to display in the reported table. *totals* can contain *rowvar*, *colvar*, and their interaction. Interactions can be specified by using the # operator.

`nototals` prevents table from displaying any totals.

### Statistics

`statistic`(*stat*[, *statopts*]) specifies the statistic to be displayed. `statistic()` may be repeated to request multiple statistics.

Available statistics are

| <i>stat</i>                | Definition                                       |
|----------------------------|--------------------------------------------------|
| <code>frequency</code>     | frequency                                        |
| <code>sumw</code>          | sum of weights                                   |
| <code>proportion</code>    | proportion                                       |
| <code>percent</code>       | percentage                                       |
| <code>rawproportion</code> | proportion ignoring optionally specified weights |
| <code>rawpercent</code>    | percentage ignoring optionally specified weights |

The following options may be specified in combination with statistics `proportion`, `percent`, `rawproportion`, and `rawpercent`:

| <i>statopts</i>                       | Definition                                 |
|---------------------------------------|--------------------------------------------|
| <code>across</code> ( <i>rowvar</i> ) | percentages or proportions across rows     |
| <code>across</code> ( <i>colvar</i> ) | percentages or proportions across columns  |
| <code>total</code>                    | compute overall percentages or proportions |

## Formats

`nformat(%fmt [results] [, basestyle])` changes the numeric format, such as the number of decimal places, for specified results. If *results* are not specified, the numeric format is changed for all results. *results* may be any statistic named in option `statistic()` (that is, any *stat*).

This option is repeatable, and when multiple formats apply to one result, the rightmost specification is applied.

This option does not affect the format of numeric layout variables (*rowspec* and *colspec*). The default format of these variables is taken from the dataset.

*basestyle* indicates that the format be applied to results that do not already have their own format instead of overriding the format for all results.

`sformat(sfmt [results])` changes the string format for specified results. You can, for instance, add symbols or text to the values reported in the table by modifying the string format.

*sfmt* may contain a mix of text and *%s*. Here *%s* refers to the numeric value that is formatted as specified using `nformat()`. The text will be placed around the numeric values in your table as it is placed around *%s* in this option. For instance, to place parentheses around the percent statistics, you can specify `sformat("(%s) percent)`.

*results* may be any statistic named in option `statistic()` (that is, any *stat*).

Two text characters must be specified using a special character sequence if you want them to be displayed in your table. To include %, type `%`. To include \, type `\\`. For instance, to place a percent sign following percent statistics, you can specify `sformat("%s%" percent)`.

This option is repeatable, and when multiple formats apply to one result, the rightmost specification is applied.

Title

`title(string)` adds the text *string* as a title to the table.

`titlestyles(text_styles)` changes the style for the table title. *text\_styles* are the following:

`font([fontfamily] [, size(# [unit]) color(color) variant(variant) [no]bold [no]italic [no]strikeout [no]underline])` specifies the font style. These font style properties are applicable when exporting the table to Microsoft Word, Microsoft Excel, PDF, HTML, and  $\LaTeX$  files, unless otherwise specified.

*fontfamily* specifies a valid font family. This font style property is applicable when publishing items from a collection to Microsoft Word, Microsoft Excel, PDF, and HTML files.

`size(# [unit])` specifies the font size as a number optionally followed by units. This font style property is applicable when publishing items from a collection to Microsoft Word, Microsoft Excel, PDF, and HTML files.

`color(color)` specifies the text color.

`variant(variant)` specifies the font variant and capitalization.

`bold` and `nobold` specify the font weight. `bold` changes the font weight to bold; `nobold` changes the font weight back to normal.

`italic` and `noitalic` specify the font style. `italic` changes the font style to italic; `noitalic` changes the font style back to normal.

`strikeout` and `nostrikeout` specify whether to add a strikeout mark to the title. `strikeout` adds a strikeout mark to the title; `nostrikeout` changes the title back to normal.

`underline` and `nounderline` specify whether to underline the table title. `underline` adds a single line under the title; `nounderline` removes the underline.

Only one of `strikeout` or `underline` is allowed when publishing to HTML files.

`smcl(smcl)` specifies how to render the table title for SMCL output. This style property is applicable only when publishing items from a collection to a SMCL file.

`latex(latex)` specifies how to render the table title for  $\LaTeX$  output. This style property is applicable only when publishing items from a collection to a  $\LaTeX$  file.

`shading(spec)` sets the background color, foreground color, and fill pattern. The background color is applicable when exporting the table to Microsoft Word, Microsoft Excel, PDF, HTML, and  $\LaTeX$  files. The foreground color and fill pattern are applicable when exporting the table to Microsoft Word and Microsoft Excel.

`note(string)` adds the text *string* as a note to the table. `note()` may be specified multiple times to add multiple notes. Each note is placed on a new line.

`notestyles(text_styles)` changes the style for the table notes. *text\_styles* are the following:

`font([fontfamily] [, size(# [unit]) color(color) variant(variant) [no]bold [no]italic [no]strikeout [no]underline])` specifies the font style. These font style properties are applicable when exporting the table to Microsoft Word, Microsoft Excel, PDF, HTML, and  $\LaTeX$  files, unless otherwise specified.

*fontfamily* specifies a valid font family. This font style property is applicable when publishing items from a collection to Microsoft Word, Microsoft Excel, PDF, and HTML files.

`size(# [unit])` specifies the font size as a number optionally followed by units. This font style property is applicable when publishing items from a collection to Microsoft Word, Microsoft Excel, PDF, and HTML files.

`color(color)` specifies the text color.

`variant(variant)` specifies the font variant and capitalization.

`bold` and `nobold` specify the font weight. `bold` changes the font weight to bold; `nobold` changes the font weight back to normal.

`italic` and `noitalic` specify the font style. `italic` changes the font style to italic; `noitalic` changes the font style back to normal.

`strikeout` and `nostrikeout` specify whether to add a strikeout mark to the notes. `strikeout` adds a strikeout mark to the note; `nostrikeout` changes the note back to normal.

`underline` and `nounderline` specify whether to underline the table notes. `underline` adds a single line under the notes; `nounderline` removes the underline.

Only one of `strikeout` or `underline` is allowed when publishing to HTML files.

`smcl(smcl)` specifies how to render the table notes for SMCL output. This style property is applicable only when publishing items from a collection to a SMCL file.

`latex(latex)` specifies how to render the table notes for  $\LaTeX$  output. This style property is applicable only when publishing items from a collection to a  $\LaTeX$  file.

`shading(sspec)` sets the background color, foreground color, and fill pattern. The background color is applicable when exporting the table to Microsoft Word, Microsoft Excel, PDF, HTML, and  $\LaTeX$  files. The foreground color and fill pattern are applicable when exporting the table to Microsoft Word and Microsoft Excel.

Export

`export(filename.suffix[ , export_opts])` exports the table to the specified file. *export\_opts* are the following:

`as(fileformat)` specifies the file format to which the table is to be exported. This option is rarely specified because, by default, `table` determines the format from the suffix of the file being created.

`replace` permits `table` to overwrite an existing file.

`noisily` specifies that `table` show the commands used to export the table to Microsoft Word, Microsoft Excel, and PDF files. The `putdocx`, `putexcel`, or `putpdf` command used to export the table will be displayed.

`dofile(filename[ , replace])` specifies that `table` save to *filename* the commands used to export the table to Microsoft Word, Microsoft Excel, and PDF files.

If *filename* already exists, it can be overwritten by specifying `replace`. If *filename* is specified without an extension, `.do` is assumed.

`append` specifies that `table` append the table to an existing file.

This option is applicable when you export the table to an HTML, a  $\LaTeX$ , a SMCL, a `txt`, or a Markdown file. When you export to HTML and  $\LaTeX$  files, the `append` option implies the `tableonly` option. Furthermore, when you export to HTML files, if the target CSS file already exists, `table` will also append to it.

`tableonly` specifies that only the table be exported to the specified HTML or  $\LaTeX$  document. By default, `table` produces complete HTML and  $\LaTeX$  documents.

When you export to an HTML file, if the `cssfile()` option is not specified, a CSS filename is constructed from *filename*, with the extension replaced with `.css`.

`cssfile(cssfile)` specifies that `table` define the styles in *cssfile* instead of *filename* when you export to HTML.

`prefix(prefix)` specifies that `table` use *prefix* to identify style classes when you export to HTML.

`sheet(sheetname [ , replace])` saves to the worksheet named *sheetname*. For more information about this option, see [\[RPT\] putexcel](#).

`cell(cell)` specifies an Excel upper-left cell as the starting position to publish the table. The default is `cell(A1)`.

`modify` permits `putexcel` set to modify an Excel file. For more information about this option, see [\[RPT\] putexcel](#).

`noopen` prevents `putexcel` from opening the Excel file in memory for modification. It does not appear in the dialog box. For more information about this option, see [\[RPT\] putexcel](#).

## Options

`missing` specifies that numeric missing values of *rowvar* or *colvar* be treated as valid categories. By default, observations with a numeric missing value in *rowvar* or *colvar* are omitted.

`zerocounts` specifies that `table` report a 0 in empty cells for the frequency statistic.

`name(cname)` specifies that a collection named *cname* be associated with the collected statistics and results. The default is `name(Table)`.

`append` specifies that `table` append its collection information into the collection named in `name()`.

`replace` permits `table` to overwrite an existing collection. This option is implied for `name(Table)` when `append` is not specified.

`label(filename)` specifies the *filename* containing the collection labels to use for your table. Labels in *filename* will be loaded for the table, and any labels not specified in *filename* will be taken from the labels defined in `c(collect_label)`. The default is to use only the collection labels set in `c(collect_label)`; see [TABLES] [set collect\\_label](#).

`style(filename [ , override ])` specifies the *filename* containing the collection styles to use for your table. The default collection styles will be discarded, and only the collection styles in *filename* will be applied.

If you prefer the default collection styles but also want to apply any styles in *filename*, specify `override`. If there are conflicts between the default collection styles and those in *filename*, the ones in *filename* will take precedence.

The default is to use only the collection styles set in `c(table_style)`; see [TABLES] [set table\\_style](#).

The following option is available with `table` but is not shown in the dialog box:

`markvar(newvar)` generates an indicator variable that identifies the observations used in the tabulation.

## Remarks and examples

Remarks are presented under the following headings:

*Tabulation of two variables*  
*Tabulation, including percentages*  
*Customizing results*

## Tabulation of two variables

To obtain a two-way tabulation that reports the number of observations across the levels of two categorical variables, we need to specify only the names of the categorical variables following `table`.

To demonstrate, we use data from the Second National Health and Nutrition Examination Survey (NHANES II) (McDowell et al. 1981) and create a two-way tabulation of self-reported health status (`hlthstat`) by region of the USA (`region`).

```
. use https://www.stata-press.com/data/r19/nhanes21
(Second National Health and Nutrition Examination Survey)
. table hlthstat region
```

|               | Region |       |       |       | Total  |
|---------------|--------|-------|-------|-------|--------|
|               | NE     | MW    | S     | W     |        |
| Health status |        |       |       |       |        |
| Excellent     | 562    | 730   | 546   | 569   | 2,407  |
| Very good     | 558    | 721   | 651   | 661   | 2,591  |
| Good          | 631    | 735   | 807   | 765   | 2,938  |
| Fair          | 257    | 419   | 532   | 462   | 1,670  |
| Poor          | 77     | 167   | 317   | 168   | 729    |
| Total         | 2,085  | 2,772 | 2,853 | 2,625 | 10,335 |

We can examine the missing values as well by adding the `missing` option.

```
. table hlthstat region, missing
```

|                      | Region |       |       |       | Total  |
|----------------------|--------|-------|-------|-------|--------|
|                      | NE     | MW    | S     | W     |        |
| Health status        |        |       |       |       |        |
| Excellent            | 562    | 730   | 546   | 569   | 2,407  |
| Very good            | 558    | 721   | 651   | 661   | 2,591  |
| Good                 | 631    | 735   | 807   | 765   | 2,938  |
| Fair                 | 257    | 419   | 532   | 462   | 1,670  |
| Poor                 | 77     | 167   | 317   | 168   | 729    |
| .                    | 1      | 1     |       |       | 2      |
| Blank but applicable | 10     | 1     |       | 3     | 14     |
| Total                | 2,096  | 2,774 | 2,853 | 2,628 | 10,351 |

We find that 16 individuals have a missing health status, and the majority of these are from individuals in the Northeast. The empty cells correspond to regions in which all the individuals have a nonmissing health status; we can fill in these empty cells with 0s:

```
. table hlthstat region, missing zerocounts
```

|                      | Region |       |       |       | Total  |
|----------------------|--------|-------|-------|-------|--------|
|                      | NE     | MW    | S     | W     |        |
| Health status        |        |       |       |       |        |
| Excellent            | 562    | 730   | 546   | 569   | 2,407  |
| Very good            | 558    | 721   | 651   | 661   | 2,591  |
| Good                 | 631    | 735   | 807   | 765   | 2,938  |
| Fair                 | 257    | 419   | 532   | 462   | 1,670  |
| Poor                 | 77     | 167   | 317   | 168   | 729    |
| .                    | 1      | 1     | 0     | 0     | 2      |
| Blank but applicable | 10     | 1     | 0     | 3     | 14     |
| Total                | 2,096  | 2,774 | 2,853 | 2,628 | 10,351 |

## Tabulation, including percentages

Instead of frequencies, we can request that table report the percentage of observations in each cell of the table by specifying the `statistic(percent)` option.

```
. table hlthstat region, statistic(percent)
```

|               | Region |       |       |       | Total  |
|---------------|--------|-------|-------|-------|--------|
|               | NE     | MW    | S     | W     |        |
| Health status |        |       |       |       |        |
| Excellent     | 5.44   | 7.06  | 5.28  | 5.51  | 23.29  |
| Very good     | 5.40   | 6.98  | 6.30  | 6.40  | 25.07  |
| Good          | 6.11   | 7.11  | 7.81  | 7.40  | 28.43  |
| Fair          | 2.49   | 4.05  | 5.15  | 4.47  | 16.16  |
| Poor          | 0.75   | 1.62  | 3.07  | 1.63  | 7.05   |
| Total         | 20.17  | 26.82 | 27.61 | 25.40 | 100.00 |

We see that 5.44% of all observations correspond to individuals in excellent health who live in the Northeast.

Rather than looking at overall percentages, we might want to examine the distribution of observations within each health status level across the four regions. To do this, we can add the `across(region)` option.

```
. table hlthstat region, statistic(percent, across(region))
```

|               | Region |       |       |       | Total  |
|---------------|--------|-------|-------|-------|--------|
|               | NE     | MW    | S     | W     |        |
| Health status |        |       |       |       |        |
| Excellent     | 23.35  | 30.33 | 22.68 | 23.64 | 100.00 |
| Very good     | 21.54  | 27.83 | 25.13 | 25.51 | 100.00 |
| Good          | 21.48  | 25.02 | 27.47 | 26.04 | 100.00 |
| Fair          | 15.39  | 25.09 | 31.86 | 27.66 | 100.00 |
| Poor          | 10.56  | 22.91 | 43.48 | 23.05 | 100.00 |
| Total         | 20.17  | 26.82 | 27.61 | 25.40 | 100.00 |

Of individuals reporting excellent health, 23.35% live in the Northeast, while 30.33% live in the Midwest, 22.68% live in the South, and 23.64% live in the West.

We can also look at the distribution of observations across health status categories within each region.

```
. table hlthstat region, statistic(percent, across(hlthstat))
```

|               | Region |        |        |        |        |
|---------------|--------|--------|--------|--------|--------|
|               | NE     | MW     | S      | W      | Total  |
| Health status |        |        |        |        |        |
| Excellent     | 26.95  | 26.33  | 19.14  | 21.68  | 23.29  |
| Very good     | 26.76  | 26.01  | 22.82  | 25.18  | 25.07  |
| Good          | 30.26  | 26.52  | 28.29  | 29.14  | 28.43  |
| Fair          | 12.33  | 15.12  | 18.65  | 17.60  | 16.16  |
| Poor          | 3.69   | 6.02   | 11.11  | 6.40   | 7.05   |
| Total         | 100.00 | 100.00 | 100.00 | 100.00 | 100.00 |

Of individuals living in the South, 11.11% report having poor health. This is notably higher than the percentage of individuals reporting poor health in the other regions.

It is often helpful to see both frequencies and percentages in the same table. To do this, we can add the `statistic(frequency)` option to our command.

```
. table hlthstat region, statistic(frequency)
> statistic(percent, across(hlthstat))
```

|               | Region |        |        |        |        |
|---------------|--------|--------|--------|--------|--------|
|               | NE     | MW     | S      | W      | Total  |
| Health status |        |        |        |        |        |
| Excellent     |        |        |        |        |        |
| Frequency     | 562    | 730    | 546    | 569    | 2,407  |
| Percent       | 26.95  | 26.33  | 19.14  | 21.68  | 23.29  |
| Very good     |        |        |        |        |        |
| Frequency     | 558    | 721    | 651    | 661    | 2,591  |
| Percent       | 26.76  | 26.01  | 22.82  | 25.18  | 25.07  |
| Good          |        |        |        |        |        |
| Frequency     | 631    | 735    | 807    | 765    | 2,938  |
| Percent       | 30.26  | 26.52  | 28.29  | 29.14  | 28.43  |
| Fair          |        |        |        |        |        |
| Frequency     | 257    | 419    | 532    | 462    | 1,670  |
| Percent       | 12.33  | 15.12  | 18.65  | 17.60  | 16.16  |
| Poor          |        |        |        |        |        |
| Frequency     | 77     | 167    | 317    | 168    | 729    |
| Percent       | 3.69   | 6.02   | 11.11  | 6.40   | 7.05   |
| Total         |        |        |        |        |        |
| Frequency     | 2,085  | 2,772  | 2,853  | 2,625  | 10,335 |
| Percent       | 100.00 | 100.00 | 100.00 | 100.00 | 100.00 |

## Customizing results

There are several ways that we can customize the results of our two-way tabulation.

For instance, in some cases, we may prefer to omit the row and column totals. We can specify the `nototals` option to suppress these totals.

```
. table hlthstat region, statistic(frequency)
> statistic(percent, across(hlthstat)) nototals
```

|               | Region |       |       |       |
|---------------|--------|-------|-------|-------|
|               | NE     | MW    | S     | W     |
| Health status |        |       |       |       |
| Excellent     |        |       |       |       |

| Percent       | 3.69   | 6.02  | 11.11 | 6.40  |

Or perhaps we want to see row totals or column totals but not both. We can include the `totals(region)` option to display only the region totals.

```
. table hlthstat region, statistic(frequency)
> statistic(percent, across(hlthstat)) totals(region)
```

|               | Region |        |        |        |
|---------------|--------|--------|--------|--------|
|               | NE     | MW     | S      | W      |
| Health status |        |        |        |        |
| Excellent     |        |        |        |        |
| Frequency     | 562    | 730    | 546    | 569    |
| Percent       | 26.95  | 26.33  | 19.14  | 21.68  |
| Very good     |        |        |        |        |
| Frequency     | 558    | 721    | 651    | 661    |
| Percent       | 26.76  | 26.01  | 22.82  | 25.18  |
| Good          |        |        |        |        |
| Frequency     | 631    | 735    | 807    | 765    |
| Percent       | 30.26  | 26.52  | 28.29  | 29.14  |
| Fair          |        |        |        |        |
| Frequency     | 257    | 419    | 532    | 462    |
| Percent       | 12.33  | 15.12  | 18.65  | 17.60  |
| Poor          |        |        |        |        |
| Frequency     | 77     | 167    | 317    | 168    |
| Percent       | 3.69   | 6.02   | 11.11  | 6.40   |
| Total         |        |        |        |        |
| Frequency     | 2,085  | 2,772  | 2,853  | 2,625  |
| Percent       | 100.00 | 100.00 | 100.00 | 100.00 |

Once we have the statistics we want in our table, we can format the way that they appear. If, for instance, we want to add a percent sign to each of our percentages, we can specify the `sformat("%s%" percent)` option. The `sformat()` option specifies that we want to add string characters to the numbers in the table. Within it, we refer to the numeric values as `%s` and place any string characters we want around this. The percent sign is unique because it already has special meaning in this context. Therefore, we must type two percent signs, `%%`, to display one. Finally, by adding `percent` within the `sformat()` option, we specify that we want to apply this format only to the percent statistics.

```
. table hlthstat region, statistic(frequency)
> statistic(percent, across(hlthstat)) totals(region)
> sformat("%s%" percent)
```

|               | Region  |         |         |         |
|---------------|---------|---------|---------|---------|
|               | NE      | MW      | S       | W       |
| Health status |         |         |         |         |
| Excellent     |         |         |         |         |
| Frequency     | 562     | 730     | 546     | 569     |
| Percent       | 26.95%  | 26.33%  | 19.14%  | 21.68%  |
| Very good     |         |         |         |         |
| Frequency     | 558     | 721     | 651     | 661     |
| Percent       | 26.76%  | 26.01%  | 22.82%  | 25.18%  |
| Good          |         |         |         |         |
| Frequency     | 631     | 735     | 807     | 765     |
| Percent       | 30.26%  | 26.52%  | 28.29%  | 29.14%  |
| Fair          |         |         |         |         |
| Frequency     | 257     | 419     | 532     | 462     |
| Percent       | 12.33%  | 15.12%  | 18.65%  | 17.60%  |
| Poor          |         |         |         |         |
| Frequency     | 77      | 167     | 317     | 168     |
| Percent       | 3.69%   | 6.02%   | 11.11%  | 6.40%   |
| Total         |         |         |         |         |
| Frequency     | 2,085   | 2,772   | 2,853   | 2,625   |
| Percent       | 100.00% | 100.00% | 100.00% | 100.00% |

Now that we have added the percent sign, we could argue that the labels `Frequency` and `Percent` are unnecessary. If we remove these statistic names from the row labels, we might also want to right-align the remaining labels in row headers. Finally, for readability, we could insert blank lines between levels of `hlthstat`. We could use the `collect` suite of commands to make these style changes. Fortunately, however, one of our [predefined styles](#), `table-tab2`, includes these style changes, and we can select it using the `style()` option.

```
. table hlthstat region, statistic(frequency)
> statistic(percent, across(hlthstat)) totals(region)
> sformat("%s%" percent) style(table-tab2)
```

|               | Region           |                  |                  |                  |
|---------------|------------------|------------------|------------------|------------------|
|               | NE               | MW               | S                | W                |
| Health status |                  |                  |                  |                  |
| Excellent     | 562<br>26.95%    | 730<br>26.33%    | 546<br>19.14%    | 569<br>21.68%    |
| Very good     | 558<br>26.76%    | 721<br>26.01%    | 651<br>22.82%    | 661<br>25.18%    |
| Good          | 631<br>30.26%    | 735<br>26.52%    | 807<br>28.29%    | 765<br>29.14%    |
| Fair          | 257<br>12.33%    | 419<br>15.12%    | 532<br>18.65%    | 462<br>17.60%    |
| Poor          | 77<br>3.69%      | 167<br>6.02%     | 317<br>11.11%    | 168<br>6.40%     |
| Total         | 2,085<br>100.00% | 2,772<br>100.00% | 2,853<br>100.00% | 2,625<br>100.00% |

You can learn more about the predefined styles described at [\[TABLES\] Predefined styles](#). If none of these provide the exact style you want for your table, you can further customize the results by using the collect suite of commands. To learn more, see [\[TABLES\] Intro](#).

If you wish to include this table in a paper, on a webpage, or in another format, you can easily export it in  $\LaTeX$ , Word, Excel, HTML, and a variety of other formats by using the `export()` option.

## Stored results

`table` stores the following in `r()`:

Scalars

`r(N)` number of observations

## Description

In this entry, we discuss how to use the `table` command to create tables displaying frequencies, percentages, and proportions across levels of three or more variables. Additionally, we demonstrate how a single `table` command can create multiple tables corresponding to levels of variables or different statistics.

## Quick start

Table of frequencies with rows defined by the levels of `a1` and columns defined by the categories of `a2` and `a3`

```
table (a1) (a2 a3)
```

Same as above, but with rows defined by levels of `a1` and `a2` and columns defined by levels of `a3`

```
table (a1 a2) (a3)
```

Separate tables for each level `a3` with the rows of each table defined by the levels of `a1` and the columns defined by levels of `a2`

```
table (a1) (a2) (a3)
```

Report percentages of observations in each cell rather than frequencies

```
table (a1) (a2 a3), statistic(percent)
```

Report both frequencies and percentages

```
table (a1) (a2 a3), statistic(percent) statistic(frequency)
```

Report the percentages across levels of `a3`

```
table (a1) (a2 a3), statistic(percent, across(a3))
```

## Menu

Statistics > Summaries, tables, and tests > Tables of frequencies, summaries, and command results

## Syntax

*Table with rows defined by multiple variables*

```
table rowvars colvar [if] [in] [weight] [, options]
```

*Table with columns defined by multiple variables*

```
table rowvar (colvars) [if] [in] [weight] [, options]
```

*Table with rows and columns defined by multiple variables*

```
table (rowvars) (colvars) [if] [in] [weight] [, options]
```

*Multiple multiway tables*

```
table (rowvars) (colvars) (tabvars) [if] [in] [weight] [, options]
```

*Customized multiway tables*

```
table (rowspec) (colspec) [(tabspec)] [if] [in] [weight] [, options]
```

*rowspec*, *colspec*, and *tabspec* may be empty or may include variable names or any of the following keywords:

| <i>keyword</i> | Description                   |
|----------------|-------------------------------|
| result         | requested statistics          |
| across         | index across() specifications |

| <i>options</i>                                      | Description                                                                                                                                     |
|-----------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Main</b>                                         |                                                                                                                                                 |
| <code>totals(totals)</code>                         | report only the specified totals                                                                                                                |
| <code>nototals</code>                               | suppress the marginal totals                                                                                                                    |
| <b>Statistics</b>                                   |                                                                                                                                                 |
| <code>statistic(stat[, statopts])</code>            | statistic to be reported; default is <code>statistic(frequency)</code> when no weights are specified and <code>statistic(sumw)</code> otherwise |
| <b>Formats</b>                                      |                                                                                                                                                 |
| <code>nformat(%fmt [results][, basestyle])</code>   | specify numeric format                                                                                                                          |
| <code>sformat(sfmt [results])</code>                | specify string format                                                                                                                           |
| <b>Title</b>                                        |                                                                                                                                                 |

| <b>Notes</b>                                        |                                                                                                                                                 |
| <code>note(string)</code>                           | add table note                                                                                                                                  |
| <code>notestyles(text_styles)</code>                | change table note styles                                                                                                                        |
| <b>Export</b>                                       |                                                                                                                                                 |
| <code>export(filename.suffix[, export_opts])</code> | export table                                                                                                                                    |
| <b>Options</b>                                      |                                                                                                                                                 |
| <code>listwise</code>                               | use listwise deletion to handle missing values                                                                                                  |
| <code>missing</code>                                | treat numeric missing values like other values                                                                                                  |
| <code>showcounts</code>                             | show sample size for all variables in <code>statistic()</code> option                                                                           |
| <code>zerocounts</code>                             | report 0 for empty cell counts                                                                                                                  |
| <code>name(cname)</code>                            | collect results into a collection named <i>cname</i>                                                                                            |
| <code>append</code>                                 | append results to an existing collection                                                                                                        |
| <code>replace</code>                                | replace results of an existing collection                                                                                                       |
| <code>label(filename)</code>                        | specify the collection labels                                                                                                                   |
| <code>style(filename [, override])</code>           | specify the collection style                                                                                                                    |
| <code>markvar(newvar)</code>                        | create <i>newvar</i> to identify observations used to compute the statistics                                                                    |

`fweights`, `aweight`s, `iweight`s, and `pweight`s are allowed; see [\[U\] 11.1.6 weight](#).

`strL` variables are not allowed; see [\[U\] 12.4.8 strL](#).

`markvar()` does not appear in the dialog box.

| <i>text_styles</i>                           | Description                                              |
|----------------------------------------------|----------------------------------------------------------|
| <code>font([fontfamily][, font_opts])</code> | specify font style                                       |
| <code>smcl(smcl)</code>                      | specify formatting for SMCL files                        |

| <i>txt_option</i> | Description                |
|-------------------|----------------------------|
| append            | append to an existing file |

| <i>md_option</i> | Description                |
|------------------|----------------------------|
| append           | append to an existing file |

*fontfamily* specifies a valid font family.

*unit* may be in (inch), pt (point), or cm (centimeter). An inch is equivalent to 72 points and 2.54 centimeters. The default is pt.

*variant* may be allcaps, smallcaps, or normal.

*variant* (allcaps) changes the text to all uppercase letters; applicable when publishing items from a collection to Microsoft Word, PDF, L<sup>A</sup>T<sub>E</sub>X, and HTML files.

*variant* (smallcaps) changes the text to use large capitals for uppercase letters and smaller capitals for lowercase letters; applicable when publishing items from a collection to Microsoft Word, L<sup>A</sup>T<sub>E</sub>X, and HTML files.

*variant* (normal) changes the font variant back to normal and leaves the capitalization unchanged from the original text; applicable when publishing items from a collection to Microsoft Word, PDF, L<sup>A</sup>T<sub>E</sub>X, and HTML files.

*smcl* specifies the name of the SMCL directive to render text for SMCL output. The supported SMCL directives are input, error, result, and text.

*latex* specifies the name of a L<sup>A</sup>T<sub>E</sub>X macro to render text for L<sup>A</sup>T<sub>E</sub>X output. Example L<sup>A</sup>T<sub>E</sub>X macro names are textbf, textsf, textrm, and texttt. Custom L<sup>A</sup>T<sub>E</sub>X macros are also allowed. If *text* is to be rendered in a cell, title, or note, then *latex* is translated to the following when you export to L<sup>A</sup>T<sub>E</sub>X:

```
\latex {text}
```

*sspec* is

```
[background(bcolor) foreground(fgcolor) pattern(fpattern)]
```

*bcolor* specifies the background color.

*fgcolor* specifies the foreground color.

*fpattern* specifies the fill pattern. A complete list of fill patterns is shown in the [Appendix](#).

*bcolor*, *fgcolor*, and *color* may be one of the colors listed in the [Appendix](#); a valid RGB value in the form ### # # #, for example, 171 248 103; or a valid RRGGBB hex value in the form #####, for example, ABF867.

## Options

Main

*totals* (*totals*) and *nototals* control which totals are to be displayed in the table. By default, all totals are reported.

*totals* (*totals*) specifies that totals be displayed only for the variables or interactions specified. *totals* can contain *rowvars*, *colvars*, *tabvars*, and interactions between any of these variables. Interactions can be specified by using the # operator.

*nototals* prevents table from displaying any totals.

## Statistics

`statistic(stat[, statopts])` specifies the statistic to be displayed. `statistic()` may be repeated to request multiple statistics.

Available statistics are

| <i>stat</i>                | Definition                                       |
|----------------------------|--------------------------------------------------|
| <code>frequency</code>     | frequency                                        |
| <code>sumw</code>          | sum of weights                                   |
| <code>proportion</code>    | proportion                                       |
| <code>percent</code>       | percentage                                       |
| <code>rawproportion</code> | proportion ignoring optionally specified weights |
| <code>rawpercent</code>    | percentage ignoring optionally specified weights |

The following options may be specified in combination with statistics `proportion`, `percent`, `rawproportion`, and `rawpercent`:

| <i>statopts</i>               | Definition                                                            |
|-------------------------------|-----------------------------------------------------------------------|
| <code>across(cellspec)</code> | percentages or proportions across levels of variables or interactions |
| <code>total</code>            | compute overall percentages or proportions                            |

*cellspec* may contain *rowvars*, *colvars*, *tabvars*, or an interaction between any of these variables. Interactions can be specified by using the `#` operator.

## Formats

`nformat(%fmt [results][, basestyle])` changes the numeric format, such as the number of decimal places, for specified results. If *results* are not specified, the numeric format is changed for all results.

*results* may be any statistic named in option `statistic()` (that is, any *stat*).

This option is repeatable, and when multiple formats apply to one result, the rightmost specification is applied.

This option does not affect the format of numeric layout variables (*rowspec*, *colspec*, and *tabspec*). The default format of these variables is taken from the dataset.

*basestyle* indicates that the format be applied to results that do not already have their own format instead of overriding the format for all results.

`sformat(%fmt [results])` changes the string format for specified results. You can, for instance, add symbols or text to the values reported in the table by modifying the string format.

*%fmt* may contain a mix of text and `%s`. Here `%s` refers to the numeric value that is formatted as specified using `nformat()`. The text will be placed around the numeric values in your table as it is placed around `%s` in this option. For instance, to place parentheses around the percent statistics, you can specify `sformat("(%s) percent)`.

*results* may be any statistic named in option `statistic()` (that is, any *stat*).

Two text characters must be specified using a special character sequence if you want them to be displayed in your table. To include `%`, type `%%`. To include `\`, type `\\`. For instance, to place a percent sign following percent statistics, you can specify `sformat("%s%%" percent)`.

This option is repeatable, and when multiple formats apply to one result, the rightmost specification is applied.

Title

`title(string)` adds the text *string* as a title to the table.

`titlestyles(text_styles)` changes the style for the table title. *text\_styles* are the following:

`font([fontfamily] [, size(# [unit]) color(color) variant(variant) [no]bold [no]italic [no]strikeout [no]underline])` specifies the font style. These font style properties are applicable when exporting the table to Microsoft Word, Microsoft Excel, PDF, HTML, and  $\LaTeX$  files, unless otherwise specified.

*fontfamily* specifies a valid font family. This font style property is applicable when publishing items from a collection to Microsoft Word, Microsoft Excel, PDF, and HTML files.

`size(# [unit])` specifies the font size as a number optionally followed by units. This font style property is applicable when publishing items from a collection to Microsoft Word, Microsoft Excel, PDF, and HTML files.

`color(color)` specifies the text color.

`variant(variant)` specifies the font variant and capitalization.

`bold` and `nobold` specify the font weight. `bold` changes the font weight to bold; `nobold` changes the font weight back to normal.

`italic` and `noitalic` specify the font style. `italic` changes the font style to italic; `noitalic` changes the font style back to normal.

`strikeout` and `nostrikeout` specify whether to add a strikeout mark to the title. `strikeout` adds a strikeout mark to the title; `nostrikeout` changes the title back to normal.

`underline` and `nounderline` specify whether to underline the table title. `underline` adds a single line under the title; `nounderline` removes the underline.

Only one of `strikeout` or `underline` is allowed when publishing to HTML files.

`smcl(smcl)` specifies how to render the table title for SMCL output. This style property is applicable only when publishing items from a collection to a SMCL file.

`latex(latex)` specifies how to render the table title for  $\LaTeX$  output. This style property is applicable only when publishing items from a collection to a  $\LaTeX$  file.

`shading(sspec)` sets the background color, foreground color, and fill pattern. The background color is applicable when exporting the table to Microsoft Word, Microsoft Excel, PDF, HTML, and  $\LaTeX$  files. The foreground color and fill pattern are applicable when exporting the table to Microsoft Word and Microsoft Excel.

`note(string)` adds the text *string* as a note to the table. `note()` may be specified multiple times to add multiple notes. Each note is placed on a new line.

`notestyles(text_styles)` changes the style for the table notes. *text\_styles* are the following:

`font([fontfamily] [, size(# [unit]) color(color) variant(variant) [no]bold [no]italic [no]strikeout [no]underline])` specifies the font style. These font style properties are applicable when exporting the table to Microsoft Word, Microsoft Excel, PDF, HTML, and  $\LaTeX$  files, unless otherwise specified.

*fontfamily* specifies a valid font family. This font style property is applicable when publishing items from a collection to Microsoft Word, Microsoft Excel, PDF, and HTML files.

`size(# [unit])` specifies the font size as a number optionally followed by units. This font style property is applicable when publishing items from a collection to Microsoft Word, Microsoft Excel, PDF, and HTML files.

`color(color)` specifies the text color.

`variant(variant)` specifies the font variant and capitalization.

`bold` and `nobold` specify the font weight. `bold` changes the font weight to bold; `nobold` changes the font weight back to normal.

`italic` and `noitalic` specify the font style. `italic` changes the font style to italic; `noitalic` changes the font style back to normal.

`strikeout` and `nostrikeout` specify whether to add a strikeout mark to the notes. `strikeout` adds a strikeout mark to the note; `nostrikeout` changes the note back to normal.

`underline` and `nounderline` specify whether to underline the table notes. `underline` adds a single line under the notes; `nounderline` removes the underline.

Only one of `strikeout` or `underline` is allowed when publishing to HTML files.

`smcl(smcl)` specifies how to render the table notes for SMCL output. This style property is applicable only when publishing items from a collection to a SMCL file.

`latex(latex)` specifies how to render the table notes for  $\LaTeX$  output. This style property is applicable only when publishing items from a collection to a  $\LaTeX$  file.

`shading(sspec)` sets the background color, foreground color, and fill pattern. The background color is applicable when exporting the table to Microsoft Word, Microsoft Excel, PDF, HTML, and  $\LaTeX$  files. The foreground color and fill pattern are applicable when exporting the table to Microsoft Word and Microsoft Excel.

Export

`export(filename.suffix[ , export_opts ])` exports the table to the specified file. *export\_opts* are the following:

`as(fileformat)` specifies the file format to which the table is to be exported. This option is rarely specified because, by default, `table` determines the format from the suffix of the file being created.

`replace` permits `table` to overwrite an existing file.

`noisily` specifies that `table` show the commands used to export the table to Microsoft Word, Microsoft Excel, and PDF files. The `putdocx`, `putexcel`, or `putpdf` command used to export the table will be displayed.

`dofile(filename[ , replace ])` specifies that `table` save to *filename* the commands used to export the table to Microsoft Word, Microsoft Excel, and PDF files.

If *filename* already exists, it can be overwritten by specifying `replace`. If *filename* is specified without an extension, `.do` is assumed.

`append` specifies that `table` append the table to an existing file.

This option is applicable when you export the table to an HTML, a  $\LaTeX$ , a SMCL, a `txt`, or a Markdown file. When you export to HTML and  $\LaTeX$  files, the `append` option implies the `tableonly` option. Furthermore, when you export to HTML files, if the target CSS file already exists, `table` will also append to it.

`tableonly` specifies that only the table be exported to the specified HTML or  $\LaTeX$  document. By default, `table` produces complete HTML and  $\LaTeX$  documents.

When you export to an HTML file, if the `cssfile()` option is not specified, a CSS filename is constructed from *filename*, with the extension replaced with `.css`.

`cssfile(cssfile)` specifies that `table` define the styles in *cssfile* instead of *filename* when you export to HTML.

`prefix(prefix)` specifies that `table` use *prefix* to identify style classes when you export to HTML.

`sheet(sheetname [ , replace ])` saves to the worksheet named *sheetname*. For more information about this option, see [\[RPT\] putexcel](#).

`cell(cell)` specifies an Excel upper-left cell as the starting position to publish the table. The default is `cell(A1)`.

`modify` permits `putexcel` set to modify an Excel file. For more information about this option, see [\[RPT\] putexcel](#).

`noopen` prevents `putexcel` from opening the Excel file in memory for modification. It does not appear in the dialog box. For more information about this option, see [\[RPT\] putexcel](#).

## Options

`listwise` handles missing values through listwise deletion, meaning that the entire observation is omitted from the sample if any variable specified in a `statistic()` option is missing for that observation. By default, `table` will omit an observation only if all variables specified in all `statistic()` options are missing for that observation.

`missing` specifies that numeric missing values of any *rowvars*, *colvars*, or *tabvars* be treated as valid categories. By default, observations with a numeric missing value in *rowvars*, *colvars*, or *tabvars* are omitted.

`showcounts` specifies that `table` report the sample size for each variable specified in option `statistic()`.

`zerocounts` specifies that `table` report a 0 in empty cells for the frequency statistic.

`name(cname)` specifies that a collection named *cname* be associated with the collected statistics and results. The default is `name(Table)`.

`append` specifies that `table` append its collection information into the collection named in `name()`.

`replace` permits `table` to overwrite an existing collection. This option is implied for `name(Table)` when `append` is not specified.

`label(filename)` specifies the *filename* containing the collection labels to use for your table. Labels in *filename* will be loaded for the table, and any labels not specified in *filename* will be taken from the labels defined in `c(collect_label)`. The default is to use only the collection labels set in `c(collect_label)`; see [TABLES] [set collect\\_label](#).

`style(filename [ , override ])` specifies the *filename* containing the collection styles to use for your table. The default collection styles will be discarded, and only the collection styles in *filename* will be applied.

If you prefer the default collection styles but also want to apply any styles in *filename*, specify `override`. If there are conflicts between the default collection styles and those in *filename*, the ones in *filename* will take precedence.

The default is to use only the collection styles set in `c(table_style)`; see [TABLES] [set table\\_style](#).

The following option is available with `table` but is not shown in the dialog box:

`markvar(newvar)` generates an indicator variable that identifies the observations used in the tabulation.

## Remarks and examples

Remarks are presented under the following headings:

- [Introduction](#)
- [Tables with columns defined by multiple variables](#)
- [Appending tables](#)
- [Multiple tables with specified totals](#)

## Introduction

The `table` command allows you to create complex tables beyond one- and two-way tabulations. In multiway tabulations, you can display frequencies across levels of two or more variables. You can have levels of one variable nested within levels of another variable in columns, in rows, or in both dimensions. And with a single command, you can create separate tables for levels of one or more variables or for different results.

## Tables with columns defined by multiple variables

We use data from the Second National Health and Nutrition Examination Survey (NHANES II) (McDowell et al. 1981). The data contain some demographic information, such as the age, sex, and race of participants. The dataset also contains some measures of health, including whether the individual has high blood pressure (`highbp`).

Before we create any tables, we will modify a few labels in our dataset so that they will appear as we wish in our tables.

```
. use https://www.stata-press.com/data/r19/nhanes21
(Second National Health and Nutrition Examination Survey)
. label define yesno 0 "No" 1 "Yes"
. label values highbp diabetes heartatk yesno
. label variable diabetes "Diabetes"
```

Suppose we want to examine how many males and females in each age group have high blood pressure. Let's place the levels of age group on the rows and the levels of high blood pressure and sex on the columns.

```
. table (agegrp) (sex highbp), nototals
```

| Age group | Sex                       |                            |                           |                            |
|-----------|---------------------------|----------------------------|---------------------------|----------------------------|
|           | Male                      |                            | Female                    |                            |
|           | High blood pressure<br>No | High blood pressure<br>Yes | High blood pressure<br>No | High blood pressure<br>Yes |
| 20–29     | 825                       | 291                        | 1,103                     | 101                        |
| 30–39     | 480                       | 290                        | 687                       | 165                        |
| 40–49     | 336                       | 274                        | 434                       | 228                        |
| 50–59     | 255                       | 347                        | 335                       | 354                        |
| 60–69     | 568                       | 801                        | 625                       | 866                        |
| 70+       | 147                       | 301                        | 180                       | 358                        |

By default, `table` includes the totals for each category; we added the `nototals` option to suppress them here.

To better compare the occurrence of high blood pressure, let's now compute percentages of `highbp`. Below, we create the same table, but within each sex and age group combination, we report the percentage of individuals with and without high blood pressure.

```
. table (agegrp) (sex highbp), nototals statistic(percent, across(highbp))
```

|           | Sex                       |                            |                           |                            |
|-----------|---------------------------|----------------------------|---------------------------|----------------------------|
|           | Male                      |                            | Female                    |                            |
|           | High blood pressure<br>No | High blood pressure<br>Yes | High blood pressure<br>No | High blood pressure<br>Yes |
| Age group |                           |                            |                           |                            |
| 20-29     | 73.92                     | 26.08                      | 91.61                     | 8.39                       |
| 30-39     | 62.34                     | 37.66                      | 80.63                     | 19.37                      |
| 40-49     | 55.08                     | 44.92                      | 65.56                     | 34.44                      |
| 50-59     | 42.36                     | 57.64                      | 48.62                     | 51.38                      |
| 60-69     | 41.49                     | 58.51                      | 41.92                     | 58.08                      |
| 70+       | 32.81                     | 67.19                      | 33.46                     | 66.54                      |

Here we see that 26.08% of males in their 20s have high blood pressure and only 8.39% of females in their 20s have high blood pressure.

If we had simply typed `statistic(percent)`, then we would see the percentage of observations in each cell. With the suboption `across()`, we can compute the percentage within each sex and age group combination (across levels of `highbp`).

Next, let's request that percentages be calculated across the categories of high blood pressure and sex. We can alternatively think of this as being percentages within age group.

```
. table (agegrp) (sex highbp), nototals statistic(percent, across(highbp#sex))
```

|           | Sex                       |                            |                           |                            |
|-----------|---------------------------|----------------------------|---------------------------|----------------------------|
|           | Male                      |                            | Female                    |                            |
|           | High blood pressure<br>No | High blood pressure<br>Yes | High blood pressure<br>No | High blood pressure<br>Yes |
| Age group |                           |                            |                           |                            |
| 20-29     | 35.56                     | 12.54                      | 47.54                     | 4.35                       |
| 30-39     | 29.59                     | 17.88                      | 42.36                     | 10.17                      |
| 40-49     | 26.42                     | 21.54                      | 34.12                     | 17.92                      |
| 50-59     | 19.75                     | 26.88                      | 25.95                     | 27.42                      |
| 60-69     | 19.86                     | 28.01                      | 21.85                     | 30.28                      |
| 70+       | 14.91                     | 30.53                      | 18.26                     | 36.31                      |

Here we see that 12.54% of individuals in their 20s are males with high blood pressure and 4.35% are females with high blood pressure.

We can reverse the order of our column variables so that we have the levels of `sex` nested within levels of high blood pressure. We will again request percentages across the categories of `highbp`.

```
. table (agegrp) (highbp sex), nototals statistic(percent, across(highbp))
```

|           | High blood pressure |        |       |        |
|-----------|---------------------|--------|-------|--------|
|           | No                  |        | Yes   |        |
|           | Sex                 |        | Sex   |        |
|           | Male                | Female | Male  | Female |
| Age group |                     |        |       |        |
| 20-29     | 73.92               | 91.61  | 26.08 | 8.39   |
| 30-39     | 62.34               | 80.63  | 37.66 | 19.37  |
| 40-49     | 55.08               | 65.56  | 44.92 | 34.44  |
| 50-59     | 42.36               | 48.62  | 57.64 | 51.38  |
| 60-69     | 41.49               | 41.92  | 58.51 | 58.08  |
| 70+       | 32.81               | 33.46  | 67.19 | 66.54  |

The last two columns represent the percentage of males with high blood pressure in the age group and the percentage of females with high blood pressure in the age group. We can clearly see that, across all age groups, the percent of males who have high blood pressure is greater than the percentage of females with high blood pressure.

Perhaps we want a table that includes only the two columns on the right. To create a table with the percentages of individuals with high blood pressure, we can take advantage of a unique feature of `table`—its results are automatically stored in a “collection” and can be easily customized. Specifically, when we create a table using the `table` command, the results are stored in a collection named `Table`, and these results replace the results from any previous `table` command. The `collect` suite of commands can be used to change the layout, style, and formatting of tables created from results in collection; see [\[TABLES\] Intro](#) to learn about collections of results and creating customized tables. For our table, we will use the `collect layout` command, which specifies how items from a collection should be arranged. Below, we arrange the percentages in a table with rows defined by the categories of `agegrp` and columns defined by the categories of `sex` and category 1 of `highbp`.

```
. collect layout (agegrp) (highbp[1]#sex)
```

```
Collection: Table
 Rows: agegrp
 Columns: highbp[1]#sex
 Table 1: 7 x 2
```

|           | High blood pressure |          |
|-----------|---------------------|----------|
|           | Yes                 |          |
|           | Sex                 |          |
|           | Male                | Female   |
| Age group |                     |          |
| 20-29     | 26.07527            | 8.388704 |
| 30-39     | 37.66234            | 19.3662  |
| 40-49     | 44.91803            | 34.44109 |
| 50-59     | 57.6412             | 51.37881 |
| 60-69     | 58.50986            | 58.08182 |
| 70+       | 67.1875             | 66.54275 |

## Appending tables

When we specify multiple variables for the row or column specification, the levels of one variable are nested within the levels of another. When you simply wish to join rows or columns from multiple tables, this can be easily done with the `append` option.

For example, we first create a table with the percentage of males and females in each age group with diabetes.

```
. table (sex agegrp) (diabetes), nototals statistic(percent, across(diabetes))
```

|        |           | Diabetes |       |
|--------|-----------|----------|-------|
|        |           | No       | Yes   |
| Sex    |           |          |       |
| Male   |           |          |       |
|        | Age group |          |       |
|        | 20-29     | 99.64    | 0.36  |
|        | 30-39     | 99.61    | 0.39  |
|        | 40-49     | 97.38    | 2.62  |
|        | 50-59     | 94.68    | 5.32  |
|        | 60-69     | 91.96    | 8.04  |
|        | 70+       | 88.39    | 11.61 |
| Female |           |          |       |
|        | Age group |          |       |
|        | 20-29     | 99.09    | 0.91  |
|        | 30-39     | 97.88    | 2.12  |
|        | 40-49     | 96.07    | 3.93  |
|        | 50-59     | 94.19    | 5.81  |
|        | 60-69     | 91.42    | 8.58  |
|        | 70+       | 89.03    | 10.97 |

We want to include the same information for `highbp` and `heartatk` in the same table, which indicates whether someone has had a heart attack. To do this, we will run the `table` command three times, once specifying each of these variables as the column variable. We will use the `name(table1)` option to specify that the results be stored in a collection named `table1`. To the second and third `table` commands, we will add the `append` option so that all the results are stored in the same collection rather than overriding the results from the previous command.

```
. quietly: table (sex agegrp) (diabetes), nototals
> statistic(percent, across(diabetes)) name(table1)
. quietly: table (sex agegrp) (highbp), nototals
> statistic(percent, across(highbp)) name(table1) append
. quietly: table (sex agegrp) (heartatk), nototals
> statistic(percent, across(heartatk)) name(table1) append
```

With the results from all our table commands stored in one collection, we can again take advantage of the `collect` layout command to arrange results into a table. We request that `sex` and `agegroup` define the rows. By including the `#` between variable names, we specify that we want the levels of these variables to be interacted to form the rows. We request that levels of `diabetes`, `highbp`, and `heartatk` form the columns. Because we did not include `#` between the variable names, their levels will not be interacted. Instead, they will be listed one after the other.

```
. collect layout (sex#agegrp) (diabetes highbp heartatk)
Collection: table1
 Rows: sex#agegrp
 Columns: diabetes highbp heartatk
Table 1: 17 x 6
```

|           | Diabetes |       | High blood pressure |       | Prior heart attack |       |
|-----------|----------|-------|---------------------|-------|--------------------|-------|
|           | No       | Yes   | No                  | Yes   | No                 | Yes   |
| Sex       |          |       |                     |       |                    |       |
| Male      |          |       |                     |       |                    |       |
| Age group |          |       |                     |       |                    |       |
| 20-29     | 99.64    | 0.36  | 73.92               | 26.08 | 100.00             |       |
| 30-39     | 99.61    | 0.39  | 62.34               | 37.66 | 99.74              | 0.26  |
| 40-49     | 97.38    | 2.62  | 55.08               | 44.92 | 98.03              | 1.97  |
| 50-59     | 94.68    | 5.32  | 42.36               | 57.64 | 92.36              | 7.64  |

## Multiple tables with specified totals

There may be times when instead of creating one large table for multiple variables, you would prefer to create separate tables for each level of one or more variables or for different statistics. For example, we previously had levels of age group nested within categories of sex. Now, we would like to create tables that show how males and females in each age group rate their own health. The variable `hlthstat` records how individuals self-rate their health. Let's create a table that shows what percent of males in each age group selected each of the health categories and a separate table to list the percent of females.

```
. table (agegrp) (hlthstat) (sex), statistic(percent, across(hlthstat))
```

Sex = Male

|           | Health status |           |       |       |       | Total  |
|-----------|---------------|-----------|-------|-------|-------|--------|
|           | Excellent     | Very good | Good  | Fair  | Poor  |        |
| Age group |               |           |       |       |       |        |
| 20-29     | 39.61         | 32.71     | 20.97 | 5.82  | 0.90  | 100.00 |
| 30-39     | 36.88         | 29.61     | 26.10 | 5.84  | 1.56  | 100.00 |
| 40-49     | 28.03         | 25.90     | 29.51 | 12.30 | 4.26  | 100.00 |
| 50-59     | 17.80         | 21.30     | 35.11 | 15.97 | 9.82  | 100.00 |
| 60-69     | 13.33         | 19.56     | 28.94 | 23.00 | 15.16 | 100.00 |
| 70+       | 14.77         | 14.99     | 26.62 | 28.41 | 15.21 | 100.00 |
| Total     | 25.50         | 24.71     | 27.30 | 14.71 | 7.78  | 100.00 |

Sex = Female

|           | Health status |           |       |       |       | Total  |
|-----------|---------------|-----------|-------|-------|-------|--------|
|           | Excellent     | Very good | Good  | Fair  | Poor  |        |
| Age group |               |           |       |       |       |        |
| 20-29     | 32.39         | 34.55     | 24.92 | 6.98  | 1.16  | 100.00 |
| 30-39     | 29.76         | 30.71     | 28.12 | 9.29  | 2.12  | 100.00 |
| 40-49     | 26.71         | 23.07     | 29.29 | 15.63 | 5.31  | 100.00 |
| 50-59     | 17.15         | 20.93     | 33.43 | 20.20 | 8.28  | 100.00 |
| 60-69     | 10.76         | 20.31     | 33.22 | 25.49 | 10.22 | 100.00 |
| 70+       | 10.78         | 19.14     | 26.39 | 30.48 | 13.20 | 100.00 |
| Total     | 21.29         | 25.40     | 29.45 | 17.47 | 6.40  | 100.00 |

Sex = Total

|           | Health status |           |       |       |       | Total  |
|-----------|---------------|-----------|-------|-------|-------|--------|
|           | Excellent     | Very good | Good  | Fair  | Poor  |        |
| Age group |               |           |       |       |       |        |
| 20-29     | 35.86         | 33.66     | 23.02 | 6.42  | 1.03  | 100.00 |
| 30-39     | 33.15         | 30.19     | 27.16 | 7.65  | 1.85  | 100.00 |
| 40-49     | 27.34         | 24.43     | 29.39 | 14.03 | 4.81  | 100.00 |
| 50-59     | 17.46         | 21.10     | 34.21 | 18.23 | 9.00  | 100.00 |
| 60-69     | 11.99         | 19.95     | 31.17 | 24.30 | 12.59 | 100.00 |
| 70+       | 12.59         | 17.26     | 26.50 | 29.54 | 14.11 | 100.00 |
| Total     | 23.29         | 25.07     | 28.43 | 16.16 | 7.05  | 100.00 |

We see that 14.77% of males in their 70s and beyond rated their health as excellent and 10.78% of females in their 70s and beyond rated their health as excellent.

Note that we actually created three tables, one for males, one for females, and one for everybody. We are mainly interested in the first two tables and would like to drop the third table. But if we use the `nototals` option, we will not get the row totals we see above. Instead, we can specify which totals we do want with the `totals()` option:

```
. table (agegrp) (hlthstat) (sex), statistic(percent, across(hlthstat))
> totals(sex#agegrp sex#hlthstat sex)
```

Sex = Male

|           | Health status |           |       |       |       | Total  |
|-----------|---------------|-----------|-------|-------|-------|--------|
|           | Excellent     | Very good | Good  | Fair  | Poor  |        |
| Age group |               |           |       |       |       |        |
| 20-29     | 39.61         | 32.71     | 20.97 | 5.82  | 0.90  | 100.00 |
| 30-39     | 36.88         | 29.61     | 26.10 | 5.84  | 1.56  | 100.00 |
| 40-49     | 28.03         | 25.90     | 29.51 | 12.30 | 4.26  | 100.00 |
| 50-59     | 17.80         | 21.30     | 35.11 | 15.97 | 9.82  | 100.00 |
| 60-69     | 13.33         | 19.56     | 28.94 | 23.00 | 15.16 | 100.00 |
| 70+       | 14.77         | 14.99     | 26.62 | 28.41 | 15.21 | 100.00 |
| Total     | 25.50         | 24.71     | 27.30 | 14.71 | 7.78  | 100.00 |

Sex = Female

|           | Health status |           |       |       |       | Total  |
|-----------|---------------|-----------|-------|-------|-------|--------|
|           | Excellent     | Very good | Good  | Fair  | Poor  |        |
| Age group |               |           |       |       |       |        |
| 20-29     | 32.39         | 34.55     | 24.92 | 6.98  | 1.16  | 100.00 |
| 30-39     | 29.76         | 30.71     | 28.12 | 9.29  | 2.12  | 100.00 |
| 40-49     | 26.71         | 23.07     | 29.29 | 15.63 | 5.31  | 100.00 |
| 50-59     | 17.15         | 20.93     | 33.43 | 20.20 | 8.28  | 100.00 |
| 60-69     | 10.76         | 20.31     | 33.22 | 25.49 | 10.22 | 100.00 |
| 70+       | 10.78         | 19.14     | 26.39 | 30.48 | 13.20 | 100.00 |
| Total     | 21.29         | 25.40     | 29.45 | 17.47 | 6.40  | 100.00 |

`sex#agegrp` gives us the row totals, the total for each age group within each category of sex. `sex#hlthstat` provides us with the column totals, one of which would be the total percent of females that rated their health as excellent. Finally, `sex` gives us the total in the rightmost cell in the bottom of each table.

In all our previous tables, we used variables to define the rows and columns, but you can also use results in the row, column, and table identifiers. For example, suppose that in addition to reporting percentages for males and females in each age group, we wanted to report frequencies. We can create separate tables for the percentages and frequencies by specifying `result` in the third set of parentheses. To include the totals for each age group and for each category of sex, we specify the interaction of `sex` and `agegrp` in the `totals()` option:

```
. table (sex agegrp) (hlthstat) (result), statistic(percent, across(hlthstat))
> statistic(frequency) totals(sex#agegrp)
```

Percent

|     |           | Health status |           |       |       |       |        |
|-----|-----------|---------------|-----------|-------|-------|-------|--------|
|     |           | Excellent     | Very good | Good  | Fair  | Poor  | Total  |
| Sex |           |               |           |       |       |       |        |
|     | Male      |               |           |       |       |       |        |
|     | Age group |               |           |       |       |       |        |
|     | 20-29     | 39.61         | 32.71     | 20.97 | 5.82  | 0.90  | 100.00 |
|     | 30-39     | 36.88         | 29.61     | 26.10 | 5.84  | 1.56  | 100.00 |
|     | 40-49     | 28.03         | 25.90     | 29.51 | 12.30 | 4.26  | 100.00 |
|     | 50-59     | 17.80         | 21.30     | 35.11 | 15.97 | 9.82  | 100.00 |

|     | 50-59     | 17.15         | 20.93     | 33.43 | 20.20 | 8.28  | 100.00 |
|     | 60-69     | 10.76         | 20.31     | 33.22 | 25.49 | 10.22 | 100.00 |
|     | 70+       | 10.78         | 19.14     | 26.39 | 30.48 | 13.20 | 100.00 |

Frequency

|     |           | Health status |           |      |      |      |       |
|-----|-----------|---------------|-----------|------|------|------|-------|
|     |           | Excellent     | Very good | Good | Fair | Poor | Total |
| Sex |           |               |           |      |      |      |       |
|     | Male      |               |           |      |      |      |       |
|     | Age group |               |           |      |      |      |       |
|     | 20-29     | 442           | 365       | 234  | 65   | 10   | 1,116 |
|     | 30-39     | 284           | 228       | 201  | 45   | 12   | 770   |
|     | 40-49     | 171           | 158       | 180  | 75   | 26   | 610   |
|     | 50-59     | 107           | 128       | 211  | 96   | 59   | 601   |
|     | 60-69     | 182           | 267       | 395  | 314  | 207  | 1,365 |
|     | 70+       | 66            | 67        | 119  | 127  | 68   | 447   |
|     | Female    |               |           |      |      |      |       |
|     | Age group |               |           |      |      |      |       |
|     | 20-29     | 390           | 416       | 300  | 84   | 14   | 1,204 |
|     | 30-39     | 253           | 261       | 239  | 79   | 18   | 850   |
|     | 40-49     | 176           | 152       | 193  | 103  | 35   | 659   |
|     | 50-59     | 118           | 144       | 230  | 139  | 57   | 688   |
|     | 60-69     | 160           | 302       | 494  | 379  | 152  | 1,487 |
|     | 70+       | 58            | 103       | 142  | 164  | 71   | 538   |

In the table of frequencies, we see that of the 1,204 females in their 20s, only 390 rated their health as excellent. In the table of percentages, we see that this is equal to 32.39% of females in their 20s.

If we wish to include one of these tables, for example, in a paper or on a webpage, we can easily export it in L<sup>A</sup>T<sub>E</sub>X, Word, Excel, HTML, and a variety of other formats by using the `export()` option.

## Stored results

`table` stores the following in `r()`:

Scalars

`r(N)` number of observations

## Description

In this entry, we discuss how to use `table` to create a table of summary statistics.

## Quick start

Table with the mean of `v1`, `v2`, and `v3` for each category of `a1` and `a2`; rows are defined by categories of `a1` and variables `v1`, `v2`, and `v3`

```
table a1 a2, stat(mean v1 v2 v3)
```

Same as above, but also report standard deviations and suppress the totals; rows are defined by the results for each variable within each category of `a1`

```
table (a1 var result) (a2), stat(mean v1 v2 v3) ///
stat(sd v1 v2 v3) nototals
```

Table with number of observations in each category of `a2` and `a3`, for each level of `a1`

```
table a1, stat(fvfrequency a2 a3)
```

Same as above, and report percentage of observations in each category

```
table a1, stat(fvfrequency a2 a3) ///
stat(fvpercent a2 a3)
```

Same as above, and report the percentages with a percent sign, using two decimal places, and enclose them in parentheses

```
table (a1) (var result), stat(fvfrequency a2 a3) ///
stat(fvpercent a2 a3) ///
nformat(%5.2f fvpercent) sformat("%s%%" fvpercent)
```

## Menu

Statistics > Summaries, tables, and tests > Tables of frequencies, summaries, and command results

## Syntax

### Basic table of summary statistics

```
table [rowvar] [colvar] [if] [in] [weight], statistic(statspec)
 [statistic(statspec) [...]] [options]
```

### Customized table of summary statistics

```
table [(rowspec)] [(colspec)] [(tabspec)] [if] [in] [weight], statistic(statspec)
 [statistic(statspec) [...]] [options]
```

*rowspec*, *colspec*, and *tabspec* may be empty or may include variable names or any of the following keywords:

| <i>keyword</i> | Description                                    |
|----------------|------------------------------------------------|
| result         | requested statistics                           |
| var            | variables from <code>statistic()</code> option |
| across         | index <code>across()</code> specifications     |

| <i>options</i>                                       | Description                                                                                                                                     |
|------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Main</b>                                          |                                                                                                                                                 |
| <code>totals(totals)</code>                          | report only the specified totals                                                                                                                |
| <code>nototals</code>                                | suppress the marginal totals                                                                                                                    |
| <b>Statistics</b>                                    |                                                                                                                                                 |
| <code>statistic(statspec)</code>                     | statistic to be reported; default is <code>statistic(frequency)</code> when no weights are specified and <code>statistic(sumw)</code> otherwise |
| <b>Formats</b>                                       |                                                                                                                                                 |
| <code>nformat(%fmt [results] [, basestyle])</code>   | specify numeric format                                                                                                                          |
| <code>sformat(sfmt [results])</code>                 | specify string format                                                                                                                           |
| <b>Title</b>                                         |                                                                                                                                                 |
| <code>title(string)</code>                           | add table title                                                                                                                                 |
| <code>titlestyles(text_styles)</code>                | change table title styles                                                                                                                       |
| <b>Notes</b>                                         |                                                                                                                                                 |
| <code>note(string)</code>                            | add table note                                                                                                                                  |
| <code>notestyles(text_styles)</code>                 | change table note styles                                                                                                                        |
| <b>Export</b>                                        |                                                                                                                                                 |
| <code>export(filename.suffix [, export_opts])</code> | export table                                                                                                                                    |
| <b>Options</b>                                       |                                                                                                                                                 |
| <code>listwise</code>                                | use listwise deletion to handle missing values                                                                                                  |
| <code>missing</code>                                 | treat numeric missing values of variables in <code>rowspec</code> , <code>colspec</code> , and <code>tabspec</code> like other values           |
| <code>showcounts</code>                              | show sample size for all variables in <code>statistic()</code> option                                                                           |
| <code>zerocounts</code>                              | report 0 for empty cell counts                                                                                                                  |
| <code>name(cname)</code>                             | collect results into a collection named <i>cname</i>                                                                                            |
| <code>append</code>                                  | append results to an existing collection                                                                                                        |
| <code>replace</code>                                 | replace results of an existing collection                                                                                                       |
| <code>label(filename)</code>                         | specify the collection labels                                                                                                                   |
| <code>style(filename [, override])</code>            | specify the collection style                                                                                                                    |
| <code>markvar(newvar)</code>                         | create <i>newvar</i> that identifies observations used in the tabulation                                                                        |

`fweights`, `aweights`, `iweights`, and `pweights` are allowed; see [U] 11.1.6 **weight**.

`strL` variables are not allowed; see [U] 12.4.8 **strL**.

`markvar()` does not appear in the dialog box.

| <i>text_styles</i>                           | Description                                              |
|----------------------------------------------|----------------------------------------------------------|
| <code>font([fontfamily][, font_opts])</code> | specify font style                                       |
| <code>smcl(smcl)</code>                      | specify formatting for SMCL files                        |
| <code>latex(latex)</code>                    | specify L <sup>A</sup> T <sub>E</sub> X macro            |
| <code>shading(sspec)</code>                  | set background color, foreground color, and fill pattern |

| <i>font_opts</i>              | Description                              |
|-------------------------------|------------------------------------------|
| <code>size(# [unit])</code>   | specify font size                        |
| <code>color(color)</code>     | specify font color                       |
| <code>variant(variant)</code> | specify font variant and capitalization  |
| <code>[no]bold</code>         | specify whether to format text as bold   |
| <code>[no]italic</code>       | specify whether to format text as italic |
| <code>[no]strikeout</code>    | specify whether to strike out text       |
| <code>[no]underline</code>    | specify whether to underline text        |

| <i>suffix</i>         | <i>fileformat</i>         | Output format                      |
|-----------------------|---------------------------|------------------------------------|
| <code>docx</code>     | <code>as(docx)</code>     | Microsoft Word                     |
| <code>html</code>     | <code>as(html)</code>     | HTML 5 with CSS                    |
| <code>pdf</code>      | <code>as(pdf)</code>      | PDF                                |
| <code>xlsx</code>     | <code>as(xlsx)</code>     | Microsoft Excel 2007/2010 or newer |
| <code>xls</code>      | <code>as(xls)</code>      | Microsoft Excel 1997/2003          |
| <code>tex</code>      | <code>as(tex)</code>      | L <sup>A</sup> T <sub>E</sub> X    |

| <i>excel_options</i>        | available when exporting to .xls and .xlsx files    |
| <i>tex_options</i>          | available when exporting to .tex files              |
| <i>smcl_option</i>          | available when exporting to .smcl files             |
| <i>txt_option</i>           | available when exporting to .txt files              |
| <i>md_option</i>            | available when exporting to .markdown and .md files |

| <i>docx_options</i>                      | Description                                                         |
|------------------------------------------|---------------------------------------------------------------------|
| <code>noisily</code>                     | show the putdocx commands used to export to the Microsoft Word file |
| <code>dofile(filename[, replace])</code> | save the putdocx commands used for exporting to the named do-file   |

| <i>html_options</i>       | Description                                                    |
|---------------------------|----------------------------------------------------------------|
| append                    | append to an existing file                                     |
| tableonly                 | export only the table to the specified file                    |
| cssfile( <i>cssfile</i> ) | define the styles in <i>cssfile</i> instead of <i>filename</i> |
| prefix( <i>prefix</i> )   | use <i>prefix</i> to identify style classes                    |

| <i>pdf_options</i>                   | Description                                                      |
|--------------------------------------|------------------------------------------------------------------|
| noisily                              | show the putpdf commands used to export to the PDF file          |
| dofile( <i>filename</i> [, replace]) | save the putpdf commands used for exporting to the named do-file |

| <i>excel_options</i>                 | Description                                                                                             |
|--------------------------------------|---------------------------------------------------------------------------------------------------------|
| noisily                              | show the putexcel commands used to export to the Excel file                                             |
| dofile( <i>filename</i> [, replace]) | save the putexcel commands used for exporting to the named do-file                                      |
| sheet( <i>sheetname</i> [, replace]) | specify the worksheet to use; the default sheet name is Sheet1                                          |
| cell( <i>cell</i> )                  | specify the Excel upper-left cell as the starting position to export the table; the default is cell(A1) |
| modify                               | modify Excel file                                                                                       |
| noopen                               | do not open Excel file in memory                                                                        |

noopen does not appear in the dialog box.

| append           | append to an existing file |

*fontfamily* specifies a valid font family.

*unit* may be in (inch), pt (point), or cm (centimeter). An inch is equivalent to 72 points and 2.54 centimeters. The default is pt.

*variant* may be allcaps, smallcaps, or normal.

*variant* (allcaps) changes the text to all uppercase letters; applicable when publishing items from a collection to Microsoft Word, PDF,  $\LaTeX$ , and HTML files.

*variant* (smallcaps) changes the text to use large capitals for uppercase letters and smaller capitals for lowercase letters; applicable when publishing items from a collection to Microsoft Word,  $\LaTeX$ , and HTML files.

*variant* (normal) changes the font variant back to normal and leaves the capitalization unchanged from the original text; applicable when publishing items from a collection to Microsoft Word, PDF,  $\LaTeX$ , and HTML files.

*smcl* specifies the name of the SMCL directive to render text for SMCL output. The supported SMCL directives are `input`, `error`, `result`, and `text`.

*latex* specifies the name of a  $\LaTeX$  macro to render text for  $\LaTeX$  output. Example  $\LaTeX$  macro names are `textbf`, `textsf`, `textrm`, and `texttt`. Custom  $\LaTeX$  macros are also allowed. If *text* is to be rendered in a cell, title, or note, then *latex* is translated to the following when you export to  $\LaTeX$ :

```
\latex {text}
```

*sspec* is

```
[background(bgcolor) foreground(fgcolor) pattern(fpattern)]
```

*bgcolor* specifies the background color.

*fgcolor* specifies the foreground color.

*fpattern* specifies the fill pattern. A complete list of fill patterns is shown in the [Appendix](#).

*bgcolor*, *fgcolor*, and *color* may be one of the colors listed in the [Appendix](#); a valid RGB value in the form `### ## #`, for example, `171 248 103`; or a valid RRGGBB hex value in the form `#####`, for example, `ABF867`.

## Options

### Main

`totals` (*totals*) and `nototals` control which totals are to be displayed in the table. By default, all totals are reported.

`totals` (*totals*) specifies which margin totals to display in the reported table. *totals* can contain variables in *rowspec*, *colspec*, *tabspec*, and their interaction. Interactions can be specified by using the # operator.

`nototals` prevents table from displaying any totals.

### Statistics

`statistic` (*statspec*) specifies the statistic to be displayed. `statistic()` may be repeated to request multiple statistics. Frequency statistics, summary statistics, and ratio statistics are available by specifying `statistic` (*freqstat*), `statistic` (*sumstat varlist*), and `statistic` (*ratiostat* [*varlist*] [*, ratio\_options* ]), respectively.

`statistic()` may be repeated to request multiple statistics.

`statistic` (*freqstat*) specifies that frequencies be computed.

| <i>freqstat</i>        | Definition     |
|------------------------|----------------|
| <code>frequency</code> | frequency      |
| <code>sumw</code>      | sum of weights |

`statistic(sumstat varlist)` specifies that summary statistic *sumstat* be computed for the variables in *varlist*.

| <i>sumstat</i>  | Definition                                              |
|-----------------|---------------------------------------------------------|
| mean            | mean                                                    |
| semean          | standard error of the mean                              |
| sebinomial      | standard error of the mean, binomial                    |
| sepoisson       | standard error of the mean, Poisson                     |
| variance        | variance                                                |
| sd              | standard deviation                                      |
| skewness        | skewness                                                |
| kurtosis        | kurtosis                                                |
| cv              | coefficient of variation                                |
| count           | number of nonmissing values                             |
| median          | median                                                  |
| p#              | #th percentile                                          |
| q1              | first quartile                                          |
| q2              | second quartile                                         |
| q3              | third quartile                                          |
| iqr             | interquartile range                                     |
| min             | minimum value                                           |
| max             | maximum value                                           |
| range           | range                                                   |
| first           | first value                                             |
| last            | last value                                              |
| firstnm         | first nonmissing value                                  |
| lastnm          | last nonmissing value                                   |
| total           | total                                                   |
| rawtotal        | unweighted total                                        |
| fvfrequency     | frequency of each factor-variable level                 |
| fvrawfrequency  | unweighted frequency of each factor-variable level      |
| fvproportion    | proportion within each factor-variable level            |
| fvrawproportion | unweighted proportion within each factor-variable level |
| fvpercent       | percentage within each factor-variable level            |
| fvrawpercent    | unweighted percentage within each factor-variable level |

`statistic(ratiostat [varlist] [, ratio_options])` specifies that ratio statistic *ratiostat* be computed. If *varlist* is specified, ratios are computed based on the totals of the specified variables. If *varlist* is not specified, ratios are computed based on frequencies.

| <i>ratiostat</i>           | Definition                                       |
|----------------------------|--------------------------------------------------|
| <code>proportion</code>    | proportion                                       |
| <code>percent</code>       | percentage                                       |
| <code>rawproportion</code> | proportion ignoring optionally specified weights |
| <code>rawpercent</code>    | percentage ignoring optionally specified weights |

| <i>ratio_options</i>          | Definition                                                            |
|-------------------------------|-----------------------------------------------------------------------|
| <code>across(cellspec)</code> | percentages or proportions across levels of variables or interactions |
| <code>total</code>            | compute overall percentages or proportions                            |

*cellspec* may contain any variables in *rowspec*, *colspec*, *tabspec*, or an interaction between any of these variables. Interactions can be specified by using the # operator.

#### Formats

`nformat(%fmt [results] [, basestyle])` changes the numeric format, such as the number of decimal places, for specified results. If *results* are not specified, the numeric format is changed for all results.

*results* may be any statistic named in option `statistic()` (that is, any *freqstat*, *sumstat*, or *ratiostat*).

This option is repeatable, and when multiple formats apply to one result, the rightmost specification is applied.

This option does not affect the format of numeric layout variables (*rowspec*, *colspec*, and *tabspec*) or the format of factor variables specified in the `statistic()` option. The default format of these variables is taken from the dataset.

*basestyle* indicates that the format be applied to results that do not already have their own format instead of overriding the format for all results.

`sformat(%fmt [results])` changes the string format for specified results. You can, for instance, add symbols or text to the values reported in the table by modifying the string format.

*%fmt* may contain a mix of text and %s. Here %s refers to the numeric value that is formatted as specified using `nformat()`. The text will be placed around the numeric values in your table as it is placed around %s in this option. For instance, to place parentheses around the percent statistics, you can specify `sformat("(%s) percent)`.

*results* may be any statistic named in option `statistic()` (that is, any *freqstat*, *sumstat*, or *ratiostat*).

Two text characters must be specified using a special character sequence if you want them to be displayed in your table. To include %, type %%. To include \, type \\ . For instance, to place a percent sign following percent statistics, you can specify `sformat("%s%" percent)`.

This option is repeatable, and when multiple formats apply to one result, the rightmost specification is applied.

Title

`title(string)` adds the text *string* as a title to the table.

`titlestyles(text_styles)` changes the style for the table title. *text\_styles* are the following:

`font([fontfamily] [, size(# [unit]) color(color) variant(variant) [no]bold [no]italic [no]strikeout [no]underline])` specifies the font style. These font style properties are applicable when exporting the table to Microsoft Word, Microsoft Excel, PDF, HTML, and  $\LaTeX$  files, unless otherwise specified.

*fontfamily* specifies a valid font family. This font style property is applicable when publishing items from a collection to Microsoft Word, Microsoft Excel, PDF, and HTML files.

`size(# [unit])` specifies the font size as a number optionally followed by units. This font style property is applicable when publishing items from a collection to Microsoft Word, Microsoft Excel, PDF, and HTML files.

`color(color)` specifies the text color.

`variant(variant)` specifies the font variant and capitalization.

`bold` and `nobold` specify the font weight. `bold` changes the font weight to bold; `nobold` changes the font weight back to normal.

`italic` and `noitalic` specify the font style. `italic` changes the font style to italic; `noitalic` changes the font style back to normal.

`strikeout` and `nostrikeout` specify whether to add a strikeout mark to the title. `strikeout` adds a strikeout mark to the title; `nostrikeout` changes the title back to normal.

`underline` and `nounderline` specify whether to underline the table title. `underline` adds a single line under the title; `nounderline` removes the underline.

Only one of `strikeout` or `underline` is allowed when publishing to HTML files.

`smcl(smcl)` specifies how to render the table title for SMCL output. This style property is applicable only when publishing items from a collection to a SMCL file.

`latex(latex)` specifies how to render the table title for  $\LaTeX$  output. This style property is applicable only when publishing items from a collection to a  $\LaTeX$  file.

`shading(sspec)` sets the background color, foreground color, and fill pattern. The background color is applicable when exporting the table to Microsoft Word, Microsoft Excel, PDF, HTML, and  $\LaTeX$  files. The foreground color and fill pattern are applicable when exporting the table to Microsoft Word and Microsoft Excel.

`note(string)` adds the text *string* as a note to the table. `note()` may be specified multiple times to add multiple notes. Each note is placed on a new line.

`notestyles(text_styles)` changes the style for the table notes. *text\_styles* are the following:

`font([fontfamily] [, size(# [unit]) color(color) variant(variant) [no]bold [no]italic [no]strikeout [no]underline])` specifies the font style. These font style properties are applicable when exporting the table to Microsoft Word, Microsoft Excel, PDF, HTML, and  $\LaTeX$  files, unless otherwise specified.

*fontfamily* specifies a valid font family. This font style property is applicable when publishing items from a collection to Microsoft Word, Microsoft Excel, PDF, and HTML files.

`size(# [unit])` specifies the font size as a number optionally followed by units. This font style property is applicable when publishing items from a collection to Microsoft Word, Microsoft Excel, PDF, and HTML files.

`color(color)` specifies the text color.

`variant(variant)` specifies the font variant and capitalization.

`bold` and `nobold` specify the font weight. `bold` changes the font weight to bold; `nobold` changes the font weight back to normal.

`italic` and `noitalic` specify the font style. `italic` changes the font style to italic; `noitalic` changes the font style back to normal.

`strikeout` and `nostrikeout` specify whether to add a strikeout mark to the notes. `strikeout` adds a strikeout mark to the note; `nostrikeout` changes the note back to normal.

`underline` and `nounderline` specify whether to underline the table notes. `underline` adds a single line under the notes; `nounderline` removes the underline.

Only one of `strikeout` or `underline` is allowed when publishing to HTML files.

`smcl(smcl)` specifies how to render the table notes for SMCL output. This style property is applicable only when publishing items from a collection to a SMCL file.

`latex(latex)` specifies how to render the table notes for  $\LaTeX$  output. This style property is applicable only when publishing items from a collection to a  $\LaTeX$  file.

`shading(sspec)` sets the background color, foreground color, and fill pattern. The background color is applicable when exporting the table to Microsoft Word, Microsoft Excel, PDF, HTML, and  $\LaTeX$  files. The foreground color and fill pattern are applicable when exporting the table to Microsoft Word and Microsoft Excel.

Export

`export(filename.suffix[, export_opts])` exports the table to the specified file. *export\_opts* are the following:

`as(fileformat)` specifies the file format to which the table is to be exported. This option is rarely specified because, by default, `table` determines the format from the suffix of the file being created.

`replace` permits `table` to overwrite an existing file.

`noisily` specifies that `table` show the commands used to export the table to Microsoft Word, Microsoft Excel, and PDF files. The `putdocx`, `putexcel`, or `putpdf` command used to export the table will be displayed.

`dofile(filename[, replace])` specifies that `table` save to *filename* the commands used to export the table to Microsoft Word, Microsoft Excel, and PDF files.

If *filename* already exists, it can be overwritten by specifying `replace`. If *filename* is specified without an extension, `.do` is assumed.

`append` specifies that `table` append the table to an existing file.

This option is applicable when you export the table to an HTML, a  $\LaTeX$ , a SMCL, a `txt`, or a Markdown file. When you export to HTML and  $\LaTeX$  files, the `append` option implies the `tableonly` option. Furthermore, when you export to HTML files, if the target CSS file already exists, `table` will also append to it.

`tableonly` specifies that only the table be exported to the specified HTML or  $\LaTeX$  document. By default, `table` produces complete HTML and  $\LaTeX$  documents.

When you export to an HTML file, if the `cssfile()` option is not specified, a CSS filename is constructed from *filename*, with the extension replaced with `.css`.

`cssfile(cssfile)` specifies that `table` define the styles in *cssfile* instead of *filename* when you export to HTML.

`prefix(prefix)` specifies that `table` use *prefix* to identify style classes when you export to HTML.

`sheet(sheetname [, replace])` saves to the worksheet named *sheetname*. For more information about this option, see [\[RPT\] putexcel](#).

`cell(cell)` specifies an Excel upper-left cell as the starting position to publish the table. The default is `cell(A1)`.

`modify` permits `putexcel` set to modify an Excel file. For more information about this option, see [\[RPT\] putexcel](#).

`noopen` prevents `putexcel` from opening the Excel file in memory for modification. It does not appear in the dialog box. For more information about this option, see [\[RPT\] putexcel](#).

## Options

`listwise` handles missing values through listwise deletion, meaning that the entire observation is omitted from the sample if any variable specified in a `statistic()` option is missing for that observation. By default, `table` will omit an observation only if all variables specified in all `statistic()` options are missing for that observation.

`missing` specifies that numeric missing values of any variables specified in `rowspec`, `colspec`, or `tabspec` be treated as valid categories. By default, observations with a numeric missing value in any of these variables are omitted.

This option does not apply to factor variables specified with statistics `fvfrequency`, `fvrawfrequency`, `fvproportion`, `fvrawproportion`, `fvpercent`, or `fvrawpercent`.

`showcounts` specifies that `table` report the sample size for each variable specified in option `statistic()`.

`zerocounts` specifies that `table` report a 0 in empty cells for results `count`, `frequency`, `fvfrequency`, and `fvrawfrequency`.

`name(cname)` specifies that a collection named *cname* be associated with the collected statistics and results. The default is `name(Table)`.

`append` specifies that `table` append its collection information into the collection named in `name()`.

`replace` permits `table` to overwrite an existing collection. This option is implied for `name(Table)` when `append` is not specified.

`label(filename)` specifies the *filename* containing the collection labels to use for your table. Labels in *filename* will be loaded for the table, and any labels not specified in *filename* will be taken from the labels defined in `c(collect_label)`. The default is to use only the collection labels set in `c(collect_label)`; see [TABLES] [set collect\\_label](#).

`style(filename [, override])` specifies the *filename* containing the collection styles to use for your table. The default collection styles will be discarded, and only the collection styles in *filename* will be applied.

If you prefer the default collection styles but also want to apply any styles in *filename*, specify *override*. If there are conflicts between the default collection styles and those in *filename*, the ones in *filename* will take precedence.

The default is to use only the collection styles set in `c(table_style)`; see [TABLES] [set table\\_style](#).

The following option is available with `table` but is not shown in the dialog box:

`markvar(newvar)` generates an indicator variable that identifies the observations used in the tabulation.

## Remarks and examples

Remarks are presented under the following headings:

*Basic summary statistic tables*  
*Classic Table 1*

### Basic summary statistic tables

The `table` command can be used to compute a variety of summary statistics and display them in a table. Summary statistics can be computed for the full dataset or across levels of one or more categorical variables.

To demonstrate, we use data from the Second National Health and Nutrition Examination Survey (NHANES II) (McDowell et al. 1981) and create a table reporting the mean body mass index (BMI) of individuals across four regions of the USA. We use the `statistic()` option to request that means be computed, and we specify `region` as our row variable for the table. Thus, means are computed for each region separately and for all the regions combined (Total).

```
. use https://www.stata-press.com/data/r19/nhanes21
(Second National Health and Nutrition Examination Survey)
. table region, statistic(mean bmi)
```

|        | Mean     |
|--------|----------|
| Region |          |
| NE     | 25.57535 |
| MW     | 25.51936 |
| S      | 25.63317 |
| W      | 25.42299 |
| Total  | 25.5376  |

The mean BMI is very similar across regions. We might want to look at some additional statistics. We can add the minimums and maximums in our table by repeating our `statistic()` option for each statistic; we will use the `stat()` abbreviation.

```
. table region, stat(mean bmi) stat(min bmi) stat(max bmi)
```

|        | Mean     | Minimum value | Maximum value |
|--------|----------|---------------|---------------|
| Region |          |               |               |
| NE     | 25.57535 | 15.36715      | 57.10803      |
| MW     | 25.51936 | 14.1351       | 61.1297       |
| S      | 25.63317 | 12.3856       | 55.43552      |
| W      | 25.42299 | 15.69046      | 54.05056      |
| Total  | 25.5376  | 12.3856       | 61.1297       |

If we want to include even more statistics, the table will become very wide. We can move the statistics to the rows of our table by specifying the keyword `result` in the first set of parentheses. We place `region` on the columns by specifying this variable in the second set of parentheses.

```
. table (result) (region),
> stat(mean bmi) stat(median bmi) stat(sd bmi)
> stat(min bmi) stat(max bmi)
```

|                    | Region   |          |          |          |          |
|--------------------|----------|----------|----------|----------|----------|
|                    | NE       | MW       | S        | W        | Total    |
| Mean               | 25.57535 | 25.51936 | 25.63317 | 25.42299 | 25.5376  |
| Median             | 25.00623 | 24.71567 | 24.98451 | 24.66734 | 24.81812 |
| Standard deviation | 4.72798  | 4.905965 | 5.084678 | 4.883534 | 4.914969 |
| Minimum value      | 15.36715 | 14.1351  | 12.3856  | 15.69046 | 12.3856  |
| Maximum value      | 57.10803 | 61.1297  | 55.43552 | 54.05056 | 61.1297  |

Instead of computing many statistics for one variable, we might want to compute one statistic for multiple variables. To do this, we can include a list of variables within a single `statistic()` option. Let's compute the means of age, BMI, and systolic blood pressure (`bpsystol`).

```
. table (result) (region), stat(mean age bmi bpsystol)
```

|                         | Region   |          |          |          |          |
|-------------------------|----------|----------|----------|----------|----------|
|                         | NE       | MW       | S        | W        | Total    |

## Classic Table 1

In many reports, the first discussion of the data is accompanied by a “Table 1”, a reporting of summary statistics for all variables of interest. Often the table includes a mixture of continuous and categorical variables. We may also want to specify these in a particular order based on importance. In many cases, the table has multiple columns with the summary statistics reported for each level of a categorical variable of interest.

Here we will demonstrate how to create one variety of such a table. We have two factor variables of interest, `diabetes` and `hlthstat`, for which we would like to compute the percentage of individuals in each category. We will use the `fvpercent` statistic to obtain these percentages. We also have three continuous variables, `age`, `bmi`, and `bpsystol`, for which we would like to compute means. We specify the `statistic()` options in the order we wish to see the results in the table. To specify that the variables in the `statistic()` options appear on the rows, we include the keyword `var` in the first set of parentheses. We place `region` on the columns by listing it in the second set of parentheses.

```
. table (var) (region),
> statistic(fvpercent diabetes)
> statistic(mean age bmi)
> statistic(fvpercent hlthstat)
> statistic(mean bpsystol)
```

|                              | Region   |          |          |          | Total    |
|------------------------------|----------|----------|----------|----------|----------|
|                              | NE       | MW       | S        | W        |          |
| Diabetes status=Not diabetic |          |          |          |          |          |
| Factor-variable percent      | 95.32    | 95.49    | 94.36    | 95.62    | 95.18    |
| Diabetes status=Diabetic     |          |          |          |          |          |
| Factor-variable percent      | 4.68     | 4.51     | 5.64     | 4.38     | 4.82     |
| Age (years)                  |          |          |          |          |          |
| Mean                         | 47.81584 | 46.52776 | 48.19068 | 47.83828 | 47.57965 |
| Body mass index (BMI)        |          |          |          |          |          |
| Mean                         | 25.57535 | 25.51936 | 25.63317 | 25.42299 | 25.5376  |
| Health status=Excellent      |          |          |          |          |          |
| Factor-variable percent      | 26.95    | 26.33    | 19.14    | 21.68    | 23.29    |
| Health status=Very good      |          |          |          |          |          |
| Factor-variable percent      | 26.76    | 26.01    | 22.82    | 25.18    | 25.07    |
| Health status=Good           |          |          |          |          |          |
| Factor-variable percent      | 30.26    | 26.52    | 28.29    | 29.14    | 28.43    |
| Health status=Fair           |          |          |          |          |          |
| Factor-variable percent      | 12.33    | 15.12    | 18.65    | 17.60    | 16.16    |
| Health status=Poor           |          |          |          |          |          |
| Factor-variable percent      | 3.69     | 6.02     | 11.11    | 6.40     | 7.05     |
| Systolic blood pressure      |          |          |          |          |          |
| Mean                         | 131.3836 | 130.4863 | 131.1626 | 130.5936 | 130.8817 |

We have the statistics we want, but clearly our table could be improved. Let's start by applying one of the [predefined styles](#), `table-1`, by adding the `style()` option.

```
. table (var) (region),
> statistic(fvpercent diabetes)
> statistic(mean age bmi)
> statistic(fvpercent hlthstat)
> statistic(mean bpsystol) style(table-1)
```

|                         | Region   |          |          |          | Total    |
|-------------------------|----------|----------|----------|----------|----------|
|                         | NE       | MW       | S        | W        |          |
| Diabetes status         |          |          |          |          |          |
| Not diabetic            | 95.32    | 95.49    | 94.36    | 95.62    | 95.18    |
| Diabetic                | 4.68     | 4.51     | 5.64     | 4.38     | 4.82     |
| Age (years)             | 47.81584 | 46.52776 | 48.19068 | 47.83828 | 47.57965 |
| Body mass index (BMI)   | 25.57535 | 25.51936 | 25.63317 | 25.42299 | 25.5376  |
| Health status           |          |          |          |          |          |
| Excellent               | 26.95    | 26.33    | 19.14    | 21.68    | 23.29    |
| Very good               | 26.76    | 26.01    | 22.82    | 25.18    | 25.07    |
| Good                    | 30.26    | 26.52    | 28.29    | 29.14    | 28.43    |
| Fair                    | 12.33    | 15.12    | 18.65    | 17.60    | 16.16    |
| Poor                    | 3.69     | 6.02     | 11.11    | 6.40     | 7.05     |
| Systolic blood pressure | 131.3836 | 130.4863 | 131.1626 | 130.5936 | 130.8817 |

This style removes the labels for the type of statistic being reported, cleans up the reporting of factor variables in the row headers, and right-aligns the content in the row headers. In addition, we may want to specify that the means be reported to two decimal places using the `nformat(%6.2f mean)` option.

```
. table (var) (region),
> statistic(fvpercent diabetes)
> statistic(mean age bmi)
> statistic(fvpercent hlthstat)
> statistic(mean bpsystol) style(table-1) nformat(%6.2f mean)
```

|                         | NE     | MW     | Region<br>S | W      | Total  |
|-------------------------|--------|--------|-------------|--------|--------|
| Diabetes status         |        |        |             |        |        |
| Not diabetic            | 95.32  | 95.49  | 94.36       | 95.62  | 95.18  |
| Diabetic                | 4.68   | 4.51   | 5.64        | 4.38   | 4.82   |
| Age (years)             | 47.82  | 46.53  | 48.19       | 47.84  | 47.58  |
| Body mass index (BMI)   | 25.58  | 25.52  | 25.63       | 25.42  | 25.54  |
| Health status           |        |        |             |        |        |
| Excellent               | 26.95  | 26.33  | 19.14       | 21.68  | 23.29  |
| Very good               | 26.76  | 26.01  | 22.82       | 25.18  | 25.07  |
| Good                    | 30.26  | 26.52  | 28.29       | 29.14  | 28.43  |
| Fair                    | 12.33  | 15.12  | 18.65       | 17.60  | 16.16  |
| Poor                    | 3.69   | 6.02   | 11.11       | 6.40   | 7.05   |
| Systolic blood pressure | 131.38 | 130.49 | 131.16      | 130.59 | 130.88 |

Let's go one step further. Perhaps we want the mean and standard deviation of each continuous variable, and we want the frequency and percent for each factor variable. We need to specify a few more `statistic()` options.

```
. table (var) (region),
> stat(fvfreq diabetes) statistic(fvpercent diabetes)
> statistic(mean age bmi) statistic(sd age bmi)
> statistic(fvfreq hlthstat) statistic(fvpercent hlthstat)
> statistic(mean bpsystol) statistic(sd bpsystol)
> style(table-1) nformat(%6.2f mean sd)
```

|                         | Region |        |        |        | Total  |
|-------------------------|--------|--------|--------|--------|--------|
|                         | NE     | MW     | S      | W      |        |
| Diabetes status         |        |        |        |        |        |
| Not diabetic            | 1,997  | 2,648  | 2,692  | 2,513  | 9,850  |
|                         | 95.32  | 95.49  | 94.36  | 95.62  | 95.18  |
| Diabetic                | 98     | 125    | 161    | 115    | 499    |
|                         | 4.68   | 4.51   | 5.64   | 4.38   | 4.82   |
| Age (years)             | 47.82  | 46.53  | 48.19  | 47.84  | 47.58  |
|                         | 17.02  | 17.38  | 16.86  | 17.53  | 17.21  |
| Body mass index (BMI)   | 25.58  | 25.52  | 25.63  | 25.42  | 25.54  |
|                         | 4.73   | 4.91   | 5.08   | 4.88   | 4.91   |
| Health status           |        |        |        |        |        |
| Excellent               | 562    | 730    | 546    | 569    | 2,407  |
|                         | 26.95  | 26.33  | 19.14  | 21.68  | 23.29  |
| Very good               | 558    | 721    | 651    | 661    | 2,591  |
|                         | 26.76  | 26.01  | 22.82  | 25.18  | 25.07  |
| Good                    | 631    | 735    | 807    | 765    | 2,938  |
|                         | 30.26  | 26.52  | 28.29  | 29.14  | 28.43  |
| Fair                    | 257    | 419    | 532    | 462    | 1,670  |
|                         | 12.33  | 15.12  | 18.65  | 17.60  | 16.16  |
| Poor                    | 77     | 167    | 317    | 168    | 729    |
|                         | 3.69   | 6.02   | 11.11  | 6.40   | 7.05   |
| Systolic blood pressure | 131.38 | 130.49 | 131.16 | 130.59 | 130.88 |
|                         | 24.31  | 22.50  | 24.21  | 22.42  | 23.33  |

Finally, to distinguish among our statistics, we can use the `sformat()` option to add parentheses around our standard deviations and percent signs to our percentages.

```
. table (var) (region),
> stat(fvfreq diabetes) statistic(fvpercent diabetes)
> statistic(mean age bmi) statistic(sd age bmi)
> statistic(fvfreq hlthstat) statistic(fvpercent hlthstat)
> statistic(mean bpsystol) statistic(sd bpsystol)
> style(table-1) nformat(%6.2f mean sd)
> sformat("(%s)" sd) sformat("%s%" fvpercent)
```

|                         | Region            |                   |                   |                   |                   |
|-------------------------|-------------------|-------------------|-------------------|-------------------|-------------------|
|                         | NE                | MW                | S                 | W                 | Total             |
| Diabetes status         |                   |                   |                   |                   |                   |
| Not diabetic            | 1,997<br>95.32%   | 2,648<br>95.49%   | 2,692<br>94.36%   | 2,513<br>95.62%   | 9,850<br>95.18%   |

We have added many customizations to our table. However, you may prefer a different look. For another style, you can select from the predefined styles described in [\[TABLES\] Predefined styles](#). If none of these provide the exact style you want for your table, you can further customize the results by using the collect suite of commands. To learn more, see [\[TABLES\] Intro](#).

If you wish to include this table in a paper, on a webpage, or in another format, you can easily export it in  $\LaTeX$ , Word, Excel, HTML, and a variety of other formats by using the `export()` option.

## Stored results

`table` stores the following in `r()`:

Scalars

`r(N)` number of observations

## Description

In this entry, we discuss how to use `table` to create tables with results of hypothesis tests.

## Quick start

Table with pairwise correlations stored in matrix `r(C)`

```
table (rowname) (colname), command(r(C): pwcorr v1 v2 v3)
```

Table with all the numeric scalars returned by `ttest`; rows correspond to the different results

```
table (result) (command), command(ttest v1, by(catvar))
```

Table with means and two-sided  $p$ -values; columns correspond to the different results

```
table (command) (result), ///
command(r(mu_1) r(mu_2) r(p): ttest v1, by(catvar))
```

Same as above, but with statistics for `v1` and `v2`

```
table (command) (result), ///
command(r(mu_1) r(mu_2) r(p): ttest v1, by(catvar)) ///
command(r(mu_1) r(mu_2) r(p): ttest v2, by(catvar))
```

## Menu

Statistics > Summaries, tables, and tests > Tables of frequencies, summaries, and command results

## Syntax

```
table ([rowspec]) ([colspec]) ([tabspec] [if] [in] [weight]),
 command(cmdsspec) [command(cmdsspec) ...] [options]
```

*rowspec*, *colspec*, and *tabspec* may be empty or may include variable names or any of the following keywords:

| <i>keyword</i>       | Description                             |
|----------------------|-----------------------------------------|
| <code>result</code>  | requested statistics                    |
| <code>stars</code>   | stars denoting statistical significance |
| <code>command</code> | index option <code>command()</code>     |
| <code>colname</code> | column names for matrix statistics      |
| <code>rowname</code> | row names for matrix statistics         |

| <i>options</i>                                                         | Description                                          |
|------------------------------------------------------------------------|------------------------------------------------------|
| <b>Commands</b>                                                        |                                                      |
| <code>command(<i>cmds</i>spec)</code>                                  | collect results from the specified Stata command     |
| <b>Formats</b>                                                         |                                                      |
| <code>nformat(<i>%fmt</i> [<i>results</i>][, <i>basestyle</i>])</code> | specify numeric format                               |
| <code>sformat(<i>sfmt</i> [<i>results</i>])</code>                     | specify string format                                |
| <b>Stars</b>                                                           |                                                      |
| <code>stars(<i>stars</i>spec)</code>                                   | add stars to denote statistical significance         |
| <b>Title</b>                                                           |                                                      |
| <code>title(<i>string</i>)</code>                                      | add table title                                      |
| <code>titlestyles(<i>text_styles</i>)</code>                           | change table title styles                            |
| <b>Notes</b>                                                           |                                                      |
| <code>note(<i>string</i>)</code>                                       | add table note                                       |
| <code>notestyles(<i>text_styles</i>)</code>                            | change table note styles                             |
| <b>Export</b>                                                          |                                                      |
| <code>export(<i>filename.suffix</i>[, <i>export_opts</i>])</code>      | export table                                         |
| <b>Options</b>                                                         |                                                      |
| <code>missing</code>                                                   | treat numeric missing values like other values       |
| <code>name(<i>cname</i>)</code>                                        | collect results into a collection named <i>cname</i> |
| <code>append</code>                                                    | append results to an existing collection             |
| <code>replace</code>                                                   | replace results of an existing collection            |
| <code>label(<i>filename</i>)</code>                                    | specify the collection labels                        |
| <code>style(<i>filename</i> [, <i>override</i>])</code>                | specify the collection style                         |
| <code>noisily</code>                                                   | display output from each command                     |

*fweights*, *awweights*, *iweights*, and *pweights* are allowed; see [\[U\] 11.1.6 weight](#).

`strL` variables are not allowed; see [\[U\] 12.4.8 strL](#).

`noisily` does not appear in the dialog box.

| <i>text_styles</i>                           | Description                                              |
|----------------------------------------------|----------------------------------------------------------|
| <code>font([fontfamily][, font_opts])</code> | specify font style                                       |
| <code>smcl(smcl)</code>                      | specify formatting for SMCL files                        |
| <code>latex(latex)</code>                    | specify L <sup>A</sup> T <sub>E</sub> X macro            |
| <code>shading(sspec)</code>                  | set background color, foreground color, and fill pattern |

| <i>font_opts</i>              | Description                              |
|-------------------------------|------------------------------------------|
| <code>size(# [unit])</code>   | specify font size                        |
| <code>color(color)</code>     | specify font color                       |
| <code>variant(variant)</code> | specify font variant and capitalization  |
| <code>[no]bold</code>         | specify whether to format text as bold   |
| <code>[no]italic</code>       | specify whether to format text as italic |
| <code>[no]strikeout</code>    | specify whether to strike out text       |
| <code>[no]underline</code>    | specify whether to underline text        |

| <i>suffix</i>         | <i>fileformat</i>         | Output format                      |
|-----------------------|---------------------------|------------------------------------|
| <code>docx</code>     | <code>as(docx)</code>     | Microsoft Word                     |
| <code>html</code>     | <code>as(html)</code>     | HTML 5 with CSS                    |
| <code>pdf</code>      | <code>as(pdf)</code>      | PDF                                |
| <code>xlsx</code>     | <code>as(xlsx)</code>     | Microsoft Excel 2007/2010 or newer |
| <code>xls</code>      | <code>as(xls)</code>      | Microsoft Excel 1997/2003          |
| <code>tex</code>      | <code>as(tex)</code>      | L <sup>A</sup> T <sub>E</sub> X    |
| <code>smcl</code>     | <code>as(smcl)</code>     | SMCL                               |

| <i>txt_option</i>           | available when exporting to .txt files              |
| <i>md_option</i>            | available when exporting to .markdown and .md files |

| <i>docx_options</i>                      | Description                                                         |
|------------------------------------------|---------------------------------------------------------------------|
| <code>noisily</code>                     | show the putdocx commands used to export to the Microsoft Word file |
| <code>dofile(filename[, replace])</code> | save the putdocx commands used for exporting to the named do-file   |

| <i>html_options</i>       | Description                                                    |
|---------------------------|----------------------------------------------------------------|
| append                    | append to an existing file                                     |
| tableonly                 | export only the table to the specified file                    |
| cssfile( <i>cssfile</i> ) | define the styles in <i>cssfile</i> instead of <i>filename</i> |
| prefix( <i>prefix</i> )   | use <i>prefix</i> to identify style classes                    |

| <i>pdf_options</i>                   | Description                                                      |
|--------------------------------------|------------------------------------------------------------------|
| noisily                              | show the putpdf commands used to export to the PDF file          |
| dofile( <i>filename</i> [, replace]) | save the putpdf commands used for exporting to the named do-file |

| <i>excel_options</i>                 | Description                                                                                             |
|--------------------------------------|---------------------------------------------------------------------------------------------------------|
| noisily                              | show the putexcel commands used to export to the Excel file                                             |
| dofile( <i>filename</i> [, replace]) | save the putexcel commands used for exporting to the named do-file                                      |
| sheet( <i>sheetname</i> [, replace]) | specify the worksheet to use; the default sheet name is Sheet1                                          |
| cell( <i>cell</i> )                  | specify the Excel upper-left cell as the starting position to export the table; the default is cell(A1) |
| modify                               | modify Excel file                                                                                       |
| noopen                               | do not open Excel file in memory                                                                        |

noopen does not appear in the dialog box.

| <i>tex_options</i> | Description                                 |
|--------------------|---------------------------------------------|
| append             | append to an existing file                  |
| tableonly          | export only the table to the specified file |

| <i>smcl_option</i> | Description                |
|--------------------|----------------------------|
| append             | append to an existing file |

| <i>txt_option</i> | Description                |
|-------------------|----------------------------|
| append            | append to an existing file |

| <i>md_option</i> | Description                |
|------------------|----------------------------|
| append           | append to an existing file |

*fontfamily* specifies a valid font family.

*unit* may be in (inch), pt (point), or cm (centimeter). An inch is equivalent to 72 points and 2.54 centimeters. The default is pt.

*variant* may be allcaps, smallcaps, or normal.

*variant* (allcaps) changes the text to all uppercase letters; applicable when publishing items from a collection to Microsoft Word, PDF, L<sup>A</sup>T<sub>E</sub>X, and HTML files.

*variant* (smallcaps) changes the text to use large capitals for uppercase letters and smaller capitals for lowercase letters; applicable when publishing items from a collection to Microsoft Word, L<sup>A</sup>T<sub>E</sub>X, and HTML files.

*variant* (normal) changes the font variant back to normal and leaves the capitalization unchanged from the original text; applicable when publishing items from a collection to Microsoft Word, PDF, L<sup>A</sup>T<sub>E</sub>X, and HTML files.

*smcl* specifies the name of the SMCL directive to render text for SMCL output. The supported SMCL directives are `input`, `error`, `result`, and `text`.

*latex* specifies the name of a L<sup>A</sup>T<sub>E</sub>X macro to render text for L<sup>A</sup>T<sub>E</sub>X output. Example L<sup>A</sup>T<sub>E</sub>X macro names are `textbf`, `textsf`, `textrm`, and `texttt`. Custom L<sup>A</sup>T<sub>E</sub>X macros are also allowed. If *text* is to be rendered in a cell, title, or note, then *latex* is translated to the following when you export to L<sup>A</sup>T<sub>E</sub>X:

```
\latex {text}
```

*sspec* is

```
[background(bgcolor) foreground(fgcolor) pattern(fpattern)]
```

*bgcolor* specifies the background color.

*fgcolor* specifies the foreground color.

*fpattern* specifies the fill pattern. A complete list of fill patterns is shown in the [Appendix](#).

*bgcolor*, *fgcolor*, and *color* may be one of the colors listed in the [Appendix](#); a valid RGB value in the form `### ## #`, for example, `171 248 103`; or a valid RRGGBB hex value in the form `#####`, for example, `ABF867`.

## Options

## Commands

`command(cmdsspec)` specifies the Stata commands from which to collect results. `command()` may be repeated to collect results from multiple commands.

*cmds*spec is [*explist*: ] *command* [*arguments*] [ , *cmdoptions* ]

*explist* specifies which results to collect and report in the table. *explist* may include *result identifiers* and *named expressions*.

*result identifiers* are results stored in `r()` and `e()` by the *command*. For instance, *result identifiers* could be `r(mean)`, `r(C)`, or `e(chi2)`. After estimation commands, *result identifiers* also include the following:

| Identifier            | Result                                                              |
|-----------------------|---------------------------------------------------------------------|
| <code>_r_b</code>     | coefficients or transformed coefficients reported by <i>command</i> |
| <code>_r_se</code>    | standard errors of <code>_r_b</code>                                |
| <code>_r_z</code>     | test statistics for <code>_r_b</code>                               |
| <code>_r_z_abs</code> | absolute value of <code>_r_z</code>                                 |
| <code>_r_p</code>     | <i>p</i> -values for <code>_r_b</code>                              |
| <code>_r_lb</code>    | lower bounds of confidence intervals for <code>_r_b</code>          |
| <code>_r_ub</code>    | upper bounds of confidence intervals for <code>_r_b</code>          |
| <code>_r_ci</code>    | confidence intervals for <code>_r_b</code>                          |
| <code>_r_crlb</code>  | lower bounds of credible intervals for <code>_r_b</code>            |
| <code>_r_crub</code>  | upper bounds of credible intervals for <code>_r_b</code>            |
| <code>_r_cri</code>   | credible intervals for <code>_r_b</code>                            |
| <code>_r_df</code>    | degrees of freedom for <code>_r_b</code>                            |

*named expressions* are specified as *name* = *exp*, where *name* may be any valid Stata name and *exp* is an expression, typically an expression that involves one or more *result identifiers*. An example of a named expression is `sd = sqrt(r(variance))`.

For r-class commands, the default is to include all numeric scalars posted to `r()` in the table results. For e-class commands, the default is to include `_r_b` in the table results.

*command* is any command that follows standard Stata syntax.

*arguments* may be anything so long as they do not include an *if* clause, *in* range, or weight specification.

Any *if* or *in* qualifier and weights should be specified directly with `table`, not within the `command()` option. Weights are passed to *command* only if they are specified.

*cmdoptions* may be anything supported by *command*.

## Formats

`nformat(%fmt [results][ , basestyle ])` changes the numeric format, such as the number of decimal places, for specified results. If *results* are not specified, the numeric format is changed for all results.

*results* may be any name in the `e()` or `r()` results produced by commands specified in option `command()`.

This option is repeatable, and when multiple formats apply to one result, the rightmost specification is applied.

This option does not affect the format of numeric layout variables (*rowspec*, *colspec*, and *tabspec*). The default format of these variables is taken from the dataset.

*basestyle* indicates that the format be applied to results that do not already have their own format instead of overriding the format for all results.

*sformat*(*sfmt* [*results*]) changes the string format for specified results. You can, for instance, add symbols or text to the values reported in the table by modifying the string format.

*sfmt* may contain a mix of text and %s. Here %s refers to the numeric value that is formatted as specified using *nformat*( ). The text will be placed around the numeric values in your table as it is placed around %s in this option. For instance, to place parentheses around the percent statistics, you can specify *sformat*("(%s)" percent).

*results* may be any name in the *e*( ) or *r*( ) results produced by commands specified in option *command*( ).

Two text characters must be specified using a special character sequence if you want them to be displayed in your table. To include %, type %%. To include \, type \\. For instance, to place a percent sign following percent statistics, you can specify *sformat*("%%%" percent).

This option is repeatable, and when multiple formats apply to one result, the rightmost specification is applied.

#### Stars

*stars*(*starspec*) specifies that stars representing statistical significance be included in the table. *starspec* identifies the result whose values determine significance, which characters should represent each significance level, and where these characters should be displayed in the table. *starspec* is

```
starres [#1 "label1" [#2 "label2" [#3 "label3" [#4 "label4" [#5 "label5"]]]]
[, attach(attachres) result dimension starsnoteopts]
```

*starres* is the name of the result whose values determine which characters, typically which number of stars, are to be displayed.

*label1* specifies the characters to be displayed when *starres* < #1.

*label2* specifies the characters to be displayed when *starres* < #2.

*label3* specifies the characters to be displayed when *starres* < #3.

*label4* specifies the characters to be displayed when *starres* < #4.

*label5* specifies the characters to be displayed when *starres* < #5.

*attach*(*attachres*) specifies the name of the result to which the characters defined by *label1*, ..., *label5* are to be attached. If *attach*( ) is not specified, a new result named *stars* is created and is automatically added to the table.

*result* and *dimension* control how *collect stars* adds items when labeling significant results. These options are mutually exclusive.

*result* specifies the default behavior, and this option is necessary only if the following *dimension* behavior is in effect and you want to change back to the *result* behavior.

*dimension* specifies that *dimension stars* be added to the collection. Items will be tagged with *stars*[*value*], and the labels will be tagged with *stars*[*label*]. Use this option for layouts where results are to be stacked within columns, and use *new dimension stars* in the column specification of the layout.

*starsnoteopts* control the display and composition of the stars note.

`noshownote` and `shownote` control whether to display the stars note.

`increasing` and `decreasing` control the order of  $p$ -values in the stars note.

`pvname(string)` specifies a name for the  $p$ -value in the stars note. The default is `pvname(p)`.

`delimiter(string)` specifies the delimiter between labels in the stars note. The default is `delimiter(",")`.

`nformat(%fmt)` specifies the numeric format for the cutoff values in the stars note. The default is `nformat(%9.0g)`.

`prefix(string)` specifies the prefix for the stars note. The prefix is empty by default.

`suffix(string)` specifies the suffix for the stars note. The suffix is empty by default.

For example, `stars(_r_p 0.01 "***" 0.05 "**" 0.1 "*", attach(_r_b))` could be added to a table of regression results to specify that stars be defined based on the  $p$ -values in `_r_p` and be attached to the reported coefficients (`_r_b`).

Title

`title(string)` adds the text *string* as a title to the table.

`titlestyles(text_styles)` changes the style for the table title. *text\_styles* are the following:

`font([fontfamily] [, size(# [unit]) color(color) variant(variant) [no]bold [no]italic [no]strikeout [no]underline)` specifies the font style. These font style properties are applicable when exporting the table to Microsoft Word, Microsoft Excel, PDF, HTML, and L<sup>A</sup>T<sub>E</sub>X files, unless otherwise specified.

*fontfamily* specifies a valid font family. This font style property is applicable when publishing items from a collection to Microsoft Word, Microsoft Excel, PDF, and HTML files.

*size*(# [*unit*]) specifies the font size as a number optionally followed by units. This font style property is applicable when publishing items from a collection to Microsoft Word, Microsoft Excel, PDF, and HTML files.

*color*(*color*) specifies the text color.

*variant*(*variant*) specifies the font variant and capitalization.

`bold` and `nobold` specify the font weight. `bold` changes the font weight to bold; `nobold` changes the font weight back to normal.

`italic` and `noitalic` specify the font style. `italic` changes the font style to italic; `noitalic` changes the font style back to normal.

`strikeout` and `nostrikeout` specify whether to add a strikeout mark to the title. `strikeout` adds a strikeout mark to the title; `nostrikeout` changes the title back to normal.

`underline` and `nounderline` specify whether to underline the table title. `underline` adds a single line under the title; `nounderline` removes the underline.

Only one of `strikeout` or `underline` is allowed when publishing to HTML files.

`smcl(smcl)` specifies how to render the table title for SMCL output. This style property is applicable only when publishing items from a collection to a SMCL file.

`latex(latex)` specifies how to render the table title for L<sup>A</sup>T<sub>E</sub>X output. This style property is applicable only when publishing items from a collection to a L<sup>A</sup>T<sub>E</sub>X file.

`shading(sspec)` sets the background color, foreground color, and fill pattern. The background color is applicable when exporting the table to Microsoft Word, Microsoft Excel, PDF, HTML, and L<sup>A</sup>T<sub>E</sub>X files. The foreground color and fill pattern are applicable when exporting the table to Microsoft Word and Microsoft Excel.

`note(string)` adds the text *string* as a note to the table. `note()` may be specified multiple times to add multiple notes. Each note is placed on a new line.

`notestyles(text_styles)` changes the style for the table notes. *text\_styles* are the following:

`font([fontfamily] [, size(# [unit]) color(color) variant(variant) [no]bold [no]italic [no]strikeout [no]underline])` specifies the font style. These font style properties are applicable when exporting the table to Microsoft Word, Microsoft Excel, PDF, HTML, and  $\LaTeX$  files, unless otherwise specified.

*fontfamily* specifies a valid font family. This font style property is applicable when publishing items from a collection to Microsoft Word, Microsoft Excel, PDF, and HTML files.

`size(# [unit])` specifies the font size as a number optionally followed by units. This font style property is applicable when publishing items from a collection to Microsoft Word, Microsoft Excel, PDF, and HTML files.

`color(color)` specifies the text color.

`variant(variant)` specifies the font variant and capitalization.

`bold` and `nobold` specify the font weight. `bold` changes the font weight to bold; `nobold` changes the font weight back to normal.

`italic` and `noitalic` specify the font style. `italic` changes the font style to italic; `noitalic` changes the font style back to normal.

`strikeout` and `nostrikeout` specify whether to add a strikeout mark to the notes. `strikeout` adds a strikeout mark to the note; `nostrikeout` changes the note back to normal.

`underline` and `nounderline` specify whether to underline the table notes. `underline` adds a single line under the notes; `nounderline` removes the underline.

Only one of `strikeout` or `underline` is allowed when publishing to HTML files.

`smcl(smcl)` specifies how to render the table notes for SMCL output. This style property is applicable only when publishing items from a collection to a SMCL file.

`latex(latex)` specifies how to render the table notes for  $\LaTeX$  output. This style property is applicable only when publishing items from a collection to a  $\LaTeX$  file.

`shading(sspec)` sets the background color, foreground color, and fill pattern. The background color is applicable when exporting the table to Microsoft Word, Microsoft Excel, PDF, HTML, and  $\LaTeX$  files. The foreground color and fill pattern are applicable when exporting the table to Microsoft Word and Microsoft Excel.

Export

`export(filename.suffix[, export_opts])` exports the table to the specified file. *export\_opts* are the following:

`as(fileformat)` specifies the file format to which the table is to be exported. This option is rarely specified because, by default, `table` determines the format from the suffix of the file being created.

`replace` permits `table` to overwrite an existing file.

`noisily` specifies that `table` show the commands used to export the table to Microsoft Word, Microsoft Excel, and PDF files. The `putdocx`, `putexcel`, or `putpdf` command used to export the table will be displayed.

`dofile(filename[, replace])` specifies that `table` save to *filename* the commands used to export the table to Microsoft Word, Microsoft Excel, and PDF files.

If *filename* already exists, it can be overwritten by specifying `replace`. If *filename* is specified without an extension, `.do` is assumed.

`append` specifies that `table` append the table to an existing file.

This option is applicable when you export the table to an HTML, a  $\LaTeX$ , a SMCL, a `txt`, or a Markdown file. When you export to HTML and  $\LaTeX$  files, the `append` option implies the `tableonly` option. Furthermore, when you export to HTML files, if the target CSS file already exists, `table` will also append to it.

`tableonly` specifies that only the table be exported to the specified HTML or  $\LaTeX$  document. By default, `table` produces complete HTML and  $\LaTeX$  documents.

When you export to an HTML file, if the `cssfile()` option is not specified, a CSS filename is constructed from *filename*, with the extension replaced with `.css`.

`cssfile(cssfile)` specifies that `table` define the styles in *cssfile* instead of *filename* when you export to HTML.

`prefix(prefix)` specifies that `table` use *prefix* to identify style classes when you export to HTML.

`sheet(sheetname [, replace])` saves to the worksheet named *sheetname*. For more information about this option, see [\[RPT\] putexcel](#).

`cell(cell)` specifies an Excel upper-left cell as the starting position to publish the table. The default is `cell(A1)`.

`modify` permits `putexcel` set to modify an Excel file. For more information about this option, see [\[RPT\] putexcel](#).

`noopen` prevents `putexcel` from opening the Excel file in memory for modification. It does not appear in the dialog box. For more information about this option, see [\[RPT\] putexcel](#).

## Options

`missing` specifies that numeric missing values of any variables specified in `rowspec`, `colspec`, or `tabspec` be treated as valid categories. By default, observations with a numeric missing value in any of these variables are omitted.

`name(cname)` specifies that a collection named `cname` be associated with the collected statistics and results. The default is `name(Table)`.

`append` specifies that `table` append its collection information into the collection named in `name()`.

`replace` permits `table` to overwrite an existing collection. This option is implied for `name(Table)` when `append` is not specified.

`label(filename)` specifies the `filename` containing the collection labels to use for your table. Labels in `filename` will be loaded for the table, and any labels not specified in `filename` will be taken from the labels defined in `c(collect_label)`. The default is to use only the collection labels set in `c(collect_label)`; see [TABLES] [set collect\\_label](#).

`style(filename [, override])` specifies the `filename` containing the collection styles to use for your table. The default collection styles will be discarded, and only the collection styles in `filename` will be applied.

If you prefer the default collection styles but also want to apply any styles in `filename`, specify `override`. If there are conflicts between the default collection styles and those in `filename`, the ones in `filename` will take precedence.

The default is to use only the collection styles set in `c(table_style)`; see [TABLES] [set table\\_style](#).

The following option is available with `table` but is not shown in the dialog box:

`noisily` specifies that output from the commands specified in `command()` options be displayed. By default, output from commands is suppressed.

## Remarks and examples

Remarks are presented under the following headings:

*Introduction*  
*Creating tables from scalars*  
*Creating tables from matrices*

### Introduction

The `table` command can be used to create tables with results of hypothesis tests. For example, you can create a table with results from a mean-comparison test, a test of proportions, or a test of normality.

`table` does not perform hypothesis tests directly. Rather, `table` will run any Stata command that you include in its `command()` option and place results from that command into the table. You determine which results you would like to see in the table. You can select any of the results stored by the command.

### Creating tables from scalars

We have data from the Second National Health and Nutrition Examination Survey (NHANES II) (McDowell et al. 1981). The data contain some demographic information, such as the age, sex, and race of participants. The data also contain some measures of health, including whether the individual has high blood pressure (`highbp`), has diabetes, or has had a heart attack previously (`heartatk`).

Suppose we want to examine the proportion of males and females that have high blood pressure, that have diabetes, and that have had a heart attack previously. With `prtest`, we can test whether the proportions are equal between males and females. For example, let's perform a test of proportions for diabetes:

```
. use https://www.stata-press.com/data/r19/nhanes21
(Second National Health and Nutrition Examination Survey)
. prtest diabetes, by(sex)
```

Two-sample test of proportions

| Group  | Mean      | Std. err. | z     | P> z  | [95% conf. interval] |
|--------|-----------|-----------|-------|-------|----------------------|
| Male   | .0441506  | .0029302  |       |       | .0384074 .0498937    |
| Female | .0518955  | .0030091  |       |       | .0459978 .0577932    |
| diff   | -.0077449 | .0042001  |       |       | -.0159769 .0004871   |
|        | under H0: | .0042169  | -1.84 | 0.066 |                      |

Male: Number of obs = 4915  
Female: Number of obs = 5434

```
diff = prop(Male) - prop(Female) z = -1.8366
H0: diff = 0
Ha: diff < 0 Ha: diff != 0 Ha: diff > 0
Pr(Z < z) = 0.0331 Pr(|Z| > |z|) = 0.0663 Pr(Z > z) = 0.9669
```

We would like to create a table that includes the proportion of men who have diabetes, the proportion of women who have diabetes, the difference in these proportions, and the  $p$ -value for a two-sided test. First, we need to determine how to refer to these statistics.

```

. return list
scalars:
 r(N1) = 4915
 r(N2) = 5434
 r(P1) = .0441505595116989
 r(P2) = .0518954729481045
 r(P_diff) = -.0077449134364056
 r(se1) = .0029302258134317
 r(se2) = .003009075122777
 r(se_diff0) = .0042169418903878
 r(se_diff) = .0042000900481081
 r(lb1) = .0384074224508032
 r(ub1) = .0498936965725946
 r(lb2) = .0459977940806861
 r(ub2) = .0577931518155229
 r(lb_diff) = -.0159769386625226
 r(ub_diff) = .0004871117897114
 r(z) = -1.836618487454034
 r(p_l) = .0331331180748532
 r(p) = .0662662361497065
 r(p_u) = .9668668819251468
 r(level) = 95

```

The statistics we want to see are stored as `r(P1)`, `r(P2)`, `r(P_diff)`, and `r(p)`. We can specify this in the `command()` option by typing

```
. table ..., command(r(P1) r(P2) r(P_diff) r(p): prtest diabetes, by(sex))
```

This will get the results we want into our table. Furthermore, because we know what these values represent, we can give them names that will appear in the table headers. We can, for instance, type

```
. table ..., command(Males=r(P1) Females=r(P2) Difference=r(P_diff) ///
 r(p): prtest diabetes, by(sex))
```

We can specify similar `command()` options for `heartatk` and `highbp` as well.

In addition, we need to specify how our results will be laid out in the table. Below, we type `command` in the first set of parentheses so that the rows correspond to the different commands. We type `result` in the second set of parentheses to specify that statistics appear in the columns.

Finally, we add two options to customize the results. We specify a numeric format so that the statistics be displayed only with three digits after the decimal. We also choose the predefined style `table-right` so that our row headers will be right-aligned. See [\[TABLES\] Predefined styles](#) for information on this and other styles.

```

. table (command) (result),
> command(Males=r(P1) Females=r(P2) Difference=r(P_diff) r(p):
> prtest diabetes, by(sex))
> command(Males=r(P1) Females=r(P2) Difference=r(P_diff) r(p):
> prtest heartatk, by(sex))
> command(Males=r(P1) Females=r(P2) Difference=r(P_diff) r(p):
> prtest highbp, by(sex))
> nformat(%5.3f) style(table-right)

```

|                          | Males | Females | Difference | Two-sided p-value |
|--------------------------|-------|---------|------------|-------------------|
| prtest diabetes, by(sex) | 0.044 | 0.052   | -0.008     | 0.066             |
| prtest heartatk, by(sex) | 0.065 | 0.029   | 0.036      | 0.000             |
| prtest highbp, by(sex)   | 0.469 | 0.381   | 0.088      | 0.000             |

Our table now includes all the statistics we want. If we are happy with it, we can export it to another format, such as HTML, Word, L<sup>A</sup>T<sub>E</sub>X, PDF, and Excel using the `export()` option. But first we want to make some modifications. Table customization can go beyond the predefined styles and options available to you in the `table` command. `table` creates a collection of results that can be used in combination with the `collect` suite of commands to produce highly customized tables and to export those tables to presentation-ready formats, such as HTML, Word, L<sup>A</sup>T<sub>E</sub>X, PDF, Excel, and more.

For this table, we want to modify the labels in our row headers. Instead of showing the full command that was run, row headers will identify the variable we are testing. In addition, we will modify the label for our *p*-value. We want to use the label `p-value`. Because this is not a valid Stata name, we could not specify it in the `table` command as we did with `Males`. However, we can use `collect label levels` to modify the label on our *p*-values.

After applying the label updates, we use `collect preview` to see our updated table.

```
. collect label levels command 1 "Diabetes" 2 "Heart attack" 3 "High BP", modify
. collect label levels result p "p-value", modify
. collect preview
```

|              | Males | Females | Difference | p-value |
|--------------|-------|---------|------------|---------|
| Diabetes     | 0.044 | 0.052   | -0.008     | 0.066   |
| Heart attack | 0.065 | 0.029   | 0.036      | 0.000   |
| High BP      | 0.469 | 0.381   | 0.088      | 0.000   |

## Creating tables from matrices

You may find that the results you want to include in your table are stored in a matrix; these results can also be easily included in a table.

To demonstrate, we create a table with *p*-values for tests of normality for `height`, `weight`, and diastolic blood pressure (`bpdiast`). The command `sktest` performs tests based on skewness, kurtosis, and a combined test statistic.

```
. sktest height weight bpdiast
Skewness and kurtosis tests for normality
```

| Variable | Obs    | Pr(skewness) | Pr(kurtosis) | Joint test  |           |
|----------|--------|--------------|--------------|-------------|-----------|
|          |        |              |              | Adj chi2(2) | Prob>chi2 |
| height   | 10,351 | 0.0000       | 0.0000       | 147.47      | 0.0000    |
| weight   | 10,351 | 0.0000       | 0.0000       | 801.40      | 0.0000    |
| bpdiast  | 10,351 | 0.0000       | 0.0000       | 362.54      | 0.0000    |

Let's look at the returned results.

```
. return list
scalars:
 r(N) = 10351
 r(p_skew) = 1.58706287446e-72
 r(p_kurt) = 6.22330331716e-26
 r(chi2) = 362.5385838320567
 r(p_chi2) = 1.88689086684e-79

matrices:
 r(table) : 3 x 5
```

The statistics we want plus a few others are stored in `r(table)`.

Now, let's place these values in a table. We specify that our table be arranged with the row names (`rowname`) of the matrix defining the rows of the table. Similarly, the column names (`colname`) of the matrix define the columns of the table. Then, we specify that we want to collect the results from the matrix `r(table)` from the `sktest` command.

```
. table (rowname) (colname),
> command(r(table): sktest height weight bpdiastr)
```

|                          | N     | p_skew   | p_kurt   | chi2     | p_chi2   |
|--------------------------|-------|----------|----------|----------|----------|
| Height (cm)              | 10351 | .0000179 | 1.87e-35 | 147.4712 | 9.48e-33 |
| Weight (kg)              | 10351 | 1.6e-166 | 1.63e-49 | 801.3958 | 9.5e-175 |
| Diastolic blood pressure | 10351 | 1.59e-72 | 6.22e-26 | 362.5386 | 1.89e-79 |

Because the row names in `r(table)` corresponded to variables, our table automatically put the variable labels in the row headers. However, the column headers are not nicely labeled.

We can create better labels and modify our table in many other ways. `table` creates a collection of results that can be used in combination with the `collect` suite of commands to further customize tables.

To clean up our table, let's use `collect label levels` to modify the labels for the  $p$ -values for the skewness, kurtosis, and joint tests; these are the statistics we will include in our table below. To use `collect label levels`, we need to know just a little about the `collect` system. In collections, values are organized according to dimensions and levels within those dimensions. In fact, we use these dimensions in `table`. The keywords that we can use to define our rows and columns are dimensions. Here `colname` is our dimension that defines the columns, and its levels are `N`, `p_skew`, `...`. To modify labels, we need to tell `collect label levels` which dimension (`colname`) we would like to change and then specify labels for levels of that dimension.

We specify the dimension and then the label for each level:

```
. collect label levels colname p_skew "Skewness p-value"
> p_kurt "Kurtosis p-value" p_chi2 "Joint p-value", modify
```

To learn more about modifying labels, see [\[TABLES\] collect label](#).

Let's also change the numeric format of our  $p$ -values. With `collect style cell`, we can modify all cells in the table, all cells in a particular dimension, or particular cells of a particular dimension. Below, we specify the numeric formatting for only three levels of `colname`.

```
. collect style cell colname[p_skew p_kurt p_chi2], nformat(%7.3f)
```

Finally, we want to show only the three  $p$ -values in our table. We can use `collect layout` to specify the statistics we want to include in our final table.

```
. collect layout (rowname) (colname[p_skew p_kurt p_chi2])
Collection: Table
 Rows: rowname
 Columns: colname[p_skew p_kurt p_chi2]
Table 1: 3 x 3
```

|                          | Skewness p-value | Kurtosis p-value | Joint p-value |
|--------------------------|------------------|------------------|---------------|
| Height (cm)              | 0.000            | 0.000            | 0.000         |
| Weight (kg)              | 0.000            | 0.000            | 0.000         |
| Diastolic blood pressure | 0.000            | 0.000            | 0.000         |

Notably, all  $p$ -values for all tests are very small, so this is not a particularly exciting table. However, our table customizations made it easy to quickly see the results of tests of normality for all our variables.

## Stored results

`table` stores the following in `r()`:

```
Scalars
 r(N) number of observations
```

## Description

In this entry, we discuss how to create tables of regression results. These tables can include coefficients, standard errors, confidence intervals, and many more results stored by estimation commands.

## Quick start

Table of regression coefficients; rows correspond to covariates (`colname`)

```
table colname, command(regress y x1 x2 x3)
```

Table of coefficients and confidence intervals; columns correspond to the statistics (`result`)

```
table (colname) (result), command(_r_b _r_ci: regress y x1 x2 x3)
```

Same as above, but use the labels defined in `mylabels.stjson` and the styles in `mystyle.stjson`

```
table (colname) (result), ///
 command(_r_b _r_ci: regress y x1 x2 x3) ///
 label(mylabels) style(mystyle)
```

## Menu

Statistics > Summaries, tables, and tests > Tables of frequencies, summaries, and command results

## Syntax

```
table ([rowspec]) ([colspec]) ([tabspec]) [if] [in] [weight],
 command(cmdsspec) [command(cmdsspec) ...] [options]
```

*rowspec*, *colspec*, and *tabspec* may be empty or may include variable names or any of the following keywords:

| <i>keyword</i> | Description                                 |
|----------------|---------------------------------------------|
| result         | requested statistics                        |
| stars          | stars denoting statistical significance     |
| command        | index option command()                      |
| colname        | column names for matrix statistics          |
| rowname        | row names for matrix statistics             |
| coleq          | column equation names for matrix statistics |
| roweq          | row equation names for matrix statistics    |

| <i>options</i>                                                | Description                                               |
|---------------------------------------------------------------|-----------------------------------------------------------|
| <b>Commands</b>                                               |                                                           |
| command( <i>cmds</i> spec)                                    | collect results from the specified Stata command          |
| <b>Formats</b>                                                |                                                           |
| nformat( <i>%fmt</i> [ <i>results</i> ][, <i>basestyle</i> ]) | specify numeric format                                    |
| sformat( <i>sfmt</i> [ <i>results</i> ])                      | specify string format                                     |
| cidelimiter( <i>char</i> )                                    | use character as delimiter for confidence interval limits |
| cridelimiter( <i>char</i> )                                   | use character as delimiter for credible interval limits   |
| <b>Stars</b>                                                  |                                                           |
| stars( <i>stars</i> spec)                                     | add stars to denote statistical significance              |
| <b>Title</b>                                                  |                                                           |
| title( <i>string</i> )                                        | add table title                                           |
| titlestyles( <i>text_styles</i> )                             | change table title styles                                 |
| <b>Notes</b>                                                  |                                                           |
| note( <i>string</i> )                                         | add table note                                            |
| notestyles( <i>text_styles</i> )                              | change table note styles                                  |
| <b>Export</b>                                                 |                                                           |
| export( <i>filename.suffix</i> [, <i>export_opts</i> ])       | export table                                              |
| <b>Options</b>                                                |                                                           |
| missing                                                       | treat numeric missing values like other values            |
| name( <i>cname</i> )                                          | collect results into a collection named <i>cname</i>      |
| append                                                        | append results to an existing collection                  |
| replace                                                       | replace results of an existing collection                 |
| label( <i>filename</i> )                                      | specify the collection labels                             |
| style( <i>filename</i> [, <i>override</i> ])                  | specify the collection style                              |
| noisily                                                       | display output from each command                          |

fweights, aweights, iweights, and pweights are allowed; see [U] 11.1.6 **weight**.

strL variables are not allowed; see [U] 12.4.8 **strL**.

noisily does not appear in the dialog box.

| <i>text_styles</i>                                | Description                                              |
|---------------------------------------------------|----------------------------------------------------------|
| font( <i>[fontfamily]</i> [ <i>, font_opts</i> ]) | specify font style                                       |
| smcl( <i>smcl</i> )                               | specify formatting for SMCL files                        |
| latex( <i>latex</i> )                             | specify L <sup>A</sup> T <sub>E</sub> X macro            |
| shading( <i>sspec</i> )                           | set background color, foreground color, and fill pattern |

| <i>font_opts</i>          | Description                              |
|---------------------------|------------------------------------------|
| size( <i># [unit]</i> )   | specify font size                        |
| color( <i>color</i> )     | specify font color                       |
| variant( <i>variant</i> ) | specify font variant and capitalization  |
| [no]bold                  | specify whether to format text as bold   |
| [no]italic                | specify whether to format text as italic |
| [no]strikeout             | specify whether to strike out text       |
| [no]underline             | specify whether to underline text        |

| <i>suffix</i> | <i>fileformat</i> | Output format                      |
|---------------|-------------------|------------------------------------|

|------------------------|---------------------------------------------|
| <code>append</code>    | append to an existing file                  |
| <code>tableonly</code> | export only the table to the specified file |

| <i>smcl_option</i>  | Description                |
|---------------------|----------------------------|
| <code>append</code> | append to an existing file |

| <i>txt_option</i>   | Description                |
|---------------------|----------------------------|
| <code>append</code> | append to an existing file |

| <i>md_option</i>    | Description                |
|---------------------|----------------------------|
| <code>append</code> | append to an existing file |

*fontfamily* specifies a valid font family.

*unit* may be in (inch), pt (point), or cm (centimeter). An inch is equivalent to 72 points and 2.54 centimeters. The default is pt.

*variant* may be allcaps, smallcaps, or normal.

*variant* (allcaps) changes the text to all uppercase letters; applicable when publishing items from a collection to Microsoft Word, PDF, L<sup>A</sup>T<sub>E</sub>X, and HTML files.

*variant* (smallcaps) changes the text to use large capitals for uppercase letters and smaller capitals for lowercase letters; applicable when publishing items from a collection to Microsoft Word, L<sup>A</sup>T<sub>E</sub>X, and HTML files.

*variant* (normal) changes the font variant back to normal and leaves the capitalization unchanged from the original text; applicable when publishing items from a collection to Microsoft Word, PDF, L<sup>A</sup>T<sub>E</sub>X, and HTML files.

*smcl* specifies the name of the SMCL directive to render text for SMCL output. The supported SMCL directives are `input`, `error`, `result`, and `text`.

*latex* specifies the name of a L<sup>A</sup>T<sub>E</sub>X macro to render text for L<sup>A</sup>T<sub>E</sub>X output. Example L<sup>A</sup>T<sub>E</sub>X macro names are `textbf`, `textsf`, `textrm`, and `texttt`. Custom L<sup>A</sup>T<sub>E</sub>X macros are also allowed. If *text* is to be rendered in a cell, title, or note, then *latex* is translated to the following when you export to L<sup>A</sup>T<sub>E</sub>X:

```
\latex {text}
```

*sspec* is

```
[background(bcolor) foreground(fgcolor) pattern(fpattern)]
```

*bcolor* specifies the background color.

*fgcolor* specifies the foreground color.

*fpattern* specifies the fill pattern. A complete list of fill patterns is shown in the [Appendix](#).

*bcolor*, *fgcolor*, and *color* may be one of the colors listed in the [Appendix](#); a valid RGB value in the form `### ## #`, for example, `171 248 103`; or a valid RRGGBB hex value in the form `#####`, for example, `ABF867`.

## Options

### Commands

`command(cmdsspec)` specifies the Stata commands from which to collect results. `command()` may be repeated to collect results from multiple commands.

*cmds*spec is `[explist:] command [arguments] [, cmdoptions]`

*explist* specifies which results to collect and report in the table. *explist* may include *result identifiers* and *named expressions*.

*result identifiers* are results stored in `r()` and `e()` by the *command*. For instance, *result identifiers* could be `r(mean)`, `r(C)`, or `e(chi2)`. After estimation commands, *result identifiers* also include the following:

| Identifier            | Result                                                              |
|-----------------------|---------------------------------------------------------------------|
| <code>_r_b</code>     | coefficients or transformed coefficients reported by <i>command</i> |
| <code>_r_se</code>    | standard errors of <code>_r_b</code>                                |
| <code>_r_z</code>     | test statistics for <code>_r_b</code>                               |
| <code>_r_z_abs</code> | absolute value of <code>_r_z</code>                                 |
| <code>_r_p</code>     | <i>p</i> -values for <code>_r_b</code>                              |
| <code>_r_lb</code>    | lower bounds of confidence intervals for <code>_r_b</code>          |
| <code>_r_ub</code>    | upper bounds of confidence intervals for <code>_r_b</code>          |
| <code>_r_ci</code>    | confidence intervals for <code>_r_b</code>                          |
| <code>_r_crlb</code>  | lower bounds of credible intervals for <code>_r_b</code>            |
| <code>_r_crub</code>  | upper bounds of credible intervals for <code>_r_b</code>            |
| <code>_r_cri</code>   | credible intervals for <code>_r_b</code>                            |
| <code>_r_df</code>    | degrees of freedom for <code>_r_b</code>                            |

*named expressions* are specified as `name = exp`, where *name* may be any valid Stata name and *exp* is an expression, typically an expression that involves one or more *result identifiers*. An example of a named expression is `sd = sqrt(r(variance))`.

For *r*-class commands, the default is to include all numeric scalars posted to `r()` in the table results. For *e*-class commands, the default is to include `_r_b` in the table results.

*command* is any command that follows standard Stata syntax.

*arguments* may be anything so long as they do not include an *if* clause, *in* range, or weight specification.

Any *if* or *in* qualifier and weights should be specified directly with `table`, not within the `command()` option. Weights are passed to *command* only if they are specified.

*cmdoptions* may be anything supported by *command*.

### Formats

`nformat(%fmt [results][, basestyle])` changes the numeric format, such as the number of decimal places, for specified results. If *results* are not specified, the numeric format is changed for all results.

*results* may be any name in the `e()` or `r()` results produced by commands specified in option `command()`.

This option is repeatable, and when multiple formats apply to one result, the rightmost specification is applied.

This option does not affect the format of numeric layout variables (*rowspec*, *colspec*, and *tabspec*). The default format of these variables is taken from the dataset.

*basestyle* indicates that the format be applied to results that do not already have their own format instead of overriding the format for all results.

*sformat*(*sfmt* [*results*]) changes the string format for specified results. You can, for instance, add symbols or text to the values reported in the table by modifying the string format.

*sfmt* may contain a mix of text and %s. Here %s refers to the numeric value that is formatted as specified using *nformat*( ). The text will be placed around the numeric values in your table as it is placed around %s in this option. For instance, to place parentheses around the percent statistics, you can specify *sformat*("(%s)" percent).

*results* may be any name in the *e*( ) or *r*( ) results produced by commands specified in option *command*( ).

Two text characters must be specified using a special character sequence if you want them to be displayed in your table. To include %, type %%. To include \, type \\. For instance, to place a percent sign following percent statistics, you can specify *sformat*("%%%" percent).

This option is repeatable, and when multiple formats apply to one result, the rightmost specification is applied.

*cidelimiter*(*char*) changes the delimiter between confidence interval limits to *char*. The default is *cidelimiter*(" "), that is, two spaces.

*cridelimiter*(*char*) changes the delimiter between credible interval limits to *char*. The default is *cridelimiter*(" "), that is, two spaces.

---

#### Stars

*stars*(*starspec*) specifies that stars representing statistical significance be included in the table. *starspec* identifies the result whose values determine significance, which characters should represent each significance level, and where these characters should be displayed in the table. *starspec* is

```
starres [#1 "label1" [#2 "label2" [#3 "label3" [#4 "label4" [#5 "label5"]]]]]
[, attach(attachres) result dimension starsnoteopts]
```

*starres* is the name of the result whose values determine which characters, typically which number of stars, are to be displayed.

*label1* specifies the characters to be displayed when *starres* < #1.

*label2* specifies the characters to be displayed when *starres* < #2.

*label3* specifies the characters to be displayed when *starres* < #3.

*label4* specifies the characters to be displayed when *starres* < #4.

*label5* specifies the characters to be displayed when *starres* < #5.

*attach*(*attachres*) specifies the name of the result to which the characters defined by *label1*, ..., *label5* are to be attached. If *attach*( ) is not specified, a new result named *stars* is created and is automatically added to the table.

*result* and *dimension* control how *collect stars* adds items when labeling significant results. These options are mutually exclusive.

*result* specifies the default behavior, and this option is necessary only if the following *dimension* behavior is in effect and you want to change back to the *result* behavior.

`dimension` specifies that dimension stars be added to the collection. Items will be tagged with `stars [value]`, and the labels will be tagged with `stars [label]`. Use this option for layouts where results are to be stacked within columns, and use new dimension stars in the column specification of the layout.

`starsnoteopts` control the display and composition of the stars note.

`noshownote` and `shownote` control whether to display the stars note.

`increasing` and `decreasing` control the order of  $p$ -values in the stars note.

`pvname(string)` specifies a name for the  $p$ -value in the stars note. The default is `pvname(p)`.

`delimiter(string)` specifies the delimiter between labels in the stars note. The default is `delimiter(",")`.

`nformat(%fmt)` specifies the numeric format for the cutoff values in the stars note. The default is `nformat(%9.0g)`.

`prefix(string)` specifies the prefix for the stars note. The prefix is empty by default.

`suffix(string)` specifies the suffix for the stars note. The suffix is empty by default.

For example, `stars(_r_p 0.01 "***" 0.05 "*" 0.1 "*", attach(_r_b))` could be added to a table of regression results to specify that stars be defined based on the  $p$ -values in `_r_p` and be attached to the reported coefficients (`_r_b`).

Title

`title(string)` adds the text *string* as a title to the table.

`titlestyles(text_styles)` changes the style for the table title. *text\_styles* are the following:

`font([fontfamily] [, size(# [unit]) color(color) variant(variant) [no]bold [no]italic [no]strikeout [no]underline])` specifies the font style. These font style properties are applicable when exporting the table to Microsoft Word, Microsoft Excel, PDF, HTML, and  $\LaTeX$  files, unless otherwise specified.

*fontfamily* specifies a valid font family. This font style property is applicable when publishing items from a collection to Microsoft Word, Microsoft Excel, PDF, and HTML files.

`size(# [unit])` specifies the font size as a number optionally followed by units. This font style property is applicable when publishing items from a collection to Microsoft Word, Microsoft Excel, PDF, and HTML files.

`color(color)` specifies the text color.

`variant(variant)` specifies the font variant and capitalization.

`bold` and `nobold` specify the font weight. `bold` changes the font weight to bold; `nobold` changes the font weight back to normal.

`italic` and `noitalic` specify the font style. `italic` changes the font style to italic; `noitalic` changes the font style back to normal.

`strikeout` and `nostrikeout` specify whether to add a strikeout mark to the title. `strikeout` adds a strikeout mark to the title; `nostrikeout` changes the title back to normal.

`underline` and `nounderline` specify whether to underline the table title. `underline` adds a single line under the title; `nounderline` removes the underline.

Only one of `strikeout` or `underline` is allowed when publishing to HTML files.

`smcl(smcl)` specifies how to render the table title for SMCL output. This style property is applicable only when publishing items from a collection to a SMCL file.

`latex(latex)` specifies how to render the table title for  $\LaTeX$  output. This style property is applicable only when publishing items from a collection to a  $\LaTeX$  file.

`shading(sspec)` sets the background color, foreground color, and fill pattern. The background color is applicable when exporting the table to Microsoft Word, Microsoft Excel, PDF, HTML, and  $\LaTeX$  files. The foreground color and fill pattern are applicable when exporting the table to Microsoft Word and Microsoft Excel.

## Notes

`note(string)` adds the text *string* as a note to the table. `note()` may be specified multiple times to add multiple notes. Each note is placed on a new line.

`notestyles(text_styles)` changes the style for the table notes. *text\_styles* are the following:

`font([fontfamily] [, size(# [unit]) color(color) variant(variant) [no]bold [no]italic [no]strikeout [no]underline])` specifies the font style. These font style properties are applicable when exporting the table to Microsoft Word, Microsoft Excel, PDF, HTML, and  $\LaTeX$  files, unless otherwise specified.

*fontfamily* specifies a valid font family. This font style property is applicable when publishing items from a collection to Microsoft Word, Microsoft Excel, PDF, and HTML files.

`size(# [unit])` specifies the font size as a number optionally followed by units. This font style property is applicable when publishing items from a collection to Microsoft Word, Microsoft Excel, PDF, and HTML files.

`color(color)` specifies the text color.

`variant(variant)` specifies the font variant and capitalization.

`bold` and `nobold` specify the font weight. `bold` changes the font weight to bold; `nobold` changes the font weight back to normal.

`italic` and `noitalic` specify the font style. `italic` changes the font style to italic; `noitalic` changes the font style back to normal.

`strikeout` and `nostrikeout` specify whether to add a strikeout mark to the notes. `strikeout` adds a strikeout mark to the note; `nostrikeout` changes the note back to normal.

`underline` and `nounderline` specify whether to underline the table notes. `underline` adds a single line under the notes; `nounderline` removes the underline.

Only one of `strikeout` or `underline` is allowed when publishing to HTML files.

`smcl(smcl)` specifies how to render the table notes for SMCL output. This style property is applicable only when publishing items from a collection to a SMCL file.

`latex(latex)` specifies how to render the table notes for  $\LaTeX$  output. This style property is applicable only when publishing items from a collection to a  $\LaTeX$  file.

`shading(sspec)` sets the background color, foreground color, and fill pattern. The background color is applicable when exporting the table to Microsoft Word, Microsoft Excel, PDF, HTML, and  $\LaTeX$  files. The foreground color and fill pattern are applicable when exporting the table to Microsoft Word and Microsoft Excel.

Export

`export(filename.suffix[ , export_opts ])` exports the table to the specified file. *export\_opts* are the following:

`as(fileformat)` specifies the file format to which the table is to be exported. This option is rarely specified because, by default, `table` determines the format from the suffix of the file being created.

`replace` permits `table` to overwrite an existing file.

`noisily` specifies that `table` show the commands used to export the table to Microsoft Word, Microsoft Excel, and PDF files. The `putdocx`, `putexcel`, or `putpdf` command used to export the table will be displayed.

`dofile(filename[ , replace ])` specifies that `table` save to *filename* the commands used to export the table to Microsoft Word, Microsoft Excel, and PDF files.

If *filename* already exists, it can be overwritten by specifying `replace`. If *filename* is specified without an extension, `.do` is assumed.

`append` specifies that `table` append the table to an existing file.

This option is applicable when you export the table to an HTML, a  $\LaTeX$ , a SMCL, a `txt`, or a Markdown file. When you export to HTML and  $\LaTeX$  files, the `append` option implies the `tableonly` option. Furthermore, when you export to HTML files, if the target CSS file already exists, `table` will also append to it.

`tableonly` specifies that only the table be exported to the specified HTML or  $\LaTeX$  document. By default, `table` produces complete HTML and  $\LaTeX$  documents.

When you export to an HTML file, if the `cssfile()` option is not specified, a CSS filename is constructed from *filename*, with the extension replaced with `.css`.

`cssfile(cssfile)` specifies that `table` define the styles in *cssfile* instead of *filename* when you export to HTML.

`prefix(prefix)` specifies that `table` use *prefix* to identify style classes when you export to HTML.

`sheet(sheetname [ , replace ])` saves to the worksheet named *sheetname*. For more information about this option, see [\[RPT\] putexcel](#).

`cell(cell)` specifies an Excel upper-left cell as the starting position to publish the table. The default is `cell(A1)`.

`modify` permits `putexcel` set to modify an Excel file. For more information about this option, see [\[RPT\] putexcel](#).

`noopen` prevents `putexcel` from opening the Excel file in memory for modification. It does not appear in the dialog box. For more information about this option, see [\[RPT\] putexcel](#).

## Options

`missing` specifies that numeric missing values of any variables specified in `rowspec`, `colspec`, or `tabspec` be treated as valid categories. By default, observations with a numeric missing value in any of these variables are omitted.

`name(cname)` specifies that a collection named *cname* be associated with the collected statistics and results. The default is `name(Table)`.

`append` specifies that `table` append its collection information into the collection named in `name()`.

`replace` permits `table` to overwrite an existing collection. This option is implied for `name(Table)` when `append` is not specified.

`label(filename)` specifies the *filename* containing the collection labels to use for your table. Labels in *filename* will be loaded for the table, and any labels not specified in *filename* will be taken from the labels defined in `c(collect_label)`. The default is to use only the collection labels set in `c(collect_label)`; see [TABLES] [set collect\\_label](#).

`style(filename [, override])` specifies the *filename* containing the collection styles to use for your table. The default collection styles will be discarded, and only the collection styles in *filename* will be applied.

If you prefer the default collection styles but also want to apply any styles in *filename*, specify *override*. If there are conflicts between the default collection styles and those in *filename*, the ones in *filename* will take precedence.

The default is to use only the collection styles set in `c(table_style)`; see [TABLES] [set table\\_style](#).

The following option is available with `table` but is not shown in the dialog box:

`noisily` specifies that output from the commands specified in `command()` options be displayed. By default, output from commands is suppressed.

## Remarks and examples

Remarks are presented under the following headings:

[Introduction](#)

[Tables with results from a single command](#)

[Tables with results from multiple estimation commands](#)

[Regression results with factor variables](#)

### Introduction

The `table` command allows us to create tables of regression results. You can create a table that reports coefficients, standard errors, test statistics, confidence intervals, and other statistics from a single model or a table that compares results from multiple models.

`table` does not fit models directly. Rather, `table` will run any Stata command that you include in its `command()` option and place results from that command into the table. You determine which results you would like to see in the table. You can select any of the results stored by the command.

You can also create a table of regression results with `etable`. However, `etable` will create tables only with active estimation results, results from `margins`, or results stored with `estimates store`. If you are working with any of these results, you can use `etable` to create and export a table of regression results. However, if you want to include results from other commands, you should use the `table` command.

## Tables with results from a single command

We have data from the Second National Health and Nutrition Examination Survey (NHANES II) (McDowell et al. 1981). The data contain some demographic information, such as the participants' age. The data also contain some measures of health, including the individual's weight, systolic blood pressure (bpsystol), and whether the individual has diabetes.

Here we will create a table with results from a linear regression model for systolic blood pressure as a function of age and weight. We type the command to fit the model in the `command()` option. In the first set of parentheses following `table`, we specify that we want the rows to correspond to the levels of `colname`—this is how we refer to the list of covariates in our regression model. In the second set of parentheses, we specify that we want the columns to correspond to the statistics (`result`).

```
. use https://www.stata-press.com/data/r19/nhanes21
(Second National Health and Nutrition Examination Survey)
. table (colname) (result), command(regress bpsystol age weight)
```

|             | Coefficient |
|-------------|-------------|
| Age (years) | .6379892    |
| Weight (kg) | .4069041    |
| Intercept   | 71.27096    |

Our table is fairly simple. By default, `table` includes only the reported coefficients when an estimation command is specified in the `command()` option.

The `table` command can easily be used to compare results across groups in our data. For instance, if we want to fit the same model for males and females, we can add `sex` to our column specification.

```
. table (colname) (sex result), command(regress bpsystol age weight)
```

|             | Sex      |          |          |
|-------------|----------|----------|----------|
|             | Male     | Female   | Total    |
| Age (years) | .4789361 | .7735499 | .6379892 |
| Weight (kg) | .3346106 | .4586108 | .4069041 |
| Intercept   | 84.08037 | 61.70456 | 71.27096 |

We can now easily compare results for males, females, and both together.

We may want to see additional statistics reported. Let's extend our table to include both coefficients and standard errors. We can refer to the reported coefficients using the keyword `_r_b` and to the reported standard errors as `_r_se`, and we can list these in the `command()` option before our regression command. Here we also move `result` to the first set of parentheses so that coefficients and standard errors will be displayed on separate rows.

```
. table (colname result) (sex),
> command(_r_b _r_se: regress bpsystol age weight)
```

|             | Sex      |          | Total    |
|-------------|----------|----------|----------|
|             | Male     | Female   |          |
| Age (years) |          |          |          |
| Coefficient | .4789361 | .7735499 | .6379892 |
| Std. error  | .0156578 | .0155743 | .0111315 |
| Weight (kg) |          |          |          |
| Coefficient | .3346106 | .4586108 | .4069041 |
| Std. error  | .0197112 | .0182401 | .0124786 |
| Intercept   |          |          |          |
| Coefficient | 84.08037 | 61.70456 | 71.27096 |
| Std. error  | 1.74867  | 1.376067 | 1.041742 |

We now have the statistics we want in this table, but we may want to modify the look a bit. `table` allows us to customize the results in our table in a number of ways. We can use the `nformat()` option to report all results to two decimal places, and we can use the `sformat()` option to place parentheses around our standard errors.

```
. table (colname result) (sex),
> command(_r_b _r_se: regress bpsystol age weight)
> nformat(%6.2f) sformat("(%s)" _r_se)
```

|             | Sex    |        | Total  |
|-------------|--------|--------|--------|
|             | Male   | Female |        |
| Age (years) |        |        |        |
| Coefficient | 0.48   | 0.77   | 0.64   |
| Std. error  | (0.02) | (0.02) | (0.01) |
| Weight (kg) |        |        |        |
| Coefficient | 0.33   | 0.46   | 0.41   |
| Std. error  | (0.02) | (0.02) | (0.01) |
| Intercept   |        |        |        |
| Coefficient | 84.08  | 61.70  | 71.27  |
| Std. error  | (1.75) | (1.38) | (1.04) |

Now that we have the parentheses to distinguish standard errors from coefficients, we may not want to see those labels in the row header. We add the `style(table-reg3)` option to use the predefined style `table-reg3`, which hides the names of these statistics, right-aligns the names of the variables in the row headers, center aligns the statistics horizontally within each column, and adds vertical space between variables.

```
. table (colname result) (sex),
> command(_r_b _r_se: regress bpsystol age weight)
> nformat(%05.3f) sformat("%s" _r_se) style(table-reg3)
```

|             | Sex               |                   | Total             |
|-------------|-------------------|-------------------|-------------------|
|             | Male              | Female            |                   |
| Age (years) | 0.479<br>(0.016)  | 0.774<br>(0.016)  | 0.638<br>(0.011)  |
| Weight (kg) | 0.335<br>(0.020)  | 0.459<br>(0.018)  | 0.407<br>(0.012)  |
| Intercept   | 84.080<br>(1.749) | 61.705<br>(1.376) | 71.271<br>(1.042) |

## Tables with results from multiple estimation commands

Above, we fit the same model to the full dataset and then to groups of observations within that dataset. We may alternatively want to fit different models and display their results in a single table. To do this, we specify multiple `command()` options.

```
. table (colname result) (command),
> command(_r_b _r_se: regress bpsystol age weight)
> command(_r_b _r_se: regress bpsystol age weight iron vitaminc zinc)
> nformat(%6.2f) sformat("%s" _r_se) style(table-reg3)
```

|                         | 1               | 2               |
|-------------------------|-----------------|-----------------|
| Age (years)             | 0.64<br>(0.01)  | 0.64<br>(0.01)  |
| Weight (kg)             | 0.41<br>(0.01)  | 0.40<br>(0.01)  |
| Serum iron (mcg/dL)     |                 | -0.01<br>(0.01) |
| Serum vitamin C (mg/dL) |                 | -0.79<br>(0.36) |
| Serum zinc (mcg/dL)     |                 | -0.05<br>(0.01) |
| Intercept               | 71.27<br>(1.04) | 77.50<br>(1.75) |

We may want to modify this table a bit further. Customization of tables can go beyond the predefined styles and options available to you in the `table` command. `table` creates a collection of results that can be used in combination with the `collect` suite of commands to produce highly customized tables.

If we want to add more descriptive labels for the two models, we can use the `collect label levels` command to define our new labels. After a change using `collect`, we can type `collect preview` to see the results.

```
. collect label levels command 1 "Model 1" 2 "Model 2", modify
. collect style header command, level(label)
. collect preview
```

|                         | Model 1         | Model 2         |
|-------------------------|-----------------|-----------------|
| Age (years)             | 0.64<br>(0.01)  | 0.64<br>(0.01)  |
| Weight (kg)             | 0.41<br>(0.01)  | 0.40<br>(0.01)  |
| Serum iron (mcg/dL)     |                 | -0.01<br>(0.01) |
| Serum vitamin C (mg/dL) |                 | -0.79<br>(0.36) |
| Serum zinc (mcg/dL)     |                 | -0.05<br>(0.01) |
| Intercept               | 71.27<br>(1.04) | 77.50<br>(1.75) |

## Regression results with factor variables

The examples above included only continuous covariates in the models. When we include factor variables, there are a variety of ways that they can be displayed in the headers of the tables. In [\[TABLES\] Pre-defined styles](#), you will find a number of styles that you can choose from. We demonstrate a few here.

We will start with the `table-reg1` style. This style is our default table style, except that it identifies the commands in the headers using values 1, 2, ... rather than labeling them with the full command we typed in the `command()` option.

```
. table (colname) (command result),
> command(regress bpsystol i.agegrp i.sex weight)
> command(regress bpsystol i.agegrp##i.sex weight)
> style(table-reg1)
```

|                              | 1        | 2         |
|------------------------------|----------|-----------|
| Age group=20-29              | 0        | 0         |
| Age group=30-39              | 1.195226 | -.7808968 |
| Age group=40-49              | 7.251555 | 2.749774  |
| Age group=50-59              | 15.94216 | 10.43724  |
| Age group=60-69              | 22.83932 | 16.53001  |
| Age group=70+                | 30.46609 | 23.3076   |
| Sex=Male                     | 0        | 0         |
| Sex=Female                   | 1.040833 | -6.777535 |
| Weight (kg)                  | .4359741 | .4242392  |
| Age group=20-29 # Sex=Male   |          | 0         |
| Age group=20-29 # Sex=Female |          | 0         |
| Age group=30-39 # Sex=Male   |          | 0         |
| Age group=30-39 # Sex=Female |          | 3.942553  |
| Age group=40-49 # Sex=Male   |          | 0         |
| Age group=40-49 # Sex=Female |          | 8.79336   |
| Age group=50-59 # Sex=Male   |          | 0         |
| Age group=50-59 # Sex=Female |          | 10.6501   |
| Age group=60-69 # Sex=Male   |          | 0         |
| Age group=60-69 # Sex=Female |          | 12.20669  |
| Age group=70+ # Sex=Male     |          | 0         |
| Age group=70+ # Sex=Female   |          | 13.51823  |
| Intercept                    | 86.71019 | 91.57774  |

In some cases, for clarity, it is helpful to see both the factor variables and their levels. The `table-reg1` style provides this in the output.

When we have nice value labels on our factor variables, we may want to see only those. The `table-reg1-fv1` style removes the extra labels. Our table above also reports zero-valued coefficients for base categories in both the main effects of the factor variables and in their interactions. The `table-reg1-fv1` style omits the rows for the base categories in the interactions.

```
. table (colname) (command result),
> command(regress bpsystol i.agegrp i.sex weight)
> command(regress bpsystol i.agegrp##i.sex weight)
> style(table-reg1-fv1)
```

|                | 1        | 2         |
|----------------|----------|-----------|
| 20-29          | 0        | 0         |
| 30-39          | 1.195226 | -.7808968 |

| 50-59          | 15.94216 | 10.43724  |
| 60-69          | 22.83932 | 16.53001  |
| 70+            | 30.46609 | 23.3076   |
| Male           | 0        | 0         |
| Female         | 1.040833 | -6.777535 |
| Weight (kg)    | .4359741 | .4242392  |
| 30-39 # Female |          | 3.942553  |
| 40-49 # Female |          | 8.79336   |
| 50-59 # Female |          | 10.6501   |
| 60-69 # Female |          | 12.20669  |
| 70+ # Female   |          | 13.51823  |
| Intercept      | 86.71019 | 91.57774  |

Sometimes, the tables are more readable when the row headers are right aligned. We can use the `table-reg2-fv1` style in this case. Let's also change the numeric format of all the results so that they report only two decimal places.

```
. table (colname) (command result),
> command(regress bpsystol i.agegrp i.sex weight)
> command(regress bpsystol i.agegrp##i.sex weight)
> style(table-reg2-fv1) nformat(%6.2f)
```

|                | 1     | 2     |
|----------------|-------|-------|
| 20-29          | 0.00  | 0.00  |
| 30-39          | 1.20  | -0.78 |
| 40-49          | 7.25  | 2.75  |
| 50-59          | 15.94 | 10.44 |
| 60-69          | 22.84 | 16.53 |
| 70+            | 30.47 | 23.31 |
| Male           | 0.00  | 0.00  |
| Female         | 1.04  | -6.78 |
| Weight (kg)    | 0.44  | 0.42  |
| 30-39 # Female |       | 3.94  |
| 40-49 # Female |       | 8.79  |
| 50-59 # Female |       | 10.65 |
| 60-69 # Female |       | 12.21 |
| 70+ # Female   |       | 13.52 |
| Intercept      | 86.71 | 91.58 |

There are many ways that we can further customize our table using the `collect` suite of commands. We can add column titles for our models as we did above. In addition, we can use `collect style row` to specify a character to be used between terms in an interaction.

```
. collect label levels command 1 "Model 1" 2 "Model 2", modify
. collect style header command, level(label)
. collect style row stack, delimiter(" X ")
. collect preview
```

|                | Model 1 | Model 2 |
|----------------|---------|---------|
| 20–29          | 0.00    | 0.00    |
| 30–39          | 1.20    | -0.78   |
| 40–49          | 7.25    | 2.75    |
| 50–59          | 15.94   | 10.44   |
| 60–69          | 22.84   | 16.53   |
| 70+            | 30.47   | 23.31   |
| Male           | 0.00    | 0.00    |
| Female         | 1.04    | -6.78   |
| Weight (kg)    | 0.44    | 0.42    |
| 30–39 X Female |         | 3.94    |
| 40–49 X Female |         | 8.79    |
| 50–59 X Female |         | 10.65   |
| 60–69 X Female |         | 12.21   |
| 70+ X Female   |         | 13.52   |
| Intercept      | 86.71   | 91.58   |

If one of the predefined styles in [TABLES] **Predefined styles** does not suit your needs for factor-variable results (or for any other table customization), you can create your own style. To do this, you will use series of `collect style` commands, and then you can save the style to use later; see [TABLES] **collect style save**.

If you wish to include your table in a paper, on a webpage, or in another format, you can easily export it in L<sup>A</sup>T<sub>E</sub>X, Word, Excel, HTML, and a variety of other formats by using `collect export`.

## Stored results

`table` stores the following in `r()`:

Scalars

`r(N)` number of observations

## Description

`tabstat` displays summary statistics for a series of numeric variables in one table. It allows you to specify the list of statistics to be displayed. Statistics can be calculated (conditioned on) another variable. `tabstat` allows substantial flexibility in terms of the statistics presented and the format of the table.

## Quick start

Mean of `v1` displayed using `v1`'s display format

```
tabstat v1, format
```

Same as above, but use format with 2 significant digits and a comma

```
tabstat v1, format(%9.2fc)
```

Nonmissing observations, mean, standard error, and coefficient of variation for `v1`

```
tabstat v1, statistics(n mean semean cv)
```

Quartiles and interquartile range of `v1` and `v2`

```
tabstat v1 v2, statistics(q iqr)
```

Same as above, but report statistics separately for each level of `catvar`

```
tabstat v1 v2, by(catvar) statistics(q iqr)
```

Same as above, but display a separate column for each statistic

```
tabstat v1 v2, by(catvar) statistics(q iqr) columns(statistics)
```

## Menu

Statistics > Summaries, tables, and tests > Other tables > Compact table of summary statistics

## Syntax

```
tabstat varlist [if] [in] [weight] [, options]
```

| <code>save</code>                             | store summary statistics in <code>r()</code>                                        |

`by` is allowed; see [\[D\] by](#).

`awweights` and `fweights` are allowed; see [\[U\] 11.1.6 weight](#).

## Options

### Main

`by(varname)` specifies that the statistics be displayed separately for each unique value of *varname*; *varname* may be numeric or string. For instance, `tabstat height` would present the overall mean of height. `tabstat height, by(sex)` would present the mean height of males, and of females, and the overall mean height. Do not confuse the `by()` option with the `by prefix` (see [D] [by](#)); both may be specified.

`statistics(statname [...])` specifies the statistics to be displayed; the default is equivalent to specifying `statistics(mean)`. (`stats()` is a synonym for `statistics()`.) Multiple statistics may be specified and are separated by white space, such as `statistics(mean sd)`. Available statistics are

| <i>statname</i>           | Definition                               | <i>statname</i> | Definition                           |

### Options

`labelwidth(#)` specifies the maximum width to be used within the stub to display the labels of the `by()` variable. The default is `labelwidth(16)`.  $8 \leq \# \leq 32$ .

`varwidth(#)` specifies the maximum width to be used within the stub to display the names of the variables. The default is `varwidth(12)`. `varwidth()` is effective only with `columns(statistics)`. Setting `varwidth()` implies `longstub`.  $8 \leq \# \leq 32$ .

`columns(variables | statistics)` specifies whether to display variables or statistics in the columns of the table. `columns(variables)` is the default when more than one variable is specified.

`format` and `format(%fmt)` specify how the statistics are to be formatted. The default is to use a %9.0g format.

`format` specifies that each variable's statistics be formatted with the variable's display format; see [D] [format](#).

`format(%fmt)` specifies the format to be used for all statistics.

The column width is the maximum width of these formats. The minimum column width is nine display characters.

`casewise` specifies casewise deletion of observations. Statistics are to be computed for the sample that is not missing for any of the variables in *varlist*. The default is to use all the nonmissing values for each variable.

`nototal` is for use with `by()`; it specifies that the overall statistics not be reported.

`missing` specifies that missing values of the `by()` variable be treated just like any other value and that statistics should be displayed for them. The default is not to report the statistics for the `by() == missing` group. If the `by()` variable is a string variable, `by() == ""` is considered to mean missing.

`noseparator` specifies that a separator line between the `by()` categories not be displayed.

`longstub` specifies that the left stub of the table be made wider so that it can include names of the statistics or variables in addition to the categories of `by(varname)`. The default is to describe the statistics or variables in a header. `longstub` is ignored if `by(varname)` is not specified.

`save` specifies that the summary statistics be returned in `r()`. The overall (unconditional) statistics are returned in matrix `r(StatTotal)` (rows are statistics, columns are variables). The conditional statistics are returned in the matrices `r(Stat1)`, `r(Stat2)`, ..., and the names of the corresponding variables are returned in the macros `r(name1)`, `r(name2)`, ....

## Remarks and examples

This command is probably most easily understood by going through a series of examples.

### ▷ Example 1

We have data on the price, weight, mileage rating, and repair record of 22 foreign and 52 domestic 1978 automobiles. We want to summarize these variables for the different origins of the automobiles.

```
. use https://www.stata-press.com/data/r19/auto
(1978 automobile data)
. tabstat price weight mpg rep78, by(foreign)
Summary statistics: Mean
Group variable: foreign (Car origin)
```

| foreign  | price    | weight   | mpg      | rep78    |
|----------|----------|----------|----------|----------|
| Domestic | 6072.423 | 3317.115 | 19.82692 | 3.020833 |
| Foreign  | 6384.682 | 2315.909 | 24.77273 | 4.285714 |
| Total    | 6165.257 | 3019.459 | 21.2973  | 3.405797 |

More summary statistics can be requested via the `statistics()` option. The group totals can be suppressed with the `nototal` option.

```
. tabstat price weight mpg rep78, by(foreign) stat(mean sd min max) nototal
```

Summary statistics: Mean, SD, Min, Max

Group variable: foreign (Car origin)

| foreign  | price    | weight   | mpg      | rep78    |
|----------|----------|----------|----------|----------|
| Domestic | 6072.423 | 3317.115 | 19.82692 | 3.020833 |
|          | 3097.104 | 695.3637 | 4.743297 | .837666  |
|          | 3291     | 1800     | 12       | 1        |
|          | 15906    | 4840     | 34       | 5        |
| Foreign  | 6384.682 | 2315.909 | 24.77273 | 4.285714 |
|          | 2621.915 | 433.0035 | 6.611187 | .7171372 |
|          | 3748     | 1760     | 14       | 3        |
|          | 12990    | 3420     | 41       | 5        |

Although the header of the table describes the statistics running vertically in the “cells”, the table may become hard to read, especially with many variables or statistics. The `longstub` option specifies that a column be added describing the contents of the cells. The `format` option can be issued to specify that `tabstat` display the statistics by using the display format of the variables rather than the overall default `%9.0g`.

```
. tabstat price weight mpg rep78, by(foreign) stat(mean sd min max) long format
```

| foreign  | Stats | price   | weight  | mpg     | rep78   |
|----------|-------|---------|---------|---------|---------|
| Domestic | Mean  | 6,072.4 | 3,317.1 | 19.8269 | 3.02083 |
|          | SD    | 3,097.1 | 695.364 | 4.7433  | .837666 |
|          | Min   | 3,291   | 1,800   | 12      | 1       |
|          | Max   | 15,906  | 4,840   | 34      | 5       |
| Foreign  | Mean  | 6,384.7 | 2,315.9 | 24.7727 | 4.28571 |
|          | SD    | 2,621.9 | 433.003 | 6.61119 | .717137 |
|          | Min   | 3,748   | 1,760   | 14      | 3       |
|          | Max   | 12,990  | 3,420   | 41      | 5       |
| Total    | Mean  | 6,165.3 | 3,019.5 | 21.2973 | 3.4058  |
|          | SD    | 2,949.5 | 777.194 | 5.7855  | .989932 |
|          | Min   | 3,291   | 1,760   | 12      | 1       |
|          | Max   | 15,906  | 4,840   | 41      | 5       |

We can specify a layout of the table in which the statistics run horizontally and the variables run vertically by specifying the `col(statistics)` option.

```
. tabstat price weight mpg rep78, by(foreign) stat(min mean max) col(stat) long
```

| foreign  | Variable | Min  | Mean     | Max   |
|----------|----------|------|----------|-------|
| Domestic | price    | 3291 | 6072.423 | 15906 |
|          | weight   | 1800 | 3317.115 | 4840  |
|          | mpg      | 12   | 19.82692 | 34    |
|          | rep78    | 1    | 3.020833 | 5     |
| Foreign  | price    | 3748 | 6384.682 | 12990 |
|          | weight   | 1760 | 2315.909 | 3420  |
|          | mpg      | 14   | 24.77273 | 41    |
|          | rep78    | 3    | 4.285714 | 5     |
| Total    | price    | 3291 | 6165.257 | 15906 |
|          | weight   | 1760 | 3019.459 | 4840  |
|          | mpg      | 12   | 21.2973  | 41    |
|          | rep78    | 1    | 3.405797 | 5     |

Finally, `tabstat` can also be used to enhance `summarize` so we can specify the statistics to be displayed. For instance, we can display the number of observations, the mean, the coefficient of variation, and the 25%, 50%, and 75% quantiles for a list of variables.

```
. tabstat price weight mpg rep78, stat(n mean cv q) col(stat)
```

| variable | N  | mean     | cv       | p25  | p50    | p75  |
|----------|----|----------|----------|------|--------|------|
| price    | 74 | 6165.257 | .478406  | 4195 | 5006.5 | 6342 |
| weight   | 74 | 3019.459 | .2573949 | 2240 | 3190   | 3600 |
| mpg      | 74 | 21.2973  | .2716543 | 18   | 20     | 25   |
| rep78    | 69 | 3.405797 | .290661  | 3    | 3      | 4    |

Because we did not specify the `by()` option, these statistics were not displayed for the subgroups of the data formed by the categories of the `by()` variable.

◀

## Video example

[Descriptive statistics in Stata](#)

## Acknowledgments

The `tabstat` command was written by Jeroen Weesie and Vincent Buskens both of the Department of Sociology at Utrecht University, The Netherlands.

## Description

`tabulate` produces a one-way table of frequency counts.

For information on a two-way table of frequency counts along with measures of association, including the common Pearson  $\chi^2$ , the likelihood-ratio  $\chi^2$ , Cramér's  $V$ , Fisher's exact test, Goodman and Kruskal's gamma, and Kendall's  $\tau_b$ , see [R] [tabulate twoway](#).

`tab1` produces a one-way tabulation for each variable specified in *varlist*.

Also see [R] [table](#) and [R] [tabstat](#) if you want one-, two-, or  $n$ -way table of frequencies and a wide variety of statistics. See [R] [tabulate, summarize\(\)](#) for a description of `tabulate` with the `summarize()` option; it produces a table (breakdowns) of means and standard deviations. `table` is better than `tabulate`, `summarize()`, but `tabulate, summarize()` is faster. See [R] [EpiTab](#) for a  $2 \times 2$  table with statistics of interest to epidemiologists.

## Quick start

One-way table of frequencies for `v1`

```
tabulate v1
```

Sort table in descending order of frequency

```
tabulate v1, sort
```

Generate indicator variables `v1_1`, `v1_2`, ... representing the levels of `v1`

```
tabulate v1, generate(v1_)
```

Treat missing values like other values of `v1`

```
tabulate v1, missing
```

Display numeric values of `v1` rather than value labels

```
tabulate v1, nolabel
```

Create one-way tables for `v1`, `v2`, and `v3`

```
tab1 v1 v2 v3
```

## Menu

### **tabulate oneway**

Statistics > Summaries, tables, and tests > Frequency tables > One-way table

### **tabulate ..., generate()**

Data > Create or change data > Other variable-creation commands > Create indicator variables

### **tab1**

Statistics > Summaries, tables, and tests > Frequency tables > Multiple one-way tables

## Syntax

### One-way table

```
tabulate varname [if] [in] [weight] [, options advanced_options]
```

### One-way table for each variable—a convenience tool

```
tab1 varlist [if] [in] [weight] [, options]
```

| <code>matrow(<i>matname</i>)</code>    | save unique values of <i>varname</i> in <i>matname</i> |

by is allowed with tabulate and tab1; see [U] 11.1.10 Prefix commands.

fweights, aweights, and iweights are allowed; see [U] 11.1.6 weight.

## Options

### Main

`subpop(varname)` excludes observations for which *varname* = 0 in tabulating frequencies. The mathematical results of `tabulate ...`, `subpop(myvar)` are the same as `tabulate ...` if *myvar* != 0, but the table may be presented differently. The identities of the rows and columns will be determined from all the data, including the *myvar* = 0 group, so there may be entries in the table with frequency 0.

Consider tabulating `answer`, a variable that takes on values 1, 2, and 3, but consider tabulating it just for the `male==1` subpopulation. Assume that `answer` is never 2 in this group. `tabulate answer if male==1` produces a table with two rows: one for `answer 1` and one for `answer 3`. There will be no row for `answer 2` because `answer 2` was never observed. `tabulate answer, subpop(male)` produces a table with three rows. The row for `answer 2` will be shown as having 0 frequency.

`missing` requests that missing values be treated like other values in calculations of counts, percentages, and other statistics.

`nofreq` suppresses the printing of the frequencies.

`no label` causes the numeric codes to be displayed rather than the value labels.

`plot` produces a bar chart of the relative frequencies in a one-way table. (Also see [\[R\] histogram.](#))

`sort` puts the table in descending order of frequency (and ascending order of the variable within equal values of frequency).

### Collect

`collect` and `collect([cname][, collect_options])` specify that results be posted to a collection. This collection produces a table that you can customize and publish to Microsoft Word, Microsoft Excel, PDF, HTML, L<sup>A</sup>T<sub>E</sub>X, SMCL, or Markdown. Output does not change when these options are specified. Use `collect preview` to see the customizable table.

`collect` is a shortcut for `collect(Tabulate)`.

*cname* specifies that a collection named *cname* be associated with the collected results. The default is `Tabulate`.

`append` specifies that results be appended to collection *cname*.

`replace` permits `tabulate` to overwrite an existing collection. This option is implied for collection `Tabulate` when `append` is not specified.

`label(filename)` specifies the *filename* containing the collection labels to use for your table. Labels in *filename* will be loaded into the collection, and any labels not specified in *filename* will be taken from the labels defined in `c(collect_label)`. The default is to use only the collection labels set in `c(collect_label)`; see [\[TABLES\] set collect\\_label.](#)

`style(filename[, override])` specifies the *filename* containing the collection styles to use for your table. The default collection styles will be discarded, and only the collection styles in *filename* will be applied.

If you prefer the default collection styles but also want to apply any styles in *filename*, specify `override`. If there are conflicts between the default collection styles and those in *filename*, the ones in *filename* will take precedence.

The default is to use only the collection styles set in `c(tabulate_style)`; see [TABLES] [set tabulate\\_style](#).

---

Advanced

---

`generate(stubname)` creates a set of indicator variables (*stubname1*, *stubname2*, ...) reflecting the observed values of the tabulated variable. The `generate()` option may not be used with the `by` prefix.

`matcell(matname)` saves the reported frequencies in *matname*.

`matrow(matname)` saves the numeric values of the  $r \times 1$  row stub in *matname*. `matrow()` may not be specified if the row variable is a string.

## Limits

A one-way table may have a maximum of 12,000 rows (Stata/MP and Stata/SE) or 3,000 rows (Stata/BE).

## Remarks and examples

Remarks are presented under the following headings:

[tabulate](#)  
[tab1](#)  
[Publish your tables](#)  
[Video example](#)

For each value of a specified variable, `tabulate` reports the number of observations with that value. The number of times a value occurs is called its *frequency*.

## tabulate

### ► Example 1

We have data summarizing the speed limit and the accident rate per million vehicle miles along various Minnesota highways in 1973. The variable containing the speed limit is called `spdlimit`. If we summarize the variable, we obtain its mean and standard deviation:

```
. use https://www.stata-press.com/data/r19/hiway
(Minnesota highway data, 1973)
. summarize spdlimit
```

| Variable | Obs | Mean | Std. dev. | Min | Max |
|----------|-----|------|-----------|-----|-----|
| spdlimit | 39  | 55   | 5.848977  | 40  | 70  |

The average speed limit is 55 miles per hour. We can learn more about this variable by tabulating it:

```
. tabulate spdlimit
```

| Speed limit | Freq. | Percent | Cum.   |
|-------------|-------|---------|--------|
| 40          | 1     | 2.56    | 2.56   |
| 45          | 3     | 7.69    | 10.26  |
| 50          | 7     | 17.95   | 28.21  |
| 55          | 15    | 38.46   | 66.67  |
| 60          | 11    | 28.21   | 94.87  |
| 65          | 1     | 2.56    | 97.44  |
| 70          | 1     | 2.56    | 100.00 |
| Total       | 39    | 100.00  |        |

We see that one highway has a speed limit of 40 miles per hour, three have speed limits of 45, 7 of 50, and so on. The column labeled *Percent* shows the percentage of highways in the dataset that have the indicated speed limit. For instance, 38.46% of highways in our dataset have a speed limit of 55 miles per hour. The final column shows the cumulative percentage. We see that 66.67% of highways in our dataset have a speed limit of 55 miles per hour or less.

◀

### ▷ Example 2

The `plot` option places a sideways histogram alongside the table:

```
. tabulate spdlimit, plot
```

| Speed limit | Freq. |       |
|-------------|-------|-------|
| 40          | 1     | *     |
| 45          | 3     | ***   |
| 50          | 7     | ***** |
| 55          | 15    | ***** |
| 60          | 11    | ***** |
| 65          | 1     | *     |
| 70          | 1     | *     |
| Total       | 39    |       |

Of course, `graph` can produce better-looking histograms; see [\[R\] histogram](#).

◀

### ▷ Example 3

`tabulate` labels tables using *variable* and *value labels* if they exist. To demonstrate how this works, let's add a new variable to our dataset that categorizes `spdlimit` into three categories. We will call this new variable `spdcat`:

```
. generate spdcat=recode(spdlimit,50,60,70)
```

The `recode()` function divides `spdlimit` into 50 miles per hour or below, 51–60, and above 60; see [\[FN\] Programming functions](#). We specified the breakpoints in the arguments (`spdlimit, 50, 60, 70`). The first argument is the variable to be recoded. The second argument is the first breakpoint, the third argument is the second breakpoint, and so on. We can specify as many breakpoints as we wish.

`recode()` used our arguments not only as the breakpoints but also to label the results. If `spdlimit` is less than or equal to 50, `spdcat` is set to 50; if `spdlimit` is between 51 and 60, `spdcat` is 60; otherwise, `spdcat` is arbitrarily set to 70. (See [\[U\] 26 Working with categorical data and factor variables](#).)

Because we just created the variable `spdcat`, it is not yet labeled. When we make a table using this variable, `tabulate` uses the variable's name to label it:

```
. tabulate spdcat
```

| spdcat | Freq. | Percent | Cum.   |
|--------|-------|---------|--------|
| 50     | 11    | 28.21   | 28.21  |
| 60     | 26    | 66.67   | 94.87  |
| 70     | 2     | 5.13    | 100.00 |
| Total  | 39    | 100.00  |        |

Even though the table is not well labeled, `recode()`'s coding scheme provides us with clues as to the table's meaning. The first line of the table corresponds to 50 miles per hour and below, the next to 51 through 60 miles per hour, and the last to above 60 miles per hour.

We can improve this table by labeling the values and variables:

```
. label define scat 50 "40 to 50" 60 "55 to 60" 70 "Above 60"
. label values spdcat scat
. label variable spdcat "Speed Limit Category"
```

We define a *value label* called `scat` that attaches labels to the numbers 50, 60, and 70 using the `label define` command; see [U] 12.6.3 [Value labels](#). We label the value 50 as “40 to 50”, because we looked back at our original tabulation in the first example and saw that the speed limit was never less than 40. Similarly, we could have labeled the last category “65 to 70” because the speed limit is never greater than 70 miles per hour.

Next, we requested that Stata label the values of the new variable `spdcat` using the value label `scat`. Finally, we labeled our variable `Speed Limit Category`. We are now ready to tabulate the result:

```
. tabulate spdcat
```

| Speed Limit<br>Category | Freq. | Percent | Cum.   |
|-------------------------|-------|---------|--------|
| 40 to 50                | 11    | 28.21   | 28.21  |
| 55 to 60                | 26    | 66.67   | 94.87  |
| Above 60                | 2     | 5.13    | 100.00 |
| Total                   | 39    | 100.00  |        |

▷ Example 4

If we have missing values in our dataset, `tabulate` ignores them unless we explicitly indicate otherwise. We have no missing data in our example, so let's add some:

```
. replace spdcat=. in 39
(1 real change made, 1 to missing)
```

We changed the first observation on `spdcat` to *missing*. Let's now tabulate the result:

```
. tabulate spdcat
```

| Speed Limit<br>Category | Freq. | Percent | Cum.   |
|-------------------------|-------|---------|--------|
| 40 to 50                | 11    | 28.95   | 28.95  |
| 55 to 60                | 26    | 68.42   | 97.37  |
| Above 60                | 1     | 2.63    | 100.00 |
| Total                   | 38    | 100.00  |        |

Comparing this output with that in the previous example, we see that the total frequency count is now one less than it was—38 rather than 39. Also, the 'Above 60' category now has only one observation where it used to have two, so we evidently changed a road with a high speed limit.

We want `tabulate` to treat missing values just as it treats numbers, so we specify the `missing` option:

```
. tabulate spdcat, missing
```

| Speed Limit<br>Category | Freq. | Percent | Cum.   |
|-------------------------|-------|---------|--------|
| 40 to 50                | 11    | 28.21   | 28.21  |
| 55 to 60                | 26    | 66.67   | 94.87  |
| Above 60                | 1     | 2.56    | 97.44  |
| .                       | 1     | 2.56    | 100.00 |
| Total                   | 39    | 100.00  |        |

We now see our missing value—the last category, labeled '.', shows a frequency count of 1. The table sum is once again 39.

Let's put our dataset back as it was originally:

```
. replace spdcat=70 in 39
(1 real change made)
```

□ Technical note

tabulate also can automatically create indicator variables from categorical variables. We will briefly review that capability here, but see [U] 26 Working with categorical data and factor variables for a complete description. Let’s begin by describing our highway dataset:

```
. describe
Contains data from https://www.stata-press.com/data/r19/hiway.dta
Observations: 39 Minnesota highway data, 1973
Variables: 3 16 Nov 2024 12:39
```

| Variable name | Storage type | Display format | Value label | Variable label                          |
|---------------|--------------|----------------|-------------|-----------------------------------------|
| spdlimit      | byte         | %8.0g          |             | Speed limit                             |
| rate          | byte         | %9.0g          | rcat        | Accident rate per million vehicle miles |
| spdcat        | float        | %9.0g          | scat        | Speed Limit Category                    |

Sorted by:  
 Note: Dataset has changed since last saved.

Our dataset contains three variables. We will type tabulate spdcat, generate(spd), describe our data, and then explain what happened.

```
. tabulate spdcat, generate(spd)
```

| Speed Limit Category | Freq. | Percent | Cum.   |
|----------------------|-------|---------|--------|
| 40 to 50             | 11    | 28.21   | 28.21  |
| 55 to 60             | 26    | 66.67   | 94.87  |
| Above 60             | 2     | 5.13    | 100.00 |
| Total                | 39    | 100.00  |        |

```
. describe

Sorted by:  
 Note: Dataset has changed since last saved.

When we typed tabulate with the generate() option, Stata responded by producing a one-way frequency table, so it appeared that the option did nothing. Yet when we describe our dataset, we find that we now have six variables instead of the original three. The new variables are named spd1, spd2, and spd3.

When we specify the `generate()` option, we are telling Stata to not only produce the table but also create a set of indicator variables that correspond to that table. Stata adds a numeric suffix to the name we specify in the parentheses. `spd1` refers to the first line of the table, `spd2` to the second line, and so on. Also, Stata labels the variables so that we know what they mean. `spd1` is an indicator variable that is *true* (takes on the value 1) when `spdcat` is between 40 and 50; otherwise, it is zero. (There is an exception: if `spdcat` is missing, so are the `spd1`, `spd2`, and `spd3` variables. This did not happen in our dataset.)

We want to prove our claim. Because we have not yet introduced two-way tabulations, we will use the `summarize` statement:

```
. summarize spdlimit if spd1==1
```

| Variable | Obs | Mean     | Std. dev. | Min | Max |
|----------|-----|----------|-----------|-----|-----|
| spdlimit | 11  | 47.72727 | 3.437758  | 40  | 50  |

```
. summarize spdlimit if spd2==1
```

| Variable | Obs | Mean     | Std. dev. | Min | Max |
|----------|-----|----------|-----------|-----|-----|
| spdlimit | 26  | 57.11538 | 2.519157  | 55  | 60  |

```
. summarize spdlimit if spd3==1
```

| Variable | Obs | Mean | Std. dev. | Min | Max |
|----------|-----|------|-----------|-----|-----|
| spdlimit | 2   | 67.5 | 3.535534  | 65  | 70  |

Notice the indicated minimum and maximum in each of the tables above. When we restrict the sample to `spd1`, `spdlimit` is between 40 and 50; when we restrict the sample to `spd2`, `spdlimit` is between 55 and 60; when we restrict the sample to `spd3`, `spdlimit` is between 65 and 70.

Thus `tabulate` provides an easy way to create indicator (sometimes called dummy) variables. For an overview of indicator and categorical variables, see [\[U\] 26 Working with categorical data and factor variables](#).

## tab1

`tab1` is a convenience tool. Typing

```
. tab1 myvar thisvar thatvar, plot
```

is equivalent to typing

```
. tabulate myvar, plot
. tabulate thisvar, plot
. tabulate thatvar, plot
```

## Publish your tables

With the `collect` option, `tabulate` posts the tabulated values to a collection named `Tabulate` and sets it as the current collection. `tab1` appends the resulting tabulations into a single collection named `Tabulate` and sets it as the current collection. With collections, you can customize the look of your table, then publish it to HTML, Word, L<sup>A</sup>T<sub>E</sub>X, PDF, Excel, or another format appropriate for your report.

With the `by` prefix, `tabulate` and `tab1` append the resulting tabulations into a single collection, and the default layout produces a separate table for each by group.

If you are not familiar with collections, see [\[TABLES\] Intro](#). The predefined styles for `tabulate` are documented in [\[TABLES\] Predefined styles](#).

### ▷ Example 5

Recall our value-labeled variable `spdcat`. Let's use `tabulate` with the `collect` option to produce a collection with its tabulated values.

```
. tabulate spdcat, collect
```

| Speed Limit<br>Category | Freq. | Percent | Cum.   |
|-------------------------|-------|---------|--------|
| 40 to 50                | 11    | 28.21   | 28.21  |
| 55 to 60                | 26    | 66.67   | 94.87  |
| Above 60                | 2     | 5.13    | 100.00 |
| Total                   | 39    | 100.00  |        |

The output does not change; however, we can use the `collect dir` command to see that `tabulate` created a collection named `Tabulate`.

```
. collect dir
```

| Collections in memory |           |
|-----------------------|-----------|
| Current: Tabulate     |           |
| Name                  | No. items |
| Tabulate              | 11        |

In this collection, frequencies are tagged with `result[frequency]`, percentages with `result[percent]`, and cumulative percentages with `result[cumulative]`. Here we use `collect label list` to show the levels and labels of the result dimension.

```
. collect label list result
```

| Collection: Tabulate |            |
|----------------------|------------|
| Dimension: result    |            |
| Label: Result        |            |
| Level labels:        |            |
| cumulative           | Cumulative |
| frequency            | Frequency  |
| percent              | Percent    |

The tabulated variable (that is, `spdcat`) is added to the collection as a dimension and is used to tag the collected results. In addition to the name, label, level values, and value labels of the tabulated variable, this dimension also has the `__margCode__` level with the `Total` label for tagging the total frequency and percentage. Here we use `collect label list` to show the levels and labels of the tabulated variable dimension.

```
. collect label list spdcat
Collection: Tabulate
Dimension: spdcat
Label: Speed Limit Category
Level labels:
 50 40 to 50
 60 55 to 60
 70 Above 60
__margCode__ Total
```

`tabulate` constructs a default layout, so you can view your customizable table with the `collect preview` command. Here we use the `collect layout` command to report the default layout specification and corresponding table.

```
. collect layout
Collection: Tabulate
Rows: cmdset#spdcat
Columns: result
Table 1: 5 x 3
```

|                      | Frequency | Percent | Cumulative |
|----------------------|-----------|---------|------------|
| Speed Limit Category |           |         |            |
| 40 to 50             | 11        | 28.21   | 28.21      |
| 55 to 60             | 26        | 66.67   | 94.87      |
| Above 60             | 2         | 5.13    | 100.00     |
| Total                | 39        | 100.00  |            |

We can make further changes to the table with the `collect` suite of commands. But we are happy with this layout and ready to publish the table to a PDF file with `collect export`. We simply specify the filename to which we want to export it.

```
. collect export tab1.pdf
(collection Tabulate exported to file tab1.pdf)
```

With `collect export` you can publish the table to several formats, such as HTML, PDF, and  $\LaTeX$  files, by specifying the appropriate file extension.

## Video example

[Tables and cross-tabulations in Stata](#)

## Stored results

`tabulate` and `tab1` store the following in `r()`:

### Scalars

|                   |                        |
|-------------------|------------------------|
| <code>r(N)</code> | number of observations |
| <code>r(r)</code> | number of rows         |

### Macros

|                            |                    |
|----------------------------|--------------------|
| <code>r(collection)</code> | name of collection |
|----------------------------|--------------------|

`r(collection)` is defined only when the `collect()` option is specified.

## Description

`tabulate` produces a two-way table of frequency counts, along with various measures of association, including the common Pearson's  $\chi^2$ , the likelihood-ratio  $\chi^2$ , Cramér's  $V$ , Fisher's exact test, Goodman and Kruskal's gamma, and Kendall's  $\tau_b$ .

Line size is respected. That is, if you resize the Results window before running `tabulate`, the resulting two-way tabulation will take advantage of the available horizontal space. Stata for Unix(console) users can instead use the `set linesize` command to take advantage of this feature.

`tab2` produces all possible two-way tabulations of the variables specified in *varlist*.

`tabi` displays the  $r \times c$  table, using the values specified; rows are separated by '\'. If no options are specified, it is as if `exact` were specified for a  $2 \times 2$  table and `chi2` were specified otherwise. See [U] 19 **Immediate commands** for a general description of immediate commands. See *Tables with immediate data* below for examples using `tabi`.

See [R] **tabulate oneway** if you want a one-way table of frequencies. See [R] **table** and [R] **tabstat** if you want one-, two-, or  $n$ -way table of frequencies and a wide variety of summary statistics. See [R] **tabulate, summarize()** for a description of `tabulate` with the `summarize()` option; it produces a table (breakdowns) of means and standard deviations. `table` is better than `tabulate`, `summarize()`, but `tabulate`, `summarize()` is faster. See [R] **Epitab** for a  $2 \times 2$  table with statistics of interest to epidemiologists.

## Quick start

Two-way table of frequencies for `v1` and `v2`

```
tabulate v1 v2
```

Add row percentages

```
tabulate v1 v2, row
```

Frequencies only for observations where `v3 = 1`

```
tabulate v1 v2 if v3==1
```

Weighted cell counts using frequency weights defined by `wvar`

```
tabulate v1 v2 [fweight=wvar]
```

Pearson's  $\chi^2$  test and each cell's contribution

```
tabulate v1 v2, chi2 cchi2
```

All available measures of association

```
tabulate v1 v2, all
```

All possible two-way tables for v1, v2, and v3

```
tab2 v1 v2 v3
```

Input cell frequencies and perform  $\chi^2$  test

```
tabi 30 18 38 \ 13 7 22, chi2
```

## Menu

### **tabulate**

| matrow( <i>matname</i> )  | save unique values of <i>varname</i> <sub>1</sub> in <i>matname</i> |
| matcol( <i>matname</i> )  | save unique values of <i>varname</i> <sub>2</sub> in <i>matname</i> |
| ‡replace                  | replace current data with given cell frequencies                    |

‡replace is available only for tabi.

## Options

### Main

chi2 calculates and displays Pearson's  $\chi^2$  for the hypothesis that the rows and columns in a two-way table are independent. chi2 may not be specified if *aweights* or *iweights* are specified.

exact[(#)] displays the significance calculated by Fisher's exact test and may be applied to  $r \times c$  as well as to  $2 \times 2$  tables. For  $2 \times 2$  tables, both one- and two-sided probabilities are displayed. For  $r \times c$  tables, two-sided probabilities are displayed. The optional positive integer # is a multiplier on the amount of memory that the command is permitted to consume. The default is 1. This option should not be necessary for reasonable  $r \times c$  tables. If the command terminates with error 910, try exact(2). The maximum row or column dimension allowed when computing Fisher's exact test is the maximum row or column dimension for tabulate (see [R] [Limits](#)).

gamma displays Goodman and Kruskal's gamma along with its asymptotic standard error. gamma is appropriate only when both variables are ordinal. gamma may not be specified if *aweights* or *iweights* are specified.

lrchi2 displays the likelihood-ratio  $\chi^2$  statistic. lrchi2 may not be specified if *aweights* or *iweights* are specified.

taub displays Kendall's  $\tau_b$  along with its asymptotic standard error. taub is appropriate only when both variables are ordinal. taub may not be specified if *aweights* or *iweights* are specified.

V (note capitalization) displays Cramér's *V*. V may not be specified if *aweights* or *iweights* are specified.

cchi2 displays each cell's contribution to Pearson's  $\chi^2$  in a two-way table.

column displays the relative frequency of each cell within its column in a two-way table.

row displays the relative frequency of each cell within its row in a two-way table.

clrchi2 displays each cell's contribution to the likelihood-ratio  $\chi^2$  in a two-way table.

cell displays the relative frequency of each cell in a two-way table.

expected displays the expected frequency of each cell in a two-way table.

`nofreq` suppresses the printing of the frequencies.

`rowsort` and `colsort` specify that the rows and columns, respectively, be presented in order of observed frequency.

By default, rows and columns are presented in ascending order of the row and column variable. For instance, if you type `tabulate a b` and `a` takes on the values 2, 3, and 5, then the first row of the table will correspond to `a = 2`; the second row will correspond to `a = 3`; and the third row will correspond to `a = 5`.

`rowsort` specifies that the rows instead be presented in descending order of observed frequency of the values. If you type `twoway a b, rowsort`, the most frequently observed value of `a` will be listed in the first row, the second most frequently observed value of `a` in the second row, and so on. If there are rows with equal frequencies, they will be presented in ascending order of the values of `a`. If `a = 5` occurs with frequency 1,000 and values `a = 2` and `a = 3` each occur with frequency 500, the rows will be presented in the order `a = 5`, `a = 2`, and `a = 3`.

`colsort` does the same as `rowsort`, except with the columns and the column variable.

`rowsort` and `colsort` may be specified together.

`missing` requests that missing values be treated like other values in calculations of counts, percentages, and other statistics.

`wrap` requests that Stata take no action on wide, two-way tables to make them readable. Unless `wrap` is specified, wide tables are broken into pieces to enhance readability.

`[no]key` suppresses or forces the display of a key above two-way tables. The default is to display the key if more than one cell statistic is requested, and otherwise to omit it. `key` forces the display of the key. `nokey` suppresses its display.

`no label` causes the numeric codes to be displayed rather than the value labels.

`nolog` suppresses the display of the log for Fisher's exact test. Using Fisher's exact test requires counting all tables that have a probability exceeding that of the observed table given the observed row and column totals. The log counts down each stage of the network computations, starting from the number of columns and counting down to 1, displaying the number of nodes in the network at each stage. A log is not displayed for  $2 \times 2$  tables.

`firstonly`, available only with `tab2`, restricts the output to only those tables that include the first variable in `varlist`. Use this option to interact one variable with a set of others.

## Collect

`collect` and `collect([cname][, collect_options])` specify that results be posted to a collection. This collection produces a table that you can customize and publish to Microsoft Word, Microsoft Excel, PDF, HTML,  $\LaTeX$ , SMCL, or Markdown. Output does not change when these options are specified. Use `collect preview` to see the customizable table.

`collect` is a shortcut for `collect(Tabulate)`.

*cname* specifies that a collection named *cname* be associated with the collected results. The default is `Tabulate`.

`append` specifies that results be appended to collection *cname*.

`replace` permits `tabulate` to overwrite an existing collection. This option is implied for collection `Tabulate` when `append` is not specified.

`label(filename)` specifies the *filename* containing the collection labels to use for your table. Labels in *filename* will be loaded into the collection, and any labels not specified in *filename* will be taken from the labels defined in `c(collect_label)`. The default is to use only the collection labels set in `c(collect_label)`; see [TABLES] [set collect\\_label](#).

`style(filename[, override])` specifies the *filename* containing the collection styles to use for your table. The default collection styles will be discarded, and only the collection styles in *filename* will be applied.

If you prefer the default collection styles but also want to apply any styles in *filename*, specify *override*. If there are conflicts between the default collection styles and those in *filename*, the ones in *filename* will take precedence.

The default is to use only the collection styles set in `c(tabulate_style)`; see [TABLES] [set tabulate\\_style](#).

## Advanced

`matcell(matname)` saves the reported frequencies in *matname*. This option is for use by programmers.

`matrow(matname)` saves the numeric values of the  $r \times 1$  row stub in *matname*. This option is for use by programmers. `matrow()` may not be specified if the row variable is a string.

`matcol(matname)` saves the numeric values of the  $1 \times c$  column stub in *matname*. This option is for use by programmers. `matcol()` may not be specified if the column variable is a string.

`replace` indicates that the immediate data specified as arguments to the `tabi` command be left as the current data in place of whatever data were there.

The following option is available with `tabulate` but is not shown in the dialog box:

`all` is equivalent to specifying `chi2 lrchi2 V gamma taub`. Note the omission of `exact`. When `all` is specified, `no` may be placed in front of the other options. `all noV` requests all association measures except Cramér's  $V$  (and Fisher's exact). `all exact` requests all association measures, including Fisher's exact test. `all` may not be specified if `aweights` or `iweights` are specified.

## Limits

Two-way tables may have a maximum of 1,200 rows and 80 columns (Stata/MP and Stata/SE) or 300 rows and 20 columns (Stata/BE). If larger tables are needed, see [R] [table](#).

## Remarks and examples

Remarks are presented under the following headings:

- [tabulate](#)
- [Measures of association](#)
- [N-way tables](#)
- [Weighted data](#)
- [Tables with immediate data](#)
- [tab2](#)
- [Publish your tables](#)
- [Video examples](#)

For each value of a specified variable (or a set of values for a pair of variables), `tabulate` reports the number of observations with that value. The number of times a value occurs is called its *frequency*.

### tabulate

#### ► Example 1

`tabulate` will make two-way tables if we specify two variables following the word `tabulate`. In our highway dataset, we have a variable called `rate` that divides the accident rate into three categories: below 4, 4–7, and above 7 per million vehicle miles. Let’s make a table of the speed limit category and the accident-rate category:

```
. use https://www.stata-press.com/data/r19/hiway2
(Minnesota highway data, 1973)
. tabulate spdcat rate
```

| Speed<br>limit<br>category | Accident rate per million<br>vehicle miles |     |         | Total |
|----------------------------|--------------------------------------------|-----|---------|-------|
|                            | Below 4                                    | 4-7 | Above 7 |       |
| 40 to 50                   | 3                                          | 5   | 3       | 11    |
| 55 to 50                   | 19                                         | 6   | 1       | 26    |
| Above 60                   | 2                                          | 0   | 0       | 2     |
| Total                      | 24                                         | 11  | 4       | 39    |

The table indicates that three stretches of highway have an accident rate below 4 and a speed limit of 40 to 50 miles per hour. The table also shows the row and column sums (called the *marginals*). The number of highways with a speed limit of 40 to 50 miles per hour is 11, which is the same result we obtained in our previous one-way tabulations.

Stata can present this basic table in several ways—16, to be precise—and we will show just a few below. It might be easier to read the table if we included the row percentages. For instance, of 11 highways in the lowest speed limit category, three are also in the lowest accident-rate category. Three-elevenths amounts to some 27.3%. We can ask Stata to fill in this information for us by using the `row` option:

```
. tabulate spdcat rate, row
```

|                       |
|-----------------------|
| Key                   |
| <i>frequency</i>      |
| <i>row percentage</i> |

| Speed<br>limit<br>category | Accident rate per million<br>vehicle miles |             |            | Total        |
|----------------------------|--------------------------------------------|-------------|------------|--------------|
|                            | Below 4                                    | 4-7         | Above 7    |              |
| 40 to 50                   | 3<br>27.27                                 | 5<br>45.45  | 3<br>27.27 | 11<br>100.00 |
| 55 to 50                   | 19<br>73.08                                | 6<br>23.08  | 1<br>3.85  | 26<br>100.00 |
| Above 60                   | 2<br>100.00                                | 0<br>0.00   | 0<br>0.00  | 2<br>100.00  |
| Total                      | 24<br>61.54                                | 11<br>28.21 | 4<br>10.26 | 39<br>100.00 |

The number listed below each frequency is the percentage of cases that each cell represents out of its row. That is easy to remember because we see 100% listed in the “Total” column. The bottom row is also informative. We see that 61.54% of all the highways in our dataset fall into the lowest accident-rate category, that 28.21% are in the middle category, and that 10.26% are in the highest.

tabulate can calculate column percentages and cell percentages, as well. It does so when we specify the column or cell options, respectively. We can even specify them together. Below is a table that includes everything:

```
. tabulate spdcat rate, row column cell
```

|                          |
|--------------------------|
| Key                      |
| <i>frequency</i>         |
| <i>row percentage</i>    |
| <i>column percentage</i> |
| <i>cell percentage</i>   |

| Speed<br>limit<br>category | Accident rate per million<br>vehicle miles |        |         | Total  |
|----------------------------|--------------------------------------------|--------|---------|--------|
|                            | Below 4                                    | 4-7    | Above 7 |        |
| 40 to 50                   | 3                                          | 5      | 3       | 11     |
|                            | 27.27                                      | 45.45  | 27.27   | 100.00 |
|                            | 12.50                                      | 45.45  | 75.00   | 28.21  |
|                            | 7.69                                       | 12.82  | 7.69    | 28.21  |
| 55 to 50                   | 19                                         | 6      | 1       | 26     |
|                            | 73.08                                      | 23.08  | 3.85    | 100.00 |
|                            | 79.17                                      | 54.55  | 25.00   | 66.67  |
|                            | 48.72                                      | 15.38  | 2.56    | 66.67  |
| Above 60                   | 2                                          | 0      | 0       | 2      |
|                            | 100.00                                     | 0.00   | 0.00    | 100.00 |
|                            | 8.33                                       | 0.00   | 0.00    | 5.13   |
|                            | 5.13                                       | 0.00   | 0.00    | 5.13   |
| Total                      | 24                                         | 11     | 4       | 39     |
|                            | 61.54                                      | 28.21  | 10.26   | 100.00 |
|                            | 100.00                                     | 100.00 | 100.00  | 100.00 |
|                            | 61.54                                      | 28.21  | 10.26   | 100.00 |

The number at the top of each cell is the frequency count. The second number is the row percentage—they sum to 100% going across the table. The third number is the column percentage—they sum to 100% going down the table. The bottom number is the cell percentage—they sum to 100% going down all the columns and across all the rows. For instance, highways with a speed limit above 60 miles per hour and in the lowest accident rate category account for 100% of highways with a speed limit above 60 miles per hour; 8.33% of highways in the lowest accident-rate category; and 5.13% of all our data.

A fourth option, `nofreq`, tells Stata not to print the frequency counts. To construct a table consisting of only row percentages, we type

```
. tabulate spdcat rate, row nofreq
```

| Speed<br>limit<br>category | Accident rate per million<br>vehicle miles |       |         | Total  |
|----------------------------|--------------------------------------------|-------|---------|--------|
|                            | Below 4                                    | 4-7   | Above 7 |        |
| 40 to 50                   | 27.27                                      | 45.45 | 27.27   | 100.00 |
| 55 to 50                   | 73.08                                      | 23.08 | 3.85    | 100.00 |
| Above 60                   | 100.00                                     | 0.00  | 0.00    | 100.00 |
| Total                      | 61.54                                      | 28.21 | 10.26   | 100.00 |

## Measures of association

### ▷ Example 2

`tabulate` will calculate the Pearson  $\chi^2$  test for the independence of the rows and columns if we specify the `chi2` option. Suppose that we have 1980 census data on 956 cities in the United States and wish to compare the age distribution across regions of the country. Assume that `agecat` is the median age in each city and that `region` denotes the region of the country in which the city is located.

```
. use https://www.stata-press.com/data/r19/citytemp2
(City temperature data)
. tabulate region agecat, chi2
```

| Census<br>region | Age category |       |     | Total |
|------------------|--------------|-------|-----|-------|
|                  | 19-29        | 30-34 | 35+ |       |
| NE               | 46           | 83    | 37  | 166   |
| N Cntrl          | 162          | 92    | 30  | 284   |
| South            | 139          | 68    | 43  | 250   |
| West             | 160          | 73    | 23  | 256   |
| Total            | 507          | 316   | 133 | 956   |

Pearson chi2(6) = 61.2877 Pr = 0.000

We obtain the standard two-way table and, at the bottom, a summary of the  $\chi^2$  test. Stata informs us that the  $\chi^2$  associated with this table has 6 degrees of freedom and is 61.29. The observed differences are significant.

The table is, perhaps, easier to understand if we suppress the frequencies and print just the row percentages:

```
. tabulate region agecat, row nofreq chi2
```

| Census region | Age category |       |       | Total  |
|---------------|--------------|-------|-------|--------|
|               | 19-29        | 30-34 | 35+   |        |
| NE            | 27.71        | 50.00 | 22.29 | 100.00 |
| N Cntrl       | 57.04        | 32.39 | 10.56 | 100.00 |
| South         | 55.60        | 27.20 | 17.20 | 100.00 |
| West          | 62.50        | 28.52 | 8.98  | 100.00 |
| Total         | 53.03        | 33.05 | 13.91 | 100.00 |

Pearson chi2(6) = 61.2877 Pr = 0.000

### ▶ Example 3

We have data on dose level and outcome for a set of patients and wish to evaluate the association between the two variables. We can obtain all the association measures by specifying the `all` and `exact` options:

```
. use https://www.stata-press.com/data/r19/dose
. tabulate dose function, all exact
```

Enumerating sample-space combinations:  
stage 3: enumerations = 1  
stage 2: enumerations = 9  
stage 1: enumerations = 0

| Dosage | Function |        |    | Total |
|--------|----------|--------|----|-------|
|        | < 1 hr   | 1 to 4 | 4+ |       |
| 1/day  | 20       | 10     | 2  | 32    |
| 2/day  | 16       | 12     | 4  | 32    |
| 3/day  | 10       | 16     | 6  | 32    |
| Total  | 46       | 38     | 12 | 96    |

Pearson chi2(4) = 6.7780 Pr = 0.148  
Likelihood-ratio chi2(4) = 6.9844 Pr = 0.137  
Cramér's V = 0.1879  
gamma = 0.3689 ASE = 0.129  
Kendall's tau-b = 0.2378 ASE = 0.086  
Fisher's exact = 0.145

We find evidence of association but not enough to be truly convincing.

If we had not also specified the `exact` option, we would not have obtained Fisher's exact test. Stata can calculate this statistic both for  $2 \times 2$  tables and for  $r \times c$ . For  $2 \times 2$  tables, the calculation is almost instant. On more general tables, however, the calculation can take longer.

We carefully constructed our example so that `all` would be meaningful. Kendall's  $\tau_b$  and Goodman and Kruskal's gamma are relevant only when both dimensions of the table can be ordered, say, from low to high or from worst to best. The other statistics, however, are always applicable.

□ Technical note

Be careful when attempting to compute the  $p$ -value for Fisher’s exact test because the number of tables that contribute to the  $p$ -value can be extremely large and a solution may not be feasible. The errors that are indicative of this situation are errors 910, exceeded memory limitations, and 1401, integer overflow due to large row-margin frequencies. If execution terminates because of memory limitations, use `exact(2)` to permit the algorithm to consume twice the memory, `exact(3)` for three times the memory, etc. The default memory usage should be sufficient for reasonable tables.

**N-way tables**

If you need more than two-way tables, your best alternative to is use `table`, not `tabulate`; see [R] `table`.

The [technical note](#) below shows you how to use `tabulate` to create a sequence of two-way tables that together form, in effect, a three-way table, but using `table` is easy and produces prettier results:

```
. use https://www.stata-press.com/data/r19/birthcat
(City data)
. table (agecat birthcat) (region), nototals
```

|                     | Census region |         |       |      |
|---------------------|---------------|---------|-------|------|
|                     | NE            | N Cntrl | South | West |
| Age category        |               |         |       |      |
| 19-29               |               |         |       |      |
| Birth-rate category |               |         |       |      |
| 29-136              | 11            | 23      | 11    | 11   |
| 137-195             | 31            | 97      | 65    | 46   |
| 196-529             | 4             | 38      | 59    | 91   |
| 30-34               |               |         |       |      |
| Birth-rate category |               |         |       |      |
| 29-136              | 34            | 27      | 10    | 8    |
| 137-195             | 48            | 58      | 45    | 42   |
| 196-529             | 1             | 3       | 12    | 21   |
| 35+                 |               |         |       |      |
| Birth-rate category |               |         |       |      |
| 29-136              | 34            | 26      | 27    | 18   |
| 137-195             | 3             | 4       | 7     | 4    |
| 196-529             |               |         | 4     |      |

□ Technical note

We can make  $n$ -way tables by combining the *by varlist*: prefix with `tabulate`. Continuing with the dataset of 956 cities, say that we want to make a table of age category by birth-rate category by region of the country. The birth-rate category variable is named `birthcat` in our dataset. To make separate tables for each age category, we would type

```
. by agecat, sort: tabulate birthcat region
```

```
-> agecat = 19-29
```

| Birth-rate category | Census region |         |       |      | Total |
|---------------------|---------------|---------|-------|------|-------|
|                     | NE            | N Cntrl | South | West |       |
| 29-136              | 11            | 23      | 11    | 11   | 56    |
| 137-195             | 31            | 97      | 65    | 46   | 239   |
| 196-529             | 4             | 38      | 59    | 91   | 192   |
| Total               | 46            | 158     | 135   | 148  | 487   |

```
-> agecat = 30-34
```

| Birth-rate category | Census region |         |       |      | Total |
|---------------------|---------------|---------|-------|------|-------|
|                     | NE            | N Cntrl | South | West |       |
| 29-136              | 34            | 27      | 10    | 8    | 79    |
| 137-195             | 48            | 58      | 45    | 42   | 193   |
| 196-529             | 1             | 3       | 12    | 21   | 37    |
| Total               | 83            | 88      | 67    | 71   | 309   |

```
-> agecat = 35+
```

| Birth-rate category | Census region |         |       |      | Total |
|---------------------|---------------|---------|-------|------|-------|
|                     | NE            | N Cntrl | South | West |       |
| 29-136              | 34            | 26      | 27    | 18   | 105   |
| 137-195             | 3             | 4       | 7     | 4    | 18    |
| 196-529             | 0             | 0       | 4     | 0    | 4     |
| Total               | 37            | 30      | 38    | 22   | 127   |

## Weighted data

### ▷ Example 4

tabulate can process weighted as well as unweighted data. As with all Stata commands, we indicate the weight by specifying the `[weight]` modifier; see [U] 11.1.6 [weight](#).

Continuing with our dataset of 956 cities, we also have a variable called `pop`, the population of each city. We can make a table of region by age category, weighted by population, by typing

```
. tabulate region agecat [fweight=pop]
```

| Census region | Age category |          |          | Total     |
|---------------|--------------|----------|----------|-----------|
|               | 19-29        | 30-34    | 35+      |           |
| NE            | 4721387      | 10421387 | 5323610  | 20466384  |
| N Cntrl       | 16901550     | 8964756  | 4015593  | 29881899  |
| South         | 13894254     | 7686531  | 4141863  | 25722648  |
| West          | 16698276     | 7755255  | 2375118  | 26828649  |
| Total         | 52215467     | 34827929 | 15856184 | 102899580 |

If we specify the `cell`, `column`, or `row` options, they will also be appropriately weighted. Below, we repeat the table, suppressing the counts and substituting row percentages:

```
. tabulate region agecat [fweight=pop], nofreq row
```

| Census region | Age category |       |       | Total  |
|---------------|--------------|-------|-------|--------|
|               | 19-29        | 30-34 | 35+   |        |
| NE            | 23.07        | 50.92 | 26.01 | 100.00 |
| N Cntrl       | 56.56        | 30.00 | 13.44 | 100.00 |
| South         | 54.02        | 29.88 | 16.10 | 100.00 |
| West          | 62.24        | 28.91 | 8.85  | 100.00 |
| Total         | 50.74        | 33.85 | 15.41 | 100.00 |

## Tables with immediate data

### ▷ Example 5

`tabi` ignores the dataset in memory and uses as the table the values that we specify on the command line:

```
. tabi 30 18 \ 38 14
```

| row   | col |    | Total |
|-------|-----|----|-------|
|       | 1   | 2  |       |
| 1     | 30  | 18 | 48    |
| 2     | 38  | 14 | 52    |
| Total | 68  | 32 | 100   |

Fisher's exact = 0.289  
1-sided Fisher's exact = 0.179

We may specify any of the options of tabulate and are not limited to  $2 \times 2$  tables:

```
. tabi 30 18 38 \ 13 7 22, chi2 exact
```

Enumerating sample-space combinations:

```
stage 3: enumerations = 1
stage 2: enumerations = 3
stage 1: enumerations = 0
```

| row   | col |    |    | Total |
|-------|-----|----|----|-------|
|       | 1   | 2  | 3  |       |
| 1     | 30  | 18 | 38 | 86    |
| 2     | 13  | 7  | 22 | 42    |
| Total | 43  | 25 | 60 | 128   |

```
Pearson chi2(2) = 0.7967 Pr = 0.671
Fisher's exact = 0.707
```

```
. tabi 30 13 \ 18 7 \ 38 22, all exact col
```

|                          |
|--------------------------|
| Key                      |
| <i>frequency</i>         |
| <i>column percentage</i> |

Enumerating sample-space combinations:

```
stage 3: enumerations = 1
stage 2: enumerations = 3
stage 1: enumerations = 0
```

| row   | col          |              | Total         |
|-------|--------------|--------------|---------------|
|       | 1            | 2            |               |
| 1     | 30<br>34.88  | 13<br>30.95  | 43<br>33.59   |
| 2     | 18<br>20.93  | 7<br>16.67   | 25<br>19.53   |
| 3     | 38<br>44.19  | 22<br>52.38  | 60<br>46.88   |
| Total | 86<br>100.00 | 42<br>100.00 | 128<br>100.00 |

```
Pearson chi2(2) = 0.7967 Pr = 0.671
Likelihood-ratio chi2(2) = 0.7985 Pr = 0.671
Cramér's V = 0.0789
gamma = 0.1204 ASE = 0.160
Kendall's tau-b = 0.0630 ASE = 0.084
Fisher's exact = 0.707
```

For  $2 \times 2$  tables, both one- and two-sided Fisher's exact probabilities are displayed; this is true of both tabulate and tabi. See [Cumulative incidence data](#) and [Case-control data](#) in [R] **Epitab** for more discussion on the relationship between one- and two-sided probabilities.

□ Technical note

tabi, as with all immediate commands, leaves any data in memory undisturbed. With the replace option, however, the data in memory are replaced by the data from the table:

```
. tabi 30 18 \ 38 14, replace
```

| row   | col |    | Total |
|-------|-----|----|-------|
|       | 1   | 2  |       |
| 1     | 30  | 18 | 48    |
| 2     | 38  | 14 | 52    |
| Total | 68  | 32 | 100   |

```

 Fisher's exact = 0.289
1-sided Fisher's exact = 0.179
. list
```

|    | row | col | pop |
|----|-----|-----|-----|
| 1. | 1   | 1   | 30  |
| 2. | 1   | 2   | 18  |
| 3. | 2   | 1   | 38  |
| 4. | 2   | 2   | 14  |

With this dataset, you could re-create the above table by typing

```
. tabulate row col [fweight=pop], exact
```

| row   | col |    | Total |
|-------|-----|----|-------|
|       | 1   | 2  |       |
| 1     | 30  | 18 | 48    |
| 2     | 38  | 14 | 52    |
| Total | 68  | 32 | 100   |

```

 Fisher's exact = 0.289
1-sided Fisher's exact = 0.179
```

**tab2**

tab2 is a convenience tool. Typing

```
. tab2 myvar thisvar thatvar, chi2
```

is equivalent to typing

```

. tabulate myvar thisvar, chi2
. tabulate myvar thatvar, chi2
. tabulate thisvar thatvar, chi2
```

## Publish your tables

With the `collect` option, `tabulate` and `tabi` post the tabulated values to a collection named `Tabulate` and set it as the current collection. `tab2` appends the resulting tabulations into a single collection named `Tabulate` and sets it as the current collection. With collections, you can customize the look of your table, then publish it to HTML, Word, L<sup>A</sup>T<sub>E</sub>X, PDF, Excel, or another format appropriate for your report.

The default `collect` layout for `tab2` when the `firstonly` option is not specified produces a table for the first pair of variables. You must specify the corresponding layout to get a table for the other two-way tabulations.

With the `by` prefix, `tabulate` and `tab2` append the resulting tabulations into a single collection, and the default layout produces a separate table for each by group.

If you are not familiar with collections, see [TABLES] [Intro](#). The predefined styles for `tabulate` are documented in [TABLES] [Predefined styles](#).

### ▷ Example 6

Recall the [example](#) where we used the `all` option to show all the supported measures of association. Let's use `tabulate` with the `collect` option to produce a collection with its tabulated values.

```
. tabulate dose function, all exact collect
```

```
Enumerating sample-space combinations:
```

```
stage 3: enumerations = 1
```

```
stage 2: enumerations = 9
```

```
stage 1: enumerations = 0
```

| Dosage | Function |        |    | Total |
|--------|----------|--------|----|-------|
|        | < 1 hr   | 1 to 4 | 4+ |       |
| 1/day  | 20       | 10     | 2  | 32    |
| 2/day  | 16       | 12     | 4  | 32    |
| 3/day  | 10       | 16     | 6  | 32    |
| Total  | 46       | 38     | 12 | 96    |

```
Pearson chi2(4) = 6.7780 Pr = 0.148
```

```
Likelihood-ratio chi2(4) = 6.9844 Pr = 0.137
```

```
Cramér's V = 0.1879
```

```
gamma = 0.3689 ASE = 0.129
```

```
Kendall's tau-b = 0.2378 ASE = 0.086
```

```
Fisher's exact = 0.145
```

The output does not change; however, we can use the `collect dir` command to see that `tabulate` created a collection named `Tabulate`.

```
. collect dir
```

```
Collections in memory
```

```
Current: Tabulate
```

| Name     | No. items |
|----------|-----------|
| Tabulate | 28        |

In this collection, frequencies are tagged with result [frequency]. The tabulated variables (that is, dose and function) are added to the collection as dimensions and are used to tag the collected results. In addition to the names, labels, level values, and value labels of the tabulated variables, these dimensions each have the `__margCode__` level with the Total label for tagging the marginal frequencies. Here we use `collect label list` to show the levels and labels of each tabulated variable dimension.

```
. collect label list dose
 Collection: Tabulate
 Dimension: dose
 Label: Dosage
Level labels:
 1 1/day
 2 2/day
 3 3/day
__margCode__ Total

. collect label list function
 Collection: Tabulate
 Dimension: function
 Label: Function
Level labels:
 1 < 1 hr
 2 1 to 4
 3 4+
__margCode__ Total
```

When measures of association are requested, `tabulate` uses a style that defines composite results for them. Each measure of association has a corresponding composite result that composes it in a single cell of a second table.

| Measure of association         | Option | Composite result  |
|--------------------------------|--------|-------------------|
| Pearson's $\chi^2$             | chi2   | Pearson_ma        |
| Fisher's exact                 | exact  | Fisher_ma         |
| 1-sided Fisher's exact         | exact  | Fisher1_ma        |
| Likelihood ratio               | lr     | LR_ma             |
| Cramér's $V$                   | V      | Cramer_ma         |
| Goodman and Kruskal's $\gamma$ | gamma  | GoodmanKruskal_ma |
| Kendall's $\tau_b$             | taub   | Pearson_ma        |

tabulate constructs a default layout, so you can view your customizable table with the collect preview command. Here we use the collect layout command to report the default layout specification and corresponding table.

```
. collect layout
Collection: Tabulate
 Rows: dose#result result
 Columns: function _overall
 Tables: cmdset#item_type
 Table 1: 5 x 4
 Table 2: 6 x 1
```

|        | Function |        |    | Total |
|--------|----------|--------|----|-------|
|        | < 1 hr   | 1 to 4 | 4+ |       |
| Dosage |          |        |    |       |
| 1/day  | 20       | 10     | 2  | 32    |
| 2/day  | 16       | 12     | 4  | 32    |
| 3/day  | 10       | 16     | 6  | 32    |
| Total  | 46       | 38     | 12 | 96    |

```
Pearson $\chi^2(4) = 6.7780$ Pr = 0.1481
LR $\chi^2(4) = 6.9844$ Pr = 0.1367
Cramér's V = 0.1879
Goodman and Kruskal's $\gamma = 0.3689$ ASE = 0.1287
Kendall's $\tau_b = 0.2378$ ASE = 0.0865
Fisher's exact = 0.1449
```

We can make further changes to the table with the collect suite of commands. But we are happy with this layout and ready to publish the table to an HTML file with collect export. We simply specify the filename to which we want to export it.

```
. collect export tab2.html
(collection Tabulate exported to file tab2.html)
```

With collect export, you can publish the table to several formats, such as HTML, PDF, and L<sup>A</sup>T<sub>E</sub>X files, by specifying the appropriate file extension.

- [Cross-tabulations and chi-squared tests calculator](#)

## Stored results

tabulate, tab2, and tabi store the following in `r()`:

### Scalars

|                          |                                           |                          |                                      |
|--------------------------|-------------------------------------------|--------------------------|--------------------------------------|
| <code>r(N)</code>        | number of observations                    | <code>r(p_exact)</code>  | Fisher's exact $p$                   |
| <code>r(r)</code>        | number of rows                            | <code>r(chi2_lr)</code>  | likelihood-ratio $\chi^2$            |
| <code>r(c)</code>        | number of columns                         | <code>r(p_lr)</code>     | $p$ -value for likelihood-ratio test |
| <code>r(chi2)</code>     | Pearson's $\chi^2$ test                   | <code>r(CramersV)</code> | Cramér's $V$                         |
| <code>r(p)</code>        | $p$ -value for of Pearson's $\chi^2$ test | <code>r(ase_gam)</code>  | ASE of gamma                         |
| <code>r(gamma)</code>    | gamma                                     | <code>r(ase_taub)</code> | ASE of $\tau_b$                      |
| <code>r(p1_exact)</code> | one-sided Fisher's exact $p$              | <code>r(taub)</code>     | $\tau_b$                             |

### Macros

`r(collection)` name of collection

`r(p1_exact)` is defined only for  $2 \times 2$  tables. `r(collection)` is defined only when the `collect()` option is specified. Also, the `matrow()`, `matcol()`, and `matcell()` options allow you to obtain the row values, column values, and frequencies, respectively.

## Methods and formulas

Let  $n_{ij}$ ,  $i = 1, \dots, I$  and  $j = 1, \dots, J$ , be the number of observations in the  $i$ th row and  $j$ th column. If the data are not weighted,  $n_{ij}$  is just a count. If the data are weighted,  $n_{ij}$  is the sum of the weights of all data corresponding to the  $(i, j)$  cell.

Define the row and column marginals as

$$n_{i.} = \sum_{j=1}^J n_{ij} \qquad n_{.j} = \sum_{i=1}^I n_{ij}$$

and let  $n = \sum_i \sum_j n_{ij}$  be the overall sum. Also, define the concordance and discordance as

$$A_{ij} = \sum_{k>i} \sum_{l>j} n_{kl} + \sum_{k<i} \sum_{l<j} n_{kl} \qquad D_{ij} = \sum_{k>i} \sum_{l<j} n_{kl} + \sum_{k<i} \sum_{l>j} n_{kl}$$

along with twice the number of concordances  $P = \sum_i \sum_j n_{ij} A_{ij}$  and twice the number of discordances  $Q = \sum_i \sum_j n_{ij} D_{ij}$ .

The Pearson  $\chi^2$  statistic with  $(I - 1)(J - 1)$  degrees of freedom (so called because it is based on [Pearson \(1900\)](#); see [Conover \[1999, 240\]](#) and [Fienberg \[1980, 9\]](#)) is defined as

$$X^2 = \sum_i \sum_j \frac{(n_{ij} - m_{ij})^2}{m_{ij}}$$

where  $m_{ij} = n_{i.} n_{.j} / n$ .

The likelihood-ratio  $\chi^2$  statistic with  $(I - 1)(J - 1)$  degrees of freedom ([Fienberg 1980, 40](#)) is defined as

$$G^2 = 2 \sum_i \sum_j n_{ij} \ln(n_{ij} / m_{ij})$$

Cramér's  $V$  ([Cramér 1946](#)) is a measure of association designed so that the attainable upper bound is 1. For  $2 \times 2$  tables,  $-1 \leq V \leq 1$ , and otherwise,  $0 \leq V \leq 1$ .

$$V = \begin{cases} (n_{11}n_{22} - n_{12}n_{21}) / (n_{1.}n_{.2}n_{.1}n_{2.})^{1/2} & \text{for } 2 \times 2 \\ \{(X^2/n) / \min(I - 1, J - 1)\}^{1/2} & \text{otherwise} \end{cases}$$

Gamma (Goodman and Kruskal 1954, 1959, 1963, 1972; also see Agresti [2010,186–188]) ignores tied pairs and is based only on the number of concordant and discordant pairs of observations,  $-1 \leq \gamma \leq 1$ ,

$$\gamma = (P - Q)/(P + Q)$$

with asymptotic variance

$$16 \sum_i \sum_j n_{ij} (QA_{ij} - PD_{ij})^2 / (P + Q)^4$$

Kendall's  $\tau_b$  (Kendall 1945; also see Agresti 2010, 188–189),  $-1 \leq \tau_b \leq 1$ , is similar to gamma, except that it uses a correction for ties,

$$\tau_b = (P - Q)/(w_r w_c)^{1/2}$$

with asymptotic variance

$$\frac{\sum_i \sum_j n_{ij} (2w_r w_c d_{ij} + \tau_b v_{ij})^2 - n^3 \tau_b^2 (w_r + w_c)^2}{(w_r w_c)^4}$$

where

$$\begin{aligned} w_r &= n^2 - \sum_i n_i^2 \\ w_c &= n^2 - \sum_j n_j^2 \\ d_{ij} &= A_{ij} - D_{ij} \\ v_{ij} &= n_i \cdot w_c + n_j \cdot w_r \end{aligned}$$

Fisher's exact test (Fisher 1935; Finney 1948; see Zelterman and Louis [1992, 293–301] for the  $2 \times 2$  case) yields the probability of observing a table that gives at least as much evidence of association as the one actually observed under the assumption of no association. Holding row and column marginals fixed, the hypergeometric probability  $P$  of every possible table  $A$  is computed, and the

$$P = \sum_{T \in A} \Pr(T)$$

where  $A$  is the set of all tables with the same marginals as the observed table,  $T^*$ , such that  $\Pr(T) \leq \Pr(T^*)$ . For  $2 \times 2$  tables, the one-sided probability is calculated by further restricting  $A$  to tables in the same tail as  $T^*$ . The first algorithm extending this calculation to  $r \times c$  tables was Pagano and Halvorsen (1981); the one implemented here is the FEXACT algorithm by Mehta and Patel (1986). This is a search-tree clipping method originally published by Mehta and Patel (1983) with further refinements by Joe (1988) and Clarkson, Fan, and Joe (1993). Fisher's exact test is a permutation test. For more information on permutation tests, see Good (2005 and 2006) and Pesarin (2001).

## Description

`tabulate`, `summarize()` produces one- and two-way tables (breakdowns) of means and standard deviations. See [R] [tabulate oneway](#) and [R] [tabulate twoway](#) for one- and two-way frequency tables. See [R] [table](#) for a more flexible command that produces one-, two-, and  $n$ -way tables of frequencies and a wide variety of summary statistics. `table` is better, but `tabulate`, `summarize()` is faster. Also see [R] [tabstat](#) for yet another alternative.

## Quick start

Tabulation of `v1`, reporting means and standard deviations of `x` and frequencies

```
tabulate v1, summarize(x)
```

Same as above, but report summary statistics for the two-way tabulation of `v1` and `v2`

```
tabulate v1 v2, summarize(x)
```

Weighted summary statistics using frequency weight `wvar`

```
tabulate v1 v2 [fweight=wvar], summarize(x)
```

Report only the mean of `x` for each group

```
tabulate v1 v2, summarize(x) means
```

Do not report standard deviations

```
tabulate v1 v2, summarize(x) nostandard
```

Show numeric values of `v1` and `v2` rather than value labels

```
tabulate v1 v2, summarize(x) nolabel
```

## Menu

Statistics > Summaries, tables, and tests > Other tables > Table of means, std. dev., and frequencies

## Syntax

```
tabulate varname1 [varname2] [if'] [in] [weight] [, options]
```

*options*

by is allowed; see [U] 11.1.10 Prefix commands.

aweights and fweights are allowed; see [U] 11.1.6 weight.

## Options

Main

`summarize(varname3)` identifies the name of the variable for which summary statistics are to be reported. If you do not specify this option, a table of frequencies is produced; see [R] [tabulate oneway](#) and [R] [tabulate twoway](#). The description here concerns `tabulate` when this option is specified.

`[no]means` includes or suppresses only the means from the table.

The `summarize()` table normally includes the mean, standard deviation, frequency, and, if the data are weighted, number of observations. Individual elements of the table may be included or suppressed by the `[no]means`, `[no]standard`, `[no]freq`, and `[no]obs` options. For example, typing

```
. tabulate category, summarize(myvar) means standard
```

produces a summary table by category containing only the means and standard deviations of `myvar`. You could also achieve the same result by typing

```
. tabulate category, summarize(myvar) nofreq
```

`[no]standard` includes or suppresses only the standard deviations from the table; see `[no]means` option above.

[no]freq includes or suppresses only the frequencies from the table; see [no]means option above.

[no]obs includes or suppresses only the reported number of observations from the table. If the data are not weighted, the number of observations is identical to the frequency, and by default only the frequency is reported. If the data are weighted, the frequency refers to the sum of the weights. See [no]means option above.

noLabel causes the numeric codes to be displayed rather than the label values.

wrap requests that no action be taken on wide tables to make them readable. Unless wrap is specified, wide tables are broken into pieces to enhance readability.

missing requests that missing values of *varname*<sub>1</sub> and *varname*<sub>2</sub> be treated as categories rather than as observations to be omitted from the analysis.

### Collect

collect and collect(*[cname]*[, *collect\_options*]) specify that results be posted to a collection. This collection produces a table that you can customize and publish to Microsoft Word, Microsoft Excel, PDF, HTML, L<sup>A</sup>T<sub>E</sub>X, SMCL, or Markdown. Output does not change when these options are specified. Use collect preview to see the customizable table.

collect is a shortcut for collect(Tabulate).

*cname* specifies that a collection named *cname* be associated with the collected results. The default is Tabulate.

append specifies that results be appended to collection *cname*.

replace permits tabulate to overwrite an existing collection. This option is implied for collection Tabulate when append is not specified.

label(*filename*) specifies the *filename* containing the collection labels to use for your table. Labels in *filename* will be loaded into the collection, and any labels not specified in *filename* will be taken from the labels defined in c(collect\_label). The default is to use only the collection labels set in c(collect\_label); see [TABLES] set collect\_label.

style(*filename*[, *override*]) specifies the *filename* containing the collection styles to use for your table. The default collection styles will be discarded, and only the collection styles in *filename* will be applied.

If you prefer the default collection styles but also want to apply any styles in *filename*, specify *override*. If there are conflicts between the default collection styles and those in *filename*, the ones in *filename* will take precedence.

The default is to use only the collection styles set in c(tabulate\_style); see [TABLES] set tabulate\_style.

## Remarks and examples

tabulate with the summarize() option produces one- and two-way tables of summary statistics. When combined with the by prefix, it can produce *n*-way tables as well.

Remarks are presented under the following headings:

- One-way tables*
- Two-way tables*
- Publish your tables*

## One-way tables

### ▷ Example 1

We have data on 74 automobiles. Included in our dataset are the variables `foreign`, which marks domestic and foreign cars, and `mpg`, the car's mileage rating. Typing `tabulate foreign` displays a breakdown of the number of observations we have by the values of the `foreign` variable.

```
. use https://www.stata-press.com/data/r19/auto
(1978 automobile data)
```

```
. tabulate foreign
```

| Car origin | Freq. | Percent | Cum.   |
|------------|-------|---------|--------|
| Domestic   | 52    | 70.27   | 70.27  |
| Foreign    | 22    | 29.73   | 100.00 |
| Total      | 74    | 100.00  |        |

We discover that we have 52 domestic cars and 22 foreign cars in our dataset. If we add the `summarize(varname)` option, however, `tabulate` produces a table of summary statistics for `varname`:

```
. tabulate foreign, summarize(mpg)
```

| Car origin | Summary of Mileage (mpg) |           | Freq. |
|------------|--------------------------|-----------|-------|
|            | Mean                     | Std. dev. |       |
| Domestic   | 19.826923                | 4.7432972 | 52    |
| Foreign    | 24.772727                | 6.6111869 | 22    |
| Total      | 21.297297                | 5.7855032 | 74    |

We also discover that the average gas mileage for domestic cars is about 20 mpg and the average foreign is almost 25 mpg. Overall, the average is 21 mpg in our dataset.

□ Technical note

We might now wonder if the difference in gas mileage between foreign and domestic cars is statistically significant. We can use the `oneway` command to find out; see [R] [oneway](#). To obtain an analysis-of-variance table of `mpg` on `foreign`, we type

```
. oneway mpg foreign
```

| Source         | Analysis of variance |    |            | F     | Prob > F |
|----------------|----------------------|----|------------|-------|----------|
|                | SS                   | df | MS         |       |          |
| Between groups | 378.153515           | 1  | 378.153515 | 13.18 | 0.0005   |
| Within groups  | 2065.30594           | 72 | 28.6848048 |       |          |
| Total          | 2443.45946           | 73 | 33.4720474 |       |          |

Bartlett's equal-variances test:  $\chi^2(1) = 3.4818$      $\text{Prob} > \chi^2 = 0.062$

The  $F$  statistic is 13.18, and the difference between foreign and domestic cars' mileage ratings is significant at the 0.05% level.

There are several ways that we could have statistically compared mileage ratings—see, for instance, [R] [anova](#), [R] [oneway](#), [R] [regress](#), and [R] [ttest](#)—but `oneway` seemed the most convenient.

## Two-way tables

▷ Example 2

`tabulate`, `summarize` can be used to obtain two-way as well as one-way breakdowns. For instance, we obtained summary statistics on `mpg` decomposed by `foreign` by typing `tabulate foreign, summarize(mpg)`. We can specify up to two variables before the comma:

```
. generate wgtcat = autocode(weight,4,1760,4840)
. tabulate wgtcat foreign, summarize(mpg)
```

Means, Standard Deviations and Frequencies of Mileage (mpg)

| wgtcat | Car origin |           | Total     |
|--------|------------|-----------|-----------|
|        | Domestic   | Foreign   |           |
| 2530   | 28.285714  | 27.0625   | 27.434783 |
|        | 3.0937725  | 5.9829619 | 5.2295149 |
|        | 7          | 16        | 23        |
| 3300   | 21.75      | 19.6      | 21.238095 |
|        | 2.4083189  | 3.4351128 | 2.7550819 |
|        | 16         | 5         | 21        |
| 4070   | 17.26087   | 14        | 17.125    |
|        | 1.8639497  | 0         | 1.9406969 |
|        | 23         | 1         | 24        |
| 4840   | 14.666667  | .         | 14.666667 |
|        | 3.32666    | .         | 3.32666   |
|        | 6          | 0         | 6         |
| Total  | 19.826923  | 24.772727 | 21.297297 |
|        | 4.7432972  | 6.6111869 | 5.7855032 |
|        | 52         | 22        | 74        |

In addition to the means, standard deviations, and frequencies for each weight–mileage cell, also reported are the summary statistics by weight, by mileage, and overall. For instance, the last row of the table reveals that the average mileage of domestic cars is 19.83 and that of foreign cars is 24.77—domestic cars yield poorer mileage than foreign cars. But we now see that domestic cars yield better gas mileage within weight class—the reason domestic cars yield poorer gas mileage is because they are, on average, heavier.

### ▷ Example 3

If we do not specify the statistics to be included in a table, `tabulate` reports the mean, standard deviation, and frequency. We can specify the statistics that we want to see using the `means`, `standard`, and `freq` options:

```
. tabulate wgtcat foreign, summarize(mpg) means
 Means of Mileage (mpg)
```

| wgtcat | Car origin |           | Total     |
|--------|------------|-----------|-----------|
|        | Domestic   | Foreign   |           |
| 2530   | 28.285714  | 27.0625   | 27.434783 |
| 3300   | 21.75      | 19.6      | 21.238095 |
| 4070   | 17.26087   | 14        | 17.125    |
| 4840   | 14.666667  | .         | 14.666667 |
| Total  | 19.826923  | 24.772727 | 21.297297 |

When we specify one or more of the `means`, `standard`, and `freq` options, only those statistics are displayed. Thus, we could obtain a table containing just the means and standard deviations by typing `means standard` after the `summarize(mpg)` option. We can also suppress selected statistics by placing `no` in front of the option name. Another way of obtaining only the means and standard deviations is to add the `nofreq` option:

```
. tabulate wgtcat foreign, summarize(mpg) nofreq
 Means and Standard Deviations of Mileage (mpg)
```

| wgtcat | Car origin |           | Total     |
|--------|------------|-----------|-----------|
|        | Domestic   | Foreign   |           |
| 2530   | 28.285714  | 27.0625   | 27.434783 |
|        | 3.0937725  | 5.9829619 | 5.2295149 |
| 3300   | 21.75      | 19.6      | 21.238095 |
|        | 2.4083189  | 3.4351128 | 2.7550819 |
| 4070   | 17.26087   | 14        | 17.125    |
|        | 1.8639497  | 0         | 1.9406969 |
| 4840   | 14.666667  | .         | 14.666667 |
|        | 3.32666    | .         | 3.32666   |
| Total  | 19.826923  | 24.772727 | 21.297297 |
|        | 4.7432972  | 6.6111869 | 5.7855032 |

## Publish your tables

With the `collect` option, `tabulate` posts the tabulated values to a collection named `Tabulate` and sets it as the current collection. With collections, you can customize the look of your table, then publish it to HTML, Word, L<sup>A</sup>T<sub>E</sub>X, PDF, Excel, or another format appropriate for your report.

With the `by` prefix, `tabulate` appends the resulting tabulations into a single collection, and the default layout produces a separate table for each by group.

If you are not familiar with collections, see [TABLES] [Intro](#). The predefined styles for `tabulate` are documented in [TABLES] [Predefined styles](#).

### ▷ Example 4

Recall our table from the [previous example](#). Let's add the `collect` option in the call to `tabulate` to produce a collection with its tabulated values.

```
. tabulate wgtcat foreign, summarize(mpg) collect
 Means, Standard Deviations and Frequencies of Mileage (mpg)
```

| wgtcat | Car origin |           | Total     |
|--------|------------|-----------|-----------|
|        | Domestic   | Foreign   |           |
| 2530   | 28.285714  | 27.0625   | 27.434783 |
|        | 3.0937725  | 5.9829619 | 5.2295149 |
|        | 7          | 16        | 23        |
| 3300   | 21.75      | 19.6      | 21.238095 |
|        | 2.4083189  | 3.4351128 | 2.7550819 |
|        | 16         | 5         | 21        |
| 4070   | 17.26087   | 14        | 17.125    |
|        | 1.8639497  | 0         | 1.9406969 |
|        | 23         | 1         | 24        |
| 4840   | 14.666667  | .         | 14.666667 |
|        | 3.32666    | .         | 3.32666   |
|        | 6          | 0         | 6         |
| Total  | 19.826923  | 24.772727 | 21.297297 |
|        | 4.7432972  | 6.6111869 | 5.7855032 |
|        | 52         | 22        | 74        |

The output does not change; however, we can use the `collect dir` command to see that `tabulate` created a collection named `Tabulate`.

```
. collect dir
Collections in memory
Current: Tabulate
```

| Name     | No. items |
|----------|-----------|
| Table    | 51        |
| Tabulate | 45        |

In this collection, means are tagged with `result[mean]`, standard deviations with `result[sd]`, and frequencies with `result[frequency]`. When weights are specified, observation counts are tagged with `result[count]`. Here we use `collect label list` to show the levels and labels of the result dimension.

```
. collect label list result
Collection: Tabulate
Dimension: result
Label: Result
Level labels:
 frequency Frequency
 mean Mean
 sd Std. dev.
```

The tabulated variables (that is, `wgtpcat` and `foreign`) are added to the collection as dimensions and are used to tag the collected results. In addition to the name, label, level values, and value labels of the tabulated variables, these dimensions each have the `__margCode__` level with the Total label for tagging the marginal summary statistics. Here we use `collect label list` to show the levels and labels of each tabulated variable dimension. For `wgtpcat`, we add the `all` option to show the levels without labels.

```
. collect label list wgtpcat, all
Collection: Tabulate
Dimension: wgtpcat
Label:
Level labels:
 2530
 3300
 4070
 4840
__margCode__ Total
. collect label list foreign
Collection: Tabulate
Dimension: foreign
Label: Car origin
Level labels:
 0 Domestic
 1 Foreign
__margCode__ Total
```

tabulate constructs a default layout, so you can view your customizable table with the collect preview command. Here we use the collect layout command to report the default layout specification and corresponding table.

```
. collect layout
Collection: Tabulate
 Rows: wgtcat#result
 Columns: var#foreign
 Tables: cmdset
Table 1: 21 x 3
```

|           | Mileage (mpg) |         |       |
|-----------|---------------|---------|-------|
|           | Car origin    |         |       |
|           | Domestic      | Foreign | Total |
| wgtcat    |               |         |       |
| 2530      |               |         |       |
| Mean      | 28.3          | 27.1    | 27.4  |
| Std. dev. | 3.1           | 6.0     | 5.2   |
| Frequency | 7             | 16      | 23    |
| 3300      |               |         |       |
| Mean      | 21.8          | 19.6    | 21.2  |
| Std. dev. | 2.4           | 3.4     | 2.8   |
| Frequency | 16            | 5       | 21    |
| 4070      |               |         |       |
| Mean      | 17.3          | 14.0    | 17.1  |
| Std. dev. | 1.9           | 0.0     | 1.9   |
| Frequency | 23            | 1       | 24    |
| 4840      |               |         |       |
| Mean      | 14.7          | .       | 14.7  |
| Std. dev. | 3.3           | .       | 3.3   |
| Frequency | 6             | 0       | 6     |
| Total     |               |         |       |
| Mean      | 19.8          | 24.8    | 21.3  |
| Std. dev. | 4.7           | 6.6     | 5.8   |
| Frequency | 52            | 22      | 74    |

We now change some cell formats, remove the summary statistic labels from the row header, and add a note suggesting the table's cell contents.

```
. collect style cell result[mean], nformat(%9.2f)
. collect style cell result[sd], nformat(%9.2f) sformat("(%s)")
. collect style header result, level(hide)
. collect note "Mean (SD) N"
. collect preview
```

|        | Mileage (mpg)   |                 |                 |
|--------|-----------------|-----------------|-----------------|
|        | Car origin      |                 |                 |
|        | Domestic        | Foreign         | Total           |
| wgtcat |                 |                 |                 |
| 2530   | 28.29<br>(3.09) | 27.06<br>(5.98) | 27.43<br>(5.23) |
|        | 7               | 16              | 23              |
| 3300   | 21.75<br>(2.41) | 19.60<br>(3.44) | 21.24<br>(2.76) |
|        | 16              | 5               | 21              |
| 4070   | 17.26<br>(1.86) | 14.00<br>(0.00) | 17.12<br>(1.94) |
|        | 23              | 1               | 24              |
| 4840   | 14.67<br>(3.33) | .<br>(.)        | 14.67<br>(3.33) |
|        | 6               | 0               | 6               |
| Total  | 19.83<br>(4.74) | 24.77<br>(6.61) | 21.30<br>(5.79) |
|        | 52              | 22              | 74              |

Mean (SD) N

We can make further changes to the table with the `collect` suite of commands. But we are happy with this layout and ready to publish the table to a  $\LaTeX$  file with `collect export`. We simply specify the filename to which we want to export it.

```
. collect export tab2.tex
(collection Tabulate exported to file tab2.tex)
```

With `collect export`, you can publish the table to several formats, such as HTML, PDF, and  $\LaTeX$  files, by specifying the appropriate file extension.

## Description

`test` performs Wald tests of simple and composite linear hypotheses about the parameters of the most recently fit model.

`test` supports `svy` estimators (see [SVY] [svy estimation](#)), carrying out an adjusted Wald test by default in such cases. `test` can be used with `svy` estimation results, see [SVY] [svy postestimation](#).

`testparm` provides a useful alternative to `test` that permits *varlist* rather than a list of coefficients (which is often nothing more than a list of variables), allowing the use of standard Stata notation, including ‘-’ and ‘\*’, which are given the expression interpretation by `test`.

`test` and `testparm` perform Wald tests. For likelihood-ratio tests, see [R] [lrtest](#). For Wald-type tests of nonlinear hypotheses, see [R] [testnl](#). To display estimates for one-dimensional linear or nonlinear expressions of coefficients, see [R] [lincom](#) and [R] [nlcom](#).

See [R] [anova postestimation](#) for additional `test` syntax allowed after `anova`.

See [MV] [manova postestimation](#) for additional `test` syntax allowed after `manova`.

## Quick start

*Linear tests after single-equation models*

Joint test that the coefficients on `x1` and `x2` are equal to 0

```
test x1 x2
```

Joint test that coefficients on [factor indicators](#) `2.a` and `3.a` are equal to 0

```
test 2.a 3.a
```

Test that coefficients on indicators `2.a` and `3.a` are equal

```
test 2.a = 3.a
```

Joint test that coefficients on indicators `1.a`, `2.a`, and `3.a` are all equal

```
test (1.a=2.a) (1.a=3.a)
```

Same as above

```
test 1.a=2.a=3.a
```

Same as above, but add separate tests for each pairing

```
test 1.a=2.a=3.a, mtest
```

Same as above, but with *p*-values adjusted for multiple comparisons using Šidák’s method

```
test (1.a=2.a) (1.a=3.a), mtest(sidak)
```

Test that the sum of the coefficients for  $x_1$  and  $x_2$  is equal to 4

```
test x1 + x2 = 4
```

Test the equality of two linear expressions involving coefficients on  $x_1$  and  $x_2$

```
test 2*x1 = 3*x2
```

### *Shorthand varlist notation*

Joint test that all coefficients on the indicators for  $a$  are equal to 0

```
testparm i.a
```

Joint test that all coefficients on the indicators for  $a$  and  $b$  are equal to 0

```
testparm i.a i.b
```

Joint test that all coefficients associated with the interaction of factor variables  $a$  and  $b$  are equal to 0

```
testparm i.a#i.b
```

Joint test that the coefficients on all variables  $x^*$  are equal to 0

```
testparm x*
```

### *Linear tests after multiple-equation models*

Joint test that the coefficient on  $x_1$  is equal to 0 in all equations

```
test x1
```

Joint test that the coefficients for  $x_1$  and  $x_2$  are equal to 0 in equation  $y_3$

```
test [y3]x1 [y3]x2
```

Test that the coefficients for  $x_1$  are equal in equations  $y_1$  and  $y_3$

```
test [y1]x1=[y3]x1
```

Same as above

```
test [y1=y3]: x1
```

Joint test of the equality of coefficients for  $x_1$  and  $x_2$  across equations  $y_1$  and  $y_3$

```
test [y1=y3]: x1 x2
```

Add coefficients for  $x_1$  and  $x_2$  from equation  $y_4$  to test

```
test [y1=y3=y4]: x1 x2
```

Test that all coefficients in the equation for  $y_1$  are equal to those in the equation for  $y_2$

```
test [y1=y2]
```

Same as above, but only for coefficients on variables common to both equations

```
test [y1=y2], common
```

*Shorthand varlist notation*

Joint test that all coefficients on the indicators for a are 0 in all equations

testparm i.a

Joint test that all coefficients on the indicators for a are equal to each other in the first equation

testparm i.a, equal

Same as above, but for the equation for y4

testparm i.a, equal equation(y4)

Joint test that the coefficients on the indicators for a and b are equal to 0 in all equations

testparm i.a i.b

Joint test that all coefficients associated with the interaction of factors a and b are 0

testparm i.a#i.b

`test` *exp=exp*[*=...*] (Syntax 2)

`test` [*eqno*] [: *coeflist*] (Syntax 3)

`test` [*eqno=eqno*[*=...*]] [: *coeflist*] (Syntax 4)

`testparm` *varlist* [, *testparm\_options*]

### Full syntax

`test` (*spec*) [(*spec*) ...] [, *test\_options*]

| <i>testparm_options</i>            | Description                                                                                                                                                                                                              |
|------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>equal</code>                 | hypothesize that the coefficients are equal to each other                                                                                                                                                                |
| <code>equation(<i>eqno</i>)</code> | specify equation name or number for which the hypothesis is tested                                                                                                                                                       |
| <code>nosvyadjust</code>           | compute unadjusted Wald tests for survey results                                                                                                                                                                         |
| <code>df(#)</code>                 | use $F$ distribution with # denominator degrees of freedom for the reference distribution of the test statistic; for survey data, # specifies the design degrees of freedom unless <code>nosvyadjust</code> is specified |

`df(#)` does not appear in the dialog box.

| <i>test_options</i>                 | Description                                                                                                                                                                                                              |
|-------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Options                             |                                                                                                                                                                                                                          |
| <code>mtest(<i>opt</i>)</code>      | test each condition separately                                                                                                                                                                                           |
| <code>coef</code>                   | report estimated constrained coefficients                                                                                                                                                                                |
| <code>accumulate</code>             | test hypothesis jointly with previously tested hypotheses                                                                                                                                                                |
| <code>notest</code>                 | suppress the output                                                                                                                                                                                                      |
| <code>common</code>                 | test only variables common to all the equations                                                                                                                                                                          |
| <code>constant</code>               | include the constant in coefficients to be tested                                                                                                                                                                        |
| <code>nosvyadjust</code>            | compute unadjusted Wald tests for survey results                                                                                                                                                                         |
| <code>minimum</code>                | perform test with the constant, drop terms until the test becomes nonsingular, and test without the constant on the remaining terms; highly technical                                                                    |
| <code>matvlc(<i>matname</i>)</code> | save the variance–covariance matrix; programmer’s option                                                                                                                                                                 |
| <code>df(#)</code>                  | use $F$ distribution with # denominator degrees of freedom for the reference distribution of the test statistic; for survey data, # specifies the design degrees of freedom unless <code>nosvyadjust</code> is specified |

`matvlc(matname)` and `df(#)` do not appear in the dialog box.

*coeflist* and *varlist* may contain factor variables and time-series operators; see [U] 11.4.3 Factor variables and [U] 11.4.4 Time-series varlists.

`collect` is allowed with `test`; see [U] 11.1.10 Prefix commands.

Syntax 1 tests that coefficients are 0.

Syntax 2 tests that linear expressions are equal.

Syntax 3 tests that coefficients in *eqno* are 0.

Syntax 4 tests equality of coefficients between equations.

*spec* is one of

```
coeflist
exp=exp [=exp]
[eqno] [: coeflist]
[eqno1=eqno2 [=...]] [: coeflist]
```

*coeflist* is

```
coef [coef ...]
[eqno]coef [[eqno]coef ...]
[eqno] _b [coef] [[eqno] _b [coef] ...]
```

*exp* is a linear expression containing

```
coef
_b [coef]
_b [eqno : coef]
[eqno]coef
[eqno] _b [coef]
```

*eqno* is

```
##
name
```

*coef* identifies a coefficient in the model. *coef* is typically a variable name, a level indicator, an interaction indicator, or an interaction involving continuous variables. Level indicators identify one level of a factor variable and interaction indicators identify one combination of levels of an interaction; see [\[U\] 11.4.3 Factor variables](#). *coef* may contain time-series operators; see [\[U\] 11.4.4 Time-series varlists](#).

Distinguish between `[]`, which are to be typed, and `[]`, which indicate optional arguments.

Although not shown in the syntax diagram, parentheses around *spec* are required only with multiple specifications. Also, the diagram does not show that `test` may be called without arguments to redisplay the results from the last test.

`anova` and `manova` (see [\[R\] anova](#) and [\[MV\] manova](#)) allow the `test` syntax above plus more (see [\[R\] anova postestimation](#) for `test` after `anova`; see [\[MV\] manova postestimation](#) for `test` after `manova`).

## Options for testparm

`equal` tests that the variables appearing in `varlist`, which also appear in the previously fit model, are equal to each other rather than jointly equal to zero.

`equation` (`eqno`) is relevant only for multiple-equation models, such as `mvreg`, `mlogit`, and `heckman`. It specifies the equation for which the all-zero or all-equal hypothesis is tested. `equation(#1)` specifies that the test be conducted regarding the first equation #1. `equation(price)` specifies that the test concern the equation named `price`.

`nosvyadjust` is for use with `svy` estimation commands; see [SVY] [svy estimation](#). It specifies that the Wald test be carried out without the default adjustment for the design degrees of freedom. That is, the test is carried out as  $W/k \sim F(k, d)$  rather than as  $(d - k + 1)W/(kd) \sim F(k, d - k + 1)$ , where  $k$  = the dimension of the test and  $d$  = the total number of sampled PSUs minus the total number of strata. When the `df()` option is used, it will override the default design degrees of freedom.

The following option is available with `testparm` but is not shown in the dialog box:

`df(#)` specifies that the  $F$  distribution with # denominator degrees of freedom be used for the reference distribution of the test statistic. The default is to use `e(df_r)` degrees of freedom or the  $\chi^2$  distribution if `e(df_r)` is missing. With survey data, # is the design degrees of freedom unless `nosvyadjust` is specified.

## Options for test

### Options

`mtest` [`opt`] specifies that tests be performed for each condition separately. `opt` specifies the method for adjusting  $p$ -values for multiple testing. Valid values for `opt` are

|                         |                             |
|-------------------------|-----------------------------|
| <code>bonferroni</code> | Bonferroni's method         |
| <code>holm</code>       | Holm's method               |
| <code>sidak</code>      | Šidák's method              |
| <code>noadjust</code>   | no adjustment is to be made |

Specifying `mtest` without an argument is equivalent to `mtest(noadjust)`.

`coef` specifies that the constrained coefficients be displayed.

`accumulate` allows a hypothesis to be tested jointly with the previously tested hypotheses.

`notest` suppresses the output. This option is useful when you are interested only in the joint test of several hypotheses, specified in a subsequent call of `test`, `accumulate`.

`common` specifies that when you use the `[eqno1=eqno2[=. . .]]` form of `spec`, the variables common to the equations `eqno1`, `eqno2`, etc., be tested. The default action is to complain if the equations have variables not in common.

`constant` specifies that `_cons` be included in the list of coefficients to be tested when using the `[eqno1=eqno2[=. . .]]` or `[eqno]` forms of `spec`. The default is not to include `_cons`.

`nosvyadjust` is for use with `svy` estimation commands; see [SVY] [svy estimation](#). It specifies that the Wald test be carried out without the default adjustment for the design degrees of freedom. That is, the test is carried out as  $W/k \sim F(k, d)$  rather than as  $(d - k + 1)W/(kd) \sim F(k, d - k + 1)$ , where  $k$  = the dimension of the test and  $d$  = the total number of sampled PSUs minus the total number of strata. When the `df()` option is used, it will override the default design degrees of freedom.

`minimum` is a highly technical option. It first performs the test with the constant added. If this test is singular, coefficients are dropped until the test becomes nonsingular. Then the test without the constant is performed with the remaining terms.

The following options are available with `test` but are not shown in the dialog box:

`matv1c(matname)`, a programmer's option, saves the variance–covariance matrix of the linear combinations involved in the suite of tests. For the test of the linear constraints  $Lb = c$ , `matname` contains  $LVL'$ , where  $V$  is the estimated variance–covariance matrix of  $b$ .

`df(#)` specifies that the  $F$  distribution with # denominator degrees of freedom be used for the reference distribution of the test statistic. The default is to use `e(df_r)` degrees of freedom or the  $\chi^2$  distribution if `e(df_r)` is missing. With survey data, # is the design degrees of freedom unless `nosvyadjust` is specified.

## Remarks and examples

Remarks are presented under the following headings:

[Introductory examples](#)

[Special syntaxes after multiple-equation estimation](#)

[Constrained coefficients](#)

[Multiple testing](#)

## Introductory examples

`test` performs  $F$  or  $\chi^2$  tests of linear restrictions applied to the most recently fit model (for example, `regress` or `svy: regress` in the linear regression case; `logit`, `stcox`, `svy: logit`, ... in the single-equation maximum-likelihood case; and `mlogit`, `mvreg`, `streg`, ... in the multiple-equation maximum-likelihood case). `test` may be used after *any* estimation command, although for maximum likelihood techniques, `test` produces a Wald test that depends only on the estimate of the covariance matrix—you may prefer to use the more computationally expensive likelihood-ratio test; see [U] [20 Estimation and postestimation commands](#) and [R] [lrtest](#).

There are several variations on the syntax for `test`. The second syntax,

```
test exp=exp[=...]
```

is allowed after any form of estimation. After fitting a model of `devar` on `x1`, `x2`, and `x3`, typing `test x1+x2=x3` tests the restriction that the coefficients on `x1` and `x2` sum to the coefficient on `x3`. The expressions can be arbitrarily complicated; for instance, typing `test x1+2*(x2+x3)=x2+3*x3` is the same as typing `test x1+x2=x3`.

As a convenient shorthand, `test` also allows you to specify equality for multiple expressions; for example, `test x1+x2 = x3+x4 = x5+x6` tests that the three specified pairwise sums of coefficients are equal.

`test` understands that when you type `x1`, you are referring to the coefficient on `x1`. You could also more explicitly type `test _b[x1]+_b[x2]=_b[x3]`; or you could `test _coef[x1]+_coef[x2]=_coef[x3]`, or `test [#1]x1+[#1]x2=[#1]x3`, or many other things because there is more than one way to refer to an estimated coefficient; see [U] 13.5 **Accessing coefficients and standard errors**. The shorthand involves less typing. On the other hand, you must be more explicit after estimation of multiple-equation models because there may be more than one coefficient associated with an independent variable. You might type, for instance, `test [#2]x1+[#2]x2=[#2]x3` to test the constraint in equation 2 or, more readably, `test [ford]x1+[ford]x2=[ford]x3`, meaning that Stata will test the constraint on the equation corresponding to `ford`, which might be equation 2. `ford` would be an equation name after, say, `sureg`, or, after `mlogit`, `ford` would be one of the outcomes. For `mlogit`, you could also type `test [2]x1+[2]x2=[2]x3`—note the lack of the `#`—meaning not equation 2, but the equation corresponding to the numeric outcome 2. You can even test constraints across equations: `test [ford]x1+[ford]x2=[buick]x3`.

The syntax

```
test coeflist
```

is available after all estimation commands and is a convenient way to test that multiple coefficients are zero following estimation. A *coeflist* can simply be a list of variable names,

```
test varname [varname ...]
```

and it is most often specified that way. After you have fit a model of `depvar` on `x1`, `x2`, and `x3`, typing `test x1 x3` tests that the coefficients on `x1` and `x3` are jointly zero. After multiple-equation estimation, this would test that the coefficients on `x1` and `x3` are zero in all equations that contain them. You can also be more explicit and type, for instance, `test [ford]x1 [ford]x3` to test that the coefficients on `x1` and `x3` are zero in the equation for `ford`.

In the multiple-equation case, there are more alternatives. You could also test that the coefficients on `x1` and `x3` are zero in the equation for `ford` by typing `test [ford]: x1 x3`. You could test that all coefficients except the coefficient on the constant are zero in the equation for `ford` by typing `test [ford]`. You could test that the coefficients on `x1` and `x3` in the equation for `ford` are equal to the corresponding coefficients in the equation corresponding to `buick` by typing `test [ford=buick]: x1 x3`. You could test that all the corresponding coefficients except the constant in three equations are equal by typing `test [ford=buick=volvo]`.

`testparm` is much like the first syntax of `test`. Its usefulness will be demonstrated below.

The examples below use `regress`, but what is said applies equally after any single-equation estimation command (such as `logistic`). It also applies after multiple-equation estimation commands as long as references to coefficients are qualified with an equation name or number in square brackets placed before them. The convenient syntaxes for dealing with tests of many coefficients in multiple-equation models are demonstrated in *Special syntaxes after multiple-equation estimation* below.

## ▷ Example 1: Testing for a single coefficient against zero

We have 1980 census data on the 50 states recording the birth rate in each state (`brate`), the median age (`medage`), and the region of the country in which each state is located.

The `region` variable is 1 if the state is in the Northeast, 2 if the state is in the North Central, 3 if the state is in the South, and 4 if the state is in the West. We estimate the following regression:

```
. use https://www.stata-press.com/data/r19/census3
(1980 Census data by state)
. regress brate medage c.medage#c.medage i.region
```

| Source   | SS         | df | MS         | Number of obs | = | 50     |
|----------|------------|----|------------|---------------|---|--------|
| Model    | 38803.4208 | 5  | 7760.68416 | F(5, 44)      | = | 100.63 |
| Residual | 3393.39921 | 44 | 77.1227094 | Prob > F      | = | 0.0000 |
|          |            |    |            | R-squared     | = | 0.9196 |
|          |            |    |            | Adj R-squared | = | 0.9104 |
| Total    | 42196.82   | 49 | 861.159592 | Root MSE      | = | 8.782  |

|                        | Coefficient | Std. err. | t     | P> t  | [95% conf. interval] |           |
|------------------------|-------------|-----------|-------|-------|----------------------|-----------|
| <code>brate</code>     |             |           |       |       |                      |           |
| <code>medage</code>    | -109.0958   | 13.52452  | -8.07 | 0.000 | -136.3527            | -81.83892 |
| <code>c.medage#</code> |             |           |       |       |                      |           |
| <code>c.medage</code>  | 1.635209    | .2290536  | 7.14  | 0.000 | 1.173582             | 2.096836  |
| <code>region</code>    |             |           |       |       |                      |           |
| <code>NCentral</code>  | 15.00283    | 4.252067  | 3.53  | 0.001 | 6.433353             | 23.57231  |
| <code>South</code>     | 7.366445    | 3.953335  | 1.86  | 0.069 | -.6009775            | 15.33387  |
| <code>West</code>      | 21.39679    | 4.650601  | 4.60  | 0.000 | 12.02412             | 30.76946  |
| <code>_cons</code>     | 1947.611    | 199.8405  | 9.75  | 0.000 | 1544.859             | 2350.363  |

`test` can now be used to perform a variety of statistical tests. Specify the `coeflegend` option with your estimation command to see a legend of the coefficients and how to specify them; see [R] [Estimation options](#). We can test the hypothesis that the coefficient on `3.region` is zero by typing

```
. test 3.region=0
(1) 3.region = 0
 F(1, 44) = 3.47
 Prob > F = 0.0691
```

The  $F$  statistic with 1 numerator and 44 denominator degrees of freedom is 3.47. The significance level of the test is 6.91%—we can reject the hypothesis at the 10% level but not at the 5% level.

This result from `test` is identical to one presented in the output from `regress`, which indicates that the  $t$  statistic on the `3.region` coefficient is 1.863 and that its significance level is 0.069. The  $t$  statistic presented in the output can be used to test the hypothesis that the corresponding coefficient is zero, although it states the test in slightly different terms. The  $F$  distribution with 1 numerator degree of freedom is, however, identical to the  $t^2$  distribution. We note that  $1.863^2 \approx 3.47$  and that the significance levels in each test agree, although one extra digit is presented by the `test` command.

## □ Technical note

After all estimation commands, including those that use the maximum likelihood method, the test that one variable is zero is identical to that reported by the command's output. The tests are performed in the same way—using the estimated covariance matrix—and are known as Wald tests. If the estimation command reports significance levels and confidence intervals using  $z$  rather than  $t$  statistics, test reports results using the  $\chi^2$  rather than the  $F$  statistic. □

## ▷ Example 2: Testing the value of a single coefficient

If that were all test could do, it would be useless. We can use test, however, to perform other tests. For instance, we can test the hypothesis that the coefficient on 2.region is 21 by typing

```
. test 2.region=21
(1) 2.region = 21
 F(1, 44) = 1.99
 Prob > F = 0.1654
```

We find that we cannot reject that hypothesis, or at least we cannot reject it at any significance level below 16.5%. ◀

## ▷ Example 3: Testing the equality of two coefficients

The previous test is useful, but we could almost as easily perform it by hand using the results presented in the regression output if we were well read on our statistics. We could type

```
. display Ftail(1,44,((_coef[2.region]-21)/4.252068)^2)
.16544873
```

So, now let's test something a bit more difficult: whether the coefficient on 2.region is the same as the coefficient on 4.region:

```
. test 2.region=4.region
(1) 2.region - 4.region = 0
 F(1, 44) = 2.84
 Prob > F = 0.0989
```

We find that we cannot reject the equality hypothesis at the 5% level, but we can at the 10% level. ◀

### ▷ Example 4

When we tested the equality of the `2.region` and `4.region` coefficients, Stata rearranged our algebra. When Stata displayed its interpretation of the specified test, it indicated that we were testing whether `2.region minus 4.region` is zero. The rearrangement is innocuous and, in fact, allows Stata to perform much more complicated algebra, for instance,

```
. test 2*(2.region-3*(3.region-4.region))=3.region+2.region+6*(4.region-3.region)
(1) 2.region - 3.region = 0
 F(1, 44) = 5.06
 Prob > F = 0.0295
```

Although we requested what appeared to be a lengthy hypothesis, once Stata simplified the algebra, it realized that all we wanted to do was test whether the coefficient on `2.region` is the same as the coefficient on `3.region`.

### □ Technical note

Stata's ability to simplify and test complex hypotheses is limited to *linear* hypotheses. If you attempt to test a nonlinear hypothesis, you will be told that it is not possible:

```
. test 2.region/3.region=2.region+3.region
not possible with test
r(131);
```

To test a nonlinear hypothesis, see [R] [testnl](#).

### ▷ Example 5: Testing joint hypotheses

The real power of `test` is demonstrated when we test *joint* hypotheses. Perhaps we wish to test whether the region variables, taken as a whole, are significant by testing whether the coefficients on `2.region`, `3.region`, and `4.region` are simultaneously zero. `test` allows us to specify multiple conditions to be tested, each embedded within parentheses.

```
. test (2.region=0) (3.region=0) (4.region=0)
(1) 2.region = 0
(2) 3.region = 0
(3) 4.region = 0
 F(3, 44) = 8.85
 Prob > F = 0.0001
```

`test` displays the set of conditions and reports an  $F$  statistic of 8.85. `test` also reports the degrees of freedom of the test to be 3, the “dimension” of the hypothesis, and the residual degrees of freedom, 44. The significance level of the test is close to 0, so we can strongly reject the hypothesis of no difference between the regions.

An alternative method to specify simultaneous hypotheses uses the convenient shorthand of conditions with multiple equality operators.

```
. test 2.region=3.region=4.region=0
(1) 2.region - 3.region = 0
(2) 2.region - 4.region = 0
(3) 2.region = 0
 F(3, 44) = 8.85
 Prob > F = 0.0001
```

## □ Technical note

Another method to test simultaneous hypotheses is to specify a test for each constraint and accumulate it with the previous constraints:

```
. test 2.region=0
(1) 2.region = 0
 F(1, 44) = 12.45
 Prob > F = 0.0010

. test 3.region=0, accumulate
(1) 2.region = 0
(2) 3.region = 0
 F(2, 44) = 6.42
 Prob > F = 0.0036

. test 4.region=0, accumulate
(1) 2.region = 0
(2) 3.region = 0
(3) 4.region = 0
 F(3, 44) = 8.85
 Prob > F = 0.0001
```

We tested the hypothesis that the coefficient on `2.region` was zero by typing `test 2.region=0`. We then tested whether the coefficient on `3.region` was also zero by typing `test 3.region=0, accumulate`. The `accumulate` option told Stata that this was not the start of a new test but a continuation of a previous one. Stata responded by showing us the two equations and reporting an  $F$  statistic of 6.42. The significance level associated with those two coefficients being zero is 0.36%.

When we added the last constraint `test 4.region=0, accumulate`, we discovered that the three region variables are significant. If all we wanted was the overall significance and we did not want to bother seeing the interim results, we could have used the `notest` option:

```
. test 2.region=0, notest
(1) 2.region = 0

. test 3.region=0, accumulate notest
(1) 2.region = 0
(2) 3.region = 0

. test 4.region=0, accumulate
(1) 2.region = 0
(2) 3.region = 0
(3) 4.region = 0
 F(3, 44) = 8.85
 Prob > F = 0.0001
```

### ▷ Example 6: Quickly testing coefficients against zero

Because tests that coefficients are zero are so common in applied statistics, the `test` command has a more convenient syntax to accommodate this case:

```
. test 2.region 3.region 4.region
(1) 2.region = 0
(2) 3.region = 0
(3) 4.region = 0
 F(3, 44) = 8.85
 Prob > F = 0.0001
```

### ▷ Example 7: Specifying varlists

We will now show how to use `testparm`. In its first syntax, `test` accepts a list of variable names but not *varlist*.

```
. test i(2/4).region
i not found
r(111);
```

In the varlist, `i(2/4).region` means all the level variables from `2.region` through `4.region`, yet we received an error. `test` does not actually understand varlists, but `testparm` does. In fact, it understands only varlists.

```
. testparm i(2/4).region
(1) 2.region = 0
(2) 3.region = 0
(3) 4.region = 0
 F(3, 44) = 8.85
 Prob > F = 0.0001
```

Another way to test all the `region` variables is to type `testparm i.region`.

That `testparm` accepts varlists has other advantages that do not involve factor variables. Suppose that we have a dataset that has dummy variables `reg2`, `reg3`, and `reg4`, rather than the categorical variable `region`.

```
. use https://www.stata-press.com/data/r19/census4
(Census data on birthrate, median age)
. regress brate medage c.medage#c.medage reg2 reg3 reg4
(output omitted)
. test reg2-reg4
- not found
r(111);
```

In a varlist, `reg2-reg4` means variables `reg2` and `reg4` and all the variables between, yet we received an error. `test` is confused because the `-` has two meanings: it means subtraction in an expression and “through” in *varlist*. Similarly, `*` means “any set of characters” in *varlist* and multiplication in an expression. `testparm` avoids this confusion—it allows only *varlist*.

```
. testparm reg2-reg4
(1) reg2 = 0
(2) reg3 = 0
(3) reg4 = 0
 F(3, 44) = 8.85
 Prob > F = 0.0001
```

testparm has another advantage. We have five variables in our dataset that start with the characters reg: region, reg1, reg2, reg3, and reg4. reg\* thus means those five variables:

```
. describe reg*
Variable Storage Display Value
 name type format label Variable label

region byte %8.0g region Census region
reg1 byte %9.0g Region: NE Region: NE
reg2 byte %9.0g Region: N Cntrl Region: N Cntrl
reg3 byte %9.0g Region: South Region: South
reg4 byte %9.0g Region: West Region: West
```

We cannot type test reg\* because, in an expression, '\*' means multiplication, but here is what would happen if we attempted to test all the variables that begin with reg:

```
. test region reg1 reg2 reg3 reg4
region not found
r(111);
```

The variable region was not included in our model, so it was not found. However, with testparm,

```
. testparm reg*
(1) reg2 = 0
(2) reg3 = 0
(3) reg4 = 0
 F(3, 44) = 8.85
 Prob > F = 0.0001
```

That is, testparm took reg\* to mean all variables that start with reg that were in our model.

## □ Technical note

Actually, reg\* means what it always does—all variables in our dataset that begin with reg—in this case, region reg1 reg2 reg3 reg4. testparm just ignores any variables you specify that are not in the model.

### ▷ Example 8: Replaying the previous test

We just used `test` (`testparm`, actually, but it does not matter) to test the hypothesis that `reg2`, `reg3`, and `reg4` are jointly zero. We can review the results of our last test by typing `test` without arguments:

```
. test
(1) reg2 = 0
(2) reg3 = 0
(3) reg4 = 0
 F(3, 44) = 8.85
 Prob > F = 0.0001
```

◀

### □ Technical note

`test` does not care how we build joint hypotheses; we may freely mix different forms of syntax. (We can even start with `testparm`, but we cannot use it thereafter because it does not have an `accumulate` option.)

Say that we type `test reg2 reg3 reg4` to test that the coefficients on our region dummies are jointly zero. We could then add a fourth constraint, say, that `medage = 100`, by typing `test medage=100, accumulate`. Or, if we had introduced the `medage` constraint first (our first `test` command had been `test medage=100`), we could then add the region dummy test by typing `test reg2 reg3 reg4, accumulate` or `test (reg2=0) (reg3=0) (reg4=0), accumulate`.

Remember that all previous tests are cleared when we do not specify the `accumulate` option. No matter what tests we performed in the past, if we type `test medage c.medage#c.medage`, omitting the `accumulate` option, we would test that `medage` and `c.medage#c.medage` are jointly zero.

□

### ▷ Example 9: Testing the equality of multiple coefficients

Let's return to our `census3.dta` dataset and test the hypothesis that all the included regions have the same coefficient—that the Northeast is significantly different from the rest of the nation:

```
. use https://www.stata-press.com/data/r19/census3
(1980 Census data by state)
. regress brate medage c.medage#c.medage i.region
(output omitted)
. test 2.region=3.region=4.region
(1) 2.region - 3.region = 0
(2) 2.region - 4.region = 0
 F(2, 44) = 8.23
 Prob > F = 0.0009
```

We find that they are not all the same. The syntax `2.region=3.region=4.region` with `multiple =` operators is just a convenient shorthand for typing that the first expression equals the second expression and that the first expression equals the third expression,

```
. test (2.region=3.region) (2.region=4.region)
```

We performed the test for equality of the three regions by imposing two constraints: region 2 has the same coefficient as region 3, and region 2 has the same coefficient as region 4. Alternatively, we could have tested that the coefficients on regions 2 and 3 are the same and that the coefficients on regions 3 and 4 are the same. We would obtain the same results in either case.

To test for equality of the three regions, we might, likely by mistake, type equality constraints for *all* pairs of regions:

```
. test (2.region=3.region) (2.region=4.region) (3.region=4.region)
(1) 2.region - 3.region = 0
(2) 2.region - 4.region = 0
(3) 3.region - 4.region = 0
 Constraint 3 dropped
 F(2, 44) = 8.23
 Prob > F = 0.0009
```

Equality of regions 2 and 3 and of regions 2 and 4, however, implies equality of regions 3 and 4. `test` recognized that the last constraint is implied by the other constraints and hence dropped it.

◀

### □ Technical note

Generally, Stata uses `=` for assignment, as in `gen newvar = exp`, and `==` as the operator for testing equality in expressions. For your convenience, `test` allows both `=` and `==` to be used.

□

### ▷ Example 10

The test for the equality of the regions is also possible with the `testparm` command. When we include the `equal` option, `testparm` tests that the coefficients of all the variables specified are equal:

```
. testparm i(2/4).region, equal
(1) - 2.region + 3.region = 0
(2) - 2.region + 4.region = 0
 F(2, 44) = 8.23
 Prob > F = 0.0009
```

We can also obtain the equality test by accumulating single equality tests.

```
. test 2.region=3.region, notest
(1) 2.region - 3.region = 0
. test 2.region=4.region, accum
(1) 2.region - 3.region = 0
(2) 2.region - 4.region = 0
 F(2, 44) = 8.23
 Prob > F = 0.0009
```

◀

## □ Technical note

If we specify a set of inconsistent constraints, `test` will tell us by dropping the constraint or constraints that led to the inconsistency. For instance, let's `test` that the coefficients on `region 2` and `region 4` are the same, add the test that the coefficient on `region 2` is 20, and finally add the test that the coefficient on `region 4` is 21:

```
. test (2.region=4.region) (2.region=20) (4.region=21)
(1) 2.region - 4.region = 0
(2) 2.region = 20
(3) 4.region = 21
 Constraint 2 dropped
 F(2, 44) = 1.82
 Prob > F = 0.1737
```

`test` informed us that it was dropping constraint 2. All three equations cannot be simultaneously true, so `test` drops whatever it takes to get back to something that makes sense.

□

## Special syntaxes after multiple-equation estimation

Everything said above about tests after single-equation estimation applies to tests after multiple-equation estimation, as long as you remember to specify the equation name. To demonstrate, let's estimate a seemingly unrelated regression by using `sureg`; see [R] [sureg](#).

```
. use https://www.stata-press.com/data/r19/auto
(1978 automobile data)
. sureg (price foreign mpg displ) (weight foreign length)
Seemingly unrelated regression
```

| Equation | Obs | Params | RMSE     | "R-squared" | chi2   | P>chi2 |
|----------|-----|--------|----------|-------------|--------|--------|
| price    | 74  | 3      | 2165.321 | 0.4537      | 49.64  | 0.0000 |
| weight   | 74  | 2      | 245.2916 | 0.8990      | 661.84 | 0.0000 |

|              | Coefficient | Std. err. | z     | P> z  | [95% conf. interval] |
|--------------|-------------|-----------|-------|-------|----------------------|
| price        |             |           |       |       |                      |
| foreign      | 3058.25     | 685.7357  | 4.46  | 0.000 | 1714.233 4402.267    |
| mpg          | -104.9591   | 58.47209  | -1.80 | 0.073 | -219.5623 9.644042   |
| displacement | 18.18098    | 4.286372  | 4.24  | 0.000 | 9.779842 26.58211    |
| _cons        | 3904.336    | 1966.521  | 1.99  | 0.047 | 50.0263 7758.645     |
| weight       |             |           |       |       |                      |
| foreign      | -147.3481   | 75.44314  | -1.95 | 0.051 | -295.2139 .517755    |
| length       | 30.94905    | 1.539895  | 20.10 | 0.000 | 27.93091 33.96718    |
| _cons        | -2753.064   | 303.9336  | -9.06 | 0.000 | -3348.763 -2157.365  |

To test the significance of `foreign` in the price equation, we could type

```
. test [price]foreign
(1) [price]foreign = 0
 chi2(1) = 19.89
 Prob > chi2 = 0.0000
```

which is the same result reported by `sureg`:  $4.460^2 \approx 19.89$ . To test `foreign` in both equations, we could type

```
. test [price]foreign [weight]foreign
(1) [price]foreign = 0
(2) [weight]foreign = 0
 chi2(2) = 31.61
 Prob > chi2 = 0.0000
```

or

```
. test foreign
(1) [price]foreign = 0
(2) [weight]foreign = 0
 chi2(2) = 31.61
 Prob > chi2 = 0.0000
```

This last syntax—typing the variable name by itself—tests the coefficients in all equations in which they appear. The variable length appears in only the `weight` equation, so typing

```
. test length
(1) [weight]length = 0
 chi2(1) = 403.94
 Prob > chi2 = 0.0000
```

yields the same result as typing `test [weight]length`. We may also specify a linear expression rather than a list of coefficients:

```
. test mpg=displ
(1) [price]mpg - [price]displacement = 0
 chi2(1) = 4.85
 Prob > chi2 = 0.0277
```

or

```
. test [price]mpg = [price]displ
(1) [price]mpg - [price]displacement = 0
 chi2(1) = 4.85
 Prob > chi2 = 0.0277
```

A variation on this syntax can be used to test cross-equation constraints:

```
. test [price]foreign = [weight]foreign
(1) [price]foreign - [weight]foreign = 0
 chi2(1) = 23.07
 Prob > chi2 = 0.0000
```

Typing an equation name in square brackets by itself tests all the coefficients except the intercept in that equation:

```
. test [price]
(1) [price]foreign = 0
(2) [price]mpg = 0
(3) [price]displacement = 0
 chi2(3) = 49.64
 Prob > chi2 = 0.0000
```

Typing an equation name in square brackets, a colon, and a list of variable names tests those variables in the specified equation:

```
. test [price]: foreign displ
(1) [price]foreign = 0
(2) [price]displacement = 0
 chi2(2) = 25.19
 Prob > chi2 = 0.0000
```

`test [eqname1=eqname2]` tests that all the coefficients in the two equations are equal. We cannot use that syntax here because there are different variables in the model:

```
. test [price=weight]
variables differ between equations
(to test equality of coefficients in common, specify option common)
r(111);
```

The common option specifies a test of the equality coefficients common to the equations price and weight,

```
. test [price=weight], common
(1) [price]foreign - [weight]foreign = 0
 chi2(1) = 23.07
 Prob > chi2 = 0.0000
```

By default, `test` does not include the constant, the coefficient of the constant variable `_cons`, in the test. The `cons` option specifies that the constant be included.

```
. test [price=weight], common cons
(1) [price]foreign - [weight]foreign = 0
(2) [price]_cons - [weight]_cons = 0
 chi2(2) = 51.23
 Prob > chi2 = 0.0000
```

We can also use a modification of this syntax with the model if we also type a colon and the names of the variables we want to test:

```
. test [price=weight]: foreign
(1) [price]foreign - [weight]foreign = 0
 chi2(1) = 23.07
 Prob > chi2 = 0.0000
```

We have only one variable in common between the two equations, but if there had been more, we could have listed them.

Finally, a simultaneous test of multiple constraints may be specified just as after single-equation estimation.

```
. test ([price]: foreign) ([weight]: foreign)
(1) [price]foreign = 0
(2) [weight]foreign = 0
 chi2(2) = 31.61
 Prob > chi2 = 0.0000
```

`test` can also test for equality of coefficients across more than two equations. For instance, `test [eq1=eq2=eq3]` specifies a test that the coefficients in the three equations `eq1`, `eq2`, and `eq3` are equal. This requires that the same variables be included in the three equations. If some variables are entered only in some of the equations, you can type `test [eq1=eq2=eq3]`, `common` to test that the coefficients of the variables common to all three equations are equal. Alternatively, you can explicitly list the variables for which equality of coefficients across the equations is to be tested. For instance, `test [eq1=eq2=eq3]: time money` tests that the coefficients of the variables `time` and `money` do not differ between the equations.

### □ Technical note

`test [eq1=eq2=eq3]`, `common` tests the equality of the coefficients common to all equations, but it does *not* test the equality of all common coefficients. Consider the case where

|                  |                                                    |
|------------------|----------------------------------------------------|
| <code>eq1</code> | contains the variables <code>var1 var2 var3</code> |
| <code>eq2</code> | contains the variables <code>var1 var2 var4</code> |
| <code>eq3</code> | contains the variables <code>var1 var3 var4</code> |

Obviously, only `var1` is common to all three equations. Thus `test [eq1=eq2=eq3]`, `common` tests that the coefficients of `var1` do not vary across the equations, so it is equivalent to `test [eq1=eq2=eq3]: var1`. To perform a test of the coefficients of variables common to two equations, you could explicitly list the constraints to be tested,

```
. test ([eq1=eq2=eq3]:var1) ([eq1=eq2]:var2) ([eq1=eq3]:var3) ([eq2=eq3]:var4)
```

or use `test` with the `accumulate` option, and maybe also with the `notest` option, to form the appropriate joint hypothesis:

```
. test [eq1=eq2], common notest
. test [eq1=eq3], common accumulate notest
. test [eq2=eq3], common accumulate
```

□

## Constrained coefficients

If the test indicates that the data do not allow you to conclude that the constraints are not satisfied, you may want to inspect the constrained coefficients. The `coef` option specified that the constrained results, estimated by GLS, are shown.

```
. test [price=weight], common coef
(1) [price]foreign - [weight]foreign = 0
 chi2(1) = 23.07
 Prob > chi2 = 0.0000
```

Constrained coefficients

|               | Coefficient | Std. err. | z     | P> z  | [95% conf. interval] |           |
|---------------|-------------|-----------|-------|-------|----------------------|-----------|
| <b>price</b>  |             |           |       |       |                      |           |
| foreign       | -216.4015   | 74.06083  | -2.92 | 0.003 | -361.558             | -71.2449  |
| mpg           | -121.5717   | 58.36972  | -2.08 | 0.037 | -235.9742            | -7.169116 |
| displacement  | 7.632566    | 3.681114  | 2.07  | 0.038 | .4177148             | 14.84742  |
| _cons         | 7312.856    | 1834.034  | 3.99  | 0.000 | 3718.215             | 10907.5   |
| <b>weight</b> |             |           |       |       |                      |           |
| foreign       | -216.4015   | 74.06083  | -2.92 | 0.003 | -361.558             | -71.2449  |
| length        | 30.34875    | 1.534815  | 19.77 | 0.000 | 27.34057             | 33.35693  |
| _cons         | -2619.719   | 302.6632  | -8.66 | 0.000 | -3212.928            | -2026.51  |

The constrained coefficient of `foreign` is  $-216.40$  with standard error  $74.06$  in equations `price` and `weight`. The other coefficients and their standard errors are affected by imposing the equality constraint of the two coefficients of `foreign` because the unconstrained estimates of these two coefficients were correlated with the estimates of the other coefficients.

### □ Technical note

The two-step constrained coefficients  $b_c$  displayed by `test`, `coef` are asymptotically equivalent to the one-stage constrained estimates that are computed by specifying the constraints during estimation using the `constraint()` option of estimation commands (Gouriéroux and Monfort 1995, chap. 10). Generally, one-step constrained estimates have better small-sample properties. For inspection and interpretation, however, two-step constrained estimates are a convenient alternative. Moreover, some estimation commands (for example, `stcox`, many `xt` estimators) do not have a `constraint()` option.

□

## Multiple testing

When performing the test of a joint hypothesis, you might want to inspect the underlying 1-degree-of-freedom hypotheses. Which constraint “is to blame”? `test` displays the univariate as well as the simultaneous test if the `mtest` option is specified. For example,

```
. test [price=weight], common cons mtest
(1) [price]foreign - [weight]foreign = 0
(2) [price]_cons - [weight]_cons = 0
```

|     | chi2  | df | p > chi2 |
|-----|-------|----|----------|
| (1) | 23.07 | 1  | 0.0000*  |
| (2) | 11.17 | 1  | 0.0008*  |
| All | 51.23 | 2  | 0.0000   |

\* Unadjusted *p*-values

Both coefficients seem to contribute to the highly significant result. The 1-degree-of-freedom test shown here is identical to those if `test` had been invoked to test just this simple hypotheses. There is, of course, a real risk in inspecting these simple hypotheses. Especially in high-dimensional hypotheses, you may easily find one hypothesis that happens to be significant. Multiple testing procedures are designed to provide some safeguard against this risk. *p*-values of the univariate hypotheses are modified so that the probability of falsely rejecting one of the null hypotheses is bounded. `test` provides the methods based on Bonferroni, Šidák, and Holm.

```
. test [price=weight], common cons mtest(b)
(1) [price]foreign - [weight]foreign = 0
(2) [price]_cons - [weight]_cons = 0
```

|     | chi2  | df | p > chi2 |
|-----|-------|----|----------|
| (1) | 23.07 | 1  | 0.0000*  |
| (2) | 11.17 | 1  | 0.0017*  |
| All | 51.23 | 2  | 0.0000   |

\* Bonferroni-adjusted *p*-values

## Stored results

`test` and `testparm` store the following in `r()`:

### Scalars

|                           |                                         |                      |                                            |
|---------------------------|-----------------------------------------|----------------------|--------------------------------------------|
| <code>r(p)</code>         | two-sided <i>p</i> -value               | <code>r(chi2)</code> | $\chi^2$                                   |

|-------------------------|-------------------------------------------|

### Matrices

|                       |                       |
|-----------------------|-----------------------|
| <code>r(mtest)</code> | multiple test results |
|-----------------------|-----------------------|

`r(ss)` and `r(rss)` are defined only when `test` is used for testing effects after anova.

## Methods and formulas

`test` and `testparm` perform Wald tests. Let the estimated coefficient vector be  $\mathbf{b}$  and the estimated variance–covariance matrix be  $\mathbf{V}$ . Let  $\mathbf{Rb} = \mathbf{r}$  denote the set of  $q$  linear hypotheses to be tested jointly.

The Wald test statistic is (Judge et al. 1985, 20–28)

$$W = (\mathbf{Rb} - \mathbf{r})'(\mathbf{RVR}')^{-1}(\mathbf{Rb} - \mathbf{r})$$

If the estimation command reports its significance levels using  $Z$  statistics, a  $\chi^2$  distribution with  $q$  degrees of freedom,

$$W \sim \chi_q^2$$

is used for computation of the significance level of the hypothesis test.

If the estimation command reports its significance levels using  $t$  statistics with  $d$  degrees of freedom, an  $F$  statistic,

$$F = \frac{1}{q}W$$

is computed, and an  $F$  distribution with  $q$  numerator degrees of freedom and  $d$  denominator degrees of freedom computes the significance level of the hypothesis test.

The two-step constrained estimates  $b_c$  displayed by `test` with the `coef` option are the GLS estimates of the unconstrained estimates  $b$  subject to the specified constraints  $Rb = c$  (Gouriéroux and Monfort 1995, chap. 10),

$$\mathbf{b}_c = \mathbf{b} - \mathbf{VR}'(\mathbf{RVR}')^{-1}(\mathbf{Rb} - \mathbf{r})$$

with variance–covariance matrix

$$\mathbf{V}_c = \mathbf{V} - \mathbf{VR}'(\mathbf{RVR}')^{-1}\mathbf{RV}$$

If `test` displays a Wald test for joint (simultaneous) hypotheses, it can also display all 1-degree-of-freedom tests, with  $p$ -values adjusted for multiple testing. Let  $p_1, p_2, \dots, p_k$  be the unadjusted  $p$ -values of these 1-degree-of-freedom tests. The Bonferroni-adjusted  $p$ -values are defined as  $p_i^b = \min(1, kp_i)$ . The Šidák-adjusted  $p$ -values are  $p_i^s = 1 - (1 - p_i)^k$ . Let  $p_{(1)}, p_{(2)}, \dots, p_{(k)}$  be the ordered unadjusted  $p$ -values. The Holm's method adjusted  $p$ -values are then defined by

$$p_{(i)}^h = \max_{j \leq i} [\min\{1, (k - j + 1)p_{(j)}\}]$$

If `test` is used after a `svy` command, it carries out an adjusted Wald test—this adjustment should not be confused with the adjustment for multiple testing. Both adjustments may actually be combined. Specifically, the survey adjustment uses an approximate  $F$  statistic  $(d - k + 1)W/(kd)$ , where  $W$  is the Wald test statistic,  $k$  is the dimension of the hypothesis test, and  $d$  = the total number of sampled PSUs minus the total number of strata. Under the null hypothesis,  $(d - k + 1)F/(kd) \sim F(k, d - k + 1)$ , where  $F(k, d - k + 1)$  is an  $F$  distribution with  $k$  numerator degrees of freedom and  $d - k + 1$  denominator degrees of freedom. If `nosvyadjust` is specified, the  $p$ -value is computed using  $W/k \sim F(k, d)$ .

See Korn and Graubard (1990) for a detailed description of the Bonferroni adjustment technique and for a discussion of the relative merits of it and of the adjusted and unadjusted Wald tests.

## Acknowledgment

The svy adjustment code was adopted from another command developed in collaboration with John L. Eltinge of the United States Census Bureau.

## Description

`testnl` tests (linear or nonlinear) hypotheses about the estimated parameters from the most recently fit model.

`testnl` produces Wald-type tests of smooth nonlinear (or linear) hypotheses about the estimated parameters from the most recently fit model. The  $p$ -values are based on the delta method, an approximation appropriate in large samples.

`testnl` can be used with `svy` estimation results; see [\[SVY\] svy postestimation](#).

The format  $(exp_1=exp_2=exp_3\dots)$  for a simultaneous-equality hypothesis is just a convenient shorthand for a list  $(exp_1=exp_2)$   $(exp_1=exp_3)$ , etc.

`testnl` may also be used to test linear hypotheses. `test` is faster if you want to test only linear hypotheses; see [\[R\] test](#). `testnl` is the only option for testing linear and nonlinear hypotheses simultaneously.

## Quick start

*After single-equation models*

Test that the product of the coefficients for `x1` and `x2` is equal to 4

```
testnl _b[x1]*_b[x2] = 4
```

Test that the ratio of the indicators for the [factor variable](#) `a = 2` and `a = 3` is 1

```
testnl _b[2.a]/_b[3.a] = 1
```

Test that an expression involving continuous [factor variable](#) syntax is equal to 16

```
testnl _b[x1]/(2*_b[c.x1#c.x1]) = 16
```

Test the equality of two expressions

```
testnl _b[x1]*_b[x2] = _b[x1]*_b[x3]
```

Joint test that two products are both equal to 2

```
testnl (_b[x1]*_b[x2] = 2) (_b[x1]*_b[x3] = 2)
```

Same as above

```
testnl _b[x1]*_b[x2] = _b[x1]*_b[x3] = 2
```

Same as above, but add separate tests for each expression

```
testnl _b[x1]*_b[x2] = _b[x1]*_b[x3] = 2, mtest
```

Same as above, but adjust  $p$ -values for multiple comparisons using Holm's method

```
testnl _b[x1]*_b[x2] = _b[x1]*_b[x3] = 2, mtest(holm)
```

Test a linear hypothesis and a nonlinear hypothesis together

```
testnl (_b[x1] = _b[x2]) (_b[x2]^2 = _b[x3])
```

*After multiple-equation models*

Test that the product of the coefficients for  $x_1$  and  $x_2$  in the equation for  $y_1$  is equal to 1

```
testnl _b[y1:x1]*_b[y1:x2] = 1
```

Test that the product of the coefficients for  $x_1$  and  $x_2$  in the equation for  $y_2$  is equal to 1

```
testnl _b[y2:x1]*_b[y2:x2] = 1
```

Test the equality of expressions involving coefficients from the equations for  $y_1$  and  $y_4$

```
testnl _b[y1:x1]*_b[y1:x2] = _b[y4:x1]*_b[y4:x2]
```

## Menu

Statistics > Postestimation

## Syntax

```
testnl exp = exp [= exp ...] [, options]
```

```
testnl (exp = exp [= exp ...]) [(exp = exp [= exp ...]) ...] [, options]
```

| <i>options</i>                 | Description                                                                                                                                           |
|--------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>mtest(<i>opt</i>)</code> | test each condition separately                                                                                                                        |
| <code>iterate(#)</code>        | use maximum # of iterations to find the optimal step size                                                                                             |
| <code>df(#)</code>             | use $F$ distribution with # denominator degrees of freedom for the reference distribution of the test statistic                                       |
| <code>nosvyadjust</code>       | carry out the Wald test as $W/k \sim F(k, d)$ ; for use with <code>svy</code> estimation commands when the <code>df()</code> option is also specified |

`collect` is allowed; see [U] 11.1.10 Prefix commands.

`df(#)` and `nosvyadjust` do not appear in the dialog box.

The second syntax means that if more than one expression is specified, each must be surrounded by parentheses.

*exp* is a possibly nonlinear expression containing

```
_b [coef]
_b [eqno:coef]
[eqno]coef
[eqno] _b [coef]
```

*eqno* is

```

name
```

*coef* identifies a coefficient in the model. *coef* is typically a variable name, a level indicator, an interaction indicator, or an interaction involving continuous variables. Level indicators identify one level of a factor variable and interaction indicators identify one combination of levels of an interaction; see [U] 11.4.3 Factor variables. *coef* may contain time-series operators; see [U] 11.4.4 Time-series varlists.

Distinguish between `[]`, which are to be typed, and `[ ]`, which indicate optional arguments.

## Options

`mtest(opt)` specifies that tests be performed for each condition separately. *opt* specifies the method for adjusting  $p$ -values for multiple testing. Valid values for *opt* are

|                         |                             |
|-------------------------|-----------------------------|
| <code>bonferroni</code> | Bonferroni's method         |
| <code>holm</code>       | Holm's method               |
| <code>sidak</code>      | Šidák's method              |
| <code>noadjust</code>   | no adjustment is to be made |

Specifying `mtest` without an argument is equivalent to specifying `mtest(noadjust)`.

`iterate(#)` specifies the maximum number of iterations used to find the optimal step size in the calculation of numerical derivatives of the test expressions. By default, the maximum number of iterations is 100, but convergence is usually achieved after only a few iterations. You should rarely have to use this option.

The following options are available with `testnl` but are not shown in the dialog box:

`df(#)` specifies that the  $F$  distribution with # denominator degrees of freedom be used for the reference distribution of the test statistic. With survey data, # is the design degrees of freedom unless `nosvyadjust` is specified.

`nosvyadjust` is for use with `svy` estimation commands when the `df()` option is also specified; see [SVY] [svy estimation](#). It specifies that the Wald test be carried out without the default adjustment for the design degrees of freedom. That is, the test is carried out as  $W/k \sim F(k, d)$  rather than as  $(d - k + 1)W/(kd) \sim F(k, d - k + 1)$ , where  $k$  = the dimension of the test and  $d$  = the design degrees of freedom specified in the `df()` option.

## Remarks and examples

Remarks are presented under the following headings:

- [Using testnl to perform linear tests](#)
- [Specifying constraints](#)
- [Dropped constraints](#)
- [Multiple constraints](#)
- [Manipulability](#)

## Introduction

### ► Example 1

We have just estimated the parameters of an earnings model on cross-sectional time-series data using one of Stata's more sophisticated estimators:

```
. use https://www.stata-press.com/data/r19/earnings
(NLS women 14-24 in 1968)

. xtgee ln_w grade age c.age#c.age, corr(exchangeable) nolog

GEE population-averaged model Number of obs = 1,326
Group variable: idcode Number of groups = 269
Family: Gaussian Obs per group:
Link: Identity min = 1
Correlation: exchangeable avg = 4.9
 max = 9
 Wald chi2(3) = 327.33
Scale parameter = .0976738 Prob > chi2 = 0.0000
```

| ln_wage     | Coefficient | Std. err. | z     | P> z  | [95% conf. interval] |           |
|-------------|-------------|-----------|-------|-------|----------------------|-----------|
| grade       | .0749686    | .0066111  | 11.34 | 0.000 | .062011              | .0879261  |
| age         | .1080806    | .0235861  | 4.58  | 0.000 | .0618526             | .1543086  |
| c.age#c.age | -.0016253   | .0004739  | -3.43 | 0.001 | -.0025541            | -.0006966 |
| _cons       | -.8788933   | .2830899  | -3.10 | 0.002 | -1.433739            | -.3240473 |

An implication of this model is that peak earnings occur at age  $-\_b[\text{age}]/(2*\_b[\text{c.age}\#\text{c.age}])$ , which here is equal to 33.2. Say that we have a theory that peak earnings should occur at age  $16 + 1/\_b[\text{grade}]$ .

```
. testnl -_b[age]/(2*_b[c.age#c.age]) = 16 + 1/_b[grade]
(1) -_b[age]/(2*_b[c.age#c.age]) = 16 + 1/_b[grade]
 chi2(1) = 1.71
 Prob > chi2 = 0.1914
```

These data do not reject our theory.

◀

## Using testnl to perform linear tests

testnl may be used to test linear constraints, but test is faster; see [R] [test](#). You could type

```
. testnl _b[x4] = _b[x1]
```

but it would take less computer time if you typed

```
. test _b[x4] = _b[x1]
```

## Specifying constraints

The constraints to be tested can be formulated in many different ways. You could type

```
. testnl _b[mpg]*_b[weight] = 1
```

or

```
. testnl _b[mpg] = 1/_b[weight]
```

or you could express the constraint any other way you wished. (To say that testnl allows constraints to be specified in different ways does not mean that the test itself does not depend on the formulation. This point is briefly discussed later.) In formulating the constraints, you must, however, exercise one caution: users of test often refer to the coefficient on a variable by specifying the variable name. For example,

```
. test mpg = 0
```

More formally, they should type

```
. test _b[mpg] = 0
```

but test allows the `_b[]` surrounding the variable name to be omitted. testnl does not allow this shorthand. Typing

```
. testnl mpg=0
```

specifies the constraint that the value of variable mpg in the first observation is zero. If you make this mistake, sometimes testnl will catch it:

```
. testnl mpg=0
equation (1) contains reference to X rather than _b[X]
r(198);
```

In other cases, `testnl` may not catch the mistake; then, the constraint will be dropped because it does not make sense:

```
. testnl mpg=0
 Constraint (1) dropped
```

(There are reasons other than this for constraints being dropped.) The worst case, however, is

```
. testnl _b[weight]*mpg = 1
```

when what you mean is not that `_b[weight]` equals the reciprocal of the value of `mpg` in the first observation, but rather that

```
. testnl _b[weight]*_b[mpg] = 1
```

Sometimes, this mistake will be caught by the “contains reference to X rather than `_b[X]`” error, and sometimes it will not. Be careful.

`testnl`, like `test`, can be used after any Stata estimation command, including the survey estimators. When you use it after a multiple-equation command, such as `mlogit` or `heckman`, you refer to coefficients by using Stata’s standard syntax: `[eqname]_b[varname]`.

Stata’s single-equation estimation output looks like this:

|        | Coef  | ... |                                           |
|--------|-------|-----|-------------------------------------------|
| weight | 12.27 | ... | <- coefficient is <code>_b[weight]</code> |
| mpg    | 3.21  | ... |                                           |

Stata’s multiple-equation output looks like this:

|        | Coef  | ... |                                                 |
|--------|-------|-----|-------------------------------------------------|
| cat1   |       | ... |                                                 |
| weight | 12.27 | ... | <- coefficient is <code>[cat1]_b[weight]</code> |
| mpg    | 3.21  | ... |                                                 |
| 8      |       | ... |                                                 |
| weight | 5.83  | ... | <- coefficient is <code>[8]_b[weight]</code>    |
| mpg    | 7.43  | ... |                                                 |

## Dropped constraints

testnl automatically drops constraints when

- They are nonbinding, for example,  $\_b[\text{mpg}] = \_b[\text{mpg}]$ . More subtle cases include

```
_b[mpg]*_b[weight] = 4
_b[weight] = 2
_b[mpg] = 2
```

In this example, the third constraint is nonbinding because it is implied by the first two.

- They are contradictory, for example,  $\_b[\text{mpg}] = 2$  and  $\_b[\text{mpg}] = 3$ . More subtle cases include

```
_b[mpg]*_b[weight] = 4
_b[weight] = 2
_b[mpg] = 3
```

The third constraint contradicts the first two.

## Multiple constraints

### ▷ Example 2

We illustrate the simultaneous test of a series of constraints using simulated data on labor-market promotion in a given year. We fit a probit model with separate effects for education, experience, and experience-squared for men and women.

```
. use https://www.stata-press.com/data/r19/promotion
(Simulated data on promotions)
. probit promo male male#c.(yedu yexp yexp2), nolog
Probit regression Number of obs = 775
 LR chi2(7) = 424.42
 Prob > chi2 = 0.0000
 Pseudo R2 = 0.4637
Log likelihood = -245.42768
```

| promo        | Coefficient | Std. err. | z     | P> z  | [95% conf. interval] |           |
|--------------|-------------|-----------|-------|-------|----------------------|-----------|
| male         | .6489974    | .203739   | 3.19  | 0.001 | .2496763             | 1.048318  |
| male#c.yedu  |             |           |       |       |                      |           |
| Female       | .9730237    | .1056136  | 9.21  | 0.000 | .7660248             | 1.180023  |
| Male         | 1.390517    | .1527288  | 9.10  | 0.000 | 1.091174             | 1.68986   |
| male#c.yexp  |             |           |       |       |                      |           |

Note: 1 failure and 2 successes completely determined.

The effects of human capital seem to differ between men and women. A formal test confirms this.

```
. test (yedu#0.male = yedu#1.male) (yexp#0.male = yexp#1.male)
> (yexp2#0.male = yexp2#1.male)
(1) [promo]0b.male#c.yedu - [promo]1.male#c.yedu = 0
(2) [promo]0b.male#c.yexp - [promo]1.male#c.yexp = 0
(3) [promo]0b.male#c.yexp2 - [promo]1.male#c.yexp2 = 0
 chi2(3) = 35.43
 Prob > chi2 = 0.0000
```

How do we interpret this gender difference? It has repeatedly been stressed (see, for example, [Long \[1997, 47–50\]](#); [Allison \[1999\]](#)) that comparison of groups in binary response models, and similarly in other latent-variable models, is hampered by an identification problem: with  $\beta$  the regression coefficients for the latent variable and  $\sigma$  the standard deviation of the latent residual, only the  $\beta/\sigma$  are identified. In fact, in terms of the latent regression, the probit coefficients should be interpreted as  $\beta/\sigma$ , not as the  $\beta$ . If we cannot claim convincingly that the residual standard deviation  $\sigma$  does not vary between the sexes, equality of the regression coefficients  $\beta$  implies that the coefficients of the probit model for men and women are *proportional* but not necessarily equal. This is a nonlinear hypothesis in terms of the probit coefficients, not a linear one.

```
. testnl _b[yedu#1.male]/_b[yedu#0.male] = _b[yexp#1.male]/_b[yexp#0.male]
> = _b[yexp2#1.male]/_b[yexp2#0.male]
(1) _b[yedu#1.male]/_b[yedu#0.male] = _b[yexp#1.male]/_b[yexp#0.male]
(2) _b[yedu#1.male]/_b[yedu#0.male] = _b[yexp2#1.male]/_b[yexp2#0.male]
 chi2(2) = 9.21
 Prob > chi2 = 0.0100
```

We conclude that we find fairly strong evidence against the proportionality of the coefficients, and hence we have to conclude that success in the labor market is produced in different ways by men and women. (But remember, these were simulated data.)

### ▷ Example 3

The syntax for specifying the equality of multiple expressions is just a convenient shorthand for specifying a series of constraints, namely, that the first expression equals the second expression, the first expression also equals the third expression, etc. The Wald test performed and the output of `testnl` are the same whether we use the shorthand or we specify the series of constraints.

```
. testnl (_b[yedu#1.male]/_b[yedu#0.male] =
> _b[yexp#1.male]/_b[yexp#0.male])
> (_b[yedu#1.male]/_b[yedu#0.male] =
> _b[yexp2#1.male]/_b[yexp2#0.male])
(1) _b[yedu#1.male]/_b[yedu#0.male] = _b[yexp#1.male]/_b[yexp#0.male]
(2) _b[yedu#1.male]/_b[yedu#0.male] = _b[yexp2#1.male]/_b[yexp2#0.male]
 chi2(2) = 9.21
 Prob > chi2 = 0.0100
```

Having established differences between men and women, we would like to do multiple testing between the ratios. Because we did not specify hypotheses in advance, we prefer to adjust the  $p$ -values of tests using, here, Bonferroni's method.

```
. testnl _b[yedu#1.male]/_b[yedu#0.male] =
> _b[yexp#1.male]/_b[yexp#0.male] =
> _b[yexp2#1.male]/_b[yexp2#0.male], mtest(b)
(1) _b[yedu#1.male]/_b[yedu#0.male] = _b[yexp#1.male]/_b[yexp#0.male]
(2) _b[yedu#1.male]/_b[yedu#0.male] = _b[yexp2#1.male]/_b[yexp2#0.male]
```

|     | chi2 | df | p > chi2 |
|-----|------|----|----------|
| (1) | 6.89 | 1  | 0.0173*  |
| (2) | 0.93 | 1  | 0.6713*  |
| All | 9.21 | 2  | 0.0100   |

\* Bonferroni-adjusted  $p$ -values

## Manipulability

Although `testnl` allows you to specify constraints in different ways that are mathematically equivalent, as noted above, this does not mean that the tests are the same. This difference is known as the manipulability of the Wald test for nonlinear hypotheses; also see [R] `boxcox`. The test might even be significant for one formulation but not significant for another formulation that is mathematically equivalent. Trying out different specifications to find a formulation with the desired  $p$ -value is totally inappropriate, though it may actually be fun to try. There is no variance under representation because the nonlinear Wald test is actually a standard Wald test for a linearization of the constraint, which depends on the particular specification. We note that the likelihood-ratio test is not manipulable in this sense.

From a statistical point of view, it is best to choose a specification of the constraints that is as linear as possible. Doing so usually improves the accuracy of the approximation of the null-distribution of the test by a  $\chi^2$  or an  $F$  distribution. The example above used the nonlinear Wald test to test whether the coefficients of human capital variables for men were proportional to those of women. A specification of proportionality of coefficients in terms of ratios of coefficients is fairly nonlinear if the coefficients in the denominator are close to 0. A more linear version of the test results from a bilinear formulation. Thus, instead of

```
. testnl _b[yedu#1.male]/_b[yedu#0.male] = _b[yexp#1.male]/_b[yexp#0.male]
(1) _b[yedu#1.male]/_b[yedu#0.male] = _b[yexp#1.male]/_b[yexp#0.male]
 chi2(1) = 6.89
 Prob > chi2 = 0.0087
```

perhaps

```
. testnl _b[yedu#1.male]*_b[yexp#0.male] = _b[yedu#0.male]*_b[yexp#1.male]
(1) _b[yedu#1.male]*_b[yexp#0.male] = _b[yedu#0.male]*_b[yexp#1.male]
 chi2(1) = 13.95
 Prob > chi2 = 0.0002
```

is better, and in fact it has been suggested that the latter version of the test is more reliable. This assertion is confirmed by performing simulations and is in line with theoretical results of [Phillips and Park \(1988\)](#). There is strong evidence against the proportionality of human capital effects between men and women, implying for this example that differences in the residual variances between the sexes can be ruled out as the explanation of the sex differences in the analysis of labor market participation.

## Stored results

`testnl` stores the following in `r()`:

### Scalars

|                      |                             |

| <code>r(R)</code>     | $R(\mathbf{b}) - \mathbf{q}$ ; see <a href="#">Methods and formulas</a> below                                |
| <code>r(mtest)</code> | multiple test results                                                                                        |

## Methods and formulas

After fitting a model, define  $\mathbf{b}$  as the resulting  $1 \times k$  parameter vector and  $\mathbf{V}$  as the  $k \times k$  covariance matrix. The (linear or nonlinear) hypothesis is given by  $R(\mathbf{b}) = \mathbf{q}$ , where  $R$  is a function returning a  $j \times 1$  vector. The Wald test formula is (Greene 2018, 512–513)

$$W = \{R(\mathbf{b}) - \mathbf{q}\}' (\mathbf{G}\mathbf{V}\mathbf{G}')^{-1} \{R(\mathbf{b}) - \mathbf{q}\}$$

where  $\mathbf{G}$  is the derivative matrix of  $R(\mathbf{b})$  with respect to  $\mathbf{b}$ .  $W$  is distributed as  $\chi^2$  if  $\mathbf{V}$  is an asymptotic covariance matrix.  $F = W/j$  is distributed as  $F$  for linear regression.

The adjustment methods for multiple testing are described in [R] [test](#). The adjustment for survey design effects is described in [SVY] [svy postestimation](#).

## Description

`tetrachoric` computes estimates of the tetrachoric correlation coefficients of the binary variables in *varlist*. All of these variables should be 0, 1, or missing values.

Tetrachoric correlations assume a latent bivariate normal distribution  $(X_1, X_2)$  for each pair of variables  $(v_1, v_2)$ , with a threshold model for the manifest variables,  $v_i = 1$  if and only if  $X_i > 0$ . The means and variances of the latent variables are not identified, but the correlation,  $r$ , of  $X_1$  and  $X_2$  can be estimated from the joint distribution of  $v_1$  and  $v_2$  and is called the tetrachoric correlation coefficient.

`tetrachoric` computes pairwise estimates of the tetrachoric correlations by the (iterative) maximum likelihood estimator obtained from bivariate probit without explanatory variables (see [R] **biprobit**) by using the [Edwards and Edwards \(1984\)](#) noniterative estimator as the initial value.

The pairwise correlation matrix is returned as `r(Rho)` and can be used to perform a factor analysis or a principal component analysis of binary variables by using the `factormat` or `pcamat` commands; see [MV] **factor** and [MV] **pca**.

## Quick start

Tetrachoric correlation of `v1` and `v2` with standard error and test of independence

```
tetrachoric v1 v2
```

Matrix of pairwise tetrachoric correlations for `v1`, `v2`, and `v3`

```
tetrachoric v1 v2 v3
```

Add standard errors and  $p$ -values

```
tetrachoric v1 v2 v3, stats(rho se p)
```

Same as above, but adjust  $p$ -values for multiple comparisons using Bonferroni's method

```
tetrachoric v1 v2 v3, stats(rho se p) bonferroni
```

Add star to correlations significant at the 5% level

```
tetrachoric v1 v2 v3, star(.05)
```

Use all available data for each pair of variables and report number of observations used

```
tetrachoric v1 v2 v3, pw stats(rho obs)
```

Adjust correlation matrix to be positive semidefinite

```
tetrachoric v1 v2 v3, posdef
```

## Options

### Main

`stats(statlist)` specifies the statistics to be displayed in the matrix of output. `stats(rho)` is the default. Up to four statistics may be specified. `stats(rho se p obs)` would display the tetrachoric correlation coefficient, its standard error, the significance level, and the number of observations. If *varlist* contains only two variables, all statistics are shown in tabular form. `stats()`, `print()`, and `star()` have no effect unless the `matrix` option is also specified.

`edwards` specifies that the noniterative Edwards and Edwards estimator be used. The default is the maximum likelihood estimator. If you analyze many binary variables, you may want to use the fast noniterative estimator proposed by [Edwards and Edwards \(1984\)](#). However, if you have skewed variables, the approximation does not perform well.

`print(#)` specifies the maximum significance level of correlation coefficients to be printed. Correlation coefficients with larger significance levels are left blank in the matrix. Typing `tetrachoric ..., print(.10)` would list only those correlation coefficients that are significant at the 10% level or lower.

`star(#)` specifies the maximum significance level of correlation coefficients to be marked with a star. Typing `tetrachoric ..., star(.05)` would “star” all correlation coefficients significant at the 5% level or lower.

`bonferroni` makes the Bonferroni adjustment to calculated significance levels. This option affects printed significance levels and the `print()` and `star()` options. Thus, `tetrachoric ..., print(.05) bonferroni` prints coefficients with Bonferroni-adjusted significance levels of 0.05 or less.

`sidak` makes the Šidák adjustment to calculated significance levels. This option affects printed significance levels and the `print()` and `star()` options. Thus, `tetrachoric ..., print(.05) sidak` prints coefficients with Šidák-adjusted significance levels of 0.05 or less.

`pw` specifies that the tetrachoric correlation be calculated by using all available data. By default, `tetrachoric` uses casewise deletion, where observations are ignored if any of the specified variables in *varlist* are missing.

`zeroadjust` specifies that when one of the cells has a zero count, a frequency adjustment be applied in such a way as to increase the zero to one-half and maintain row and column totals.

`matrix` forces `tetrachoric` to display the statistics as a matrix, even if *varlist* contains only two variables. `matrix` is implied if more than two variables are specified.

`notable` suppresses the output.

`posdef` modifies the correlation matrix so that it is positive semidefinite, that is, a proper correlation matrix. The modified result is the correlation matrix associated with the least-squares approximation of the tetrachoric correlation matrix by a positive-semidefinite matrix. If the correlation matrix is modified, the standard errors and significance levels are not displayed and are returned in `r()`.

## Remarks and examples

Remarks are presented under the following headings:

*Association in 2-by-2 tables*  
*Factor analysis of dichotomous variables*  
*Tetrachoric correlations with simulated data*

### Association in 2-by-2 tables

Although a wide variety of measures of association in cross tabulations have been proposed, such measures are essentially equivalent (monotonically related) in the special case of  $2 \times 2$  tables—there is only 1 degree of freedom for nonindependence. Still, some measures have more desirable properties than others. Here we compare two measures: the standard Pearson correlation coefficient and the tetrachoric correlation coefficient. Given asymmetric row or column margins, Pearson correlations are limited to a range smaller than  $-1$  to  $1$ , although tetrachoric correlations can still span the range from  $-1$  to  $1$ . To illustrate, consider the following set of tables for two binary variables, X and Z:

|       | Z = 0  | Z = 1  |    |
|-------|--------|--------|----|
| X = 0 | 20 - a | 10 + a | 30 |
| X = 1 | a      | 10 - a | 10 |
|       | 20     | 20     | 40 |

For  $a$  equal to 0, 1, 2, 5, 8, 9, and 10, the Pearson and tetrachoric correlations for the above table are

| $a$         | 0     | 1     | 2     | 5 | 8      | 9      | 10     |
|-------------|-------|-------|-------|---|--------|--------|--------|
| Pearson     | 0.577 | 0.462 | 0.346 | 0 | -0.346 | -0.462 | -0.577 |
| Tetrachoric | 1.000 | 0.792 | 0.607 | 0 | -0.607 | -0.792 | -1.000 |

The restricted range for the Pearson correlation is especially unfortunate when you try to analyze the association between binary variables by using models developed for continuous data, such as factor analysis and principal component analysis.

The tetrachoric correlation of two variables  $(Y_1, Y_2)$  can be thought of as the Pearson correlation of two latent bivariate normal distributed variables  $(Y_1^*, Y_2^*)$  with threshold measurement models  $Y_i = (Y_i^* > c_i)$  for unknown cutpoints  $c_i$ . Or equivalently,  $Y_i = (Y_i^{**} > 0)$  where the latent bivariate normal  $(Y_1^{**}, Y_2^{**})$  are shifted versions of  $(Y_1^*, Y_2^*)$  so that the cutpoints are zero. Obviously, you must judge whether assuming underlying latent variables is meaningful for the data. If this assumption is justified, tetrachoric correlations have two advantages. First, you have an intuitive understanding of the size of correlations that are substantively interesting in your field of research, and this intuition is based on correlations that range from  $-1$  to  $1$ . Second, because the tetrachoric correlation for binary variables estimates the Pearson correlation of the latent continuous variables (assumed multivariate normal distributed), you can use the tetrachoric correlations to analyze multivariate relationships between the dichotomous variables. When doing so, remember that you must interpret the model in terms of the underlying continuous variables.

▷ Example 1

To illustrate tetrachoric correlations, we examine three binary variables from the familyvalues dataset (described in example 2).

|-------|--------|--------|--------|
| RS074 | 1.0000 |        |        |
| RS075 | 0.0396 | 1.0000 |        |
| RS076 | 0.1595 | 0.3830 | 1.0000 |

```
. tetrachoric RS074 RS075 RS076
(obs=3,291)
```

|       | RS074  | RS075  | RS076  |
|-------|--------|--------|--------|
| RS074 | 1.0000 |        |        |
| RS075 | 0.0689 | 1.0000 |        |
| RS076 | 0.2480 | 0.6427 | 1.0000 |

As usual, the tetrachoric correlation coefficients are larger (in absolute value) and more dispersed than the Pearson correlations.

## Factor analysis of dichotomous variables

### ► Example 2

Factor analysis is a popular model for measuring latent continuous traits. The standard estimators are appropriate only for continuous unimodal data. Because of the skewness implied by Bernoulli-distributed variables (especially when the probability is distributed unevenly), a factor analysis of a Pearson correlation matrix can be rather misleading when used in this context. A factor analysis of a matrix of tetrachoric correlations is more appropriate under these conditions (Uebersax 2000). We illustrate this with data on gender, relationship, and family attitudes of spouses using the Households in The Netherlands survey 1995 (Weesie et al. 1995). For attitude variables, it seems reasonable to assume that agreement or disagreement is just a coarse measurement of more nuanced underlying attitudes.

To demonstrate, we examine a few of the variables from the familyvalues dataset.

```
. use https://www.stata-press.com/data/r19/familyvalues
(Attitudes on gender, relationships and family)
. describe RS056-RS063
```

Again, we see that the tetrachoric correlations are generally larger in absolute value than the Pearson correlations. The bivariate probit and Edwards and Edwards estimators (the `edwards` option) implemented in `tetrachoric` may return a correlation matrix that is not positive semidefinite—a mathematical property of any real correlation matrix. Positive definiteness is required by commands for analyses of correlation matrices, such as `factormat` and `pcamat`; see [\[MV\] factor](#) and [\[MV\] pca](#). The `posdef` option of `tetrachoric` tests for positive definiteness and projects the estimated correlation matrix to a positive-semidefinite matrix if needed.

```
. tetrachoric RS056-RS063, notable posdef
. matrix C = r(Rho)
```

This time, we suppressed the display of the correlations with the `notable` option and requested that the correlation matrix be positive semidefinite with the `posdef` option. Had the correlation matrix not been positive definite, `tetrachoric` would have displayed a warning message and then adjusted the matrix to be positive semidefinite. We placed the resulting tetrachoric correlation matrix into a matrix, `C`, so that we can perform a factor analysis upon it.

`tetrachoric` with the `posdef` option asserted that `C` was positive definite because no warning message was displayed. We can verify this by using a familiar characterization of symmetric positive-definite matrices: all eigenvalues are real and positive.

```
. matrix symeigen eigenvectors eigenvalues = C
. matrix list eigenvalues
eigenvalues[1,8]
 e1 e2 e3 e4 e5 e6 e7
r1 2.5974789 1.3544664 1.0532476 .77980391 .73462018 .57984565 .54754512
 e8
r1 .35299228
```

We can proceed with a factor analysis on the matrix C. We use `factormat` and select iterated principal factors as the estimation method; see [\[MV\] factor](#).

```
. factormat C, n(3221) ipf factor(2)
(obs=3,221)
Factor analysis/correlation Number of obs = 3,221

▷ Example 3

We noted in [example 2](#) that the matrix of estimates of the tetrachoric correlation coefficients need not be positive definite. Here is an example:

```
. use https://www.stata-press.com/data/r19/familyvalues
(Attitudes on gender, relationships and family)
. tetrachoric RS056-RS063 in 1/20, posdef
(obs=18)
matrix with tetrachoric correlations is not positive semidefinite;
it has 2 negative eigenvalues
maxdiff(corr,adj-corr) = 0.2346
(adj-corr: tetrachoric correlations adjusted to be positive semidefinite)
```

| adj-corr | RS056   | RS057   | RS058   | RS059   | RS060   | RS061   | RS062  |
|----------|---------|---------|---------|---------|---------|---------|--------|
| RS056    | 1.0000  |         |         |         |         |         |        |
| RS057    | 0.5284  | 1.0000  |         |         |         |         |        |
| RS058    | 0.3012  | 0.2548  | 1.0000  |         |         |         |        |
| RS059    | 0.3251  | 0.2791  | 0.0550  | 1.0000  |         |         |        |
| RS060    | -0.5197 | -0.4222 | -0.7163 | 0.0552  | 1.0000  |         |        |
| RS061    | 0.3448  | 0.4815  | -0.0958 | -0.1857 | -0.0980 | 1.0000  |        |
| RS062    | 0.1066  | -0.0375 | 0.0072  | 0.3909  | -0.2333 | -0.7654 | 1.0000 |
| RS063    | 0.3830  | 0.4939  | 0.4336  | 0.0075  | -0.8937 | -0.0337 | 0.4934 |
| adj-corr | RS063   |         |         |         |         |         |        |
| RS063    | 1.0000  |         |         |         |         |         |        |

```
. mata:
----- mata (type end to exit) -----
: C2 = st_matrix("r(Rho)")
: eigenvecs = .
: eigenvals = .
: symeigensystem(C2, eigenvecs, eigenvals)
: eigenvals
 1 2 3 4
1 | 3.156592567 2.065279398 1.324911199 .7554904485
 |
 | 5 6 7 8
1 | .4845368741 .2131895139 -1.11022e-16 -2.27918e-16
: end
```

The estimated tetrachoric correlation matrix is rank-2 deficient. With this C2 matrix, we can only use models of correlation that allow for singular cases.

## Tetrachoric correlations with simulated data

### ▷ Example 4

We use `drawnorm` (see [D] [drawnorm](#)) to generate a sample of 1,000 observations from a bivariate normal distribution with means  $-1$  and  $1$ , unit variances, and correlation  $0.4$ .

```
. clear
. set seed 11000
. matrix m = (1, -1)
. matrix V = (1, 0.4 \ 0.4, 1)
. drawnorm c1 c2, n(1000) means(m) cov(V)
(obs 1,000)
```

Now, consider the measurement model assumed by the tetrachoric correlations. We observe only whether  $c_1$  and  $c_2$  are greater than zero,

```
. generate d1 = (c1 > 0)
. generate d2 = (c2 > 0)
. tabulate d1 d2
```

| d1    | d2  |     | Total |
|-------|-----|-----|-------|
|       | 0   | 1   |       |
| 0     | 141 | 6   | 147   |
| 1     | 706 | 147 | 853   |
| Total | 847 | 153 | 1,000 |

We want to estimate the correlation of  $c_1$  and  $c_2$  from the binary variables  $d_1$  and  $d_2$ . Pearson's correlation of the binary variables  $d_1$  and  $d_2$  is  $0.129$ —a seriously biased estimate of the underlying correlation  $\rho = 0.4$ .

```
. correlate d1 d2
(obs=1,000)
```

|    | d1     | d2     |
|----|--------|--------|
| d1 | 1.0000 |        |
| d2 | 0.1294 | 1.0000 |

The tetrachoric correlation coefficient of  $d_1$  and  $d_2$  estimates the Pearson correlation of the latent continuous variables,  $c_1$  and  $c_2$ .

```
. tetrachoric d1 d2
Number of obs = 1,000
Tetrachoric rho = 0.3875
Std error = 0.0787
Test of H0: d1 and d2 are independent
2-sided exact P = 0.0000
```

The estimate of the tetrachoric correlation of  $d_1$  and  $d_2$ ,  $0.3875$ , is much closer to the underlying correlation,  $0.4$ , between  $c_1$  and  $c_2$ .

## Stored results

`tetrachoric` stores the following in `r()`:

### Scalars

|                        |                                                                            |
|------------------------|----------------------------------------------------------------------------|
| <code>r(rho)</code>    | tetrachoric correlation coefficient between variables 1 and 2              |
| <code>r(N)</code>      | number of observations                                                     |
| <code>r(nneg)</code>   | number of negative eigenvalues (posdef only)                               |
| <code>r(se_rho)</code> | standard error of <code>r(rho)</code>                                      |
| <code>r(p)</code>      | $p$ -value for two-sided Fisher's exact test (for the first two variables) |

### Macros

### Matrices

|                        |                                                         |
|------------------------|---------------------------------------------------------|
| <code>r(Rho)</code>    | tetrachoric correlation matrix                          |
| <code>r(Se_Rho)</code> | standard errors of <code>r(Rho)</code>                  |
| <code>r(Nobs)</code>   | number of observations used in computing correlation    |
| <code>r(P)</code>      | matrix of $p$ -values for two-sided Fisher's exact test |

## Methods and formulas

`tetrachoric` provides two estimators for the tetrachoric correlation  $\rho$  of two binary variables with the frequencies  $n_{ij}$ ,  $i, j = 0, 1$ . `tetrachoric` defaults to the slower (iterative) maximum likelihood estimator obtained from bivariate probit without explanatory variables (see [R] [biprobit](#)) by using the Edwards and Edwards noniterative estimator as the initial value. A fast (noniterative) estimator is also available by specifying the `edwards` option (Edwards and Edwards 1984; Digby 1983)

$$\hat{\rho} = \frac{\alpha - 1}{\alpha + 1}$$

where

$$\alpha = \left( \frac{n_{00}n_{11}}{n_{01}n_{10}} \right)^{\pi/4} \quad (\pi = 3.14\dots)$$

if all  $n_{ij} > 0$ . If  $n_{00} = 0$  or  $n_{11} = 0$ ,  $\hat{\rho} = -1$ ; if  $n_{01} = 0$  or  $n_{10} = 0$ ,  $\hat{\rho} = 1$ .

The asymptotic variance of the Edwards and Edwards estimator of the tetrachoric correlation is easily obtained by the delta method,

$$\text{avar}(\hat{\rho}) = \left\{ \frac{\pi\alpha}{2(1+\alpha)^2} \right\}^2 \left( \frac{1}{n_{00}} + \frac{1}{n_{01}} + \frac{1}{n_{10}} + \frac{1}{n_{11}} \right)$$

provided all  $n_{ij} > 0$ , otherwise it is left undefined (missing). The Edwards and Edwards estimator is fast, but may be inaccurate if the margins are very skewed.

`tetrachoric` reports exact  $p$ -values for statistical independence, computed by the `exact` option of [R] [tabulate twoway](#).

## Description

`tnbreg` estimates the parameters of a truncated negative binomial model by maximum likelihood. The dependent variable *devar* is regressed on *indevars*, where *devar* is a positive count variable whose values are all above the truncation point.

## Quick start

Truncated negative binomial regression of *y* on *x* with truncation at 0

```
tnbreg y x
```

Report incidence-rate ratios

```
tnbreg y x, irr
```

Add categorical variable *a* using [factor variable](#) syntax

```
tnbreg y x i.a
```

Same as above, but specify a constant truncation point of 2

```
tnbreg y x i.a, ll(2)
```

With exposure variable *exp*

```
tnbreg y x i.a, exposure(exp)
```

Same as above, but specifying a variable truncation point stored in variable *min*

```
tnbreg y x i.a, exposure(exp) ll(min)
```

With cluster-robust standard errors clustering by the levels of *cvar*

```
tnbreg y x i.a, exposure(exp) ll(min) vce(cluster cvar)
```

## Menu

Statistics > Count outcomes > Truncated negative binomial regression

## Syntax

```
tnbreg depvar [indepvars] [if] [in] [weight] [, options]
```

## Options

Model

noconstant; see [R] **Estimation options**.

ll(#|*varname*) specifies the truncation point, which is a nonnegative integer. The default is zero truncation, ll(0).

`dispersion(mean | constant)` specifies the parameterization of the model. `dispersion(mean)`, the default, yields a model with dispersion equal to  $1 + \alpha \exp(\mathbf{x}_j\boldsymbol{\beta} + \text{offset}_j)$ ; that is, the dispersion is a function of the expected mean:  $\exp(\mathbf{x}_j\boldsymbol{\beta} + \text{offset}_j)$ . `dispersion(constant)` has dispersion equal to  $1 + \delta$ ; that is, it is a constant for all observations.

`exposure(varnamee)`, `offset(varnameo)`, `constraints(constraints)`; see [R] [Estimation options](#).

SE/Robust

`vce(vcetype)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory (`oim`, `opg`), that are robust to some kinds of misspecification (`robust`), that allow for intragroup correlation (`cluster clustvar`), and that use bootstrap or jackknife methods (`bootstrap`, `jackknife`); see [R] [vce\\_option](#).

Reporting

`level(#)`; see [R] [Estimation options](#).

`no1rtest` suppresses fitting the Poisson model. Without this option, a comparison Poisson model is fit, and the likelihood is used in a likelihood-ratio test of the null hypothesis that the dispersion parameter is zero.

`irr` reports estimated coefficients transformed to incidence-rate ratios, that is,  $e^{\beta_i}$  rather than  $\beta_i$ . Standard errors and confidence intervals are similarly transformed. This option affects how results are displayed, not how they are estimated or stored. `irr` may be specified at estimation or when replaying previously estimated results.

`nocnsreport`; see [R] [Estimation options](#).

`display_options`: `nocl`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `no1stretch`; see [R] [Estimation options](#).

Maximization

`maximize_options`: `difficult`, `technique(algorithm_spec)`, `iterate(#)`, `[no]log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `1tolerance(#)`, `nrtolerance(#)`, `nonrtolerance`, and `from(init_specs)`; see [R] [Maximize](#). These options are seldom used.

Setting the optimization type to `technique(bhhh)` resets the default `vcetype` to `vce(opg)`.

The following options are available with `tnbreg` but are not shown in the dialog box:

`collinear`, `coeflegend`; see [R] [Estimation options](#).

## Remarks and examples

Grogger and Carson (1991) showed that overdispersion causes inconsistent estimation of the mean in the truncated Poisson model. To solve this problem, they proposed using the truncated negative binomial model as an alternative. If data are truncated but do not exhibit overdispersion, the truncated Poisson model is more appropriate; see [R] [tpoisson](#). For an introduction to negative binomial regression, see Cameron and Trivedi (2005, 2022) and Long and Freese (2014). For an introduction to truncated negative binomial models, see Cameron and Trivedi (2013) and Long (1997, chap. 8).

tnbreg fits the mean-dispersion and the constant-dispersion parameterizations of truncated negative binomial models. These parameterizations extend those implemented in nbreg; see [R] nbreg.

▷ Example 1

We illustrate the truncated negative binomial model using the 1997 MedPar dataset (Hilbe 1999). The data are from 1,495 patients in Arizona who were assigned to a diagnostic-related group (DRG) of patients having a ventilator. Length of stay (los), the dependent variable, is a positive integer; it cannot have zero values. The data are truncated because there are no observations on individuals who stayed for zero days.

The objective of this example is to determine whether the length of stay was related to the binary variables: died, hmo, type1, type2, and type3.

The died variable was recorded as a 0 unless the patient died, in which case, it was recorded as a 1. The other variables also adopted this encoding. The hmo variable was set to 1 if the patient belonged to a health maintenance organization (HMO).

The type1–type3 variables indicated the type of admission used for the patient. The type1 variable indicated an emergency admit. The type2 variable indicated an urgent admit—that is, the first available bed. The type3 variable indicated an elective admission. Because type1–type3 were mutually exclusive, only two of the three could be used in the truncated negative binomial regression shown below.

| /lnalpha | -.630108    | .0764019  |       |       | -.779853             | -.480363  |
| alpha    | .5325343    | .0406866  |       |       | .4584734             | .6185588  |

Because observations within the same hospital (provnum) are likely to be correlated, we specified the vce(cluster provnum) option. The results show that whether the patient died in the hospital and the type of admission have significant effects on the patient’s length of stay.

▷ Example 2

To illustrate truncated negative binomial regression with more complex data than the previous example, similar data were created from 100 hospitals. Each hospital had its own way of tracking patient data. In particular, hospitals only recorded data from patients with a minimum length of stay, denoted by the variable `minstay`.

Definitions for minimum length of stay varied among hospitals, typically, from 5 to 18 days. The objective of this example is the same as before: to determine whether the length of stay, recorded in `los`, was related to the binary variables: `died`, `hmo`, `type1`, `type2`, and `type3`.

The binary variables encode the same information as in [example 1](#) above. The `minstay` variable was used to allow for varying truncation points.

```
. use https://www.stata-press.com/data/r19/medproviders
. tnbreg los died hmo type2-type3, ll(minstay) vce(cluster hospital) nolog

| /lnalpha | -.996512    | .0828691  |        |       | -1.158932            | -.8340916 |
| alpha    | .3691649    | .0305923  |        |       | .313821              | .4342688  |

In this analysis, two variables have a statistically significant relationship with length of stay. On average, patients who died in the hospital had longer lengths of stay ( $p = 0.01$ ). Because the coefficient for HMO is negative, that is,  $b_{HMO} = -0.073$ , on average, patients who were insured by an HMO had shorter lengths of stay ( $p = 0.047$ ). The type of admission was not statistically significant ( $p > 0.05$ ).

## Stored results

tnbreg stores the following in `e()`:

## Methods and formulas

Methods and formulas are presented under the following headings:

*Mean-dispersion model*  
*Constant-dispersion model*

### Mean-dispersion model

A negative binomial distribution can be regarded as a gamma mixture of Poisson random variables. The number of times an event occurs,  $y_j$ , is distributed as Poisson( $\nu_j \mu_j$ ). That is, its conditional likelihood is

$$f(y_j | \nu_j) = \frac{(\nu_j \mu_j)^{y_j} e^{-\nu_j \mu_j}}{\Gamma(y_j + 1)}$$

where  $\mu_j = \exp(\mathbf{x}_j \boldsymbol{\beta} + \text{offset}_j)$  and  $\nu_j$  is an unobserved parameter with a Gamma( $1/\alpha, \alpha$ ) density:

$$g(\nu) = \frac{\nu^{(1-\alpha)/\alpha} e^{-\nu/\alpha}}{\alpha^{1/\alpha} \Gamma(1/\alpha)}$$

This gamma distribution has a mean of 1 and a variance of  $\alpha$ , where  $\alpha$  is our ancillary parameter.

The unconditional likelihood for the  $j$ th observation is therefore

$$f(y_j) = \int_0^\infty f(y_j | \nu) g(\nu) d\nu = \frac{\Gamma(m + y_j)}{\Gamma(y_j + 1) \Gamma(m)} p_j^m (1 - p_j)^{y_j}$$

where  $p_j = 1/(1 + \alpha \mu_j)$  and  $m = 1/\alpha$ . Solutions for  $\alpha$  are handled by searching for  $\ln \alpha$  because  $\alpha$  must be greater than zero. The conditional probability of observing  $y_j$  events given that  $y_j$  is greater than the truncation point  $\tau_j$  is

$$\Pr(Y = y_j | y_j > \tau_j, \mathbf{x}_j) = \frac{f(y_j)}{\Pr(Y > \tau_j | \mathbf{x}_j)}$$

The log likelihood (with weights  $w_j$  and offsets) is given by

$$m = 1/\alpha \quad p_j = 1/(1 + \alpha \mu_j) \quad \mu_j = \exp(\mathbf{x}_j \boldsymbol{\beta} + \text{offset}_j)$$

$$\ln L = \sum_{j=1}^n w_j \left[ \ln\{\Gamma(m + y_j)\} - \ln\{\Gamma(y_j + 1)\} - \ln\{\Gamma(m)\} + m \ln(p_j) + y_j \ln(1 - p_j) - \ln\{\Pr(Y > \tau_j | p_j, m)\} \right]$$

## Constant-dispersion model

The constant-dispersion model assumes that  $y_j$  is conditionally distributed as Poisson( $\mu_j^*$ ), where  $\mu_j^* \sim \text{Gamma}(\mu_j/\delta, \delta)$  for some dispersion parameter  $\delta$  [by contrast, the mean-dispersion model assumes that  $\mu_j^* \sim \text{Gamma}(1/\alpha, \alpha\mu_j)$ ]. The log likelihood is given by

$$m_j = \mu_j/\delta \quad p = 1/(1 + \delta)$$

$$\ln L = \sum_{j=1}^n w_j \left[ \ln\{\Gamma(m_j + y_j)\} - \ln\{\Gamma(y_j + 1)\} - \ln\{\Gamma(m_j)\} + m_j \ln(p) + y_j \ln(1 - p) - \ln\{\Pr(Y > \tau_j | p, m_j)\} \right]$$

with everything else defined as shown above in the calculations for the mean-dispersion model.

This command supports the Huber/White/sandwich estimator of the variance and its clustered version using `vce(robust)` and `vce(cluster clustvar)`, respectively. See [P] [\\_robust](#), particularly *Maximum likelihood estimators* and *Methods and formulas*.

`tnbreg` also supports estimation with survey data. For details on VCEs with survey data, see [SVY] [Variance estimation](#).

## Postestimation commands

The following postestimation commands are available after `tnbreg`:

| Command                      | Description                                                                                                                             |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <code>contrast</code>        | contrasts and ANOVA-style joint tests of parameters                                                                                     |
| <code>estat ic</code>        | Akaike's, consistent Akaike's, corrected Akaike's, and Schwarz's Bayesian information criteria (AIC, CAIC, AICc, and BIC, respectively) |
| <code>estat summarize</code> | summary statistics for the estimation sample                                                                                            |
| <code>estat vce</code>       | variance–covariance matrix of the estimators (VCE)                                                                                      |
| <code>estat (svy)</code>     | postestimation statistics for survey data                                                                                               |
| <code>estimates</code>       | cataloging estimation results                                                                                                           |
| <code>etable</code>          | table of estimation results                                                                                                             |
| * <code>forecast</code>      | dynamic forecasts and simulations                                                                                                       |
| * <code>hausman</code>       | Hausman's specification test                                                                                                            |
| <code>lincom</code>          | point estimates, standard errors, testing, and inference for linear combinations of parameters                                          |
| * <code>lrtest</code>        | likelihood-ratio test                                                                                                                   |
| <code>margins</code>         | marginal means, predictive margins, marginal effects, and average marginal effects                                                      |
| <code>marginsplot</code>     | graph the results from margins (profile plots, interaction plots, etc.)                                                                 |
| <code>nlcom</code>           | point estimates, standard errors, testing, and inference for nonlinear combinations of parameters                                       |
| <code>predict</code>         | number of events, incidence rates, probabilities, etc.                                                                                  |
| <code>predictnl</code>       | point estimates, standard errors, testing, and inference for generalized predictions                                                    |
| <code>pwcompare</code>       | pairwise comparisons of parameters                                                                                                      |
| <code>suest</code>           | seemingly unrelated estimation                                                                                                          |
| <code>test</code>            | Wald tests of simple and composite linear hypotheses                                                                                    |
| <code>testnl</code>          | Wald tests of nonlinear hypotheses                                                                                                      |

\*`forecast`, `hausman`, and `lrtest` are not appropriate with `svy` estimation results.

# predict

## Description for predict

`predict` creates a new variable containing predictions such as numbers of events, incidence rates, conditional means, probabilities, conditional probabilities, linear predictions, and standard errors.

## Menu for predict

Statistics > Postestimation

## Syntax for predict

```
predict [type] newvar [if] [in] [, statistic nooffset]
```

```
predict [type] stub* [if] [in] , scores
```

| <i>statistic</i>      | Description                                                     |
|-----------------------|-----------------------------------------------------------------|
| <b>Main</b>           |                                                                 |
| <code>n</code>        | number of events; the default                                   |
| <code>ir</code>       | incidence rate                                                  |
| <code>cm</code>       | conditional mean, $E(y_j   y_j > \tau_j)$                       |
| <code>pr(n)</code>    | probability $\Pr(y_j = n)$                                      |
| <code>pr(a,b)</code>  | probability $\Pr(a \leq y_j \leq b)$                            |
| <code>cpr(n)</code>   | conditional probability $\Pr(y_j = n   y_j > \tau_j)$           |
| <code>cpr(a,b)</code> | conditional probability $\Pr(a \leq y_j \leq b   y_j > \tau_j)$ |
| <code>xb</code>       | linear prediction                                               |
| <code>stdp</code>     | standard error of the linear prediction                         |

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

## Options for predict

Main

`n`, the default, calculates the predicted number of events, which is  $\exp(\mathbf{x}_j\beta)$  if neither `offset()` nor `exposure()` was specified when the model was fit;  $\exp(\mathbf{x}_j\beta + \text{offset}_j)$  if `offset()` was specified; or  $\exp(\mathbf{x}_j\beta) \times \text{exposure}_j$  if `exposure()` was specified.

`ir` calculates the incidence rate  $\exp(\mathbf{x}_j\beta)$ , which is the predicted number of events when exposure is 1. This is equivalent to specifying both the `n` and the `nooffset` options.

`cm` calculates the conditional mean,

$$E(y_j | y_j > \tau_j) = \frac{E(y_j, y_j > \tau_j)}{\Pr(y_j > \tau_j)}$$

where  $\tau_j$  is the truncation point found in `e(1lopt)`.

`pr(n)` calculates the probability  $\Pr(y_j = n)$ , where  $n$  is a nonnegative integer that may be specified as a number or a variable.

`pr(a,b)` calculates the probability  $\Pr(a \leq y_j \leq b)$ , where  $a$  and  $b$  are nonnegative integers that may be specified as numbers or variables;

$b$  missing ( $b \geq .$ ) means  $+\infty$ ;

`pr(20,.)` calculates  $\Pr(y_j \geq 20)$ ;

`pr(20,b)` calculates  $\Pr(y_j \geq 20)$  in observations for which  $b \geq .$  and calculates  $\Pr(20 \leq y_j \leq b)$  elsewhere.

`pr(.,b)` produces a syntax error. A missing value in an observation of the variable  $a$  causes a missing value in that observation for `pr(a,b)`.

`cpr(n)` calculates the conditional probability  $\Pr(y_j = n \mid y_j > \tau_j)$ , where  $\tau_j$  is the truncation point found in `e(11opt)`.  $n$  is an integer greater than the truncation point that may be specified as a number or a variable.

`cpr(a,b)` calculates the conditional probability  $\Pr(a \leq y_j \leq b \mid y_j > \tau_j)$ , where  $\tau_j$  is the truncation point found in `e(11opt)`. The syntax for this option is analogous to that used for `pr(a,b)` except that  $a$  must be greater than the truncation point.

`xb` calculates the linear prediction, which is  $\mathbf{x}_j\boldsymbol{\beta}$  if neither `offset()` nor `exposure()` was specified when the model was fit;  $\mathbf{x}_j\boldsymbol{\beta} + \text{offset}_j$  if `offset()` was specified; or  $\mathbf{x}_j\boldsymbol{\beta} + \ln(\text{exposure}_j)$  if `exposure()` was specified; see `nooffset` below.

`stdp` calculates the standard error of the linear prediction.

`nooffset` is relevant only if you specified `offset()` or `exposure()` when you fit the model. It modifies the calculations made by `predict` so that they ignore the offset or exposure variable; the linear prediction is treated as  $\mathbf{x}_j\boldsymbol{\beta}$  rather than as  $\mathbf{x}_j\boldsymbol{\beta} + \text{offset}_j$  or  $\mathbf{x}_j\boldsymbol{\beta} + \ln(\text{exposure}_j)$ . Specifying `predict ..., nooffset` is equivalent to specifying `predict ..., ir`.

`scores` calculates equation-level score variables.

The first new variable will contain  $\partial \ln L / \partial (\mathbf{x}_j\boldsymbol{\beta})$ .

The second new variable will contain  $\partial \ln L / \partial (\ln \alpha)$  for `dispersion(mean)`.

The second new variable will contain  $\partial \ln L / \partial (\ln \delta)$  for `dispersion(constant)`.

# margins

## Description for margins

margins estimates margins of response for numbers of events, incidence rates, conditional means, probabilities, conditional probabilities, and linear predictions.

## Menu for margins

Statistics > Postestimation

## Syntax for margins

```
margins [marginlist] [, options]
margins [marginlist] , predict(statistic ...) [predict(statistic ...) ...] [options]
```

| <i>statistic</i> | Description                                                     |
|------------------|-----------------------------------------------------------------|
| n                | number of events; the default                                   |
| ir               | incidence rate                                                  |
| cm               | conditional mean, $E(y_j   y_j > \tau_j)$                       |
| pr(n)            | probability $\Pr(y_j = n)$                                      |
| pr(a,b)          | probability $\Pr(a \leq y_j \leq b)$                            |
| cpr(n)           | conditional probability $\Pr(y_j = n   y_j > \tau_j)$           |
| cpr(a,b)         | conditional probability $\Pr(a \leq y_j \leq b   y_j > \tau_j)$ |
| xb               | linear prediction                                               |
| stdp             | not allowed with margins                                        |

Statistics not allowed with margins are functions of stochastic quantities other than e(b).

For the full syntax, see [R] margins.

## Methods and formulas

In the following formulas, we use the same notation as in [R] tnbreg.

Methods and formulas are presented under the following headings:

- Mean-dispersion model*
- Constant-dispersion model*

## Mean-dispersion model

The equation-level scores are given by

$$\begin{aligned} \text{score}(\mathbf{x}\boldsymbol{\beta})_j &= p_j(y_j - \mu_j) - \frac{p_j^{(m+1)}\mu_j}{\Pr(Y > \tau_j | p_j, m)} \\ \text{score}(\omega)_j &= -m \left\{ \frac{\alpha(\mu_j - y_j)}{1 + \alpha\mu_j} - \ln(1 + \alpha\mu_j) + \psi(y_j + m) - \psi(m) \right\} \\ &\quad - \frac{p_j^m}{\Pr(Y > \tau_j | p_j, m)} \{m \ln(p_j) + \mu_j p_j\} \end{aligned}$$

where  $\omega_j = \ln\alpha_j$ ,  $\psi(z)$  is the digamma function, and  $\tau_j$  is the truncation point found in `e(11opt)`.

## Constant-dispersion model

The equation-level scores are given by

$$\begin{aligned} \text{score}(\mathbf{x}\boldsymbol{\beta})_j &= m_j \left\{ \psi(y_j + m_j) - \psi(m_j) + \ln(p) + \frac{p^{m_j} \ln(p)}{\Pr(Y > \tau_j | p, m_j)} \right\} \\ \text{score}(\omega)_j &= y_j - (y_j + m_j)(1 - p) - \text{score}(\mathbf{x}\boldsymbol{\beta})_j - \frac{\mu_j p}{\Pr(Y > \tau_j | p, m_j)} \end{aligned}$$

where  $\omega_j = \ln\delta_j$  and  $\tau_j$  is the truncation point found in `e(11opt)`.

## Description

`tobit` fits models for continuous responses where the outcome variable is censored. Censoring limits may be fixed for all observations or vary across observations.

## Quick start

Tobit regression of  $y$  on  $x_1$  and  $x_2$ , specifying that  $y$  is censored at the minimum of  $y$

```
tobit y x1 x2, ll
```

Same as above, but where the lower-censoring limit is zero

```
tobit y x1 x2, ll(0)
```

Same as above, but specify the lower- and upper-censoring limits

```
tobit y x1 x2, ll(17) ul(34)
```

Same as above, but where `lower` and `upper` are variables containing the censoring limits

```
tobit y x1 x2, ll(lower) ul(upper)
```

## Menu

Statistics > Linear models and related > Censored regression > Tobit regression

## Syntax

```
tobit depvar [indepvars] [if] [in] [weight] [, options]
```

| <i>options</i>                                                                                                                                                                                                                                                                                                                                                                                                                        | Description                                                                                                                                                          |

## Options

### Model

`noconstant`; see [R] **Estimation options**.

`ll[(varname) #]` and `ul[(varname) #]` indicate the lower and upper limits for censoring, respectively. Observations with  $depvar \leq ll()$  are left-censored; observations with  $depvar \geq ul()$  are right-censored; and remaining observations are not censored. You do not have to specify the censoring values. If you specify `ll`, the lower limit is the minimum of *depvar*. If you specify `ul`, the upper limit is the maximum of *depvar*.

`offset(varname)`, `constraints(constraints)`; see [R] **Estimation options**.

## SE/Robust

`vce(vcetype)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory (`oim`, `opg`), that are robust to some kinds of misspecification (`robust`), that allow for intragroup correlation (`cluster clustvar`), and that use bootstrap or jackknife methods (`bootstrap`, `jackknife`); see [R] [vce\\_option](#).

## Reporting

`level(#)`, `nocnsreport`; see [R] [Estimation options](#).

`display_options`: `nocl`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `no1stretch`; see [R] [Estimation options](#).

## Maximization

`maximize_options`: `difficult`, `technique(algorithm_spec)`, `iterate(#)`, `[no]log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `ltolerance(#)`, `nrtolerance(#)`, `nonrtolerance`, and `from(init_specs)`; see [R] [Maximize](#). These options are seldom used.

The following options are available with `tobit` but are not shown in the dialog box:

`collinear`, `coeflegend`; see [R] [Estimation options](#).

## Remarks and examples

`tobit` fits a linear regression model for a censored continuous outcome. Censoring occurs when the dependent variable is observed only within a certain range of values. When it is not, we know only that it is either above (right-censoring) or below (left-censoring) the censoring value. Censoring differs from truncation. When the data are truncated, we do not observe either the dependent variable or the covariates; see [R] [truncreg](#).

Censoring may result from study design or may be a result of how the outcome is measured. Right-censoring of data may occur, for example, in income surveys that top code the highest income category. Any respondent that earns the censoring limit or more reports only the value at the limit, and we do not know the respondent's true income. Left-censoring arises naturally when measurements are obtained from an instrument or a laboratory procedure that has a limit of detection. If we observe a value at the measurement limit, we know the true value is at the limit or below it. `tobit` allows the censoring limits to be the same for all observations or to vary from observation to observation.

[Tobin \(1958\)](#) originally conceived the tobit model as one of consumption of consumer durables where purchases were left-censored at zero. Contemporary literature treats this and similar cases as a corner solution model. See [Wooldridge \(2020, sec. 17.2\)](#), [Long \(1997, 196–210\)](#), and [Maddala and Lahiri \(2006, 333–336\)](#) for an introduction to the tobit model. [Wooldridge \(2010, chap. 17 and 19\)](#) provides an advanced treatment of censored regression models. [Cameron and Trivedi \(2022, chap. 19\)](#) discuss the tobit model using Stata examples.

The tobit model can be written as the latent regression model  $\mathbf{y} = \mathbf{x}\beta + \epsilon$  with a continuous outcome that is either observed or unobserved. Following Cong (2000), the observed outcome for observation  $i$  is defined as

$$y_i^* = \begin{cases} y_i & \text{if } a < y_i < b \\ a & \text{if } y_i \leq a \\ b & \text{if } y_i \geq b \end{cases}$$

where  $a$  is the lower-censoring limit and  $b$  is the upper-censoring limit. The tobit model assumes that the error term is normally distributed;  $\epsilon \sim N(\mathbf{0}, \sigma^2 \mathbf{I})$ . Depending on the problem at hand, the quantity of interest in a tobit model may be the censored outcome,  $y_i^*$ , or the uncensored outcome,  $y_i$ . In the measurement instrument scenario above, we may wish to predict the values that fall below the measurement threshold. By contrast, in the consumption of consumer durables scenario above, the latent variable is an artificial construct and the variable of interest is the observed consumer expenditure.

### ► Example 1: Constant-censoring limit

University administrators want to know the relationship between high school grade point average (GPA) and students' performance in college. `gpa.dta` contains fictional data on a cohort of 4,000 college students. College GPA (`gpa2`) and high school GPA (`hsgpa`) are measured on a continuous scale between zero and four. The outcome of interest is the student's college GPA. But, for reasons of confidentiality, GPAs below 2.0 are reported as 2.0. In other words, the outcome is censored on the left.

We believe that GPA is also a function of the logarithm of income of the student's parents (`pincome`) and whether or not the student participated in a study-skills program while in college (`program`).

```
. use https://www.stata-press.com/data/r19/gpa
(High school GPA and performance in college)
. tobit gpa2 hsgpa pincome program, ll

tobit reports the coefficients for the latent regression model. Thus, we can interpret the coefficients just as we would the coefficients from OLS. For example, participation in a study-skills program increases the expected uncensored GPA by 0.56 points.

▷ Example 2: Tobit model for a corner solution

Suppose that we are interested in the number of hours married women spend working for wages, and we treat observations recording zero hours as observed, per the corner-solution approach discussed [Wooldridge \(2010, chap. 16\)](#). We use the labor supply data extracted by [Mroz \(1987\)](#) from the 1975 PSID for 753 married women. The variable `whrs75` records the annual number of hours worked. Forty-three percent of the surveyed women worked zero hours, and the remaining women worked on average 1,303 hours a year.

We regress hours worked on household income excluding wife’s income (`nwinc`), years of schooling (`wedyrs`), years of labor market experience (`wexper`) and its square, age (`wifeage`), an indicator for the presence of children under 6 years of age at home (`k16`), and an indicator for the presence of children from 6 to 18 years old at home (`k618`).

Unlike in [example 1](#), we are interested in the marginal effect of the covariates on the observed outcome. We can use [margins](#) to estimate, for example, the average marginal effect of years of education on the expected value of the actual hours worked.

```
. margins, dydx(wedyrs) predict(ystar(0,.))
Average marginal effects Number of obs = 753
Model VCE: OIM
Expression: E(whrs75*|whrs75>0), predict(ystar(0,.))
dy/dx wrt: wedyrs
```

|        | Delta-method |           |      |       |                      |
|--------|--------------|-----------|------|-------|----------------------|
|        | dy/dx        | std. err. | z    | P> z  | [95% conf. interval] |
| wedyrs | 47.47306     | 12.6214   | 3.76 | 0.000 | 22.73558 72.21054    |

The average marginal effect of years of education on the actual hours worked is 47.47. See [\[R\] tobit postestimation](#) for more examples using [margins](#).

[James Tobin](#) (1918–2002) was an American economist who after education and research at Harvard moved to Yale, where he was on the faculty from 1950 to 1988. He made many outstanding contributions to economics and was awarded the Nobel Prize in 1981 “for his analysis of financial markets and their relations to expenditure decisions, employment, production and prices”. He trained in the US Navy with the writer, Herman Wouk, who later fashioned a character after Tobin in the novel *The Caine Mutiny* (1951): “A mandarin-like midshipman named Tobit, with a domed forehead, measured quiet speech, and a mind like a sponge, was ahead of the field by a spacious percentage.”

In addition to the above, the following is stored in `r()`:

|                       |                                                                                                                            |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------|
| Matrices              |                                                                                                                            |
| <code>r(table)</code> | matrix containing the coefficients with their standard errors, test statistics, <i>p</i> -values, and confidence intervals |

Note that results stored in `r()` are updated when the command is replayed and will be replaced when any `r`-class command is run after the estimation command.

## Methods and formulas

See *Methods and formulas* in [R] [intreg](#).

This command supports the Huber/White/sandwich estimator of the variance and its clustered version using `vce(robust)` and `vce(cluster clustvar)`, respectively. See [P] [\\_robust](#), particularly *Maximum likelihood estimators* and *Methods and formulas*.

`tobit` also supports estimation with survey data. For details on VCEs with survey data, see [SVY] [Variance estimation](#).

## Postestimation commands

The following postestimation commands are available after `tobit`:

| Command                      | Description                                                                                                                             |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <code>contrast</code>        | contrasts and ANOVA-style joint tests of parameters                                                                                     |
| <code>estat ic</code>        | Akaike's, consistent Akaike's, corrected Akaike's, and Schwarz's Bayesian information criteria (AIC, CAIC, AICc, and BIC, respectively) |
| <code>estat summarize</code> | summary statistics for the estimation sample                                                                                            |
| <code>estat vce</code>       | variance–covariance matrix of the estimators (VCE)                                                                                      |
| <code>estat (svy)</code>     | postestimation statistics for survey data                                                                                               |
| <code>estimates</code>       | cataloging estimation results                                                                                                           |
| <code>etable</code>          | table of estimation results                                                                                                             |
| * <code>forecast</code>      | dynamic forecasts and simulations                                                                                                       |
| * <code>hausman</code>       | Hausman's specification test                                                                                                            |
| <code>lincom</code>          | point estimates, standard errors, testing, and inference for linear combinations of parameters                                          |
| <code>linktest</code>        | link test for model specification                                                                                                       |
| * <code>lrtest</code>        | likelihood-ratio test                                                                                                                   |
| <code>margins</code>         | marginal means, predictive margins, marginal effects, and average marginal effects                                                      |
| <code>marginsplot</code>     | graph the results from margins (profile plots, interaction plots, etc.)                                                                 |
| <code>nlcom</code>           | point estimates, standard errors, testing, and inference for nonlinear combinations of parameters                                       |
| <code>predict</code>         | linear, censored, and truncated predictions                                                                                             |
| <code>predictnl</code>       | point estimates, standard errors, testing, and inference for generalized predictions                                                    |
| <code>pwcompare</code>       | pairwise comparisons of parameters                                                                                                      |
| <code>suest</code>           | seemingly unrelated estimation                                                                                                          |
| <code>test</code>            | Wald tests of simple and composite linear hypotheses                                                                                    |
| <code>testnl</code>          | Wald tests of nonlinear hypotheses                                                                                                      |

\*`forecast`, `hausman`, and `lrtest` are not appropriate with `svy` estimation results.

# predict

## Description for predict

`predict` creates a new variable containing predictions such as linear predictions, standard errors, probabilities, and expected values.

## Menu for predict

Statistics > Postestimation

## Syntax for predict

```
predict [type] newvar [if] [in] [, statistic nooffset]
```

```
predict [type] stub* [if] [in] , scores
```

| <i>statistic</i> | Description |
|------------------|-------------|
|------------------|-------------|

Main

|                                       |                                              |
|---------------------------------------|----------------------------------------------|
| <code>xb</code>                       | linear prediction; the default               |
| <code>stdp</code>                     | standard error of the linear prediction      |
| <code>stdf</code>                     | standard error of the forecast               |
| <code>pr(<i>a</i>,<i>b</i>)</code>    | $\Pr(a < y_j < b)$                           |
| <code>e(<i>a</i>,<i>b</i>)</code>     | $E(y_j   a < y_j < b)$                       |
| <code>ystar(<i>a</i>,<i>b</i>)</code> | $E(y_j^*   y_j^* = \max\{a, \min(y_j, b)\})$ |

These statistics are available both in and out of sample; type `predict ... if e(sample)` ... if wanted only for the estimation sample.

`stdf` is not allowed with `svy` estimation results.

where *a* and *b* may be numbers or variables; *a* missing (*a* ≥ .) means  $-\infty$ , and *b* missing (*b* ≥ .) means  $+\infty$ ; see [U] 12.2.1 Missing values.

## Options for predict

Main

`xb`, the default, calculates the linear prediction.

`stdp` calculates the standard error of the prediction, which can be thought of as the standard error of the predicted expected value or mean for the observation's covariate pattern. The standard error of the prediction is also referred to as the standard error of the fitted value.

`stdf` calculates the standard error of the forecast, which is the standard error of the point prediction for 1 observation. It is commonly referred to as the standard error of the future or forecast value. By construction, the standard errors produced by `stdf` are always larger than those produced by `stdp`; see *Methods and formulas* in [R] [regress postestimation](#).

`pr(a,b)` calculates  $\Pr(a < \mathbf{x}_j\boldsymbol{\beta} + \epsilon_j < b)$ , the probability that  $y_j|\mathbf{x}_j$  would be observed in the interval  $(a,b)$ .

$a$  and  $b$  may be specified as numbers or variable names;  $lb$  and  $ub$  are variable names;

`pr(20,30)` calculates  $\Pr(20 < \mathbf{x}_j\boldsymbol{\beta} + \epsilon_j < 30)$ ;

`pr(lb,ub)` calculates  $\Pr(lb < \mathbf{x}_j\boldsymbol{\beta} + \epsilon_j < ub)$ ; and

`pr(20,ub)` calculates  $\Pr(20 < \mathbf{x}_j\boldsymbol{\beta} + \epsilon_j < ub)$ .

$a$  missing ( $a \geq .$ ) means  $-\infty$ ; `pr(.,30)` calculates  $\Pr(-\infty < \mathbf{x}_j\boldsymbol{\beta} + \epsilon_j < 30)$ ;

`pr(lb,30)` calculates  $\Pr(-\infty < \mathbf{x}_j\boldsymbol{\beta} + \epsilon_j < 30)$  in observations for which  $lb \geq .$

and calculates  $\Pr(lb < \mathbf{x}_j\boldsymbol{\beta} + \epsilon_j < 30)$  elsewhere.

$b$  missing ( $b \geq .$ ) means  $+\infty$ ; `pr(20,.)` calculates  $\Pr(+\infty > \mathbf{x}_j\boldsymbol{\beta} + \epsilon_j > 20)$ ;

`pr(20,ub)` calculates  $\Pr(+\infty > \mathbf{x}_j\boldsymbol{\beta} + \epsilon_j > 20)$  in observations for which  $ub \geq .$

and calculates  $\Pr(20 < \mathbf{x}_j\boldsymbol{\beta} + \epsilon_j < ub)$  elsewhere.

`e(a,b)` calculates  $E(\mathbf{x}_j\boldsymbol{\beta} + \epsilon_j | a < \mathbf{x}_j\boldsymbol{\beta} + \epsilon_j < b)$ , the expected value of  $y_j|\mathbf{x}_j$  conditional on  $y_j|\mathbf{x}_j$  being in the interval  $(a,b)$ , meaning that  $y_j|\mathbf{x}_j$  is truncated.

$a$  and  $b$  are specified as they are for `pr()`.

`ystar(a,b)` calculates  $E(y_j^*)$ , where  $y_j^* = a$  if  $\mathbf{x}_j\boldsymbol{\beta} + \epsilon_j \leq a$ ,  $y_j^* = b$  if  $\mathbf{x}_j\boldsymbol{\beta} + \epsilon_j \geq b$ , and  $y_j^* = \mathbf{x}_j\boldsymbol{\beta} + \epsilon_j$  otherwise, meaning that  $y_j^*$  is censored.  $a$  and  $b$  are specified as they are for `pr()`.

`nooffset` is relevant only if you specified `offset(varname)`. It modifies the calculations made by `predict` so that they ignore the offset variable; the linear prediction is treated as  $\mathbf{x}_j\boldsymbol{\beta}$  rather than as  $\mathbf{x}_j\boldsymbol{\beta} + \text{offset}_j$ .

`scores` calculates equation-level score variables.

The first new variable will contain  $\partial \ln L / \partial (\mathbf{x}_j\boldsymbol{\beta})$ .

The second new variable will contain  $\partial \ln L / \partial \sigma$ .

# margins

## Description for margins

`margins` estimates margins of response for linear predictions, probabilities, and expected values.

## Menu for margins

Statistics > Postestimation

## Syntax for margins

```
margins [marginlist] [, options]
```

```
margins [marginlist] , predict(statistic ...) [predict(statistic ...) ...] [options]
```

| <i>statistic</i>                      | Description                                 |
|---------------------------------------|---------------------------------------------|
| <code>xb</code>                       | linear prediction; the default              |
| <code>pr(<i>a</i>,<i>b</i>)</code>    | $\Pr(a < y_j < b)$                          |
| <code>e(<i>a</i>,<i>b</i>)</code>     | $E(y_j   a < y_j < b)$                      |
| <code>ystar(<i>a</i>,<i>b</i>)</code> | $E(y_j^*), y_j^* = \max\{a, \min(y_j, b)\}$ |
| <code>stdp</code>                     | not allowed with <code>margins</code>       |
| <code>stdf</code>                     | not allowed with <code>margins</code>       |

Statistics not allowed with `margins` are functions of stochastic quantities other than `e(b)`.

For the full syntax, see [R] [margins](#).

## Remarks and examples

### ▷ Example 1: Marginal predictions

In [example 2](#) of [\[R\] tobit](#), we fit a tobit model of annual number of hours that married women spend working and then obtained estimated average marginal effect of 47.47 for years of education on observed hours worked.

```
. use https://www.stata-press.com/data/r19/mroz87
(1975 PSID data from Mroz, 1987)
. tobit whrs75 nwinc wedyrs wexper c.wexper#c.wexper wifeage k16 k618, ll(0)
(output omitted)
. margins, dydx(wedyrs) predict(ystar(0,.))
(output omitted)
```

However, we may not want this overall effect. To obtain marginal effects for specific alternative scenarios, we use `margins` with the `at()` option. For example, continuing with [example 2](#) of [\[R\] tobit](#) to estimate the means of the marginal effects on the expected value of the censored outcome conditional on education ranging from 8 years to 17 years, we type

```
. margins, dydx(wedyrs) predict(ystar(0,.)) at(wedyrs=(8(1)17))
Average marginal effects Number of obs = 753
Model VCE: OIM
Expression: E(whrs75*|whrs75>0), predict(ystar(0,.))
dy/dx wrt: wedyrs
1._at: wedyrs = 8
2._at: wedyrs = 9
3._at: wedyrs = 10
4._at: wedyrs = 11
5._at: wedyrs = 12
6._at: wedyrs = 13
7._at: wedyrs = 14
8._at: wedyrs = 15
9._at: wedyrs = 16
10._at: wedyrs = 17
```

|        |     | Delta-method |           | z    | P> z  | [95% conf. interval] |          |
|--------|-----|--------------|-----------|------|-------|----------------------|----------|
|        |     | dy/dx        | std. err. |      |       |                      |          |
| wedyrs |     |              |           |      |       |                      |          |
|        | _at |              |           |      |       |                      |          |
|        | 1   | 39.58775     | 8.432006  | 4.69 | 0.000 | 23.06132             | 56.11418 |
|        | 2   | 41.4497      | 9.421414  | 4.40 | 0.000 | 22.98407             | 59.91533 |
|        | 3   | 43.30531     | 10.41233  | 4.16 | 0.000 | 22.89752             | 63.71309 |
|        | 4   | 45.14859     | 11.39804  | 3.96 | 0.000 | 22.80885             | 67.48833 |
|        | 5   | 46.97371     | 12.37208  | 3.80 | 0.000 | 22.72489             | 71.22254 |
|        | 6   | 48.77504     | 13.32825  | 3.66 | 0.000 | 22.65216             | 74.89793 |
|        | 7   | 50.54717     | 14.26071  | 3.54 | 0.000 | 22.5967              | 78.49765 |
|        | 8   | 52.28499     | 15.16403  | 3.45 | 0.001 | 22.56403             | 82.00594 |
|        | 9   | 53.98369     | 16.03324  | 3.37 | 0.001 | 22.55912             | 85.40827 |
|        | 10  | 55.63887     | 16.8639   | 3.30 | 0.001 | 22.58624             | 88.6915  |

The estimated mean of the marginal effects is about 39.59 hours for 8 years of schooling, about 41.45 hours for 9 years of schooling, and so on.

## Description

`total` produces estimates of totals, along with standard errors.

## Quick start

Total of continuous variable `v1`

```
total v1
```

Same as above, but restrict estimation to observations where `catvar = 1`

```
total v1 if catvar==1
```

Same as above, but using `svyset` data

```
svy, subpop(if catvar==1): total v1
```

Total of `v1` for each level of `catvar`

```
total v1, over(catvar)
```

With jackknife standard errors

```
total v1, vce(jackknife)
```

## Menu

Statistics > Summaries, tables, and tests > Summary and descriptive statistics > Totals

## Syntax

```
total varlist [if] [in] [weight] [, options]
```

*varlist* may contain factor variables; see [U] 11.4.3 **Factor variables**.

`bayesboot`, `bootstrap`, `collect`, `jackknife`, `mi estimate`, `rolling`, `statsby`, and `svy` are allowed; see [U] 11.1.10 **Prefix commands**.

`vce(bootstrap)` and `vce(jackknife)` are not allowed with the `mi estimate` prefix.

Weights are not allowed with the `bootstrap` prefix; see [R] **bootstrap**.

`vce()` and weights are not allowed with the `svy` prefix; see [SVY] **svy**.

`fweights`, `iweights`, and `pweights` are allowed; see [U] 11.1.6 **weight**.

`coeflegend` does not appear in the dialog box.

See [U] 20 **Estimation and postestimation commands** for more capabilities of estimation commands.

## Options

`if/in/over`

`over(varlisto)` specifies that estimates be computed for multiple subpopulations, which are identified by the different values of the variables in *varlist*<sub>o</sub>. Only numeric, nonnegative, integer-valued variables are allowed in `over(varlisto)`.

SE/Cluster

`vce(vcetype)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory (`analytic`), that allow for intragroup correlation (`cluster clustvar`), and that use bootstrap or jackknife methods (`bootstrap`, `jackknife`); see [R] **vce\_option**.

`vce(analytic)`, the default, uses the analytically derived variance estimator associated with the sample total.

## Reporting

level(#); see [R] [Estimation options](#).

noheader prevents the table header from being displayed.

*display\_options*: `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, and `nolstretch`; see [R] [Estimation options](#).

The following option is available with `total` but is not shown in the dialog box:

`coeflegend`; see [R] [Estimation options](#).

## Remarks and examples

### ▷ Example 1

Suppose that we collected data on incidence of heart attacks. The variable `heartatk` indicates whether a person ever had a heart attack (1 means yes; 0 means no). We can then estimate the total number of persons who have had heart attacks for each sex in the population represented by the data we collected.

```
. use https://www.stata-press.com/data/r19/total
(Fictional incidence of heart-attack data)
. total heartatk [pw=swgt], over(sex)
```

Total estimation Number of obs = 4,946

|                | Total  | Std. err. | [95% conf. interval] |          |
|----------------|--------|-----------|----------------------|----------|
| c.heartatk@sex |        |           |                      |          |
| Male           | 944559 | 104372.3  | 739943               | 1149175  |
| Female         | 581590 | 82855.59  | 419156.3             | 744023.7 |

## Stored results

`total` stores the following in `e()`:

### Scalars

|                         |                                          |

| <code>e(over)</code>         | <i>varlist</i> from <code>over()</code>        |
| <code>e(vce)</code>          | <i>vcetype</i> specified in <code>vce()</code> |
| <code>e(vcetype)</code>      | title used to label Std. err.                  |
| <code>e(properties)</code>   | <code>b V</code>                               |
| <code>e(estat_cmd)</code>    | program used to implement <code>estat</code>   |
| <code>e(marginsnotok)</code> | predictions disallowed by <code>margins</code> |

### Matrices

|                       |                                               |
|-----------------------|-----------------------------------------------|
| <code>e(b)</code>     | vector of total estimates                     |
| <code>e(V)</code>     | (co)variance estimates                        |
| <code>e(_N)</code>    | vector of numbers of nonmissing observations  |
| <code>e(error)</code> | error code corresponding to <code>e(b)</code> |

### Functions

|                        |                         |
|------------------------|-------------------------|
| <code>e(sample)</code> | marks estimation sample |
|------------------------|-------------------------|

In addition to the above, the following is stored in `r()`:

### Matrices

|                       |                                                                                                                            |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------|
| <code>r(table)</code> | matrix containing the coefficients with their standard errors, test statistics, <i>p</i> -values, and confidence intervals |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------|

Note that results stored in `r()` are updated when the command is replayed and will be replaced when any `r-class` command is run after the estimation command.

## Methods and formulas

Methods and formulas are presented under the following headings:

*The total estimator*  
*Survey data*  
*The survey total estimator*  
*The poststratified total estimator*  
*Subpopulation estimation*

## The total estimator

Let  $y$  denote the variable on which to calculate the total and  $y_j, j = 1, \dots, n$ , denote an individual observation on  $y$ . Let  $w_j$  be the frequency weight (or `weight` or `pweight`), and if no weight is specified, define  $w_j = 1$  for all  $j$ . The sum of the weights is an estimate of the population size:

$$\widehat{N} = \sum_{j=1}^n w_j$$

If the population values of  $y$  are denoted by  $Y_j, j = 1, \dots, N$ , the associated population total is

$$Y = \sum_{j=1}^N Y_j = N\bar{y}$$

where  $\bar{y}$  is the population mean. The total is estimated as

$$\widehat{Y} = \widehat{N}\bar{y}$$

The variance estimator for the total is

$$\widehat{V}(\widehat{Y}) = \widehat{N}^2 \widehat{V}(\bar{y})$$

where  $\widehat{V}(\bar{y})$  is the variance estimator for the mean; see [\[R\] mean](#). The standard error of the total is the square root of the variance.

If  $x, x_j, \bar{x}$ , and  $\widehat{X}$  are similarly defined for another variable (observed jointly with  $y$ ), the covariance estimator between  $\widehat{X}$  and  $\widehat{Y}$  is

$$\widehat{\text{Cov}}(\widehat{X}, \widehat{Y}) = \widehat{N}^2 \widehat{\text{Cov}}(\bar{x}, \bar{y})$$

where  $\widehat{\text{Cov}}(\bar{x}, \bar{y})$  is the covariance estimator between two means; see [\[R\] mean](#).

## Survey data

See [\[SVY\] Variance estimation](#) and [\[SVY\] Poststratification](#) for discussions that provide background information for the following formulas.

## The survey total estimator

Let  $Y_j$  be a survey item for the  $j$ th individual in the population, where  $j = 1, \dots, M$  and  $M$  is the size of the population. The associated population total for the item of interest is

$$Y = \sum_{j=1}^M Y_j$$

Let  $y_j$  be the survey item for the  $j$ th sampled individual from the population, where  $j = 1, \dots, m$  and  $m$  is the number of observations in the sample.

The estimator  $\hat{Y}$  for the population total  $Y$  is

$$\hat{Y} = \sum_{j=1}^m w_j y_j$$

where  $w_j$  is a sampling weight. The estimator for the number of individuals in the population is

$$\hat{M} = \sum_{j=1}^m w_j$$

The score variable for the total estimator is the variable itself,

$$z_j(\hat{Y}) = y_j$$

## The poststratified total estimator

Let  $P_k$  denote the set of sampled observations that belong to poststratum  $k$ , and define  $I_{P_k}(j)$  to indicate if the  $j$ th observation is a member of poststratum  $k$ , where  $k = 1, \dots, L_P$  and  $L_P$  is the number of poststrata. Also, let  $M_k$  denote the population size for poststratum  $k$ .  $P_k$  and  $M_k$  are identified by specifying the `poststrata()` and `postweight()` options on `svyset`; see [\[SVY\] svyset](#).

The estimator for the poststratified total is

$$\hat{Y}^P = \sum_{k=1}^{L_P} \frac{M_k}{\hat{M}_k} \hat{Y}_k = \sum_{k=1}^{L_P} \frac{M_k}{\hat{M}_k} \sum_{j=1}^m I_{P_k}(j) w_j y_j$$

where

$$\hat{M}_k = \sum_{j=1}^m I_{P_k}(j) w_j$$

The score variable for the poststratified total is

$$z_j(\hat{Y}^P) = \sum_{k=1}^{L_P} I_{P_k}(j) \frac{M_k}{\hat{M}_k} \left( y_j - \frac{\hat{Y}_k}{\hat{M}_k} \right)$$

## Subpopulation estimation

Let  $S$  denote the set of sampled observations that belong to the subpopulation of interest, and define  $I_S(j)$  to indicate if the  $j$ th observation falls within the subpopulation.

The estimator for the subpopulation total is

$$\hat{Y}^S = \sum_{j=1}^m I_S(j) w_j y_j$$

and its score variable is

$$z_j(\hat{Y}^S) = I_S(j) y_j$$

The estimator for the poststratified subpopulation total is

$$\hat{Y}^{PS} = \sum_{k=1}^{L_P} \frac{M_k}{\widehat{M}_k} \hat{Y}_k^S = \sum_{k=1}^{L_P} \frac{M_k}{\widehat{M}_k} \sum_{j=1}^m I_{P_k}(j) I_S(j) w_j y_j$$

and its score variable is

$$z_j(\hat{Y}^{PS}) = \sum_{k=1}^{L_P} I_{P_k}(j) \frac{M_k}{\widehat{M}_k} \left\{ I_S(j) y_j - \frac{\hat{Y}_k^S}{\widehat{M}_k} \right\}$$

## Postestimation commands

The following postestimation commands are available after `total`:

| Command                  | Description                                                                                       |
|--------------------------|---------------------------------------------------------------------------------------------------|
| <code>contrast</code>    | contrasts and ANOVA-style joint tests of parameters                                               |
| <code>estat vce</code>   | variance–covariance matrix of the estimators (VCE)                                                |
| <code>estat (svy)</code> | postestimation statistics for survey data                                                         |
| <code>estimates</code>   | cataloging estimation results                                                                     |
| <code>etable</code>      | table of estimation results                                                                       |
| <code>lincom</code>      | point estimates, standard errors, testing, and inference for linear combinations of parameters    |
| <code>marginsplot</code> | graph the results from <code>total</code>                                                         |
| <code>nlcom</code>       | point estimates, standard errors, testing, and inference for nonlinear combinations of parameters |
| <code>pwcompare</code>   | pairwise comparisons of parameters                                                                |
| <code>test</code>        | Wald tests of simple and composite linear hypotheses                                              |
| <code>testnl</code>      | Wald tests of nonlinear hypotheses                                                                |

## Remarks and examples

### ► Example 1

Continuing with our data on incidence of heart attacks from [example 1](#) in [\[R\] total](#), we want to test whether there are twice as many heart attacks among men than women in the population.

```
. use https://www.stata-press.com/data/r19/total
(Fictional incidence of heart-attack data)
. total heartatk [pw=swgt], over(sex)
(output omitted)
. test heartatk@1.sex = 2 * heartatk@2.sex
(1) c.heartatk@1bn.sex - 2*c.heartatk@2.sex = 0
 F(1, 4945) = 1.25
 Prob > F = 0.2643
```

Thus we do not reject our hypothesis that the total number of heart attacks for men is twice that for women in the population.

[Description](#)[Options](#)[Acknowledgment](#)[Quick start](#)[Remarks and examples](#)[References](#)[Menu](#)[Stored results](#)[Also see](#)[Syntax](#)[Methods and formulas](#)

## Description

`tpoisson` fits a truncated Poisson regression model when the number of occurrences of an event is restricted to be above a truncation point, below a truncation point, or between two truncation points. Truncated Poisson models are appropriate when neither the dependent variable nor the covariates are observed in the truncated part of the distribution. By default, `tpoisson` assumes left-truncation occurs at zero, but truncation may be specified at other fixed points or at values that vary across observations.

## Quick start

Truncated Poisson regression of `y` on `x1` and `x2` with left-truncation at 0

```
tpoisson y x1 x2
```

Add categorical variable `a` using [factor-variable](#) syntax

```
tpoisson y x1 x2 i.a
```

Same as above, but report incidence-rate ratios and use a constant truncation point of 4

```
tpoisson y x1 x2 i.a, irr ll(4)
```

With offset variable `lnexp`

```
tpoisson y x1 x2 i.a, offset(lnexp)
```

Same as above, but with a variable truncation point stored in variable `min`

```
tpoisson y x1 x2 i.a, offset(lnexp) ll(min)
```

With variable left- and right-truncation points

```
tpoisson y x1 x2, ll(min) ul(max)
```

With variable right-truncation points

```
tpoisson y x1 x2, ul(max)
```

Constrain the coefficients for 2. `a` and 3. `a` to equality

```
constraint define 1 2.a = 3.a
tpoisson y x1 x2 i.a, constraints(1)
```

## Menu

Statistics > Count outcomes > Truncated Poisson regression

## Syntax

```
tpoisson devar [indepvars] [if] [in] [weight] [, options]
```

| <i>options</i>                                    | Description                                                                                                                                                                 |

*indepvars* may contain factor variables; see [U] 11.4.3 **Factor variables**.

*devar* and *indepvars* may contain time-series operators; see [U] 11.4.4 **Time-series varlists**.

`bayes`, `bayesboot`, `bootstrap`, `by`, `collect`, `fmm`, `fp`, `jackknife`, `rolling`, `statsby`, and `svy` are allowed; see [U] 11.1.10 **Prefix commands**. For more details, see [BAYES] `bayes: tpoisson` and [FMM] `fmm: tpoisson`.

Weights are not allowed with the `bootstrap` prefix; see [R] **bootstrap**.

`vce()` and weights are not allowed with the `svy` prefix; see [SVY] **svy**.

`fweights`, `iwweights`, and `pweights` are allowed; see [U] 11.1.6 **weight**.

`collinear` and `coeflegend` do not appear in the dialog box.

See [U] 20 **Estimation and postestimation commands** for more capabilities of estimation commands.

## Options

### Model

`noconstant`; see [R] [Estimation options](#).

`ll(#|varname)` and `ul(#|varname)` specify the lower and upper limits for truncation, respectively. You may specify nonnegative integer values for one or both.

When neither `ll()` nor `ul()` is specified, the default is zero truncation, `ll(0)`, equivalent to left-truncation at zero.

`exposure(varnamee)`, `offset(varnameo)`, `constraints(constraints)`; see [R] [Estimation options](#).

### SE/Robust

`vce(vcetype)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory (`oim`, `opg`), that are robust to some kinds of misspecification (`robust`), that allow for intragroup correlation (`cluster clustvar`), and that use bootstrap or jackknife methods (`bootstrap`, `jackknife`); see [R] [vce\\_option](#).

### Reporting

`level(#)`; see [R] [Estimation options](#).

`irr` reports estimated coefficients transformed to incidence-rate ratios, that is,  $e^{\beta_i}$  rather than  $\beta_i$ . Standard errors and confidence intervals are similarly transformed. This option affects how results are displayed, not how they are estimated. `irr` may be specified at estimation or when replaying previously estimated results.

`nocnsreport`; see [R] [Estimation options](#).

*display\_options*: `nocl`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `no1stretch`; see [R] [Estimation options](#).

### Maximization

*maximize\_options*: `difficult`, `technique(algorithm_spec)`, `iterate(#)`, `[no]log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `ltolerance(#)`, `nrtolerance(#)`, `nonrtolerance`, and `from(init_specs)`; see [R] [Maximize](#). These options are seldom used.

Setting the optimization type to `technique(bhhh)` resets the default `vcetype` to `vce(opg)`.

The following options are available with `tpoisson` but are not shown in the dialog box:

`collinear`, `coeflegend`; see [R] [Estimation options](#).

## Remarks and examples

`tpoisson` fits a truncated Poisson regression model by maximum likelihood estimation when the number of occurrences of an event is restricted to be above a truncation point, below a truncation point, or between two truncation points. If the dependent variable is not truncated, standard Poisson regression may be more appropriate; see [R] [poisson](#).

When the data are truncated, we do not observe either the dependent variable or the covariates. For example, consider a study about the number of days that individuals with hyperglycemia are hospitalized after presenting to the hospital. If we select our sample only from admission records, then the sample is truncated at zero because we have data only on individuals who stayed at least one day. Now assume that we are relying on billing data and that hospitals may submit either a final bill when a patient is discharged or an interim bill every 30 days. In this case, we have no information about patients who are hospitalized fewer than 1 day or more than 30 days. Our data are left-truncated at 0 and right-truncated at 30.

A related phenomenon is censoring. For censored observations, we observe complete covariate information but only a censored value of the dependent variable. Different research designs can give rise to censored data or truncated data. See [R] [cpoisson](#) for information about censored Poisson regression.

Truncated Poisson regression was first proposed by [Grogger and Carson \(1991\)](#). For an introduction to Poisson regression, see [Cameron and Trivedi \(2005, 2022\)](#) and [Long and Freese \(2014\)](#). For an introduction to truncated Poisson models, see [Cameron and Trivedi \(2013\)](#) and [Long \(1997, chap. 8\)](#).

### ▷ Example 1: Left-truncation at zero

Consider the [Simonoff \(2003\)](#) dataset of running shoes for a sample of runners who registered an online running log. A running-shoe marketing executive is interested in knowing how the number of pairs of running shoes purchased relates to other factors such as gender, marital status, age, education, income, typical number of runs per week, average miles run per week, and the preferred type of running. These data are naturally truncated at zero. A truncated Poisson model is fit to the number of pairs of shoes owned on runs per week, miles run per week, gender, age, and marital status.

No options are needed because zero truncation is the default for `tpoisson`.

```
. use https://www.stata-press.com/data/r19/runshoes
(Running shoes)
. tpoisson shoes rpweek mpweek male age married
Iteration 0: Log likelihood = -88.328151
Iteration 1: Log likelihood = -86.272639
Iteration 2: Log likelihood = -86.257999
Iteration 3: Log likelihood = -86.257994

Truncated Poisson regression Number of obs = 60
Limits: lower = 0 LR chi2(5) = 22.75
 upper = +inf Prob > chi2 = 0.0004
Log likelihood = -86.257994 Pseudo R2 = 0.1165
```

| shoes   | Coefficient | Std. err. | z     | P> z  | [95% conf. interval] |          |
|---------|-------------|-----------|-------|-------|----------------------|----------|
| rpweek  | .1575811    | .1097893  | 1.44  | 0.151 | -.057602             | .3727641 |
| mpweek  | .0210673    | .0091113  | 2.31  | 0.021 | .0032094             | .0389252 |
| male    | .0446134    | .2444626  | 0.18  | 0.855 | -.4345246            | .5237513 |
| age     | .0185565    | .0137786  | 1.35  | 0.178 | -.008449             | .045562  |
| married | -.1283912   | .2785044  | -0.46 | 0.645 | -.6742498            | .4174674 |
| _cons   | -1.205844   | .6619774  | -1.82 | 0.069 | -2.503296            | .0916078 |

Using the zero-truncated Poisson regression with these data, only the coefficient on average miles per week is statistically significant at the 5% level.

## ▷ Example 2: Left-truncation with a fixed-truncation point

Semiconductor manufacturing requires that silicon wafers be coated with a layer of metal oxide. The depth of this layer is strictly controlled. In this example, a critical oxide layer is designed for  $300 \pm 20$  angstroms (Å).

After the oxide layer is coated onto a wafer, the wafer enters a photolithography step in which the lines representing the electrical connections are printed on the oxide and later etched and filled with metal. The widths of these lines are measured. In this example, they are controlled to  $90 \pm 5$  micrometers ( $\mu\text{m}$ ).

After these and other steps, each wafer is electrically tested at probe. If too many failures are discovered, the wafer is rejected and sent for engineering analysis. In this example, the maximum number of probe failures tolerated for this product is 10.

A major failure at probe has been encountered—88 wafers had more than 10 failures each. The 88 wafers that failed were tested using 4 probe machines. The engineer suspects that the failures were a result of faulty probe machines, poor depth control, or poor line widths. The line widths and depths in these data are the actual measurement minus its specification target,  $300 \text{ \AA}$  for the oxide depths and  $90 \mu\text{m}$  for the line widths.

The following table tabulates the average failure rate for each probe using Stata's `mean` command; see [R] [mean](#).

```
. use https://www.stata-press.com/data/r19/probe
(Silicon wafers)
. mean failures, over(probe)
```

| Mean estimation  |          | Number of obs = 88 |                      |          |
|------------------|----------|--------------------|----------------------|----------|
|                  | Mean     | Std. err.          | [95% conf. interval] |          |
| c.failures@probe |          |                    |                      |          |
| 1                | 15.875   | 1.186293           | 13.51711             | 18.23289 |
| 2                | 14.95833 | .5912379           | 13.78318             | 16.13348 |
| 3                | 16.47059 | .9279866           | 14.62611             | 18.31506 |
| 4                | 23.09677 | .9451117           | 21.21826             | 24.97529 |

The 95% confidence intervals in this table suggest that there are about 5–11 additional failures per wafer on probe 4. These are unadjusted for varying line widths and oxide depths. Possibly, probe 4 received the wafers with larger line widths or extreme oxide depths.

Truncated Poisson regression more clearly identifies the root causes for the increased failures by estimating the differences between probes adjusted for the line widths and oxide depths. It also allows us to determine whether the deviations from specifications in line widths or oxide depths might be contributing to the problem.

```
. tpoisson failures i.probe depth width, ll(10) nolog
Truncated Poisson regression Number of obs = 88
Limits: lower = 10 LR chi2(5) = 73.70
 upper = +inf Prob > chi2 = 0.0000
Log likelihood = -239.35746 Pseudo R2 = 0.1334
```

| failures | Coefficient | Std. err. | z     | P> z  | [95% conf. interval] |          |
|----------|-------------|-----------|-------|-------|----------------------|----------|
| probe    |             |           |       |       |                      |          |
| 2        | -.1113037   | .1019786  | -1.09 | 0.275 | -.3111781            | .0885707 |
| 3        | .0114339    | .1036032  | 0.11  | 0.912 | -.1916245            | .2144924 |
| 4        | .4254115    | .0841277  | 5.06  | 0.000 | .2605242             | .5902989 |
| depth    | -.0005034   | .0033375  | -0.15 | 0.880 | -.0070447            | .006038  |
| width    | .0330225    | .015573   | 2.12  | 0.034 | .0025001             | .063545  |
| _cons    | 2.714025    | .0752617  | 36.06 | 0.000 | 2.566515             | 2.861536 |

The coefficients listed for the probes are testing the null hypothesis:  $H_0 : \text{probe}_i = \text{probe}_1$ , where  $i$  equals 2, 3, and 4. Because the only coefficient that is statistically significant is the one for testing for  $H_0 : \text{probe}_4 = \text{probe}_1$ ,  $p < 0.001$ , and because the  $p$ -values for the other probes are not statistically significant, that is,  $p \geq 0.275$ , the implication is that there is a difference between probe 4 and the other machines. Because the coefficient for this test is positive, 0.425, the conclusion is that the average failure rate for probe 4, after adjusting for line widths and oxide depths, is higher than the other probes. Possibly, probe 4 needs calibration or the head used with this machine is defective.

Line-width control is statistically significant,  $p = 0.034$ , but variation in oxide depths is not causing the increased failure rate. The engineer concluded that the sudden increase in failures is the result of two problems. First, probe 4 is malfunctioning, and second, there is a possible lithography or etching problem.

## Stored results

tpoisson stores the following in `e()`:

### Scalars

|                            |                                           |

| <code>e(offset)</code>     | linear offset variable                                                                               |
| <code>e(chi2type)</code>   | Wald or LR; type of model $\chi^2$ test                                                              |
| <code>e(vce)</code>        | <i>vcetype</i> specified in <code>vce()</code>                                                       |
| <code>e(vcetype)</code>    | title used to label Std. err.                                                                        |
| <code>e(opt)</code>        | type of optimization                                                                                 |
| <code>e(which)</code>      | max or min; whether optimizer is to perform maximization or minimization                             |
| <code>e(ml_method)</code>  | type of ml method                                                                                    |
| <code>e(user)</code>       | name of likelihood-evaluator program                                                                 |
| <code>e(technique)</code>  | maximization technique                                                                               |
| <code>e(properties)</code> | b V                                                                                                  |
| <code>e(predict)</code>    | program used to implement predict                                                                    |
| <code>e(asbalanced)</code> | factor variables <code>fvset</code> as <code>asbalanced</code>                                       |
| <code>e(asobserved)</code> | factor variables <code>fvset</code> as <code>asobserved</code>                                       |

### Matrices

|                              |                                              |
|------------------------------|----------------------------------------------|
| <code>e(b)</code>            | coefficient vector                           |
| <code>e(Cns)</code>          | constraints matrix                           |
| <code>e(ilog)</code>         | iteration log (up to 20 iterations)          |
| <code>e(gradient)</code>     | gradient vector                              |
| <code>e(V)</code>            | variance–covariance matrix of the estimators |
| <code>e(V_modelbased)</code> | model-based variance                         |

### Functions

|                        |                         |
|------------------------|-------------------------|
| <code>e(sample)</code> | marks estimation sample |
|------------------------|-------------------------|

In addition to the above, the following is stored in `r()`:

|                       |                                                                                                                            |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------|
| Matrices              |                                                                                                                            |
| <code>r(table)</code> | matrix containing the coefficients with their standard errors, test statistics, <i>p</i> -values, and confidence intervals |

Note that results stored in `r()` are updated when the command is replayed and will be replaced when any *r*-class command is run after the estimation command.

## Methods and formulas

For a nonnegative count outcome  $Y$  with left-truncation point  $ll_j$  and right-truncation point  $ul_j$ , we can write the truncated Poisson model as

$$f(y_j) = \frac{\exp(-\lambda_j)\lambda_j^{y_j}}{y_j! \Pr(ll_j < Y < ul_j | \xi_j)}$$

where

$$\begin{aligned}\xi_j &= \mathbf{x}_j\boldsymbol{\beta} + \text{offset}_j \\ \lambda_j &= \exp(\xi_j)\end{aligned}$$

and  $\mathbf{x}_j$  is a vector of observed covariates. The conditional probability of observing  $y_j$  events, therefore given by  $ll_j < y_j < ul_j$ , is

$$\Pr(Y = y_j | ll_j < y_j < ul_j, \mathbf{x}_j) = \frac{\exp(-\lambda_j)\lambda_j^{y_j}}{y_j! \Pr(ll_j < Y < ul_j | \mathbf{x}_j)}$$

The log likelihood is given by

$$\ln L = \sum_{j=1}^n w_j [-\lambda_j + \xi_j y_j - \ln(y_j!) - \ln \{ \Pr(ll_j < Y < ul_j | \xi_j) \}]$$

If no weights are specified,  $w_j = 1$ .

This command supports the Huber/White/sandwich estimator of the variance and its clustered version using `vce(robust)` and `vce(cluster clustvar)`, respectively. See [P] [\\_robust](#), particularly [Maximum likelihood estimators](#) and [Methods and formulas](#).

`tpoisson` also supports estimation with survey data. For details on VCEs with survey data, see [SVY] [Variance estimation](#).

## Postestimation commands

The following postestimation commands are available after `tpoisson`:

| Command                      | Description                                                                                                                             |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <code>contrast</code>        | contrasts and ANOVA-style joint tests of parameters                                                                                     |
| <code>estat ic</code>        | Akaike's, consistent Akaike's, corrected Akaike's, and Schwarz's Bayesian information criteria (AIC, CAIC, AICc, and BIC, respectively) |
| <code>estat summarize</code> | summary statistics for the estimation sample                                                                                            |
| <code>estat vce</code>       | variance–covariance matrix of the estimators (VCE)                                                                                      |
| <code>estat (svy)</code>     | postestimation statistics for survey data                                                                                               |
| <code>estimates</code>       | cataloging estimation results                                                                                                           |
| <code>etable</code>          | table of estimation results                                                                                                             |
| * <code>forecast</code>      | dynamic forecasts and simulations                                                                                                       |
| * <code>hausman</code>       | Hausman's specification test                                                                                                            |
| <code>lincom</code>          | point estimates, standard errors, testing, and inference for linear combinations of parameters                                          |
| * <code>lrtest</code>        | likelihood-ratio test                                                                                                                   |
| <code>margins</code>         | marginal means, predictive margins, marginal effects, and average marginal effects                                                      |
| <code>marginsplot</code>     | graph the results from margins (profile plots, interaction plots, etc.)                                                                 |
| <code>nlcom</code>           | point estimates, standard errors, testing, and inference for nonlinear combinations of parameters                                       |
| <code>predict</code>         | number of events, incidence rates, probabilities, etc.                                                                                  |
| <code>predictnl</code>       | point estimates, standard errors, testing, and inference for generalized predictions                                                    |
| <code>pwcompare</code>       | pairwise comparisons of parameters                                                                                                      |
| <code>suest</code>           | seemingly unrelated estimation                                                                                                          |
| <code>test</code>            | Wald tests of simple and composite linear hypotheses                                                                                    |
| <code>testnl</code>          | Wald tests of nonlinear hypotheses                                                                                                      |

\*`forecast`, `hausman`, and `lrtest` are not appropriate with `svy` estimation results.

# predict

## Description for predict

predict creates a new variable containing predictions such as numbers of events, incidence rates, conditional means, probabilities, conditional probabilities, linear predictions, standard errors, and the equation-level score.

## Menu for predict

Statistics > Postestimation

## Syntax for predict

```
predict [type] newvar [if] [in] [, statistic nooffset]
```

| <i>statistic</i>        | Description                                                                |
|-------------------------|----------------------------------------------------------------------------|
| <b>Main</b>             |                                                                            |
| <b>n</b>                | number of events; the default                                              |
| <b>ir</b>               | incidence rate                                                             |
| <b>cm</b>               | conditional mean, $E(y_j   ll_j < y_j < ul_j)$                             |
| <b>pr(<i>n</i>)</b>     | probability $\Pr(y_j = n)$                                                 |
| <b>pr(<i>a, b</i>)</b>  | probability $\Pr(a \leq y_j \leq b)$                                       |
| <b>cpr(<i>n</i>)</b>    | conditional probability $\Pr(y_j = n   ll_j < y_j < ul_j)$                 |
| <b>cpr(<i>a, b</i>)</b> | conditional probability $\Pr(a \leq y_j \leq b   ll_j < y_j < ul_j)$       |
| <b>xb</b>               | linear prediction                                                          |
| <b>stdp</b>             | standard error of the linear prediction                                    |
| <b>score</b>            | first derivative of the log likelihood with respect to $\mathbf{x}_j\beta$ |

These statistics are available both in and out of sample; type predict ... if e(sample) ... if wanted only for the estimation sample.

## Options for predict

### Main

**n**, the default, calculates the predicted number of events, which is  $\exp(\mathbf{x}_j\beta)$  if neither `offset()` nor `exposure()` was specified when the model was fit;  $\exp(\mathbf{x}_j\beta + \text{offset}_j)$  if `offset()` was specified; or  $\exp(\mathbf{x}_j\beta) \times \text{exposure}_j$  if `exposure()` was specified.

**ir** calculates the incidence rate  $\exp(\mathbf{x}_j\beta)$ , which is the predicted number of events when exposure is 1. This is equivalent to specifying both the **n** and the `nooffset` options.

**cm** calculates the conditional mean,

$$E(y_j | ll_j < y_j < ul_j) = \frac{E(y_j, ll_j < y_j < ul_j)}{\Pr(ll_j < y_j < ul_j)}$$

where  $ll_j$  is the left-truncation point specified at estimation and  $ul_j$  is the right-truncation point specified at estimation.

`pr(n)` calculates the probability  $\Pr(y_j = n)$ , where  $n$  is a nonnegative integer that may be specified as a number or a variable.

`pr(a,b)` calculates the probability  $\Pr(a \leq y_j \leq b)$ , where  $a$  and  $b$  are nonnegative integers that may be specified as numbers or variables;

$b$  missing ( $b \geq .$ ) means  $+\infty$ ;

`pr(20, .)` calculates  $\Pr(y_j \geq 20)$ ;

`pr(20,b)` calculates  $\Pr(y_j \geq 20)$  in observations for which  $b \geq .$  and calculates  $\Pr(20 \leq y_j \leq b)$  elsewhere.

`pr(., b)` produces a syntax error. A missing value in an observation of the variable  $a$  causes a missing value in that observation for `pr(a,b)`.

`cpr(n)` calculates the conditional probability  $\Pr(y_j = n \mid ll_j < y_j < ul_j)$ , where  $n$  is a nonnegative integer that may be specified as a number or a variable.  $ll_j$  and  $ul_j$  are as defined in `cm`.

`cpr(a,b)` calculates the conditional probability  $\Pr(a \leq y_j \leq b \mid ll_j < y_j < ul_j)$ , where  $a$  and  $b$  are as defined in `pr(a,b)` with the additional restrictions that  $a > ll_j$  and  $b < ul_j$ .  $ll_j$  and  $ul_j$  are as defined in `cm`.

`xb` calculates the linear prediction, which is  $\mathbf{x}_j\boldsymbol{\beta}$  if neither `offset()` nor `exposure()` was specified when the model was fit;  $\mathbf{x}_j\boldsymbol{\beta} + \text{offset}_j$  if `offset()` was specified; or  $\mathbf{x}_j\boldsymbol{\beta} + \ln(\text{exposure}_j)$  if `exposure()` was specified; see `nooffset` below.

`stdp` calculates the standard error of the linear prediction.

`score` calculates the equation-level score,  $\partial \ln L / \partial (\mathbf{x}_j\boldsymbol{\beta})$ .

`nooffset` is relevant only if you specified `offset()` or `exposure()` when you fit the model. It modifies the calculations made by `predict` so that they ignore the offset or exposure variable; the linear prediction is treated as  $\mathbf{x}_j\boldsymbol{\beta}$  rather than as  $\mathbf{x}_j\boldsymbol{\beta} + \text{offset}_j$  or  $\mathbf{x}_j\boldsymbol{\beta} + \ln(\text{exposure}_j)$ . Specifying `predict . . . , nooffset` is equivalent to specifying `predict . . . , ir`.

# margins

## Description for margins

margins estimates margins of response for numbers of events, incidence rates, conditional means, probabilities, conditional probabilities, and linear predictions.

## Menu for margins

| ir                 | incidence rate                                                       |
| cm                 | conditional mean, $E(y_j   ll_j < y_j < ul_j)$                       |
| pr( <i>n</i> )     | probability $\Pr(y_j = n)$                                           |
| pr( <i>a, b</i> )  | probability $\Pr(a \leq y_j \leq b)$                                 |
| cpr( <i>n</i> )    | conditional probability $\Pr(y_j = n   ll_j < y_j < ul_j)$           |
| cpr( <i>a, b</i> ) | conditional probability $\Pr(a \leq y_j \leq b   ll_j < y_j < ul_j)$ |
| xb                 | linear prediction                                                    |
| stdp               | not allowed with margins                                             |
| score              | not allowed with margins                                             |

Statistics not allowed with margins are functions of stochastic quantities other than e(b).

For the full syntax, see [R] margins.

## Remarks and examples

### ▷ Example 1: Obtaining margins of the conditional mean

In [example 1](#) of [\[R\] tpoisson](#), a truncated Poisson model is fit to the number of pairs of shoes owned on runs per week, miles run per week, gender, age, and marital status. We continue that example to determine the effect of miles run per week on the average number of pairs of shoes owned.

After reading in the data, we use [summarize](#) to obtain the 25th, 50th, and 75th percentiles for miles run per week.

```
. use https://www.stata-press.com/data/r19/runshoes
(Running shoes)
. summarize mpweek, detail
```

|     |      | Miles per week |          |             |          |
|-----|------|----------------|----------|-------------|----------|
|     |      | Percentiles    | Smallest |             |          |
| 1%  | 5    | 5              | 5        |             |          |
| 5%  | 5    | 5              | 5        |             |          |
| 10% | 5    | 5              | 5        | Obs         | 60       |
| 25% | 12.5 | 5              | 5        | Sum of wgt. | 60       |
| 50% | 27.5 |                |          | Mean        | 24.71167 |
|     |      |                | Largest  | Std. dev.   | 14.34934 |
| 75% | 32.5 | 47.5           | 47.5     |             |          |
| 90% | 47.5 | 47.5           | 47.5     | Variance    | 205.9034 |
| 95% | 47.5 | 47.5           | 47.5     | Skewness    | .1948568 |
| 99% | 57.5 | 57.5           | 57.5     | Kurtosis    | 2.065304 |

We fit the model from [example 1](#) of [\[R\] tpoisson](#) again. We next specify these values for the percentiles to margins to estimate the conditional mean of the number of pairs of shoes at different quantiles of miles run per week. To do this, we use the `at()` option of `margins`.

```
. quietly tpoisson shoes rpweek mpweek male age married
. margins, at(mpweek=(12.5 27.5 32.5)) predict(cm)
```

Predictive margins Number of obs = 60  
 Model VCE: OIM  
 Expression: Conditional mean of  $n > ll(0)$ , `predict(cm)`  
 1.\_at: mpweek = 12.5  
 2.\_at: mpweek = 27.5  
 3.\_at: mpweek = 32.5

|     | Delta-method |           |       |       |                      |
|-----|--------------|-----------|-------|-------|----------------------|
|     | Margin       | std. err. | z     | P> z  | [95% conf. interval] |
| _at |              |           |       |       |                      |
| 1   | 1.942149     | .2111564  | 9.20  | 0.000 | 1.52829 2.356008     |
| 2   | 2.376253     | .1714522  | 13.86 | 0.000 | 2.040213 2.712293    |
| 3   | 2.564339     | .1948129  | 13.16 | 0.000 | 2.182513 2.946165    |

We see that people who run 12.5 miles per week are expected to own 1.94 pairs of shoes. The expected number of pairs of shoes owned increases as the average miles per week increases. We expect people who run 27.5 miles per week have 2.38 pairs of shoes and those who run 32.5 miles per week have 2.56 pairs of shoes.

## Methods and formulas

Continuing from *Methods and formulas* in [R] **tpoisson**, the equation-level score is given by

$$\text{score}(\mathbf{x}\boldsymbol{\beta})_j = y_j - \lambda_j - \frac{\{\exp(-\lambda_j)\lambda_j^{ll_j}/ll_j! - \exp(-\lambda_j)\lambda_j^{(ul_j-1)}/(ul_j-1)!\}\lambda_j}{\Pr(ll_j < Y < ul_j | \xi_j)}$$

[Description](#)[Options for translate](#)[Quick start](#)[Remarks and examples](#)[Syntax](#)[Stored results](#)[Options for print](#)[Also see](#)

## Description

`print` prints log, SMCL, and text files. `translate` translates log and SMCL files from one format to another, the other typically being suitable for printing. `translate` can also translate SMCL logs to plain text.

## Quick start

Translate SMCL-format log `mylog.smcl` to a text log file `mylog.log`

```
translate mylog.smcl mylog.log
```

Same as above, but translate `mylog.smcl` to PostScript file `mylog.ps`

```
translate mylog.smcl mylog.ps
```

Send output from the Results window to new `mylog.txt` when no log was started

```
translate @Results mylog.txt
```

## Syntax

*Print log and SMCL files*

```
print filename [, like(ext) name(window) override_options]
```

*Translate log files to SMCL files and vice versa*

```
translate filenamein filenameout [, translator(tname) name(window)
override_options replace]
```

*View translator parameter settings*

```
translator query [tname]
```

*Change translator parameter settings*

```
translator set [tname setopt setval]
```

*Return translator parameter settings to default values*

```
translator reset tname
```

*List current mappings from one extension to another*

```
transmap query [.ext]
```

*Specify that files with one extension be treated the same as files with another extension*

```
transmap define .extnew .extold
```

*filename* in `print`, in addition to being a filename to be printed, may be specified as `@Results` to mean the Results window and `@Viewer` to mean the Viewer window.

*filename*<sub>in</sub> in `translate` may be specified just as *filename* in `print`.

*tname* in `translator` specifies the name of a translator; see the `translator()` option under *Options for translate*.

## Options for print

`like(ext)` specifies how the file should be translated to a form suitable for printing. The default is to determine the translation method from the extension of *filename*. Thus, `mylog.smcl` is translated according to the rule for translating `smcl` files, `myfile.txt` is translated according to the rule for translating `txt` files, and so on. (These rules are, in fact, `translate`'s `smcl2prn` and `txt2prn` translators, but put that aside for the moment.)

Rules for the following extensions are predefined:

|                    |                                           |
|--------------------|-------------------------------------------|
| <code>.txt</code>  | assume input file contains plain text     |
| <code>.log</code>  | assume input file contains Stata log text |
| <code>.smcl</code> | assume input file contains SMCL           |

To print a file that has an extension different from those listed above, you can define a new extension, but you do not have to do that. Assume that you wish to print the file `read.me`, which you know to contain plain text. If you were just to type `print read.me`, you would be told that Stata cannot translate `.me` files. (You would actually be told that the translator for `me2prn` was not found.) You could type `print read.me, like(txt)` to tell `print` to print `read.me` like a `.txt` file.

On the other hand, you could type

```
. transmap define .me .txt
```

to tell Stata that `.me` files are always to be treated like `.txt` files. If you did that, Stata would remember the new rule, even in future sessions.

When you specify the `like()` option, you override the recorded rules. So, if you were to type `print mylog.smcl, like(txt)`, the file would be printed as plain text (meaning that all the SMCL commands would show).

`name(windowname)` specifies which window to print when printing a Viewer. The default is for Stata to print the topmost Viewer [Unix(GUI) users: See the third [technical note](#) in *Printing files, Unix*]. The `name()` option is ignored when printing the Results window.

The window name is located inside the parentheses in the window title. For example, if the title for a Viewer window is `Viewer (#1) [help print]`, the name for the window is `#1`.

`override_options` refer to `translate`'s options for overriding default values. `print` uses `translate` to translate the file into a format suitable for sending to the printer, and thus `translate`'s `override_options` may also be used with `print`. The settings available vary between each translator (for example, `smcl2ps` will have different settings than `smcl2txt`) and may also differ across operating systems (for example, Windows may have different printing options than macOS). To find out what you can override when printing `.smcl` files, type

```
. translator query smcl2prn
(output omitted)
```

In the omitted output, you might learn that there is an `rmargin #` tunable value, which specifies the right margin in inches. You could specify the `override_option` `rmargin(#)` to temporarily override the default value, or you could type `translator set smcl2prn rmargin #` beforehand to permanently reset the value.

Alternatively, on some computers with some translators, you might discover that nothing can be set.

## Options for translate

`translator(tname)` specifies the name of the translator to be used to translate the file. The available translators are

| <i>tname</i>             | Input             | Output                 |
|--------------------------|-------------------|------------------------|
| <code>smcl2ps</code>     | SMCL              | PostScript             |
| <code>log2ps</code>      | Stata text log    | PostScript             |
| <code>txt2ps</code>      | generic text file | PostScript             |
| <code>Viewer2ps</code>   | Viewer window     | PostScript             |
| <code>Results2ps</code>  | Results window    | PostScript             |
| <code>smcl2prn</code>    | SMCL              | default printer format |
| <code>log2prn</code>     | Stata text log    | default printer format |
| <code>txt2prn</code>     | generic text log  | default printer format |
| <code>Results2prn</code> | Results window    | default printer format |
| <code>Viewer2prn</code>  | Viewer window     | default printer format |
| <code>smcl2txt</code>    | SMCL              | generic text log       |
| <code>smcl2log</code>    | SMCL              | Stata text log         |
| <code>Results2txt</code> | Results window    | generic text file      |
| <code>Viewer2txt</code>  | Viewer window     | generic text file      |
| <code>smcl2pdf</code>    | SMCL              | PDF                    |
| <code>log2pdf</code>     | Stata text log    | PDF                    |
| <code>txt2pdf</code>     | generic text log  | PDF                    |
| <code>Results2pdf</code> | Results window    | PDF                    |
| <code>Viewer2pdf</code>  | Viewer window     | PDF                    |

If `translator()` is not specified, `translate` determines which translator to use from extensions of the filenames specified. Typing `translate myfile.smcl myfile.ps` would use the `smcl2ps` translator. Typing `translate myfile.smcl myfile.ps, translate(smcl2prn)` would override the default and use the `smcl2prn` translator.

Actually, when you type `translate a.b c.d`, `translate` looks up `.b` in the `transmap` extension-synonym table. If `.b` is not found, the translator `b2d` is used. If `.b` is found in the table, the mapped extension is used (call it `b'`), and then the translator `b'2d` is used. For example,

| Command                                        | Translator used                                      |
|------------------------------------------------|------------------------------------------------------|
| <code>. translate myfile.smcl myfile.ps</code> | <code>smcl2ps</code>                                 |
| <code>. translate myfile.odd myfile.ps</code>  | <code>odd2ps</code> , which does not exist, so error |
| <code>. transmap define .odd .txt</code>       |                                                      |
| <code>. translate myfile.odd myfile.ps</code>  | <code>txt2ps</code>                                  |

You can list the mappings that `translate` uses by typing `transmap query`.

`name(windowname)` specifies which window to translate when translating a Viewer. The default is for Stata to translate the topmost Viewer. The `name()` option is ignored when translating the Results window.

The window name is located inside the parentheses in the window title. For example, if the title for a Viewer window is `Viewer (#1) [help print]`, the name for the window is `#1`.

`override_options` override any of the default options of the specified or implied translator. To find out what you can override for, say, `log2ps`, type

```
. translator query log2ps
```

In the omitted output, you might learn that there is an `rmargin #` tunable value, which, for `log2ps`, specifies the right margin in inches. You could specify the `override_option rmargin (#)` to temporarily override the default value or type `translator set log2ps rmargin #` beforehand to permanently reset the value.

`replace` specifies that *filename*<sub>out</sub> be replaced if it already exists.

## Remarks and examples

Remarks are presented under the following headings:

- [Overview](#)
- [Printing files](#)
- [Printing files, Mac and Windows](#)
- [Printing files, Unix](#)
- [Translating files from one format to another](#)

## Overview

`print` prints log, SMCL, and text files. Although there is considerable flexibility in how `print` (and `translate`, which `print` uses) can be set to work, they have already been set up and should just work:

```
. print mylog.smcl
. print mylog.log
```

Unix users may discover that they need to do a bit of setup before `print` works; see [Printing files, Unix](#) below. International Unix users may also wish to modify the default paper size. All users can tailor `print` and `translate` to their needs.

`print` may also be used to print the current contents of the Results window or the Viewer. For instance, the current contents of the Results window could be printed by typing

```
. print @Results
```

`translate` translates log and SMCL files from one format to another, the other typically being suitable for printing. `translate` can also translate SMCL logs (logs created by typing, say, log using `mylog`) to plain text:

```
. translate mylog.smcl mylog.log
```

You can use `translate` to recover a log when you have forgotten to start one. You may type

```
. translate @Results mylog.txt
```

to capture as plain text what is currently shown in the Results window.

This entry provides a general overview of `print` and `translate` and covers in detail the printing and translation of text (nongraphic) files.

`translator query`, `translator set`, and `translator reset` show, change, and restore the default values of the settings for each translator.

`transmap define` and `transmap query` create and show mappings from one file extension to another for use with `print` and `translate`.

For example, `print myfile.txt` knows to use a translator appropriate for printing text files because of the `.txt` extension. However, it does not know what to do with `.xyz` files. If you have `.xyz` files and always wish to treat them as `.txt` files, you can type `transmap define .xyz .txt`.

## Printing files

Printing should be easy; just type

```
. print mylog.smcl
. print mylog.log
```

You can use `print` to print SMCL files, plain text files, and even the contents of the Results and Viewer windows:

```
. print @Results
. print @Viewer
. print @Viewer, name(#2)
```

For information about printing and translating graph files, see [\[G-2\] graph print](#) and see [\[G-2\] graph export](#).

## Printing files, Mac and Windows

When you type `print`, you are using the same facility that you would be using if you had selected **Print** from the **File** menu. If you try to print a file that Stata does not know about, Stata will complain:

```
. print read.me
translator me2prn not found
r(111);
```

Then, you could type

```
. print read.me, like(txt)
```

to indicate that you wanted `read.me` sent to the printer in the same fashion as if the file were named `readme.txt`, or you could type

```
. transmap define .me .txt
. print read.me
```

Here you are telling Stata once and for all that you want files ending in `.me` to be treated in the same way as files ending in `.txt`. Stata will remember this mapping, even across sessions. To clear the `.me` mapping, type

```
. transmap define .me
```

To see all the mappings, type

```
. transmap query
```

To print to a file, use the `translate` command, not `print`:

```
. translate mylog.smcl mylog.prn
```

`translate` prints to a file by using the Windows print driver when the new filename ends in `.prn`. Under Mac, the `prn` translators are the same as the `pdf` translators. We suggest that you simply use the `.pdf` file extension when printing to a file.

## Printing files, Unix

Stata assumes that you have a PostScript printer attached to your Unix computer and that the Unix command `lpr(1)` can be used to send PostScript files to it, but you can change this. On your Unix system, typing

```
mycomputer$ lpr < filename
```

may not be sufficient to print PostScript files. For instance, perhaps on your system you would need to type

```
mycomputer$ lpr -Plexmark < filename
```

or

```
mycomputer$ lpr -Plexmark filename
```

or something else. To set the print command to be `lpr -Plexmark filename` and to state that the printer expects to receive PostScript files, type

```
. printer define prn ps "lpr -Plexmark @"
```

To set the print command to `lpr -Plexmark < filename` and to state that the printer expects to receive plain text files, type

```
. printer define prn txt "lpr -Plexmark < @"
```

That is, just type the command necessary to send files to your printer and include an `@` sign where the filename should be substituted. Two file formats are available: `ps` and `txt`. The default setting, as shipped from the factory, is

```
. printer define prn ps "lpr < @"
```

We will return to the `printer` command in the technical note that follows because it has some other capabilities you should know about.

In any case, after you redefine the default printer, the following should just work:

```
. print mylog.smcl
. print mylog.log
```

If you try to print a file that Stata does not know about, it will complain:

```
. print read.me
translator me2prn not found
r(111);
```

Here you could type

```
. print read.me, like(txt)
```

to indicate that you wanted `read.me` sent to the printer in the same fashion as if the file were named `readme.txt`, or you could type

```
. transmap define .me .txt
. print read.me
```

Here you are telling Stata once and for all that you want files ending in `.me` to be treated in the same way as files ending in `.txt`. Stata will remember this setting for `.me`, even across sessions.

If you want to clear the `.me` setting, type

```
. transmap define .me
```

If you want to see all your settings, type

```
. transmap query
```

## □ Technical note

If the text you wish to print contains Unicode characters, those characters may not appear correctly in PostScript files because the PostScript fonts do not support Unicode. Stata will map as many characters as possible to characters supported by Unicode but will print a question mark (?) for any unsupported character. We recommend that you export the text to a PDF file, which has fonts with better support for Unicode characters.

□

## □ Technical note

The syntax of the `printer` command is

```
printer define printername [{ ps | txt } "Unix command with @"]
printer query [printername]
```

You may define multiple printers. By default, `print` uses the printer named `prn`, but `print` has the syntax

```
print filename [, like(ext) printer(printername) override_options]
```

so, if you define multiple printers, you may route your output to them.

For instance, if you have a second printer on your system, you might type

```
. printer define lexmark ps "lpr -Plexmark < @"
```

After doing that, you could type

```
. print myfile.smcl, printer(lexmark)
```

Any printers that you set will be remembered even across sessions. You can delete printers:

```
. printer define lexmark
```

You can list all the defined printers by typing `printer query`, and you can list the definition of a particular printer, say, `prn`, by typing `printer query prn`.

The default printer `prn` we have predefined for you is

```
. printer define prn ps "lpr < @"
```

meaning that we assume that it is a PostScript printer and that the Unix command `lpr(1)`, without options, is sufficient to cause files to print. Feel free to change the default definition. If you change it, the change will be remembered across sessions.

□

## □ Technical note

Unix(GUI) users should note that X-Windows does not have the concept of a window z-order, which prevents Stata from determining which window is the topmost window. Instead, Stata determines which window is topmost based on which window has the focus. However, some window managers will set the focus to a window without bringing the window to the top. What Stata considers the topmost window may not appear topmost visually. For this reason, you should always use the `name()` option to ensure that the correct window is printed. □

## □ Technical note

When you select the Results window to print from the **Print** menu or toolbar button, the result is the same as if you were to issue the `print` command. When you select a Viewer window to print from the **Print** menu or toolbar button, the result is the same as if you were to issue the `print` command with a `name()` option. □

The translation to PostScript format is done by `translate` and, in particular, is performed by the translators `smcl2ps`, `log2ps`, and `txt2ps`. There are many tunable parameters in each of these translators. You can display the current values of these tunable parameters for, say, `smcl2ps` by typing

```
. translator query smcl2ps
(output omitted)
```

and you can set any of the tunable parameters (for instance, setting `smcl2ps`'s `rmargin` value to 1) by typing

```
. translator set smcl2ps rmargin 1
(output omitted)
```

Any settings you make will be remembered across sessions. You can reset `smcl2ps` to be as it was when Stata was shipped by typing

```
. translator reset smcl2ps
```

## Translating files from one format to another

If you have a SMCL log, which you might have created by previously typing `log using mylog`, you can translate it to a text log by typing

```
. translate myfile.smcl myfile.log
```

and you can translate it to a PostScript file by typing

```
. translate myfile.smcl myfile.ps
```

`translate` translates files from one format to another, and, in fact, `print` uses `translate` to produce a file suitable for sending to the printer.

When you type

```
. translate a.b c.d
```

`translate` looks for the predefined translator `b2d` and uses that to perform the translation. If there is a `transmap` synonym for `b`, however, the mapped value `b'` is used: `b'2d`.

Only certain translators exist, and they are listed under the description of the `translate()` option in *Options for translate* above, or you can type

```
. translator query
```

for a complete (and perhaps more up-to-date) list.

Anyway, `translate` forms the name *b2d* or *b'2d*, and if the translator does not exist, `translate` issues an error message. With the `translator()` option, you can specify exactly which translator to use, and then it does not matter how your files are named.

The only other thing to know is that some translators have tunable parameters that affect how they perform their translation. You can type

```
. translator query translator_name
```

to find out what those parameters are. Some translators have no tunable parameters, and some have many:

```
. translator query smcl2ps
```

You can temporarily override any setting by specifying the *setopt(setval)* option on the `translate` (or `print`) command. For instance, you can type

```
. translate ..., ... cmdnumber(off)
```

or you can reset the value permanently by typing

```
. translator set smcl2ps setopt setval
```

For instance,

```
. translator set smcl2ps cmdnumber off
```

If you reset a value, Stata will remember the change, even in future sessions.

Mac and Windows users: The `smcl2ps` (and the other `*2ps` translators) are not used by `print`, even when you have a PostScript printer attached to your computer. Instead, the Mac or Windows print driver is used. Resetting `smcl2ps` values will not affect printing; instead, you change the defaults in the Printers Control Panel in Windows and by selecting **Page Setup...** from the **File** menu in Mac. You can, however, `translate` files yourself using the `smcl2ps` translator and the other `*2ps` translators.

## □ Technical note: Using PDF translators (Windows and Unix)

When using `translate` to translate a log, SMCL, or text file or a Stata graph into a PDF file, some characters may not display correctly in the resulting PDF file. This happens when translating content that contains Unicode characters from different languages; one font may not be adequate to display every character used. If an appropriate font is not available for a character, that character will not display correctly in the resulting PDF file.

Specific fonts can be used to build a font chain. Those fonts are specified using *fontname* and are separated by commas. The most preferred font should be listed first, followed by the less preferred fonts. A maximum of 16 fonts can be specified. Stata will inspect each character in the original content, and if a glyph for the corresponding character is not available in the default font, then each font in the font chain will be checked until a font is found to display that character.

You can set fonts in the font chain by specifying `addfonts` for each PDF translator as follows:

```
. translator set tname addfonts fontname
```

Here *tname* is the name of a PDF translator, which can be `smcl2pdf`, `log2pdf`, `txt2pdf`, `Results2pdf`, `Viewer2pdf`, or `Graph2pdf`. See the `translator()` option under *Options for translate*.

Stata has the ability to select a font automatically if the default font and the fonts in the font chain do not contain a glyph for the character. Automatic font selection can be controlled using the following:

```
. translator set tname autofont on|off
```

By default, `autofont` is on. Unix (console) users will need to set the font directories so the fonts can be found.

PDF files accept Base 14 fonts, Type 1 fonts (.pfa or .pfb), TrueType fonts (.ttf or .ttc), and OpenType fonts (.otf). If *fontname* refers to a TrueType font, an OpenType font, or a Type 1 font, the corresponding TrueType, OpenType, or Type 1 font file will be searched for within the default font directory. Unix (console) users can type

```
. translator set tname fontdir fontdirectory
```

to set the default font directory. *fontdirectory* can contain multiple font directories separated by semi-colons. If the specified TrueType, OpenType, or Type 1 font cannot be found under the current font directory, an error message will be issued.

□

## Stored results

`transmap query .ext` stores in macro `r(suffix)` the mapped extension (without the leading period) or stores `ext` if the `ext` is not mapped.

`translator query translatorname` stores `setval` in macro `r(setopt)` for every `setopt, setval` pair.

`printer query printername` (Unix only) stores in macro `r(suffix)` the “filetype” of the input that the printer expects (currently “ps” or “txt”) and, in macro `r(command)`, the command to send output to the printer.

## Description

`truncreg` fits a regression model of *depvar* on *indepvars* from a sample drawn from a restricted part of the population. Under the normality assumption for the whole population, the error terms in the truncated regression model have a truncated normal distribution, which is a normal distribution that has been scaled upward so that the distribution integrates to one over the restricted range.

## Quick start

Truncated regression of *y* on *x1* and *x2* truncated below 16

```
truncreg y x1 x2, ll(16)
```

Specify that *y* is truncated above 35

```
truncreg y x1 x2, ul(35)
```

With *y* truncated below 17 and above 35

```
truncreg y x1 x2, ll(17) ul(35)
```

Specify a lower truncation point that varies across observations using the variable `trunc`

```
truncreg y x1 x2, ll(trunc)
```

Same as above, but with bootstrap standard errors using 200 replications

```
truncreg y x1 x2, ll(trunc) vce(bootstrap, reps(200))
```

See last estimates with legend of coefficient names instead of statistics

```
truncreg, coeflegend
```

## Menu

Statistics > Linear models and related > Truncated regression

## Syntax

```
truncreg deprvar [indepvars] [if] [in] [weight] [, options]
```

*indepvars* may contain factor variables; see [U] 11.4.3 **Factor variables**.

*deprvar* and *indepvars* may contain time-series operators; see [U] 11.4.4 **Time-series varlists**.

`bayes`, `bootstrap`, `by`, `collect`, `fmm`, `fp`, `jackknife`, `mi estimate`, `rolling`, `statsby`, and `svy` are allowed; see [U] 11.1.10 **Prefix commands**. For more details, see [BAYES] **bayes: truncreg** and [FMM] **fmm: truncreg**.

`vce(bootstrap)` and `vce(jackknife)` are not allowed with the `mi estimate` prefix; see [MI] **mi estimate**.

Weights are not allowed with the `bootstrap` prefix; see [R] **bootstrap**.

`aweight`s are not allowed with the `jackknife` prefix; see [R] **jackknife**.

`vce()`, `lrmodel`, and `weights` are not allowed with the `svy` prefix; see [SVY] **svy**.

`aweight`s, `fweight`s, `iweight`s, and `pweight`s are allowed; see [U] 11.1.6 **weight**.

`collinear` and `coeflegend` do not appear in the dialog box.

See [U] 20 **Estimation and postestimation commands** for more capabilities of estimation commands.

## Options

### Model

`noconstant`; see [R] [Estimation options](#).

`ll(varname | #)` and `ul(varname | #)` indicate the lower and upper limits for truncation, respectively.

You may specify one or both. Observations with `depvar ≤ ll()` are left-truncated, observations with `depvar ≥ ul()` are right-truncated, and the remaining observations are not truncated. See [R] [tobit](#) for a more detailed description.

`offset(varname)`, `constraints(constraints)`; see [R] [Estimation options](#).

### SE/Robust

`vce(vcetype)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory (`oim`, `opg`), that are robust to some kinds of misspecification (`robust`), that allow for intragroup correlation (`cluster clustvar`), and that use bootstrap or jackknife methods (`bootstrap`, `jackknife`); see [R] [vce\\_option](#).

### Reporting

`level(#)`, `lrmmodel`, `nocnsreport`; see [R] [Estimation options](#).

`display_options`: `nocl`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `nolstretch`; see [R] [Estimation options](#).

### Maximization

`maximize_options`: `difficult`, `technique(algorithm_spec)`, `iterate(#)`, `[no]log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `ltolerance(#)`, `nrtolerance(#)`, `nonrtolerance`, and `from(init_specs)`; see [R] [Maximize](#). These options are seldom used, but you may use the `ltol(#)` option to relax the convergence criterion; the default is  $1e-6$  during specification searches.

Setting the optimization type to `technique(bhhh)` resets the default `vcetype` to `vce(opg)`.

The following options are available with `truncreg` but are not shown in the dialog box:

`collinear`, `coeflegend`; see [R] [Estimation options](#).

## Remarks and examples

Truncated regression fits a model of a dependent variable on independent variables from a restricted part of a population. Truncation is essentially a characteristic of the distribution from which the sample data are drawn. If  $x$  has a normal distribution with mean  $\mu$  and standard deviation  $\sigma$ , the density of the truncated normal distribution is

$$\begin{aligned} f(x \mid a < x < b) &= \frac{f(x)}{\Phi\left(\frac{b-\mu}{\sigma}\right) - \Phi\left(\frac{a-\mu}{\sigma}\right)} \\ &= \frac{\frac{1}{\sigma}\phi\left(\frac{x-\mu}{\sigma}\right)}{\Phi\left(\frac{b-\mu}{\sigma}\right) - \Phi\left(\frac{a-\mu}{\sigma}\right)} \end{aligned}$$

where  $\phi$  and  $\Phi$  are the density and distribution functions of the standard normal distribution.

Compared with the mean of the untruncated variable, the mean of the truncated variable is greater if the truncation is from below, and the mean of the truncated variable is smaller if the truncation is from above. Moreover, truncation reduces the variance compared with the variance in the untruncated distribution.

### ▷ Example 1

We will demonstrate `truncreg` with part of the Mroz dataset distributed with [Berndt \(1996\)](#). This dataset contains 753 observations on women's labor supply. Our subsample is of 250 observations, with 150 market laborers and 100 nonmarket laborers.

```

## □ Technical note

Whether truncated regression is more appropriate than the ordinary least-squares estimation depends on the purpose of that estimation. If we are interested in the mean of wife's working hours conditional on the subsample of market laborers, least-squares estimation is appropriate. However if we are interested in the mean of wife's working hours regardless of market or nonmarket labor status, least-squares estimates could be seriously misleading.

Truncation and censoring are different concepts. A sample has been censored if no observations have been systematically excluded but some of the information contained in them has been suppressed. In a truncated distribution, only the part of the distribution above (or below, or between) the truncation points is relevant to our computations. We need to scale it up by the probability that an observation falls in the range that interests us to make the distribution integrate to one. The censored distribution used by tobit, however, is a mixture of discrete and continuous distributions. Instead of rescaling over the observable range, we simply assign the full probability from the censored regions to the censoring points. The truncated regression model is sometimes less well behaved than the tobit model. Davidson and MacKinnon (1993) provide an example where truncation results in more inconsistency than censoring. □

## Stored results

truncreg stores the following in `e()`:

### Scalars

|                            |                                           |
|----------------------------|-------------------------------------------|

| <code>e(which)</code>      | max or min; whether optimizer is to perform maximization or minimization |
| <code>e(ml_method)</code>  | type of ml method                                                        |
| <code>e(user)</code>       | name of likelihood-evaluator program                                     |
| <code>e(technique)</code>  | maximization technique                                                   |
| <code>e(properties)</code> | b V                                                                      |
| <code>e(predict)</code>    | program used to implement predict                                        |
| <code>e(marginsok)</code>  | predictions allowed by margins                                           |
| <code>e(asbalanced)</code> | factor variables <code>fvset</code> as <code>asbalanced</code>           |
| <code>e(asobserved)</code> | factor variables <code>fvset</code> as <code>asobserved</code>           |

|                 |                                              |
|-----------------|----------------------------------------------|
| Matrices        |                                              |
| e(b)            | coefficient vector                           |
| e(Cns)          | constraints matrix                           |
| e(iolog)        | iteration log (up to 20 iterations)          |
| e(gradient)     | gradient vector                              |
| e(V)            | variance–covariance matrix of the estimators |
| e(V_modelbased) | model-based variance                         |
| e(means)        | means of independent variables               |
| e(dummy)        | indicator for dummy variables                |
| Functions       |                                              |
| e(sample)       | marks estimation sample                      |

In addition to the above, the following is stored in `r()`:

|          |                                                                                                                       |
|----------|-----------------------------------------------------------------------------------------------------------------------|
| Matrices |                                                                                                                       |
| r(table) | matrix containing the coefficients with their standard errors, test statistics, $p$ -values, and confidence intervals |

Note that results stored in `r()` are updated when the command is replayed and will be replaced when any `r-class` command is run after the estimation command.

## Methods and formulas

Greene (2018, 918–924) and Davidson and MacKinnon (1993, 534–537) provide introductions to the truncated regression model.

Let  $\mathbf{y} = \mathbf{X}\boldsymbol{\beta} + \boldsymbol{\epsilon}$  be the model.  $\mathbf{y}$  represents continuous outcomes either observed or not observed. Our model assumes that  $\boldsymbol{\epsilon} \sim N(\mathbf{0}, \sigma^2 \mathbf{I})$ .

Let  $a$  be the lower limit and  $b$  be the upper limit. The log likelihood is

$$\ln L = -\frac{n}{2} \log(2\pi\sigma^2) - \frac{1}{2\sigma^2} \sum_{j=1}^n (y_j - \mathbf{x}_j\boldsymbol{\beta})^2 - \sum_{j=1}^n \log \left\{ \Phi\left(\frac{b - \mathbf{x}_j\boldsymbol{\beta}}{\sigma}\right) - \Phi\left(\frac{a - \mathbf{x}_j\boldsymbol{\beta}}{\sigma}\right) \right\}$$

This command supports the Huber/White/sandwich estimator of the variance and its clustered version using `vce(robust)` and `vce(cluster clustvar)`, respectively. See [P] [\\_robust](#), particularly *Maximum likelihood estimators* and *Methods and formulas*.

`truncreg` also supports estimation with survey data. For details on VCEs with survey data, see [SVY] [Variance estimation](#).

## Postestimation commands

The following postestimation commands are available after `truncreg`:

| Command                      | Description                                                                                                                             |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <code>contrast</code>        | contrasts and ANOVA-style joint tests of parameters                                                                                     |
| <code>estat ic</code>        | Akaike's, consistent Akaike's, corrected Akaike's, and Schwarz's Bayesian information criteria (AIC, CAIC, AICc, and BIC, respectively) |
| <code>estat summarize</code> | summary statistics for the estimation sample                                                                                            |
| <code>estat vce</code>       | variance–covariance matrix of the estimators (VCE)                                                                                      |
| <code>estat (svy)</code>     | postestimation statistics for survey data                                                                                               |
| <code>estimates</code>       | cataloging estimation results                                                                                                           |
| <code>etable</code>          | table of estimation results                                                                                                             |
| * <code>forecast</code>      | dynamic forecasts and simulations                                                                                                       |
| * <code>hausman</code>       | Hausman's specification test                                                                                                            |
| <code>lincom</code>          | point estimates, standard errors, testing, and inference for linear combinations of parameters                                          |
| * <code>lrtest</code>        | likelihood-ratio test                                                                                                                   |
| <code>margins</code>         | marginal means, predictive margins, marginal effects, and average marginal effects                                                      |
| <code>marginsplot</code>     | graph the results from margins (profile plots, interaction plots, etc.)                                                                 |
| <code>nlcom</code>           | point estimates, standard errors, testing, and inference for nonlinear combinations of parameters                                       |
| <code>predict</code>         | linear, censored, and truncated predictions                                                                                             |
| <code>predictnl</code>       | point estimates, standard errors, testing, and inference for generalized predictions                                                    |
| <code>pwcompare</code>       | pairwise comparisons of parameters                                                                                                      |
| <code>suest</code>           | seemingly unrelated estimation                                                                                                          |
| <code>test</code>            | Wald tests of simple and composite linear hypotheses                                                                                    |
| <code>testnl</code>          | Wald tests of nonlinear hypotheses                                                                                                      |

\*`forecast`, `hausman`, and `lrtest` are not appropriate with `svy` estimation results. `forecast` is also not appropriate with `mi` estimation results.

# predict

## Description for predict

`predict` creates a new variable containing predictions such as linear predictions, standard errors, probabilities, and expected values.

## Menu for predict

Statistics > Postestimation

## Syntax for predict

```
predict [type] newvar [if] [in] [, statistic nooffset]
```

```
predict [type] stub* [if] [in] , scores
```

| <i>statistic</i> | Description |
|------------------|-------------|
|------------------|-------------|

Main

|                         |                                             |
|-------------------------|---------------------------------------------|
| <code>xb</code>         | linear prediction; the default              |
| <code>stdp</code>       | standard error of the prediction            |
| <code>stdf</code>       | standard error of the forecast              |
| <code>pr(a,b)</code>    | $\Pr(a < y_j < b)$                          |
| <code>e(a,b)</code>     | $E(y_j   a < y_j < b)$                      |
| <code>ystar(a,b)</code> | $E(y_j^*), y_j^* = \max\{a, \min(y_j, b)\}$ |

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

`stdf` is not allowed with `svy` estimation results.

where  $a$  and  $b$  may be numbers or variables;  $a$  missing ( $a \geq .$ ) means  $-\infty$ , and  $b$  missing ( $b \geq .$ ) means  $+\infty$ ; see [U] [12.2.1 Missing values](#).

## Options for predict

Main

`xb`, the default, calculates the linear prediction.

`stdp` calculates the standard error of the prediction, which can be thought of as the standard error of the predicted expected value or mean for the observation's covariate pattern. The standard error of the prediction is also referred to as the standard error of the fitted value.

`stdf` calculates the standard error of the forecast, which is the standard error of the point prediction for 1 observation. It is commonly referred to as the standard error of the future or forecast value. By construction, the standard errors produced by `stdf` are always larger than those produced by `stdp`; see *Methods and formulas* in [R] [regress postestimation](#).

`pr(a,b)` calculates  $\Pr(a < \mathbf{x}_j\mathbf{b} + u_j < b)$ , the probability that  $y_j|\mathbf{x}_j$  would be observed in the interval  $(a, b)$ .

$a$  and  $b$  may be specified as numbers or variable names;  $lb$  and  $ub$  are variable names;

`pr(20,30)` calculates  $\Pr(20 < \mathbf{x}_j\mathbf{b} + u_j < 30)$ ;

`pr(lb,ub)` calculates  $\Pr(lb < \mathbf{x}_j\mathbf{b} + u_j < ub)$ ; and

`pr(20,ub)` calculates  $\Pr(20 < \mathbf{x}_j\mathbf{b} + u_j < ub)$ .

$a$  missing ( $a \geq .$ ) means  $-\infty$ ; `pr(. , 30)` calculates  $\Pr(-\infty < \mathbf{x}_j\mathbf{b} + u_j < 30)$ ;

`pr(lb, 30)` calculates  $\Pr(-\infty < \mathbf{x}_j\mathbf{b} + u_j < 30)$  in observations for which  $lb \geq .$

and calculates  $\Pr(lb < \mathbf{x}_j\mathbf{b} + u_j < 30)$  elsewhere.

$b$  missing ( $b \geq .$ ) means  $+\infty$ ; `pr(20, .)` calculates  $\Pr(+\infty > \mathbf{x}_j\mathbf{b} + u_j > 20)$ ;

`pr(20,ub)` calculates  $\Pr(+\infty > \mathbf{x}_j\mathbf{b} + u_j > 20)$  in observations for which  $ub \geq .$

and calculates  $\Pr(20 < \mathbf{x}_j\mathbf{b} + u_j < ub)$  elsewhere.

`e(a,b)` calculates  $E(\mathbf{x}_j\mathbf{b} + u_j | a < \mathbf{x}_j\mathbf{b} + u_j < b)$ , the expected value of  $y_j|\mathbf{x}_j$  conditional on  $y_j|\mathbf{x}_j$  being in the interval  $(a, b)$ , meaning that  $y_j|\mathbf{x}_j$  is truncated.

$a$  and  $b$  are specified as they are for `pr()`.

`ystar(a,b)` calculates  $E(y_j^*)$ , where  $y_j^* = a$  if  $\mathbf{x}_j\mathbf{b} + u_j \leq a$ ,  $y_j^* = b$  if  $\mathbf{x}_j\mathbf{b} + u_j \geq b$ , and  $y_j^* = \mathbf{x}_j\mathbf{b} + u_j$  otherwise, meaning that  $y_j^*$  is censored.  $a$  and  $b$  are specified as they are for `pr()`.

`nooffset` is relevant only if you specified `offset(varname)`. It modifies the calculations made by `predict` so that they ignore the offset variable; the linear prediction is treated as  $\mathbf{x}_j\mathbf{b}$  rather than as  $\mathbf{x}_j\mathbf{b} + \text{offset}_j$ .

`scores` calculates equation-level score variables.

The first new variable will contain  $\partial \ln L / \partial (\mathbf{x}_j\boldsymbol{\beta})$ .

The second new variable will contain  $\partial \ln L / \partial \sigma$ .

## margins

### Description for margins

`margins` estimates margins of response for linear predictions, probabilities, and expected values.

### Menu for margins

Statistics > Postestimation

### Syntax for margins

```
margins [marginlist] [, options]
```

```
margins [marginlist] , predict(statistic ...) [predict(statistic ...) ...] [options]
```

| <i>statistic</i>                      | Description                                 |
|---------------------------------------|---------------------------------------------|
| <code>xb</code>                       | linear prediction; the default              |
| <code>pr(<i>a</i>,<i>b</i>)</code>    | $\Pr(a < y_j < b)$                          |
| <code>e(<i>a</i>,<i>b</i>)</code>     | $E(y_j   a < y_j < b)$                      |
| <code>ystar(<i>a</i>,<i>b</i>)</code> | $E(y_j^*), y_j^* = \max\{a, \min(y_j, b)\}$ |
| <code>stdp</code>                     | not allowed with <code>margins</code>       |
| <code>stdf</code>                     | not allowed with <code>margins</code>       |

Statistics not allowed with `margins` are functions of stochastic quantities other than `e(b)`.

For the full syntax, see [R] [margins](#).

## **ttest** — *t* tests (mean-comparison tests)

Description  
Options  
References

Quick start  
Remarks and examples  
Also see

Menu  
Stored results

Syntax  
Methods and formulas

### Description

`ttest` performs *t* tests on the equality of means. The test can be performed for one sample against a hypothesized population mean. Two-sample tests can be conducted for paired and unpaired data. The assumption of equal variances can be optionally relaxed in the unpaired two-sample case.

`ttesti` is the immediate form of `ttest`; see [\[U\] 19 Immediate commands](#).

### Quick start

Test that the mean of `v1` is equal between two groups defined by `catvar`

```
ttest v1, by(catvar)
```

Same as above, but assume unequal variances

```
ttest v1, by(catvar) unequal
```

Paired *t* test of `v2` and `v3`

```
ttest v2 == v3
```

Same as above, but with unpaired data and conduct test separately for each level of `catvar`

```
by catvar: ttest v2 == v3, unpaired
```

Test that the mean of `v4` is 3 at the 90% confidence level

```
ttest v4 == 3, level(90)
```

Test  $\mu_1 = \mu_2$  if  $\bar{x}_1 = 3.2$ ,  $sd_1 = 0.1$ ,  $\bar{x}_2 = 3.4$ , and  $sd_2 = 0.15$  with  $n_1 = n_2 = 12$

```
ttesti 12 3.2 .1 12 3.4 .15
```

---

*by* and *collect* are allowed with *ttest* and *ttesti*; see [U] 11.1.10 Prefix commands.

## Options

Main

`by(groupvar)` specifies the *groupvar* that defines the two groups that `ttest` will use to test the hypothesis that their means are equal. Specifying `by(groupvar)` implies an unpaired (two sample) *t* test. Do not confuse the `by()` option with the `by` prefix; you can specify both.

`reverse` reverses the order of the mean difference between groups defined in `by()`. By default, the mean of the group corresponding to the largest value in the variable in `by()` is subtracted from the mean of the group with the smallest value in `by()`. `reverse` reverses this behavior and the order in which variables appear on the table.

`unpaired` specifies that the data be treated as unpaired. The `unpaired` option is used when the two sets of values to be compared are in different variables.

`unequal` specifies that the unpaired data not be assumed to have equal variances.

`welch` specifies that the approximate degrees of freedom for the test be obtained from Welch's formula (1947) rather than from Satterthwaite's approximation formula (1946), which is the default when `unequal` is specified. Specifying `welch` implies `unequal`.

`level(#)` specifies the confidence level, as a percentage, for confidence intervals. The default is `level(95)` or as set by `set level`; see [U] 20.8 [Specifying the width of confidence intervals](#).

## Remarks and examples

Remarks are presented under the following headings:

- [One-sample \*t\* test](#)
- [Two-sample \*t\* test](#)
- [Paired \*t\* test](#)
- [Two-sample \*t\* test compared with one-way ANOVA](#)
- [Immediate form](#)
- [Video examples](#)

### One-sample *t* test

#### ▷ Example 1

In the first form, `ttest` tests whether the mean of the sample is equal to a known constant under the assumption of unknown variance. Assume that we have a sample of 74 automobiles. We know each automobile's average mileage rating and wish to test whether the overall average for the sample is 20 miles per gallon.

```
. use https://www.stata-press.com/data/r19/auto
(1978 automobile data)
. ttest mpg==20
```

One-sample *t* test

| Variable | Obs | Mean    | Std. err. | Std. dev. | [95% conf. interval] |          |
|----------|-----|---------|-----------|-----------|----------------------|----------|
| mpg      | 74  | 21.2973 | .6725511  | 5.785503  | 19.9569              | 22.63769 |

```
mean = mean(mpg)
HO: mean = 20
Ha: mean < 20
Pr(T < t) = 0.9712

Degrees of freedom = 73
Ha: mean != 20
Pr(|T| > |t|) = 0.0576

t = 1.9289
Ha: mean > 20
Pr(T > t) = 0.0288
```

The test indicates that the underlying mean is not 20 with a significance level of 5.8%.

## Two-sample *t* test

### ► Example 2: Two-sample *t* test using groups

We are testing the effectiveness of a new fuel additive. We run an experiment in which 12 cars are given the fuel treatment and 12 cars are not. The results of the experiment are as follows:

| treated | mpg |
|---------|-----|
| 0       | 20  |
| 0       | 23  |
| 0       | 21  |
| 0       | 25  |
| 0       | 18  |
| 0       | 17  |
| 0       | 18  |
| 0       | 24  |
| 0       | 20  |
| 0       | 24  |
| 0       | 23  |
| 0       | 19  |
| 1       | 24  |
| 1       | 25  |
| 1       | 21  |
| 1       | 22  |
| 1       | 23  |
| 1       | 18  |
| 1       | 17  |
| 1       | 28  |
| 1       | 24  |
| 1       | 27  |
| 1       | 21  |
| 1       | 23  |

The treated variable is coded as 1 if the car received the fuel treatment and 0 otherwise.

We can test the equality of means of the treated and untreated group by typing

```
. use https://www.stata-press.com/data/r19/fuel3
. ttest mpg, by(treated)
```

Two-sample t test with equal variances

| Group    | Obs | Mean   | Std. err. | Std. dev. | [95% conf. interval] |          |
|----------|-----|--------|-----------|-----------|----------------------|----------|
| 0        | 12  | 21     | .7881701  | 2.730301  | 19.26525             | 22.73475 |
| 1        | 12  | 22.75  | .9384465  | 3.250874  | 20.68449             | 24.81551 |
| Combined | 24  | 21.875 | .6264476  | 3.068954  | 20.57909             | 23.17091 |
| diff     |     | -1.75  | 1.225518  |           | -4.291568            | .7915684 |

```
diff = mean(0) - mean(1) t = -1.4280
HO: diff = 0 Degrees of freedom = 22
Ha: diff < 0 Ha: diff != 0
Pr(T < t) = 0.0837 Pr(|T| > |t|) = 0.1673
 Ha: diff > 0
 Pr(T > t) = 0.9163
```

We do not find a statistically significant difference in the means.

If we were not willing to assume that the variances were equal and wanted to use Welch's formula, we could type

```
. ttest mpg, by(treated) welch
```

Two-sample t test with unequal variances

| Group    | Obs | Mean   | Std. err. | Std. dev. | [95% conf. interval] |          |
|----------|-----|--------|-----------|-----------|----------------------|----------|
| 0        | 12  | 21     | .7881701  | 2.730301  | 19.26525             | 22.73475 |
| 1        | 12  | 22.75  | .9384465  | 3.250874  | 20.68449             | 24.81551 |
| Combined | 24  | 21.875 | .6264476  | 3.068954  | 20.57909             | 23.17091 |
| diff     |     | -1.75  | 1.225518  |           | -4.28369             | .7836902 |

```
diff = mean(0) - mean(1) t = -1.4280
HO: diff = 0 Welch's degrees of freedom = 23.2465
Ha: diff < 0 Ha: diff != 0
Pr(T < t) = 0.0833 Pr(|T| > |t|) = 0.1666
 Ha: diff > 0
 Pr(T > t) = 0.9167
```

◀

## □ Technical note

In two-sample randomized designs, subjects will sometimes refuse the assigned treatment but still be measured for an outcome. In this case, take care to specify the group properly. You might be tempted to let *varname* contain missing where the subject refused and thus let `ttest` drop such observations from the analysis. Zelen (1979) argues that it would be better to specify that the subject belongs to the group in which he or she was randomized, even though such inclusion will dilute the measured effect.

□

▷ Example 3: Two-sample *t* test using variables

There is a second, inferior way to organize the data in the preceding example. We ran a test on 24 cars, 12 without the additive and 12 with. We now create two new variables, mpg1 and mpg2.

| mpg1 | mpg2 |
|------|------|
| 20   | 24   |
| 23   | 25   |
| 21   | 21   |
| 25   | 22   |
| 18   | 23   |
| 17   | 18   |
| 18   | 17   |
| 24   | 28   |
| 20   | 24   |
| 24   | 27   |
| 23   | 21   |
| 19   | 23   |

This method is inferior because it suggests a connection that is not there. There is no link between the car with 20 mpg and the car with 24 mpg in the first row of the data. Each column of data could be arranged in any order. Nevertheless, if our data are organized like this, ttest can accommodate us.

```
. use https://www.stata-press.com/data/r19/fuel
. ttest mpg1==mpg2, unpaired
```

Two-sample t test with equal variances

| Variable | Obs | Mean   | Std. err. | Std. dev. | [95% conf. interval] |          |
|----------|-----|--------|-----------|-----------|----------------------|----------|
| mpg1     | 12  | 21     | .7881701  | 2.730301  | 19.26525             | 22.73475 |
| mpg2     | 12  | 22.75  | .9384465  | 3.250874  | 20.68449             | 24.81551 |
| Combined | 24  | 21.875 | .6264476  | 3.068954  | 20.57909             | 23.17091 |
| diff     |     | -1.75  | 1.225518  |           | -4.291568            | .7915684 |

```
diff = mean(mpg1) - mean(mpg2) t = -1.4280
HO: diff = 0 Degrees of freedom = 22
Ha: diff < 0 Ha: diff != 0
Pr(T < t) = 0.0837 Pr(|T| > |t|) = 0.1673 Ha: diff > 0
 Pr(T > t) = 0.9163
```

## Paired t test

### ▷ Example 4

Suppose that the preceding data were actually collected by running a test on 12 cars. Each car was run once with the fuel additive and once without. Our data are stored in the same manner as in [example 3](#), but this time, there is most certainly a connection between the mpg values that appear in the same row. These come from the same car. The variables mpg1 and mpg2 represent mileage without and with the treatment, respectively.

```
. use https://www.stata-press.com/data/r19/fuel
. ttest mpg1==mpg2
```

Paired t test

| Variable | Obs | Mean  | Std. err. | Std. dev. | [95% conf. interval] |           |
|----------|-----|-------|-----------|-----------|----------------------|-----------|
| mpg1     | 12  | 21    | .7881701  | 2.730301  | 19.26525             | 22.73475  |
| mpg2     | 12  | 22.75 | .9384465  | 3.250874  | 20.68449             | 24.81551  |
| diff     | 12  | -1.75 | .7797144  | 2.70101   | -3.46614             | -.0338602 |

```

 mean(diff) = mean(mpg1 - mpg2) t = -2.2444
H0: mean(diff) = 0 Degrees of freedom = 11
Ha: mean(diff) < 0 Ha: mean(diff) != 0 Ha: mean(diff) > 0
Pr(T < t) = 0.0232 Pr(|T| > |t|) = 0.0463 Pr(T > t) = 0.9768

```

We find that the means are statistically different from each other at any level greater than 4.6%.

## Two-sample t test compared with one-way ANOVA

### ▷ Example 5

In [example 2](#), we saw that `ttest` can be used to test the equality of a pair of means; see [\[R\] oneway](#) for an extension that allows testing the equality of more than two means.

Suppose that we have data on the 50 states. The dataset contains the median age of the population (`medage`) and the region of the country (`region`) for each state. Region 1 refers to the Northeast, region 2 to the North Central, region 3 to the South, and region 4 to the West. Using `oneway`, we can test the equality of all four means.

```
. use https://www.stata-press.com/data/r19/census
(1980 Census data by state)
. oneway medage region
```

| Source         | Analysis of variance |    |            | F    | Prob > F |
|----------------|----------------------|----|------------|------|----------|
|                | SS                   | df | MS         |      |          |
| Between groups | 46.3961903           | 3  | 15.4653968 | 7.56 | 0.0003   |
| Within groups  | 94.1237947           | 46 | 2.04616945 |      |          |
| Total          | 140.519985           | 49 | 2.8677548  |      |          |

```
Bartlett's equal-variances test: chi2(3) = 10.5757 Prob>chi2 = 0.014
```

We find that the means are different, but we are interested only in testing whether the means for the Northeast (region==1) and West (region==4) are different. We could use oneway:

```
. oneway medage region if region==1 | region==4
```

| Source         | Analysis of variance |    |            | F     | Prob > F |
|----------------|----------------------|----|------------|-------|----------|
|                | SS                   | df | MS         |       |          |
| Between groups | 46.241247            | 1  | 46.241247  | 20.02 | 0.0002   |
| Within groups  | 46.1969169           | 20 | 2.30984584 |       |          |
| Total          | 92.4381638           | 21 | 4.40181733 |       |          |

Bartlett's equal-variances test: chi2(1) = 2.4679 Prob>chi2 = 0.116

We could also use ttest:

```
. ttest medage if region==1 | region==4, by(region)
```

Two-sample t test with equal variances

| Group    | Obs | Mean     | Std. err. | Std. dev. | [95% conf. interval] |          |
|----------|-----|----------|-----------|-----------|----------------------|----------|
| NE       | 9   | 31.23333 | .3411581  | 1.023474  | 30.44662             | 32.02005 |
| West     | 13  | 28.28462 | .4923577  | 1.775221  | 27.21186             | 29.35737 |
| Combined | 22  | 29.49091 | .4473059  | 2.098051  | 28.56069             | 30.42113 |
| diff     |     | 2.948718 | .6590372  |           | 1.57399              | 4.323445 |

diff = mean(NE) - mean(West) t = 4.4743  
 HO: diff = 0 Degrees of freedom = 20  
 Ha: diff < 0 Ha: diff != 0 Ha: diff > 0  
 Pr(T < t) = 0.9999 Pr(|T| > |t|) = 0.0002 Pr(T > t) = 0.0001

The significance levels of both tests are the same.

## Immediate form

### ➤ Example 6

ttesti is like ttest, except that we specify summary statistics rather than variables as arguments. For instance, we are reading an article that reports the mean number of sunspots per month as 62.6 with a standard deviation of 15.8. There are 24 months of data. We wish to test whether the mean is 75:

```
. ttesti 24 62.6 15.8 75
```

One-sample t test

|   | Obs | Mean | Std. err. | Std. dev. | [95% conf. interval] |          |
|---|-----|------|-----------|-----------|----------------------|----------|
| x | 24  | 62.6 | 3.225161  | 15.8      | 55.92825             | 69.27175 |

mean = mean(x) t = -3.8448  
 HO: mean = 75 Degrees of freedom = 23  
 Ha: mean < 75 Ha: mean != 75 Ha: mean > 75  
 Pr(T < t) = 0.0004 Pr(|T| > |t|) = 0.0008 Pr(T > t) = 0.9996

▷ Example 7

There is no immediate form of `ttest` with paired data because the test is also a function of the covariance, a number unlikely to be reported in any published source. For unpaired data, however, we might type

```
. ttesti 20 20 5 32 15 4
Two-sample t test with equal variances
```

|          | Obs | Mean     | Std. err. | Std. dev. | [95% conf. interval] |          |
|----------|-----|----------|-----------|-----------|----------------------|----------|
| x        | 20  | 20       | 1.118034  | 5         | 17.65993             | 22.34007 |
| y        | 32  | 15       | .7071068  | 4         | 13.55785             | 16.44215 |
| Combined | 52  | 16.92308 | .6943785  | 5.007235  | 15.52905             | 18.3171  |
| diff     |     | 5        | 1.256135  |           | 2.476979             | 7.523021 |

```

diff = mean(x) - mean(y)
t = 3.9805
HO: diff = 0
Degrees of freedom = 50
Ha: diff < 0
Pr(T < t) = 0.9999
Ha: diff != 0
Pr(|T| > |t|) = 0.0002
Ha: diff > 0
Pr(T > t) = 0.0001

```

If we had typed `ttesti 20 20 5 32 15 4, unequal`, the test would have assumed unequal variances.

| <code>r(p)</code>   | two-sided $p$ -value       | <code>r(mu_2)</code>  | $\bar{x}_2$ mean for population 2      |
| <code>r(se)</code>  | estimate of standard error | <code>r(df_t)</code>  | degrees of freedom                     |
| <code>r(t)</code>   | $t$ statistic              | <code>r(level)</code> | confidence level                       |

## Methods and formulas

See, for instance, [Hoel \(1984, 140–161\)](#) or [Dixon and Massey \(1983, 121–130\)](#) for an introduction and explanation of the calculation of these tests. [Acock \(2023, 165–179\)](#) and [Hamilton \(2013, 145–150\)](#) describe *t* tests using applications in Stata.

The test for  $\mu = \mu_0$  for unknown  $\sigma$  is given by

$$t = \frac{(\bar{x} - \mu_0)\sqrt{n}}{s}$$

The statistic is distributed as Student's *t* with  $n - 1$  degrees of freedom ([Gosset \[Student, pseud.\] 1908](#)).

The test for  $\mu_x = \mu_y$  when  $\sigma_x$  and  $\sigma_y$  are unknown but  $\sigma_x = \sigma_y$  is given by

$$t = \frac{\bar{x} - \bar{y}}{\left\{ \frac{(n_x - 1)s_x^2 + (n_y - 1)s_y^2}{n_x + n_y - 2} \right\}^{1/2} \left( \frac{1}{n_x} + \frac{1}{n_y} \right)^{1/2}}$$

The result is distributed as Student's *t* with  $n_x + n_y - 2$  degrees of freedom.

You could perform `ttest` (without the `unequal` option) in a regression setting given that regression assumes a homoskedastic error model. To compare with the `ttest` command, denote the underlying observations on *x* and *y* by  $x_j$ ,  $j = 1, \dots, n_x$ , and  $y_j$ ,  $j = 1, \dots, n_y$ . In a regression framework, typing `ttest` without the `unequal` option is equivalent to

1. creating a new variable  $z_j$  that represents the stacked observations on *x* and *y* (so that  $z_j = x_j$  for  $j = 1, \dots, n_x$  and  $z_{n_x+j} = y_j$  for  $j = 1, \dots, n_y$ )
2. and then estimating the equation  $z_j = \beta_0 + \beta_1 d_j + \epsilon_j$ , where  $d_j = 0$  for  $j = 1, \dots, n_x$  and  $d_j = 1$  for  $j = n_x + 1, \dots, n_x + n_y$  (that is,  $d_j = 0$  when the *z* observations represent *x*, and  $d_j = 1$  when the *z* observations represent *y*).

The estimated value of  $\beta_1$ ,  $b_1$ , will equal  $\bar{y} - \bar{x}$ , and the reported *t* statistic will be the same *t* statistic as given by the formula above.

The test for  $\mu_x = \mu_y$  when  $\sigma_x$  and  $\sigma_y$  are unknown and  $\sigma_x \neq \sigma_y$  is given by

$$t = \frac{\bar{x} - \bar{y}}{\left( s_x^2/n_x + s_y^2/n_y \right)^{1/2}}$$

The result is distributed as Student's *t* with  $\nu$  degrees of freedom, where  $\nu$  is given by (with [Satterthwaite's \[1946\]](#) formula)

$$\frac{\left( s_x^2/n_x + s_y^2/n_y \right)^2}{\frac{\left( s_x^2/n_x \right)^2}{n_x - 1} + \frac{\left( s_y^2/n_y \right)^2}{n_y - 1}}$$

With Welch's formula (1947), the number of degrees of freedom is given by

$$-2 + \frac{\left(s_x^2/n_x + s_y^2/n_y\right)^2}{\frac{\left(s_x^2/n_x\right)^2}{n_x+1} + \frac{\left(s_y^2/n_y\right)^2}{n_y+1}}$$

The test for  $\mu_x = \mu_y$  for matched observations (also known as paired observations, correlated pairs, or permanent components) is given by

$$t = \frac{\bar{d}\sqrt{n}}{s_d}$$

where  $\bar{d}$  represents the mean of  $x_i - y_i$  and  $s_d$  represents the standard deviation. The test statistic  $t$  is distributed as Student's  $t$  with  $n - 1$  degrees of freedom.

You can also use `tttest` without the `unpaired` option in a regression setting because a paired comparison includes the assumption of constant variance. The `tttest` with an unequal variance assumption does not lend itself to an easy representation in regression settings and is not discussed here.

$$(x_j - y_j) = \beta_0 + \epsilon_j.$$

[William Sealy Gosset](#) (1876–1937) was born in Canterbury, England. He studied chemistry and mathematics at Oxford and worked as a chemist with the brewers Guinness in Dublin. Gosset became interested in statistical problems, which he discussed with Karl Pearson and later with Fisher and Neyman. He published several important papers under the pseudonym “Student”, and he lent that name to the  $t$  test he invented.

[Stella Cunliffe](#) (1917–2012) was an advocate for increased understanding of the role of human nature in experiments and methodological rigor in social statistics. She was born in Battersea, England. She was the first person from her local public girls' school to attend college, obtaining a bachelor of science from the London School of Economics. Her first job was with the Danish Bacon Company during World War II, where she was in charge of bacon rations for London. After the war, she moved to Germany and again helped to ration food, this time for refugees.

She then spent a long career in quality control at the Guinness Brewing Company. Cunliffe observed that the weights of rejected casks skewed lighter. Noting that workers had to roll casks that were too light or too heavy uphill to be remade, she had the scales moved to the top of the hill. With workers able to roll rejected casks downhill, the weight of these casks began to follow a normal distribution.

After 25 years at Guinness, Cunliffe joined the British Home Office, where she would go on to become the first woman to serve as director of statistics. During her tenure at the Home Office, she emphasized applying principles of experimental design she had learned at Guinness to the study of such topics as birthrates, recidivism, and criminology. In 1975, she became the first woman to serve as president of the Royal Statistical Society.

## Description

The `update` command reports on the current update level and installs official updates. Official updates are updates to Stata as it was originally shipped from StataCorp, not the additions to Stata published in, for instance, the *Stata Journal* (SJ). Those additions are installed using the `net` command and updated using the `ado update` command; see [\[R\] net](#) and [\[R\] ado update](#).

`update` without arguments reports on the update level of the currently installed Stata.

`update from` sets an update source, which may be a directory name or URL. If you are on the internet, type `update from https://www.stata.com`.

`update query` compares the update level of the currently installed Stata with that available from the update source and displays a report.

`update all` updates all necessary files. This is what you should type to check for and install updates.

`set update_query` determines if `update query` is to be automatically performed when Stata is launched. Only Mac and Windows platforms can be set for automatic updating.

`set update_interval #` sets the number of days to elapse before performing the next automatic update query. The default # is 7. The interval starts from the last time an update query was performed (automatically or manually). Only Mac and Windows platforms can be set for automatic updating.

`set update_prompt` determines whether a dialog is to be displayed before performing an automatic update query. The dialog allows you to perform an update query now, perform one the next time Stata is launched, perform one after the next interval has passed, or disable automatic update query. Only Mac and Windows platforms can be set for automatic updating.

## Menu

Help > Check for updates

## Syntax

*Report on update level of currently installed Stata*

```
update
```

*Set update source*

```
update from location
```

*Compare update level of currently installed Stata with that of source*

```
update query [, from(location)]
```

*Perform update if necessary*

```
update all [, from(location) detail force exit]
```

*Set automatic updates (Mac and Windows only)*

```
set update_query { on | off }
```

```
set update_interval #
```

```
set update_prompt { on | off }
```

## Options

`from(location)` specifies the location of the update source. You can specify the `from()` option on the individual update commands or use the `update from` command. Which you do makes no difference. You typically do not need to use this option.

`detail` specifies to display verbose output during the update process.

`force` specifies to force downloading of all files even if, based on the date comparison, Stata does not think it is necessary. There is seldom a reason to specify this option.

`exit` instructs Stata to exit when the update has successfully completed. There is seldom a reason to specify this option.

## Remarks and examples

`update` updates the official components of Stata from the official source: <https://www.stata.com>. If you are connected to the internet, the easy thing to do is to type

```
. update all
```

and follow the instructions. If Stata is up to date, `update all` will do nothing. Otherwise, it will download whatever is necessary and install the files. If you just want to know what updates are available, type

```
. update query
```

update query will check if any updates are available and report that information. If updates are available, it will recommend that you type `update all`.

If you want to report the current update level, type

```
. update
```

update will report the update level of the Stata installation. update will also show you the date that updates were last checked and if any updates were available at that time.

## Stored results

update without a subcommand, update from, and update query store the following in `r()`:

### Notes:

\* Dates are stored as integers counting the number of days since January 1, 1960; see [\[D\] Datetime](#).

\*\* These dates are not stored by update without a subcommand because update by itself reports information solely about the local computer and does not check what is available on the web.

## Description

This entry describes the `vce()` option, which is common to most estimation commands. `vce()` specifies how to estimate the variance–covariance matrix (VCE) corresponding to the parameter estimates. The standard errors reported in the table of parameter estimates are the square root of the variances (diagonal elements) of the VCE.

## Syntax

*estimation\_cmd* ... [ , *vce(vcetype)* ... ]

| <i>vcetype</i>                                        | Description                                 |
|-------------------------------------------------------|---------------------------------------------|

| <code>bootstrap</code> [ , <i>bootstrap_options</i> ] | bootstrap estimation                        |
| <code>jackknife</code> [ , <i>jackknife_options</i> ] | jackknife estimation                        |

## Options

SE/Robust

`vce(oim)` is usually the default for models fit using maximum likelihood. `vce(oim)` uses the observed information matrix (OIM); see [R] [ml](#).

`vce(opg)` uses the sum of the outer product of the gradient (OPG) vectors; see [R] [ml](#). This is the default VCE when the `technique(bhhh)` option is specified; see [R] [Maximize](#).

`vce(robust)` uses the robust or sandwich estimator of variance. This estimator is robust to some types of misspecification so long as the observations are independent; see [U] [20.22 Obtaining robust variance estimates](#).

If the command allows `pweights` and you specify them, `vce(robust)` is implied; see [U] [20.24.3 Sampling weights](#).

`vce(cluster clustvar)` specifies that the standard errors allow for intragroup correlation, relaxing the usual requirement that the observations be independent. That is, the observations are independent across groups (clusters) but not necessarily within groups. *clustvar* specifies to which group each observation belongs, for example, `vce(cluster personid)` in data with repeated observations on individuals. `vce(cluster clustvar)` affects the standard errors and variance–covariance matrix of the estimators but not the estimated coefficients; see [U] 20.22 **Obtaining robust variance estimates**.

`vce(bootstrap [ , bootstrap_options ])` uses a bootstrap; see [R] **bootstrap**. After estimation with `vce(bootstrap)`, see [R] **bootstrap postestimation** to obtain percentile-based or bias-corrected confidence intervals.

`vce(jackknife [ , jackknife_options ])` uses the delete-one jackknife; see [R] **jackknife**.

## Remarks and examples

Remarks are presented under the following headings:

*Prefix commands*

*Passing options in vce()*

### Prefix commands

Specifying `vce(bootstrap)` or `vce(jackknife)` is often equivalent to using the corresponding prefix command. Here is an example using `jackknife` with `regress`.

```
. use https://www.stata-press.com/data/r19/auto
(1978 automobile data)
. regress mpg turn trunk, vce(jackknife)
(running regress on estimation sample)
Jackknife replications (74):10.....20.....30.....40.....
> ..50.....60.....70.... done

Linear regression Number of obs = 74
 Replications = 74
 F(2, 73) = 66.26
 Prob > F = 0.0000
 R-squared = 0.5521
 Adj R-squared = 0.5395
 Root MSE = 3.9260
```

|       | Coefficient | Jackknife<br>std. err. | t     | P> t  | [95% conf. interval] |           |
|-------|-------------|------------------------|-------|-------|----------------------|-----------|
| turn  | -.7610113   | .150726                | -5.05 | 0.000 | -1.061408            | -.4606147 |
| trunk | -.3161825   | .1282326               | -2.47 | 0.016 | -.5717498            | -.0606152 |
| _cons | 55.82001    | 5.031107               | 11.09 | 0.000 | 45.79303             | 65.84699  |

```
. jackknife: regress mpg turn trunk
(running regress on estimation sample)
Jackknife replications (74):10.....20.....30.....40.....
> ..50.....60.....70.... done

Linear regression Number of obs = 74
 Replications = 74
 F(2, 73) = 66.26
 Prob > F = 0.0000
 R-squared = 0.5521
 Adj R-squared = 0.5395
 Root MSE = 3.9260
```

| mpg   | Coefficient | Jackknife<br>std. err. | t     | P> t  | [95% conf. interval] |           |
|-------|-------------|------------------------|-------|-------|----------------------|-----------|
| turn  | -.7610113   | .150726                | -5.05 | 0.000 | -1.061408            | -.4606147 |
| trunk | -.3161825   | .1282326               | -2.47 | 0.016 | -.5717498            | -.0606152 |
| _cons | 55.82001    | 5.031107               | 11.09 | 0.000 | 45.79303             | 65.84699  |

Here it does not matter whether we specify the `vce(jackknife)` option or instead use the `jackknife` prefix.

However, `vce(jackknife)` should be used in place of the `jackknife` prefix whenever available because they are not always equivalent. For example, to use the `jackknife` prefix with `clogit` properly, you must tell `jackknife` to omit whole groups rather than individual observations. Specifying `vce(jackknife)` does this automatically.

```
. use https://www.stata-press.com/data/r19/clogitid
. jackknife, cluster(id): clogit y x1 x2, group(id)
(output omitted)
```

This extra information is automatically communicated to `jackknife` by `clogit` when the `vce()` option is specified.

```
. clogit y x1 x2, group(id) vce(jackknife)
(running clogit on estimation sample)
Jackknife replications (66):10.....20.....30.....40.....
> ..50.....60..... done

Conditional (fixed-effects) logistic regression Number of obs = 369
 Replications = 66
 F(2, 65) = 4.58
 Prob > F = 0.0137
 Pseudo R2 = 0.0355

Log likelihood = -123.41386

(Replications based on 66 clusters in id)
```

| y  | Coefficient | Jackknife<br>std. err. | t    | P> t  | [95% conf. interval] |          |
|----|-------------|------------------------|------|-------|----------------------|----------|
| x1 | .653363     | .3010608               | 2.17 | 0.034 | .052103              | 1.254623 |
| x2 | .0659169    | .0487858               | 1.35 | 0.181 | -.0315151            | .1633489 |

## Passing options in vce()

If you wish to specify more options to the bootstrap or jackknife estimation, you can include them within the `vce()` option. Below, we request 300 bootstrap replications and save the replications in `bsreg.dta`:

```
. use https://www.stata-press.com/data/r19/auto
(1978 automobile data)
. regress mpg turn trunk, vce(bootstrap, nodots seed(123) rep(300) saving(bsreg))
Linear regression
```

```
Number of obs = 74
Replications = 300
Wald chi2(2) = 144.17
Prob > chi2 = 0.0000
R-squared = 0.5521
Adj R-squared = 0.5395
Root MSE = 3.9260
```

|       | Observed<br>coefficient | Bootstrap<br>std. err. | z     | P> z  | Normal-based<br>[95% conf. interval] |           |
|-------|-------------------------|------------------------|-------|-------|--------------------------------------|-----------|
| turn  | -.7610113               | .1497877               | -5.08 | 0.000 | -1.05459                             | -.4674329 |
| trunk | -.3161825               | .1286802               | -2.46 | 0.014 | -.5683909                            | -.063974  |
| _cons | 55.82001                | 4.9221                 | 11.34 | 0.000 | 46.17287                             | 65.46715  |

```
. bstat using bsreg
```

```
Bootstrap results
```

```
Number of obs = 74
Replications = 300
```

```
Command: regress mpg turn trunk
```

|       | Observed<br>coefficient | Bootstrap<br>std. err. | z     | P> z  | Normal-based<br>[95% conf. interval] |           |
|-------|-------------------------|------------------------|-------|-------|--------------------------------------|-----------|
| turn  | -.7610113               | .1497877               | -5.08 | 0.000 | -1.05459                             | -.4674329 |
| trunk | -.3161825               | .1286802               | -2.46 | 0.014 | -.5683909                            | -.063974  |
| _cons | 55.82001                | 4.9221                 | 11.34 | 0.000 | 46.17287                             | 65.46715  |

## Methods and formulas

By default, Stata's maximum likelihood estimators display standard errors based on variance estimates given by the inverse of the negative Hessian (second derivative) matrix. If `vce(robust)`, `vce(cluster clustvar)`, or `pweights` is specified, standard errors are based on the robust variance estimator (see [\[U\] 20.22 Obtaining robust variance estimates](#)); likelihood-ratio tests are not appropriate here (see [\[SVY\] Survey](#)), and the model  $\chi^2$  is from a Wald test. If `vce(opg)` is specified, the standard errors are based on the outer product of the gradients; this option has no effect on likelihood-ratio tests, though it does affect Wald tests.

If `vce(bootstrap)` or `vce(jackknife)` is specified, the standard errors are based on the chosen replication method; here the model  $\chi^2$  or  $F$  statistic is from a Wald test using the respective replication-based covariance matrix. The  $t$  distribution is used in the coefficient table when the `vce(jackknife)` option is specified. `vce(bootstrap)` and `vce(jackknife)` are also available with some commands that are not maximum likelihood estimators.

## Description

`view` displays file contents in the Viewer.

`view file` displays the specified file. `file` is optional, so if you had a SMCL session log created by typing `log using mylog`, you could view it by typing `view mylog.smcl`. `view file` can properly display `.smcl` files (logs and the like), `.sthlp` files, and text files. `view file`'s `asis` option specifies that the file be displayed as plain text, regardless of the `filename`'s extension.

`view browse` opens your browser pointed to `url`. Typing `view browse https://www.stata.com` would bring up your browser pointed to the website <https://www.stata.com>.

`[view] help` displays the specified topic in the Viewer. For example, to review the help for Stata's print command, you could type `help print`. See [\[R\] help](#) for more details.

`[view] search` displays the results of the `search` command in the Viewer. For instance, to search the system help for information on robust regression, you could type `search robust regression`. See [\[R\] search](#) for more details.

`view net` does the same as the `net` command—see [\[R\] net](#)—but displays the result in the Viewer. For instance, typing `view net search hausman test` would search the internet for additions to Stata related to the Hausman test. Typing `view net from https://www.stata.com` would go to the Stata additions download site at <https://www.stata.com>.

`view ado` does the same as the `ado` command—see [\[R\] net](#)—but displays the result in the Viewer. For instance, typing `view ado dir` would show a list of files you have installed.

`view update` does the same as the `update` command—see [\[R\] update](#)—but displays the result in the Viewer. Typing `view update` would show the dates of what you have installed, and from there you could click to compare those dates with the latest updates available. Typing `view update query` would skip the first step and show the comparison.

## Menu

File > View...

## Syntax

*Display file in Viewer*

```
view [file] ["filename"] [, asis adopath]
```

*Bring up browser pointed to specified URL*

```
view browse ["url"]
```

*Display help results in Viewer*

```
[view] help [topic_or_command_name]
```

*Display search results in Viewer*

```
[view] search keywords
```

*Display net results in Viewer*

```
view net [netcmd]
```

*Display ado-results in Viewer*

```
view ado [adocmd]
```

*Display update results in Viewer*

```
view update [updatecmd]
```

## Options

*asis*, allowed with `view file`, specifies that the file be displayed as text, regardless of the *filename*'s extension. `view file`'s default action is to display files ending in `.smcl` and `.sthlp` as SMCL; see [P] [smcl](#).

*adopath*, allowed with `view file`, specifies that Stata search the `S_ADO` path for *filename* and display it, if found.

## Remarks and examples

Most users access the Viewer by selecting **File > View...** and proceeding from there. Some commands allow you to skip that step. Some common interactive uses of commands that display their results in the Viewer are the following:

```
. view mysession.smcl
. view mysession.log
. help print
. help regress
. search hausman test
. view net
. view ado
. view update query
```

## Description

`vwls` estimates a linear regression using variance-weighted least squares. It differs from ordinary least-squares (OLS) regression in that it does not assume homogeneity of variance, but requires that the conditional variance of *depvar* be estimated prior to the regression. The estimated variance need not be constant across observations. `vwls` treats the estimated variance as if it were the true variance when it computes standard errors of the coefficients.

You must supply an estimate of the conditional standard deviation of *depvar* to `vwls` by using the `sd(varname)` option, or you must have grouped data with the groups defined by the *indepvars* variables. In the latter case, `vwls` treats all *indepvars* as categorical variables, computes the mean and standard deviation of *depvar* separately for each subgroup, and computes the regression of the subgroup means on *indepvars*.

`regress` with analytic weights can be used to produce another kind of “variance-weighted least squares”; see [Remarks and examples](#) for an explanation of the difference.

## Quick start

Variance-weighted least-squares regression of *y* on *x1* and *x2*, with the estimated conditional std. dev. of *y* stored in `sd`

```
vwls y1 x1 x2, sd(sd)
```

Add categorical variable *a* using [factor-variable](#) syntax

```
vwls y1 x1 x2 i.a, sd(sd)
```

Same as above, but restrict the sample to cases where *v* is greater than 1

```
vwls y1 x1 x2 i.a if v>1, sd(sd)
```

Variance-weighted least-squares regression for grouped data with subgroups defined by *a2* and *a3*

```
vwls y2 i.a2 i.a3
```

## Menu

Statistics > Linear models and related > Other > Variance-weighted least squares

## Syntax

```
vwls depvar indepvars [if] [in] [weight] [, options]
```

| <i>options</i>                  | Description                                                                                                                                      |
|---------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| Model                           |                                                                                                                                                  |
| <code>noconstant</code>         | suppress constant term                                                                                                                           |
| <code>sd(<i>varname</i>)</code> | variable containing estimate of conditional standard deviation                                                                                   |
| Reporting                       |                                                                                                                                                  |
| <code>level(#)</code>           | set confidence level; default is level(95)                                                                                                       |
| <code>display_options</code>    | control columns and column formats, row spacing, line width, display of omitted variables and base and empty cells, and factor-variable labeling |
| <code>coeflegend</code>         | display legend instead of statistics                                                                                                             |

*indepvars* may contain factor variables; see [U] 11.4.3 **Factor variables**.

`bootstrap`, `by`, `collect`, `jackknife`, `rolling`, and `statsby` are allowed; see [U] 11.1.10 **Prefix commands**.

Weights are not allowed with the `bootstrap` prefix; see [R] **bootstrap**.

`fweights` are allowed; see [U] 11.1.6 **weight**.

`coeflegend` does not appear in the dialog box.

See [U] 20 **Estimation and postestimation commands** for more capabilities of estimation commands.

## Options

### Model

`noconstant`; see [R] **Estimation options**.

`sd(varname)` is an estimate of the conditional standard deviation of *depvar* (that is, it can vary observation by observation). All values of *varname* must be  $> 0$ . If you specify `sd()`, you cannot use `fweights`.

If `sd()` is not given, the data will be grouped by *indepvars*. Here *indepvars* are treated as categorical variables, and the means and standard deviations of *depvar* for each subgroup are calculated and used for the regression. Any subgroup for which the standard deviation is zero is dropped.

### Reporting

`level(#)`; see [R] **Estimation options**.

`display_options`: `nocl`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `no1stretch`; see [R] **Estimation options**.

The following option is available with `vwls` but is not shown in the dialog box:

`coeflegend`; see [R] **Estimation options**.

## Remarks and examples

The `vwls` command is intended for use with two special—and different—types of data. The first contains data that consist of measurements from physical science experiments in which all error is due solely to measurement errors and the sizes of the measurement errors are known.

You can also use variance-weighted least-squares linear regression for certain problems in categorical data analysis, such as when all the independent variables are categorical and the outcome variable is either continuous or a quantity that can sensibly be averaged. If each of the subgroups defined by the categorical variables contains a reasonable number of subjects, then the variance of the outcome variable can be estimated independently within each subgroup. For the purposes of estimation, `vwls` treats each subgroup as one observation, with the dependent variable being the subgroup mean of the outcome variable.

The `vwls` command fits the model

$$y_i = \mathbf{x}_i\boldsymbol{\beta} + \varepsilon_i$$

where the errors  $\varepsilon_i$  are independent normal random variables with the distribution  $\varepsilon_i \sim N(0, \nu_i)$ . The independent variables  $\mathbf{x}_i$  are assumed to be known without error.

As described above, `vwls` assumes that you already have estimates  $s_i^2$  for the variances  $\nu_i$ . The error variance is not estimated in the regression. The estimates  $s_i^2$  are used to compute the standard errors of the coefficients; see [Methods and formulas](#) below.

In contrast, weighted OLS regression assumes that the errors have the distribution  $\varepsilon_i \sim N(0, \sigma^2/w_i)$ , where the  $w_i$  are known weights and  $\sigma^2$  is an unknown parameter that is estimated in the regression. This is the difference from variance-weighted least squares: in weighted OLS, the magnitude of the error variance is estimated in the regression using all the data.

### ▷ Example 1

An artificial, but informative, example illustrates the difference between variance-weighted least squares and weighted OLS.

We measure the quantities  $x_i$  and  $y_i$  and estimate that the standard deviation of  $y_i$  is  $s_i$ . We enter the data into Stata:

```
. use https://www.stata-press.com/data/r19/vwlsxmpl
. list
```

|    | x | y   | s  |
|----|---|-----|----|
| 1. | 1 | 1.2 | .5 |
| 2. | 2 | 1.9 | .5 |
| 3. | 3 | 3.2 | 1  |
| 4. | 4 | 4.3 | 1  |
| 5. | 5 | 4.9 | 1  |
| 6. | 6 | 6.0 | 2  |
| 7. | 7 | 7.2 | 2  |
| 8. | 8 | 7.9 | 2  |

Because we want observations with smaller variance to carry larger weight in the regression, we compute an OLS regression with analytic weights proportional to the inverse of the squared standard deviations:

```
. regress y x [aweight=s^(-2)]
(sum of wgt is 11.75)
```

| Source   | SS         | df | MS         | Number of obs | = | 8      |
|----------|------------|----|------------|---------------|---|--------|
| Model    | 22.6310183 | 1  | 22.6310183 | F(1, 6)       | = | 702.26 |
| Residual | .193355117 | 6  | .032225853 | Prob > F      | = | 0.0000 |
|          |            |    |            | R-squared     | = | 0.9915 |
|          |            |    |            | Adj R-squared | = | 0.9901 |
| Total    | 22.8243734 | 7  | 3.26062477 | Root MSE      | = | .17952 |

| y     | Coefficient | Std. err. | t     | P> t  | [95% conf. interval] |          |
|-------|-------------|-----------|-------|-------|----------------------|----------|
| x     | .9824683    | .0370739  | 26.50 | 0.000 | .8917517             | 1.073185 |
| _cons | .1138554    | .1120078  | 1.02  | 0.349 | -.1602179            | .3879288 |

If we compute a variance-weighted least-squares regression by using `vwls`, we get the same results for the coefficient estimates but very different standard errors:

```
. vwls y x, sd(s)
```

|                                            |  |  |  |               |   |        |
|--------------------------------------------|--|--|--|---------------|---|--------|
| Variance-weighted least-squares regression |  |  |  | Number of obs | = | 8      |
| Goodness-of-fit chi2(6) = 0.28             |  |  |  | Model chi2(1) | = | 33.24  |
| Prob > chi2 = 0.9996                       |  |  |  | Prob > chi2   | = | 0.0000 |

| y     | Coefficient | Std. err. | z    | P> z  | [95% conf. interval] |          |
|-------|-------------|-----------|------|-------|----------------------|----------|
| x     | .9824683    | .170409   | 5.77 | 0.000 | .6484728             | 1.316464 |
| _cons | .1138554    | .51484    | 0.22 | 0.825 | -.8952124            | 1.122923 |

Although the values of  $y_i$  were nicely linear with  $x_i$ , the `vwls` regression used the large estimates for the standard deviations to compute large standard errors for the coefficients. For weighted OLS regression, however, the scale of the analytic weights has no effect on the standard errors of the coefficients—only the relative proportions of the analytic weights affect the regression.

If we are sure of the sizes of our error estimates for  $y_i$ , using `vwls` is valid. However, if we can estimate only the relative proportions of error among the  $y_i$ , then `vwls` is not appropriate.

## ► Example 2

Let's now consider an example of the use of `vwls` with categorical data. Suppose that we have blood pressure data for  $n = 400$  subjects, categorized by gender and race (black or white). Here is a description of the data:

```
. use https://www.stata-press.com/data/r19/bp
. table gender race, statistic(mean bp) statistic(sd bp) statistic(freq)
> nformat(%8.1f)
```

|                    | Race  |       |       |
|--------------------|-------|-------|-------|
|                    | White | Black | Total |
| Gender             |       |       |       |
| Female             |       |       |       |
| Mean               | 117.1 | 118.5 | 117.8 |
| Standard deviation | 10.3  | 11.6  | 10.9  |
| Frequency          | 100.0 | 100.0 | 200.0 |
| Male               |       |       |       |
| Mean               | 122.1 | 125.8 | 124.0 |
| Standard deviation | 10.6  | 15.5  | 13.3  |
| Frequency          | 100.0 | 100.0 | 200.0 |
| Total              |       |       |       |
| Mean               | 119.6 | 122.2 | 120.9 |
| Standard deviation | 10.7  | 14.1  | 12.6  |
| Frequency          | 200.0 | 200.0 | 400.0 |

Performing a variance-weighted regression using vwls gives

```
. vwls bp gender race
Variance-weighted least-squares regression Number of obs = 400
Goodness-of-fit chi2(1) = 0.88 Model chi2(2) = 27.11
Prob > chi2 = 0.3486 Prob > chi2 = 0.0000
```

| bp     | Coefficient | Std. err. | z      | P> z  | [95% conf. interval] |          |
|--------|-------------|-----------|--------|-------|----------------------|----------|
| gender | 5.876522    | 1.170241  | 5.02   | 0.000 | 3.582892             | 8.170151 |
| race   | 2.372818    | 1.191683  | 1.99   | 0.046 | .0371631             | 4.708473 |
| _cons  | 116.6486    | .9296297  | 125.48 | 0.000 | 114.8266             | 118.4707 |

By comparison, an OLS regression gives the following result:

```
. regress bp gender race
Source	SS df MS Number of obs = 400
Model | 4485.66639 2 2242.83319 F(2, 397) = 15.24
Residual | 58442.7305 397 147.210908 Prob > F = 0.0000
-----|-----
Total | 62928.3969 399 157.71528 R-squared = 0.0713
 Adj R-squared = 0.0666
 Root MSE = 12.133
```

| bp     | Coefficient | Std. err. | t      | P> t  | [95% conf. interval] |          |
|--------|-------------|-----------|--------|-------|----------------------|----------|
| gender | 6.1775      | 1.213305  | 5.09   | 0.000 | 3.792194             | 8.562806 |
| race   | 2.5875      | 1.213305  | 2.13   | 0.034 | .2021938             | 4.972806 |
| _cons  | 116.4862    | 1.050753  | 110.86 | 0.000 | 114.4205             | 118.552  |

Note the larger value for the race coefficient (and smaller *p*-value) in the OLS regression. The assumption of homogeneity of variance in OLS means that the mean for black men pulls the regression line higher than in the vwls regression, which takes into account the larger variance for black men and reduces its effect on the regression.

## Stored results

vwls stores the following in `e()`:

### Scalars

|                         |                                    |
|-------------------------|------------------------------------|
| <code>e(N)</code>       | number of observations             |
| <code>e(df_m)</code>    | model degrees of freedom           |
| <code>e(chi2)</code>    | model $\chi^2$                     |
| <code>e(df_gf)</code>   | goodness-of-fit degrees of freedom |
| <code>e(chi2_gf)</code> | goodness-of-fit $\chi^2$           |
| <code>e(rank)</code>    | rank of $e(V)$                     |

### Macros

|                            |                                      |
|----------------------------|--------------------------------------|
| <code>e(cmd)</code>        | vwls                                 |
| <code>e(cmdline)</code>    | command as typed                     |
| <code>e(depvar)</code>     | name of dependent variable           |
| <code>e(properties)</code> | b V                                  |
| <code>e(predict)</code>    | program used to implement predict    |
| <code>e(asbalanced)</code> | factor variables fvset as asbalanced |
| <code>e(asobserved)</code> | factor variables fvset as asobserved |

### Matrices

|                   |                                              |
|-------------------|----------------------------------------------|
| <code>e(b)</code> | coefficient vector                           |
| <code>e(V)</code> | variance–covariance matrix of the estimators |

### Functions

|                        |                         |
|------------------------|-------------------------|
| <code>e(sample)</code> | marks estimation sample |
|------------------------|-------------------------|

In addition to the above, the following is stored in `r()`:

### Matrices

|                       |                                                                                                                       |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------|
| <code>r(table)</code> | matrix containing the coefficients with their standard errors, test statistics, $p$ -values, and confidence intervals |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------|

Note that results stored in `r()` are updated when the command is replayed and will be replaced when any `r-class` command is run after the estimation command.

## Methods and formulas

Let  $\mathbf{y} = (y_1, y_2, \dots, y_n)'$  be the vector of observations of the dependent variable, where  $n$  is the number of observations. When `sd()` is specified, let  $s_1, s_2, \dots, s_n$  be the standard deviations supplied by `sd()`. For categorical data, when `sd()` is not given, the means and standard deviations of  $y$  for each subgroup are computed, and  $n$  becomes the number of subgroups,  $\mathbf{y}$  is the vector of subgroup means, and  $s_i$  are the standard deviations for the subgroups.

Let  $\mathbf{V} = \text{diag}(s_1^2, s_2^2, \dots, s_n^2)$  denote the estimate of the variance of  $\mathbf{y}$ . Then the estimated regression coefficients are

$$\mathbf{b} = (\mathbf{X}'\mathbf{V}^{-1}\mathbf{X})^{-1}\mathbf{X}'\mathbf{V}^{-1}\mathbf{y}$$

and their estimated covariance matrix is

$$\widehat{\text{Cov}}(\mathbf{b}) = (\mathbf{X}'\mathbf{V}^{-1}\mathbf{X})^{-1}$$

A statistic for the goodness of fit of the model is

$$Q = (\mathbf{y} - \mathbf{Xb})' \mathbf{V}^{-1} (\mathbf{y} - \mathbf{Xb})$$

where  $Q$  has a  $\chi^2$  distribution with  $n - k$  degrees of freedom ( $k$  is the number of independent variables plus the constant, if any).

| <a href="#">test</a>            | Wald tests of simple and composite linear hypotheses                                              |
| <a href="#">testnl</a>          | Wald tests of nonlinear hypotheses                                                                |

# predict

## Description for predict

`predict` creates a new variable containing predictions such as linear predictions and standard errors.

## Menu for predict

Statistics > Postestimation

## Syntax for predict

```
predict [type] newvar [if] [in] [, xb stdp]
```

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

## Options for predict

Main

---

`xb`, the default, calculates the linear prediction.

`stdp` calculates the standard error of the linear prediction.

# margins

## Description for margins

`margins` estimates margins of response for linear predictions.

## Menu for margins

Statistics > Postestimation

## Syntax for margins

```
margins [marginlist] [, options]
```

```
margins [marginlist] , predict(statistic ...) [options]
```

| <i>statistic</i>  | Description                           |
|-------------------|---------------------------------------|
| <code>xb</code>   | linear prediction; the default        |
| <code>stdp</code> | not allowed with <code>margins</code> |

Statistics not allowed with `margins` are functions of stochastic quantities other than  $e(b)$ .

For the full syntax, see [\[R\] margins](#).

## Also see

[\[R\] vwls](#) — Variance-weighted least squares

[\[U\] 20 Estimation and postestimation commands](#)

## Description

`which` looks for file *fname.ftype* along the S\_ADO path. If Stata finds the file, `which` displays the full path and filename, along with, if the file is text, all lines in the file that begin with “\*!” in the first column. If Stata cannot find the file, `which` issues the message “file not found along ado-path” and sets the return code to 111. *ftype* must be a file type for which Stata usually looks along the ado-path to find. Allowable *ftypes* are

```
.ado, .class, .dlg, .idlg, .sthlp, .ihlp, .hlp, .jar, .key, .maint, .mata, .mlib,
.mo, .mnu, .plugin, .png, .py, .scheme, .stbc, and .style
```

If *ftype* is omitted, `which` assumes `.ado`. When searching for `.ado` files, if Stata cannot find the file, Stata then checks to see if *fname* is a built-in Stata command, allowing for valid abbreviations. If it is, the message “built-in command” is displayed; if not, the message “command not found as either built-in or ado-file” is displayed and the return code is set to 111.

## Syntax

```
which fname[.ftype] [, all]
```

## Option

`all` forces `which` to report the location of all files matching the *fname.ftype* found along the search path. The default is to report just the first one found.

## Remarks and examples

If you write programs, you know that you make changes to the programs over time. If you are like us, you also end up with multiple versions of the program stored on your disk, perhaps in different directories. You may even have given copies of your programs to other Stata users, and you may not remember which version of a program you or your friends are using. The `which` command helps you solve this problem.

## ▷ Example 1

The `which` command displays the path for `filename.ado` and any lines in the code that begin with “\*!”. For example, we might want information about the `test` command, described in [R] `test`, which is an ado-file written by StataCorp. Here is what happens when we type `which test`:

```
. which test
C:\Program Files\Stata19\ado\base\t\test.ado
*! version 2.4.1 28jan2021
```

`which` displays the path for the `test.ado` file and also a line beginning with “\*!” that indicates the version of the file.

Do not confuse “version 2.4.1” above with the `version` command or the version of Stata. The “\*!” code indicates notes. In this case, the `*! version 2.4.1` line is merely a note to the author to identify the iteration (version) of the `test` program. It is an unfortunate coincidence that the word `version` is overloaded in this manner.

We do not need to be so formal. `which` will display anything typed after lines that begin with “\*!”. For instance, we might write `myprog.ado`:

```
. which myprog
.\myprog.ado
*! first written 1/03/2025
*! bug fix on 1/05/2025 (no variance case)
*! updated 1/24/2025 to include noconstant option
*! still suspicious if variable takes on only two values
```

It does not matter where in the program the lines beginning with `*!` are—`which` will list them (in particular, our “still suspicious” comment was buried about 50 lines down in the code). All that is important is that the `*!` marker appear in the first two columns of a line.

◀

## ▷ Example 2

If we type `which command`, where `command` is a built-in command rather than an ado-file, Stata responds with

```
. which summarize
built-in command: summarize
```

If `command` was neither a built-in command nor an ado-file, Stata would respond with

```
. which junk
command junk not found as either built-in or ado-file

## Description

`wildbootstrap` performs wild cluster bootstrap (WCB) inference for linear hypotheses about parameters in linear regression models. These hypotheses can be simple or composite. When the assumptions required for the consistency of the cluster-robust variance estimator (CRVE) do not hold, the WCB is a good alternative.

## Quick start

Estimate the WCB  $p$ -value and confidence interval (CI) for the coefficient on `x1` in a linear regression of `y` on `x1` with clusters identified in `cvar`

```
wildbootstrap regress y x1, cluster(cvar)
```

Same as above, but test whether the coefficients on `x1` and `x2` are equal in a regression of `y` on `x1` and `x2`

```
wildbootstrap regress y x1 x2, cluster(cvar) test(x1 = x2)
```

## Menu

## Syntax

```
wildbootstrap estimator deprvar [indepvars] [if] [in] [weight] [, options]
```

| <i>estimator</i>     | Description                                           |
|----------------------|-------------------------------------------------------|
| <code>regress</code> | linear regression                                     |
| <code>areg</code>    | linear regression with a large indicator-variable set |
| <code>xtreg</code>   | fixed-effects linear models                           |

| <i>options</i> | Description |
|----------------|-------------|
|----------------|-------------|

### Main

|                                     |                                                                                                      |
|-------------------------------------|------------------------------------------------------------------------------------------------------|
| <code>noconstant</code>             | suppress constant term; available only with estimator <code>regress</code>                           |
| <code>hascons</code>                | has user-supplied constant; available only with estimator <code>regress</code>                       |
| <code>absorb(<i>varname</i>)</code> | categorical variable to be absorbed; required by and available only with estimator <code>areg</code> |

### Statistics

|                                            |                                                |
|--------------------------------------------|------------------------------------------------|
| <code>coefficients(<i>coeflist</i>)</code> | perform inference for a subset of coefficients |
| <code>test(<i>testspec</i>)</code>         | specify linear test parameters                 |

### Bootstrap

|                                           |                                                                                                           |
|-------------------------------------------|-----------------------------------------------------------------------------------------------------------|
| <code>cluster(<i>clustvar</i>)</code>     | specify variable identifying clusters; required for estimators <code>regress</code> and <code>areg</code> |
| <code>pvalue(<i>pvalue</i>)</code>        | specify the <i>p</i> -value type; may be <code>equal</code> (the default) or <code>symmetric</code>       |
| <code>errorweight(<i>wcbwtype</i>)</code> | specify WCB weight; default is <code>errorweight</code> ( <code>rademacher</code> )                       |
| <code>reps(#)</code>                      | set number of bootstrap repetitions; default is <code>reps(1000)</code>                                   |
| <code>rseed(#   <i>statecode</i>)</code>  | set random-number seed to <code>#</code> or <code>statecode</code>                                        |
| <code>blocksize(#)</code>                 | set bootstrap repetition block size; default is <code>min(reps(#), 1000)</code>                           |
| <code>cistop(largest   first)</code>      | specify stopping rule for CI computation                                                                  |

### Reporting

|                              |                                                         |
|------------------------------|---------------------------------------------------------|
| <code>level(#)</code>        | set confidence level; default is <code>level(95)</code> |
| <code>display_options</code> | control column formats and display of CIs               |

*indepvars* and *coeflist* may contain factor variables; see [U] 11.4.3 **Factor variables**.

*deprvar*, *indepvars*, and *coeflist* may contain time-series operators; see [U] 11.4.4 **Time-series varlists**.

`collect` is allowed; see [U] 11.1.10 **Prefix commands**.

Any weight that is allowed by the estimator is allowed; see [U] 11.1.6 **weight**.

## Options

### Main

`noconstant` and `hascons`; see [R] **regress**. These options may be specified only when estimator `regress` is specified.

`absorb(varname)`; see [R] **areg**. This option must be specified when estimator `areg` is specified.

## Statistics

`coefficients` (*coeflist*) performs an inference for a subset of coefficients. It reports the bootstrap  $p$ -value for a test of the subset of coefficients, *coeflist*, equal to 0 and the bootstrap CI. The default is to perform inference for all variables specified in *indepvars*. `coefficients()` may not be specified with `test()`.

`test` (*testspec*) specifies a linear test. You may also specify multiple linear tests by using `test((testspec1) (testspec2) ...)`. The test specification must be consistent with specifying a linear constraint. See [R] [test](#) and [R] [constraint](#).

## Bootstrap

`cluster` (*clustvar*) specifies the variable identifying the cluster groups. `cluster()` is required with estimators `regress` and `areg`. With estimator `xtreg`, *clustvar* defaults to the `xtset panelvar`.

`ptype` (*ptype*) specifies the  $p$ -value criterion: symmetric (`symmetric`) or equal tailed (`equal`). The default is `ptype(equal)`. See [Methods and formulas](#) for more details.

`errorweight` (*wcbwtype*) specifies the type of wild weight. *wcbwtype* may be one of the following:

| <i>wcbwtype</i>         | Description                                                                                                                                  |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| <code>rademacher</code> | two-point distribution assigns values 1 and $-1$ with equal probability; the default                                                         |
| <code>mammen</code>     | two-point distribution assigns value $1 - \phi$ with probability $\phi/\sqrt{5}$ and value $\phi$ otherwise, where $\phi = (1 + \sqrt{5})/2$ |
| <code>webb</code>       | six-point distribution assigns probability of $1/6$ to the points $\pm\sqrt{1/2}$ , $\pm 1$ , and $\pm\sqrt{3/2}$                            |
| <code>normal</code>     | standard normal distribution                                                                                                                 |
| <code>gamma</code>      | gamma distribution with shape parameter 4 and scale parameter $1/2$ centered on its mean of 2                                                |

`reps` (*#*) sets the number of repetitions for the bootstrap. The default is `reps(1000)`. For the `ptype(equal)` option, the values of `level()` and `reps()` should be chosen so that  $\alpha/2 \times \text{reps}(\#)$  is an integer, where  $\alpha = (100 - \text{level}(\#))/100$ . For the `ptype(symmetric)` option, such values should be chosen so that  $\alpha \times \text{reps}(\#)$  is an integer. When the product is not an integer, the number of repetitions is increased so that it is. Integer values improve the search efficiency of the `wildbootstrap` algorithm.

`rseed` (*#* | *statecode*) sets the random-number seed to *#* or *statecode*. See [R] [set seed](#).

`blocksize` (*#*) sets the bootstrap block size. This is an integer less than or equal to `reps(#)` and is used to reduce the amount of memory the bootstrap computation will consume. The default is `min(reps(#), 1000)`.

`cistop` (*largest* | *first*) specifies the stopping rule for the CI computation. The bootstrap distribution is a step function, so for each bound, there is an interval of values that meet the CI level criterion. `cistop(largest)`, the default, specifies that the largest value within the interval be selected. `cistop(first)` specifies that the first value the algorithm finds within the interval be selected; therefore, specifying `cistop(first)` will result in faster CI computation. The `cistop()` option may not be combined with the `noci` option.

## Reporting

`level(#)`; see [R] [Estimation options](#). The `level()` option will not work on replay because CIs are based on estimator-specific enumerations. To change the confidence level, you must refit the model.

`display_options`: `noci`, `cformat(%fmt)`, `pformat(%fmt)`, and `sformat(%fmt)`; see [R] [Estimation options](#). The `noci` option may not be combined with the `cistop()` option.

## Remarks and examples

`wildbootstrap` implements the WCB, which was proposed by [Cameron, Gelbach, and Miller \(2008\)](#). It is an extension of the original wild bootstrap procedure proposed by [Wu \(1986\)](#), which was designed to work well for models with heteroskedasticity, to the case of cluster-level correlation. The wild bootstrap has proven to work well in cases where cluster-robust standard errors do not perform well. A good discussion of the methodology can be found in [Cameron and Miller \(2015\)](#), [MacKinnon \(2019\)](#), [MacKinnon and Webb \(2018\)](#), and [MacKinnon, Nielsen, and Webb \(2023\)](#), and the references therein. Specifically, the WCB is a good inference tool when one or more of the CRVE *t*-statistic consistency assumptions are violated. [MacKinnon and Webb](#) list the assumptions as follows:

1. The number of clusters goes to infinity.
2. The within-cluster error correlations are the same for all clusters.
3. Each cluster contains an equal number of observations.

Below, we illustrate how to use `wildbootstrap`; however, note that alternatives exist in the literature to address the inference problems noted above. For example, the [Bell and McCaffrey \(2002\)](#) *t*-statistic degrees-of-freedom correction is an alternative to `wildbootstrap` when at least one of the above assumptions is violated. The degrees-of-freedom correction is computed with option `vce(hc2 clustvar, dfadjust)` for `regress`, `areg`, and `xtreg`, `fe`.

### ► Example 1: Simple regression

Say we are interested in the effect of tenure on wages for a panel of individuals sampled from 2013 to 2016. We would like to use wild bootstrap CIs clustering at the `personid` level. For reproducibility, we set the seed by using option `rseed()`.

```
. use https://www.stata-press.com/data/r19/wagework
(Wages for 20 to 77 year olds, 2013–2016)
. wildbootstrap regress wage tenure, cluster(personid) rseed(12345)
Performing 1,000 replications for p-value for tenure = 0 ...
Computing confidence interval for tenure
 Lower bound:10.....20. done (21)
 Upper bound:10..... done (17)

Wild cluster bootstrap Number of obs = 1,928
Linear regression Number of clusters = 589
 Cluster size:
Cluster variable: personid min = 1
Error weight: Rademacher avg = 3.3
 max = 4
```

|            | wage       | Estimate | t     | p-value | [95% conf. interval] |          |
|------------|------------|----------|-------|---------|----------------------|----------|
| constraint | tenure = 0 | .7807403 | 27.19 | 0.000   | .7209754             | .8368386 |

The iteration log indicates the number of iterations used to compute the lower and upper bound for the CIs. In *Methods and formulas* below, we discuss how these bounds are computed. Notably, there is a separate optimization procedure used to compute each one of these bounds.

The table header also tells us the error weights used for the sampling algorithm of the wild bootstrap, which, by default, are Rademacher weights. See the `errorweight()` option for more details about error weights.

The column header labeled *p*-value indicates that the *t*-statistic equal-tailed *p*-value has been computed. The `ptype(equal)` option is the default. Alternatively, the symmetric *p*-value is computed when the `ptype(symmetric)` option is specified and is identified with the column header of `P>|t|`.

```
. wildbootstrap regress wage tenure, cluster(personid) rseed(12345)
> ptype(symmetric)
Performing 1,000 replications for p-value for tenure = 0 ...
Computing confidence interval for tenure
 Lower bound:10.....20.. done (22)
 Upper bound:10..... done (15)

Wild cluster bootstrap
Linear regression
Cluster variable: personid
Error weight: Rademacher
Number of obs = 1,928
Number of clusters = 589
Cluster size:
min = 1
avg = 3.3
max = 4
```

|            | wage       | Estimate | t     | P> t  | [95% conf. interval] |
|------------|------------|----------|-------|-------|----------------------|
| constraint | tenure = 0 | .7807403 | 27.19 | 0.000 | .7240502 .8399896    |

We can always compare the CIs from the wild bootstrap with what we would have obtained using the underlying command, in this case, `regress`.

```
. regress
Linear regression
Number of obs = 1,928
F(1, 588) = 739.36
Prob > F = 0.0000
R-squared = 0.4212
Root MSE = 3.5097
(Std. err. adjusted for 589 clusters in personid)
```

| wage   | Coefficient | Robust std. err. | t     | P> t  | [95% conf. interval] |
|--------|-------------|------------------|-------|-------|----------------------|
| tenure | .7807403    | .028713          | 27.19 | 0.000 | .7243477 .8371328    |
| _cons  | 20.89884    | .2135686         | 97.86 | 0.000 | 20.47939 21.31829    |

Note that typing this command will replace the return matrix `r(table)`. Observe that the *t* statistics are the same in both tables because `regress` and `wildbootstrap` use the same CRVE, but the *p*-values and CIs may vary between tables.

Similarly, you can redisplay the `wildbootstrap` table by typing `wildbootstrap`, which may be abbreviated as `wildboot`.

▷ Example 2: Small number of clusters with wildly varying cluster sizes

As in [example 1](#), we would like to see the effect of tenure on wages; in this case, however, we would like to cluster at the industry level. Here, for year 1988, we use a wage dataset with only 12 clusters, for which cluster sizes vary wildly from 4 to 817, violating the CRVE  $t$ -statistic consistency [assumptions 1 and 3](#) outlined previously.

```
. use https://www.stata-press.com/data/r19/nlsw88
(NLSW, 1988 extract)
. wildbootstrap regress wage tenure, cluster(industry) rseed(12345)
Performing 1,000 replications for p-value for tenure = 0 ...
Computing confidence interval for tenure
 Lower bound:10.....20..... done (26)
 Upper bound:10.....20.... done (24)
Wild cluster bootstrap Number of obs = 2,217
Linear regression Number of clusters = 12
 Cluster size:
Cluster variable: industry min = 4
Error weight: Rademacher avg = 184.8
 max = 817
```

|            | wage       | Estimate | t    | p-value | [95% conf. interval] |          |
|------------|------------|----------|------|---------|----------------------|----------|
| constraint | tenure = 0 | .1830716 | 6.95 | 0.000   | .1274023             | .3258156 |

## ▷ Example 3: Small number of clusters with more regressors

Continuing with [example 2](#), we look at a more complex and perhaps more realistic example. We add to the model explanatory variables for total work experience, `ttl_exp`; a college graduate indicator, `collgrad`; and an indicator for union membership, `union`.

```
. wildbootstrap regress wage c.tenure#c.ttl_exp ib0.collgrad ib0.union,
> cluster(industry) rseed(12345)

Performing 1,000 replications for p-value for tenure = 0 ...
Computing confidence interval for tenure
 Lower bound:10.....20.....30.... done (34)
 Upper bound:10.....20.... done (24)

Performing 1,000 replications for p-value for ttl_exp = 0 ...
Computing confidence interval for ttl_exp
 Lower bound:10.....20.... done (25)
 Upper bound:10..... done (19)

Performing 1,000 replications for p-value for c.tenure#c.ttl_exp = 0 ...
Computing confidence interval for c.tenure#c.ttl_exp
 Lower bound:10.....20... done (23)
 Upper bound:10.....20..... done (27)
note: upper-bound CI achieved $1-F(-3.65e-04) = 0.0240$, but target is $1-F(x) = .025$.
note: the sorted bootstrap t statistics have at least two tied values
 adjacent to the t statistic under the null; this prevents the CI bound
 from converging to the target.

Performing 1,000 replications for p-value for 1.collgrad = 0 ...
Computing confidence interval for 1.collgrad
 Lower bound:10.....20.....30.. done (32)
note: lower-bound CI achieved $F(1.66) = 0.0240$, but target is $F(x) = .025$.
note: at least one bootstrap t statistic matches the t statistic under the
 null; this prevents the CI bound from converging to the target.
 Upper bound:10.....20..... done (26)

Performing 1,000 replications for p-value for 1.union = 0 ...
Computing confidence interval for 1.union
 Lower bound:10.....20.....30 done (30)
 Upper bound:10.....20..... done (25)

Wild cluster bootstrap Number of obs = 1,855
Linear regression Number of clusters = 12
 Cluster size:
Cluster variable: industry min = 2
Error weight: Rademacher avg = 154.6
 max = 717
```

|             | wage                   | Estimate  | t     | p-value | [95% conf. interval] |           |
|-------------|------------------------|-----------|-------|---------|----------------------|-----------|
| constraints |                        |           |       |         |                      |           |
|             | tenure = 0             | .204166   | 2.81  | 0.026   | .0729495             | .4699121  |
|             | ttl_exp = 0            | .3025249  | 11.72 | 0.004   | .2566267             | .4110114  |
|             | c.tenure#c.ttl_exp = 0 | -.0097942 | -2.76 | 0.046   | -.022061             | -.0003651 |
|             | 1.collgrad = 0         | 3.077377  | 7.59  | 0.034   | 1.662277             | 5.218396  |
|             | 1.union = 0            | .9114564  | 2.31  | 0.040   | .1060322             | 2.470924  |

We did not specify the `coefficients()` option, so `wildbootstrap` computes  $p$ -values and CIs for all coefficients in the model, with the exception of the constant term, using the default `ptype(equal)` option to compute the equal-tailed  $p$ -values.

The iteration log states that the CI-target tail values were not achieved for two of the reported constraints. This is because the sorted vector of bootstrap  $t$  statistics can have ties due to computer finite numeric precision and the finite number of draws for the Rademacher, Mammen, and Webb distributions. When ties occur with the  $t$  statistic under the null, or those adjacent to it, and the desired CI tail area cannot be achieved, `wildbootstrap` will choose a bound that results in a smaller tail area. This is the case when `wildbootstrap` searches for the `c.tenure#c.ttl_exp` CI upper bound and the `1.collgrad` CI lower bound.

Numerical computations will contain a roundoff error; `wildbootstrap` retains 13 digits on the mantissa of the  $t$  statistics before making comparisons.

◀

#### ▷ Example 4: Linear regression with an indicator-variable set

We would like to include an individual's occupation code (`occupation`) as an additional control in the regression to avoid potential omitted-variable bias. We keep the other control variables we introduced in [example 3](#). For this analysis, we use the estimator `areg` with the `absorb(occupation)` option. We use the `test()` option to test linear combinations of regression estimates.

```
. wildbootstrap areg wage c.tenure##c.ttl_exp ib0.collgrad ib0.union,
> absorb(occupation) cluster(industry) rseed(12345)
> test((tenure=ttl_exp) (1.collgrad-1.union=1)) reps(1250)
note: for equal-tailed 95% CI, better performance is obtained when
 .025*reps() is an integer.
note: setting repetitions to 1,280.
Performing 1,280 replications for p-value for constraint
 tenure - ttl_exp = 0 ...
Computing confidence interval for tenure - ttl_exp
 Lower bound:10.....20... done (23)
 Upper bound:10.....20.... done (25)
note: upper-bound CI achieved 1-F(0.15) = 0.0242, but target is 1-F(x) =
 .025.
note: the sorted bootstrap t statistics have at least two tied values
 adjacent to the t statistic under the null; this prevents the CI bound
 from converging to the target.
Performing 1,280 replications for p-value for constraint
 1.collgrad - 1.union = 1 ...
Computing confidence interval for 1.collgrad - 1.union
 Lower bound:10.....20..... done (26)
 Upper bound:10.....20..... done (27)
note: upper-bound CI achieved 1-F(3.91) = 0.0242, but target is 1-F(x) =
 .025.
note: the sorted bootstrap t statistics have at least two tied values
 adjacent to the t statistic under the null; this prevents the CI bound
 from converging to the target.

Wild cluster bootstrap Number of obs = 1,851
Linear regression, absorbing indicators Number of clusters = 12
 Cluster size:
Cluster variable: industry min = 2
Error weight: Rademacher avg = 154.2
 max = 717
```

|                          | wage | Estimate   | t     | p-value | [95% conf. interval] |
|--------------------------|------|------------|-------|---------|----------------------|
| constraints              |      |            |       |         |                      |
| tenure - ttl_exp = 0     |      | -0.0391243 | -0.71 | 0.517   | -.1915527 .1495055   |
| 1.collgrad - 1.union = 1 |      | 1.356332   | 0.77  | 0.395   | -.1882941 3.913359   |

The `test()` option allows us to specify a linear combination of the regression coefficients that we would like to test. The syntax is the same as specifying linear constraints, `constraint`, or linear hypothesis tests, `test`. In this example, we are inquiring how probable it would be for `tenure = ttl_exp` and `1.collgrad - 1.union = 1`.

The `reps()` option allows us to set the number of bootstrap repetitions. The default is 1,000. Because the Rademacher and Mammen distributions have two possible realizations, the maximum number of possible bootstrap samples is  $2^G$ , where  $G$  is the number of clusters. The Webb distribution, on the other hand, has six outcomes and therefore  $6^G$  possible combinations.

In this example, we intentionally specify a number of bootstrap repetitions that results in a non-integer product, `reps() × α/2`: `reps() × (100 - level())/200 = 1250 × 0.025 = 31.25`. In this case, we lose efficiency in searching for the CI bounds, so `wildbootstrap` adjusts the number of repetitions to 1,280; when we specify `reps(1250)` with `level(95)`, `wildbootstrap` chooses `reps() = ceil(1250 × α/2)/(α/2) = 32/0.025 = 1280`. If an integer alternative cannot be found, the original `reps()` specification will be used. For details, see *Methods and formulas* below.

Because the WCB distribution is a step function, there is a range of values for each CI bound. For example, the lower-bound interval of values for the linear combination `tenure - ttl_exp` is  $-0.191586 < a_{lb} \leq -0.191553$ . The reported bounds are the largest value of each interval. We obtain  $-0.191586$  by running `wildbootstrap` specifying `level(#)` with  $\# = (0.95 + 2/1280) \times 100$ . We would likely report the CIs using three digits of precision, for instance,  $[-0.192, 0.150]$ , so this interval is negligible but significant in a numerical root search where a convergence tolerance for  $r_l$  might be  $10^{-8}$ .

The estimate of `tenure - ttl_exp` is reported to be  $-0.0391$  with a 95% CI of  $[-0.192, 0.150]$ . We therefore fail to reject the hypothesis that `tenure = ttl_exp`. Similarly, the estimate of `1.collgrad - 1.union` is 1.36 with a CI of  $[-0.188, 3.91]$ , and we conclude the difference of 1 is feasible.

◀

### ▷ Example 5: Fixed-effects linear regression with panels

Our final example demonstrates the use of `wildbootstrap` with estimator `xtreg`. Continuing with the data in the [previous example](#), we use `industry` as the variable defining the panels.

We specify normal error weights, `errorweight(normal)`, thereby reducing the chance of identical draws for the error weights. Draws from the Rademacher distribution for 12 clusters have  $2^{12} = 4096$  combinations.

We compute  $p$ -values and CIs on a subset of the model estimates: work tenure, work experience, and their interaction. If we replay the `xtreg` coefficient table, we will see that the fitted model includes `tenure`, `ttl_exp`, `c.tenure#c.ttl_exp`, `1.collgrad`, and `1.union`.

Finally, we use the symmetric  $p$ -value, option `pctype(symmetr ic)`, instead of the default equal-tailed, `pctype(equal)`. The table identifies the symmetric  $p$ -value with the header `P>|t|`.

The command and the results are as follows:

```
. xtset industry
Panel variable: industry (unbalanced)
. wildbootstrap xtreg wage c.tenure##c.ttl_exp i.collgrad i.union,
> rseed(12345) coef(ten ttl ten#ttl) errorweight(normal)
> ptype(symmetric)
Panel variable: industry (unbalanced)
Performing 1,000 replications for p-value for constraint
tenure = 0 ...
Computing confidence interval for tenure
Lower bound:10.....20..... done (26)
Upper bound:10.....20. done (21)
Performing 1,000 replications for p-value for constraint
ttl_exp = 0 ...
Computing confidence interval for ttl_exp
Lower bound:10.....20..... done (26)
Upper bound:10..... done (18)
Performing 1,000 replications for p-value for constraint
c.tenure#c.ttl_exp = 0 ...
Computing confidence interval for c.tenure#c.ttl_exp
Lower bound:10.....20..... done (26)
Upper bound:10.....20... done (23)

Wild cluster bootstrap Number of obs = 1,855
Fixed-effects linear regression Number of clusters = 12
 Cluster size:
Cluster variable: industry min = 2
Error weight: Normal avg = 154.6
 max = 717
```

|             | wage                   | Estimate  | t     | P> t  | [95% conf. interval] |           |
|-------------|------------------------|-----------|-------|-------|----------------------|-----------|
| constraints |                        |           |       |       |                      |           |
|             | tenure = 0             | .2026682  | 2.95  | 0.024 | .0555676             | .3753468  |
|             | ttl_exp = 0            | .2716375  | 11.59 | 0.000 | .2227054             | .3372929  |
|             | c.tenure#c.ttl_exp = 0 | -.0104125 | -2.55 | 0.046 | -.0201336            | -.0003384 |

The fixed-effects model is the only xtreg model allowed with wildbootstrap, so specifying the fe option is not required.

Also note that the cluster() option is not specified. When the estimator xtreg is specified, the default cluster variable is the panel variable that is xtset. If the specified cluster variable is different from the panel variable, then the levels of the panel variable must be nested within the cluster variable levels.

## Stored results

wildbootstrap stores the following in `e()`:

### Scalars

|                          |                                             |

| <code>e(wb_pci)</code> | WCB CI coverage       |
| <code>e(wb_Cns)</code> | WCB constraint matrix |

wildbootstrap will also carry forward most of the results already in `e()` from *command*.

In addition to the above, the following is stored in `r()`:

### Matrices

|                       |                                                                                                                       |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------|
| <code>r(table)</code> | matrix containing the coefficients with their standard errors, test statistics, $p$ -values, and confidence intervals |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------|

Note that results stored in `r()` are updated when the command is replayed and will be replaced when any `r-class` command is run after the estimation command.

## Methods and formulas

Methods and formulas are presented under the following headings:

[Introduction](#)

[CIs for linear combinations of coefficients](#)

[Constructing a CI inverting the hypothesis test](#)

## Introduction

We will focus our discussion of the WCB on linear regression, which easily extends to the other fixed-effects estimators. A linear regression model with clustered errors and  $G$  clusters can be written as

$$\mathbf{y} = \begin{pmatrix} \mathbf{y}_1 \\ \mathbf{y}_2 \\ \vdots \\ \mathbf{y}_G \end{pmatrix} = \mathbf{X}\beta + \epsilon = \begin{pmatrix} \mathbf{X}_1 \\ \mathbf{X}_2 \\ \vdots \\ \mathbf{X}_G \end{pmatrix} \begin{pmatrix} \beta_1 \\ \beta_2 \\ \vdots \\ \beta_k \end{pmatrix} + \begin{pmatrix} \epsilon_1 \\ \epsilon_2 \\ \vdots \\ \epsilon_G \end{pmatrix} \quad (1)$$

where for each cluster  $g$ ,  $N_g$  is the number of observations,  $y_g$  is an  $N_g \times 1$  vector of outcomes,  $X_g$  is an  $N_g \times k$  matrix of covariates, and  $\epsilon_g$  is an  $N_g \times 1$  vector of errors. The parameter of interest is the  $k \times 1$  vector of coefficients  $\beta$ . Error terms are assumed uncorrelated between observations of different clusters but possibly correlated between observations within the same cluster.

Without loss of generality, we will first focus on testing the null hypothesis  $H_0: \beta_k = 0$  using the WCB algorithm. Let  $\hat{\beta}$  denote the ordinary least-squares estimator for  $\beta$ . We compute the  $t$  statistic for the  $k$ th coefficient as

$$t_k = \frac{\hat{\beta}_k}{\sqrt{\widehat{\mathbf{V}}_{k,k}}}$$

where  $\widehat{\mathbf{V}}_{k,k}$  is the CRVE for  $\hat{\beta}_k$ . This is the  $k$ th diagonal element of the matrix

$$\widehat{\mathbf{V}} = \frac{G(N-1)}{(G-1)(N-k)} (\mathbf{X}\mathbf{X}')^{-1} \left( \sum_{g=1}^G \mathbf{X}'_g \hat{\epsilon}_g \hat{\epsilon}'_g \mathbf{X}_g \right) (\mathbf{X}\mathbf{X}')^{-1} \quad (2)$$

where  $\hat{\epsilon}_g$  is the  $N_g \times 1$  vector of ordinary least-squares residuals for cluster  $g$  and  $N = \sum_{g=1}^G N_g$  is the total number of observations.

The WCB algorithm proceeds as follows:

1. Refit model (1) subject to the restriction  $\beta_k = 0$ . Let  $\tilde{\beta}$  denote the restricted estimates and  $\tilde{\epsilon}$  denote the restricted residuals.
2. For each individual bootstrap replication  $b$  (out of a total of  $B$  replications):
  - (a) Generate random variable  $\nu_g^b$  for each cluster  $g$  according to the distribution specified in the `errorweight()` option.
  - (b) For each cluster  $g$  and each observation in the cluster  $i = 1, 2, \dots, N_g$ , generate a new bootstrap-dependent variable  $y_{ig}^b$  using the data-generating process:

$$y_{ig}^b = X_{ig} \tilde{\beta} + \tilde{\epsilon}_{ig} \nu_g^b$$

- (c) Fit model (1) using the bootstrap variable  $y_{ig}^b$  as regressand. Calculate the  $t$  statistic for  $\beta_k = 0$ ,

$$t_k^b = \frac{\hat{\beta}_k^b}{\sqrt{\widehat{\mathbf{V}}_{k,k}^b}}$$

where  $\hat{\beta}_k^b$  and  $\widehat{\mathbf{V}}_{k,k}^b$  are the ordinary least-squares coefficient and the CRVE for that coefficient in the bootstrap replication, respectively. In this case, the CRVE is the  $k$ th diagonal element of matrix (2) obtained when using the residuals from bootstrap replication  $b$ .

3. The  $p$ -values for the one-sided alternative hypotheses  $H_1: \beta_k > 0$  and  $H_2: \beta_k < 0$  are given by

$$p_1 = \frac{1}{B} \sum_{b=1}^B I(t_k^b > t_k)$$

$$p_2 = \frac{1}{B} \sum_{b=1}^B I(t_k^b < t_k)$$

For the alternative hypothesis  $H_3: \beta_k \neq 0$ , the  $p$ -value assuming that the distribution of the  $t$  statistic is symmetric around 0 is given by

$$p_S = \frac{1}{B} \sum_{b=1}^B I(|t_k^b| > |t_k|)$$

If the assumption of symmetry is not appropriate, then the  $p$ -value is given by the equal-tailed  $p$ -value  $p_e = 2 \min(p_1, p_2)$ . See [Djogbenou, MacKinnon, and Nielsen \(2019\)](#).

To increase computational speed, at the expense of computer memory usage, the `wildbootstrap` command uses the matrix algebra of [Roodman et al. \(2019\)](#). By doing this, the computational complexity (run time) of the WCB algorithm is reduced from the order  $O(NB)$  to the order  $O(GB)$ . The WCB uses a  $G \times B$  matrix of random variables. By organizing these variables in column-major order, `wildbootstrap` reduces overall memory usage with minimal extra computation by breaking up the number of bootstrap replicates into blocks (the `blocksize(#)` option).

## CIs for linear combinations of coefficients

By inverting hypotheses tests, we can apply the WCB algorithm to find CIs for any linear combination of coefficients. Suppose we wanted to compute a CI for the linear combination of parameters  $\mathbf{R}\beta$ , where  $\mathbf{R}$  is a  $1 \times k$  vector. In this case, the associated null hypothesis is  $H_0: \mathbf{R}\beta = r$ , where  $r$  is an arbitrary scalar. We can test this null hypothesis with the WCB algorithm described in the previous section by using the bootstrap  $t$  statistics

$$t^b(r) = \frac{\mathbf{R}\hat{\beta}^b - r}{\sqrt{\mathbf{R}\hat{\mathbf{V}}^b\mathbf{R}'}}$$

for  $b = 1, \dots, B$ . For more on restricted regression with linear constraints on multiple coefficients, see [\[P\] makecns](#).

The associated one-sided alternative hypotheses are now  $H_1: \mathbf{R}\beta > r$  and  $H_2: \mathbf{R}\beta < r$ . As before, their respective bootstrap  $p$ -values are given by

$$p_1(r) = \frac{1}{B} \sum_{b=1}^B I\{t^b(r) > t(r)\}$$

$$p_2(r) = \frac{1}{B} \sum_{b=1}^B I\{t^b(r) < t(r)\}$$

where  $t(r)$  is the  $t$  statistic from the original sample:

$$t(r) = \frac{\mathbf{R}\hat{\beta} - r}{\sqrt{\mathbf{R}\hat{\mathbf{V}}\mathbf{R}'}}$$

The associated two-sided alternative hypothesis is  $H_3: \mathbf{R}\beta \neq r$ , and its bootstrap  $p$ -value under the assumption of symmetry is given by

$$p_S(r) = \frac{1}{B} \sum_{b=1}^B I\{|t^{(b)}(r)| > |t(r)|\}$$

When using the equal-tailed criterion (the `ptype(equal)` option), the  $100(1-\alpha)\%$  CI for  $\mathbf{R}\beta$  is given by  $[r_l, r_u]$ , where  $r_l$  and  $r_u$  satisfy  $p_1(r_l) = p_2(r_u) = \alpha/2$ . On the other hand, when using the symmetric criterion (the `ptype(symmetric)` option),  $r_l$  and  $r_u$  satisfy  $p_S(r_l) = p_S(r_u) = \alpha$ . The parameter  $\alpha$  can be specified with the `level()` option, that is,  $\alpha = (100 - \text{level}()) / 100$ .

The bootstrap  $p$ -values are step functions on  $r$ , and therefore a range of values for  $r_l$  and for  $r_u$  will solve the  $p$ -value conditions above. Because distribution functions are right continuous, `wildbootstrap` chooses the rightmost point in each range of solutions.

For the equal-tailed CIs, the starting values for the search of solutions to the  $p$ -value conditions are chosen as follows. First, the bootstrap  $t$  statistics are sorted  $t^{(1)} \leq t^{(2)} \leq \dots < t^{(B)}$ . Second, we define  $b_l = \text{ceil}\{B(1 - \alpha/2)\}$  so that  $t^{(b_l)}$  is smaller than  $B(\alpha/2)$  of the  $t$  statistics. Similarly, we define  $b_u = \text{floor}\{B(\alpha/2)\}$  so that  $t^{(b_u)}$  is larger than  $B(\alpha/2)$  of the  $t$  statistics. Third and finally, the initial lower and upper bounds of the CI are given by

$$\begin{aligned} r_l &= \mathbf{R}\hat{\beta} - t^{(b_l)} \sqrt{\widehat{\mathbf{R}\mathbf{V}\mathbf{R}'}} \\ r_u &= \mathbf{R}\hat{\beta} - t^{(b_u)} \sqrt{\widehat{\mathbf{R}\mathbf{V}\mathbf{R}'}} \end{aligned}$$

where  $\hat{\beta}$  and  $\widehat{\mathbf{V}}$  are the unrestricted estimator for  $\beta$  and the unrestricted CRVE in the original sample.

## Constructing a CI inverting the hypothesis test

For a linear combination of coefficients  $\sum R_j \beta_j$ , we can construct a CI by inverting the hypothesis test  $H_0: \mathbf{R}\beta = r$ , where  $\mathbf{R}$  is a row vector that includes the coefficients  $R_j$  and  $r$  is an arbitrary scalar. To do this, `wildbootstrap` searches for the CI lower bound  $r_l$  such that  $\Pr(\mathbf{R}\beta \leq r_l) = \alpha/2$  (equal-tailed criterion, the `ptype(equal)` option). The WCB distribution of  $\mathbf{R}\beta$  is a step function with a step size of  $1/\text{reps}(\#)$ . When  $\text{reps}(\#) \times \alpha/2$  is an integer, call it  $S$ , then we search for the  $r_l$  that produces the ordered bootstrapped  $t$  statistics

$$t^{(b)} = \frac{\mathbf{R}\hat{\beta}^{(b)} - r_l}{\sqrt{\mathbf{R}'\mathbf{V}^{(b)}\mathbf{R}}}$$

with the property  $\sum_{b=1}^{\text{reps}(\#)} I(t^{(b)} > t) = S$  and therefore  $\Pr(\mathbf{R}\beta \leq r_l) = S/\text{reps}(\#) = \alpha/2$ .

## Acknowledgments

We thank David Roodman of Open Philanthropy for his insights on the wild bootstrap computation.

We also acknowledge previous and ongoing contributions to this area from the Stata community. In particular, we acknowledge David Roodman, James G. MacKinnon, Morten Ørregaard Nielsen, and Matthew D. Webb for their command `boottest` and Mitchell Petersen, Douglas Miller, and Judson Caskey for their command `cgmwildboot`.

## Menu

Data > Create or change data > Other variable-creation commands > Interaction expansion

Most commands in Stata now allow factor variables; see [U] [11.4.3 Factor variables](#). To determine if a command allows factor variables, see the information printed below the options table for the command. If the command allows factor variables, it will say something like “*indepvars* may contain factor variables”.

We recommend that you use factor variables instead of `xi` if a command allows factor variables.

We include [R] [xi](#) in our documentation so that readers can consult it when using a Stata command that does not allow factor variables.

## Syntax

```
xi [, prefix(string) noomit] term(s)
```

```
xi [, prefix(string) noomit] : any_stata_command varlist_with_terms ...
```

where a *term* has the form

|                                                          |    |                                                          |
|----------------------------------------------------------|----|----------------------------------------------------------|
| <code>i.varname</code>                                   | or | <code>I.varname</code>                                   |
| <code>i.varname<sub>1</sub>*i.varname<sub>2</sub></code> |    | <code>I.varname<sub>1</sub>*I.varname<sub>2</sub></code> |
| <code>i.varname<sub>1</sub>*varname<sub>3</sub></code>   |    | <code>I.varname<sub>1</sub>*varname<sub>3</sub></code>   |
| <code>i.varname<sub>1</sub> varname<sub>3</sub></code>   |    | <code>I.varname<sub>1</sub> varname<sub>3</sub></code>   |

*varname*, *varname<sub>1</sub>*, and *varname<sub>2</sub>* denote numeric or string categorical variables. *varname<sub>3</sub>* denotes a continuous, numeric variable.

## Options

`prefix(string)` allows you to choose a prefix other than `_I` for the newly created interaction variables.

The prefix cannot be longer than four characters. By default, `xi` will create interaction variables starting with `_I`. When you use `xi`, it drops all previously created interaction variables starting with the prefix specified in the `prefix(string)` option or with `_I` by default. Therefore, if you want to keep the variables with a certain prefix, specify a different prefix in the `prefix(string)` option.

`noomit` prevents `xi` from omitting groups. This option provides a way to generate an indicator variable for every category having one or more variables, which is useful when combined with the `noconstant` option of an estimation command.

## Remarks and examples

Remarks are presented under the following headings:

- [Background](#)
- [Indicator variables for simple effects](#)
- [Controlling the omitted dummy](#)
- [Categorical variable interactions](#)
- [Interactions with continuous variables](#)
- [Using xi: Interpreting output](#)
- [How xi names variables](#)
- [xi as a command rather than a command prefix](#)
- [Warnings](#)

`xi` provides a convenient way to include dummy or indicator variables when fitting a model (say, with `regress` or `logistic`). For instance, assume that the categorical variable `agegrp` contains 1 for ages 20–24, 2 for ages 25–39, 3 for ages 40–44, etc. Typing

```
. xi: logistic outcome weight i.agegrp bp
```

estimates a logistic regression of `outcome` on `weight`, dummies for each `agegrp` category, and `bp`. That is, `xi` searches out and expands terms starting with “i.” or “I.” but ignores the other variables. `xi` will expand both numeric and string categorical variables, so if you had a string variable `race` containing “white”, “black”, and “other”, typing

```
. xi: logistic outcome weight bp i.agegrp i.race
```

would include indicator variables for the race group as well.

The `i.` indicator variables `xi` expands may appear anywhere in the *varlist*, so

```
. xi: logistic outcome i.agegrp weight i.race bp
```

would fit the same model.

You can also create interactions of categorical variables; typing

```
xi: logistic outcome weight bp i.agegrp*i.race
```

fits a model with indicator variables for all `agegrp` and `race` combinations, including the `agegrp` and `race` main-effect terms (that is, the terms that are created when you just type `i. agegrp i. race`).

You can interact dummy variables with continuous variables; typing

```
xi: logistic outcome bp i.agegrp*weight i.race
```

fits a model with indicator variables for all `agegrp` categories interacted with `weight`, plus the main-effect terms `weight` and `i. agegrp`.

You can get the interaction terms without the `agegrp` main effect (but with the `weight` main effect) by typing

```
xi: logistic outcome bp i.agegrp|weight i.race
```

You can also include multiple interactions:

```
xi: logistic outcome bp i.agegrp*weight i.agegrp*i.race
```

We will now back up and describe the construction of dummy variables in more detail.

## Background

The terms *continuous*, *categorical*, and *indicator* or *dummy* variables are used below. Continuous variables measure something—such as height or weight—and at least conceptually can take on any real number over some range. Categorical variables, on the other hand, take on a finite number of values, each denoting membership in a subclass—for example, excellent, good, and poor, which might be coded 0, 1, 2, or 1, 2, 3, or even “Excellent”, “Good”, and “Poor”. An indicator or dummy variable—the terms are used interchangeably—is a special type of two-valued categorical variable that contains values 0, denoting false, and 1, denoting true. The information contained in any  $k$ -valued categorical variable can be equally well represented by  $k$  indicator variables. Instead of one variable recording values representing excellent, good, and poor, you can have three indicator variables, indicating the truth or falseness of “result is excellent”, “result is good”, and “result is poor”.

`xi` provides a convenient way to convert categorical variables to dummy or indicator variables when you fit a model (say, with `regress` or `logistic`).

### ► Example 1

For instance, assume that the categorical variable `agegrp` contains 1 for ages 20–24, 2 for ages 25–39, and 3 for ages 40–44. (There is no one over 44 in our data.) As it stands, `agegrp` would be a poor candidate for inclusion in a model even if we thought age affected the outcome. The reason is that the coding would restrict the effect of being in the second age group to be twice the effect of being in the first, and, similarly, the effect of being in the third to be three times the first. That is, if we fit the model,

$$y = \beta_0 + \beta_1 \text{agegrp} + X\beta_2$$

the effect of being in the first age group is  $\beta_1$ , the second  $2\beta_1$ , and the third  $3\beta_1$ . If the coding 1, 2, and 3 is arbitrary, we could just as well have coded the age groups 1, 4, and 9, making the effects  $\beta_1$ ,  $4\beta_1$ , and  $9\beta_1$ .

The solution is to convert the categorical variable `agegrp` to a set of indicator variables,  $a_1$ ,  $a_2$ , and  $a_3$ , where  $a_i$  is 1 if the individual is a member of the  $i$ th age group and 0 otherwise. We can then fit the model

$$y = \beta_0 + \beta_{11}a_1 + \beta_{12}a_2 + \beta_{13}a_3 + X\beta_2$$

The effect of being in age group 1 is now  $\beta_{11}$ ; 2,  $\beta_{12}$ ; and 3,  $\beta_{13}$ ; and these results are independent of our (arbitrary) coding. The only difficulty at this point is that the model is unidentified in the sense that there are an infinite number of  $(\beta_0, \beta_{11}, \beta_{12}, \beta_{13})$  that fit the data equally well.

To see this, pretend that  $(\beta_0, \beta_{11}, \beta_{12}, \beta_{13}) = (1, 1, 3, 4)$ . The predicted values of  $y$  for the various age groups are

$$y = \begin{cases} 1 + 1 + X\beta_2 = 2 + X\beta_2 & \text{(age group 1)} \\ 1 + 3 + X\beta_2 = 4 + X\beta_2 & \text{(age group 2)} \\ 1 + 4 + X\beta_2 = 5 + X\beta_2 & \text{(age group 3)} \end{cases}$$

Now, pretend that  $(\beta_0, \beta_{11}, \beta_{12}, \beta_{13}) = (2, 0, 2, 3)$ . The predicted values of  $y$  are

$$y = \begin{cases} 2 + 0 + X\beta_2 = 2 + X\beta_2 & \text{(age group 1)} \\ 2 + 2 + X\beta_2 = 4 + X\beta_2 & \text{(age group 2)} \\ 2 + 3 + X\beta_2 = 5 + X\beta_2 & \text{(age group 3)} \end{cases}$$

These two sets of predictions are indistinguishable: for age group 1,  $y = 2 + X\beta_2$  regardless of the coefficient vector used, and similarly for age groups 2 and 3. This arises because we have three equations and four unknowns. Any solution is as good as any other, and, for our purposes, we merely need to choose one of them. The popular selection method is to set the coefficient on the first indicator variable to 0 (as we have done in our second coefficient vector). This is equivalent to fitting the model

$$y = \beta_0 + \beta_{12}a_2 + \beta_{13}a_3 + X\beta_2$$

How we select a particular coefficient vector (identifies the model) does not matter. It does, however, affect the *interpretation* of the coefficients.

For instance, we could just as well choose to omit the second group. In our artificial example, this would yield  $(\beta_0, \beta_{11}, \beta_{12}, \beta_{13}) = (4, -2, 0, 1)$  instead of  $(2, 0, 2, 3)$ . These coefficient vectors are the same in the sense that

$$y = \begin{cases} 2 + 0 + X\beta_2 = 2 + X\beta_2 = 4 - 2 + X\beta_2 & \text{(age group 1)} \\ 2 + 2 + X\beta_2 = 4 + X\beta_2 = 4 + 0 + X\beta_2 & \text{(age group 2)} \\ 2 + 3 + X\beta_2 = 5 + X\beta_2 = 4 + 1 + X\beta_2 & \text{(age group 3)} \end{cases}$$

But what does it mean that  $\beta_{13}$  can just as well be 3 or 1? We obtain  $\beta_{13} = 3$  when we set  $\beta_{11} = 0$ , so  $\beta_{13} = \beta_{13} - \beta_{11}$  and  $\beta_{13}$  measures the difference between age groups 3 and 1.

In the second case, we obtain  $\beta_{13} = 1$  when we set  $\beta_{12} = 0$ , so  $\beta_{13} - \beta_{12} = 1$  and  $\beta_{13}$  measures the difference between age groups 3 and 2. There is no inconsistency. According to our  $\beta_{12} = 0$  model, the difference between age groups 3 and 1 is  $\beta_{13} - \beta_{11} = 1 - (-2) = 3$ , the same result we got in the  $\beta_{11} = 0$  model.

◀

## ▷ Example 2

The issue of interpretation is important because it can affect the way we discuss results. Imagine that we are studying recovery after a coronary bypass operation. Assume that the age groups are children under 13 (we have two of them), young adults under 25 (we have a handful of them), adults under 46 (of which we have even more), mature adults under 56, older adults under 65, and elderly adults. We follow the prescription of omitting the first group, so all our results are reported relative to children under 13. While there is nothing statistically wrong with this, readers will be suspicious when we make statements like “compared with young children, older and elder adults ...”. Moreover, we will probably have to end each statement with “although results are not statistically significant” because we have only two children in our comparison group. Of course, even with results reported in this way, we can do reasonable comparisons (say, with mature adults), but we will have to do extra work to perform the appropriate linear hypothesis test using Stata’s `test` command.

Here it would be better to force the omitted group to be more reasonable, such as mature adults. There is, however, a generic rule for automatic comparison group selection that, although less popular, tends to work better than the omit-the-first-group rule. That rule is to omit the most prevalent group. The most prevalent is usually a reasonable baseline.

◀

In any case, the prescription for categorical variables is

1. Convert each  $k$ -valued categorical variable to  $k$  indicator variables.
2. Drop one of the  $k$  indicator variables; any one will do, but dropping the first is popular, dropping the most prevalent is probably better in terms of having the computer guess at a reasonable interpretation, and dropping a specified one often eases interpretation the most.
3. Fit the model on the remaining  $k - 1$  indicator variables.

xi automates this procedure.

We will now consider each of xi’s features in detail.

## Indicator variables for simple effects

When you type `i.varname`, `xi` internally tabulates *varname* (which may be a string or a numeric variable) and creates indicator (dummy) variables for each observed value, omitting the indicator for the smallest value. For instance, say that `agegrp` takes on the values 1, 2, 3, and 4. Typing

```
xi: logistic outcome i.agegrp
```

creates indicator variables named `_Iagegrp_2`, `_Iagegrp_3`, and `_Iagegrp_4`. (`xi` chooses the names and tries to make them readable; `xi` guarantees that the names are unique.) The expanded logistic model is

```
. logistic outcome _Iagegrp_2 _Iagegrp_3 _Iagegrp_4
```

Afterward, you can drop the new variables `xi` leaves behind by typing `'drop _I*'` (note the capitalization).

`xi` provides the following features when you type `i.varname`:

- *varname* may be string or numeric.
- Dummy variables are created automatically.
- By default, the dummy-variable set is identified by dropping the dummy corresponding to the smallest value of the variable (how to specify otherwise is discussed below).
- The new dummy variables are left in your dataset. By default, the names of the new dummy variables start with `_I`; therefore, you can drop them by typing `'drop _I*'`. You do not have to do this; each time you use `xi`, any automatically generated dummies with the same prefix as the one specified in the `prefix(string)` option, or `_I` by default, are dropped and new ones are created.
- The new dummy variables have variable labels so that you can determine what they correspond to by typing `'describe'`.
- `xi` may be used with any Stata command (not just `logistic`).

## Controlling the omitted dummy

By default, `i.varname` omits the dummy corresponding to the smallest value of *varname*; for a string variable, this is interpreted as dropping the first in an alphabetical, case-sensitive sort. `xi` provides two alternatives to dropping the first: `xi` will drop the dummy corresponding to the most prevalent value of *varname*, or `xi` will let you choose the particular dummy to be dropped.

To change `xi`'s behavior to dropping the most prevalent dummy, type

```
. char _dta[omit] prevalent
```

although whether you type “prevalent” or “yes” or anything else does not matter. Setting this characteristic affects the expansion of all categorical variables in the dataset. If you resave your dataset, the prevalent preference will be remembered. If you want to change the behavior back to the default drop-the-first rule, type

```
. char _dta[omit]
```

to clear the characteristic.

Once you set `_dta[omit]`, `i.varname` omits the dummy corresponding to the most prevalent value of `varname`. Thus, the coefficients on the dummies have the interpretation of change from the most prevalent group. For example,

```
. char _dta[omit] prevalent
. xi: regress y i.agegrp
```

might create `_Iagegrp_1` through `_Iagegrp_4`, resulting in `_Iagegrp_2` being omitted if `agegrp = 2` is most common (as opposed to the default dropping of `_Iagegrp_1`). The model is then

$$y = b_0 + b_1 \_Iagegrp\_1 + b_3 \_Iagegrp\_3 + b_4 \_Iagegrp\_4 + u$$

Then,

|                                        |                                        |
|----------------------------------------|----------------------------------------|
| Predicted y for agegrp 1 = $b_0 + b_1$ | Predicted y for agegrp 3 = $b_0 + b_3$ |
| Predicted y for agegrp 2 = $b_0$       | Predicted y for agegrp 4 = $b_0 + b_4$ |

Thus, the model's reported *t* or *Z* statistics are for a test of whether each group is different from the most prevalent group.

Perhaps you wish to omit the dummy for agegrp 3 instead. You do this by setting the variable's omit characteristic:

```
. char agegrp[omit] 3
```

This overrides `_dta[omit]` if you have set it. Now, when you type

```
. xi: regress y i.agegrp
```

`_Iagegrp_3` will be omitted, and you will fit the model

$$y = b'_0 + b'_1 \_Iagegrp\_1 + b'_2 \_Iagegrp\_2 + b'_4 \_Iagegrp\_4 + u$$

Later, if you want to return to the default omission, type

```
. char agegrp[omit]
```

to clear the characteristic.

In summary, `i.varname` omits the first group by default, but if you define

```
. char _dta[omit] prevalent
```

the default behavior changes to dropping the most prevalent group. Either way, if you define a characteristic of the form

```
. char varname[omit] #
```

or, if `varname` is a string,

```
. char varname[omit] string-literal
```

the specified value will be omitted.

```
Examples: . char agegrp[omit] 1
 . char race[omit] White (for race, a string variable)
 . char agegrp[omit] (to restore default for agegrp)
```

## Categorical variable interactions

`i.varname1*i.varname2` creates the dummy variables associated with the interaction of the categorical variables `varname1` and `varname2`. The identification rules—which categories are omitted—are the same as those for `i.varname`. For instance, assume that `agegrp` takes on four values and `race` takes on three values. Typing

```
. xi: regress y i.agegrp*i.race
```

results in

|                                                                  |               |
|------------------------------------------------------------------|---------------|
| model:                                                           | dummies for:  |
| $y = a + b_2 \_Iagegrp\_2 + b_3 \_Iagegrp\_3 + b_4 \_Iagegrp\_4$ | (agegrp)      |
| $+ c_2 \_Irace\_2 + c_3 \_Irace\_3$                              | (race)        |
| $+ d_{22} \_IageXrac\_2\_2 + d_{23} \_IageXrac\_2\_3$            |               |
| $+ d_{32} \_IageXrac\_3\_2 + d_{33} \_IageXrac\_3\_3$            | (agegrp*race) |
| $+ d_{42} \_IageXrac\_4\_2 + d_{43} \_IageXrac\_4\_3$            |               |
| $+ u$                                                            |               |

That is, typing

```
. xi: regress y i.agegrp*i.race
```

is the same as typing

```
. xi: regress y i.agegrp i.race i.agegrp*i.race
```

Although there are many other ways the interaction could have been parameterized, this method has the advantage that you can test the joint significance of the interactions by typing

```
. testparm _IageXrac*
```

When you perform the estimation step, whether you use `i.agegrp*i.race` or `i.race*i.agegrp` makes no difference (other than in the names given to the interaction terms; in the first case, the names will begin with `_IageXrac`; in the second, `_IracXage`). Thus,

```
. xi: regress y i.race*i.agegrp
```

fits the same model.

You may also include multiple interactions simultaneously:

```
. xi: regress y i.agegrp*i.race i.agegrp*i.sex
```

The model fit is

|                                                                                                                                                                                                                                                                                                                                                                                              |                                                                                                         |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------|
| <p>model:</p> $y = a + b_2 \_Iagegrp\_2 + b_3 \_Iagegrp\_3 + b_4 \_Iagegrp\_4$ $+ c_2 \_Irace\_2 + c_3 \_Irace\_3$ $+ d_{22} \_IageXrac\_2\_2 + d_{23} \_IageXrac\_2\_3$ $+ d_{32} \_IageXrac\_3\_2 + d_{33} \_IageXrac\_3\_3$ $+ d_{42} \_IageXrac\_4\_2 + d_{43} \_IageXrac\_4\_3$ $+ e_2 \_Isex\_2$ $+ f_{22} \_IageXsex\_2\_2 + f_{23} \_IageXsex\_2\_3 + f_{24} \_IageXsex\_2\_4$ $+ u$ | <p>dummies for:</p> <p>(agegrp)</p> <p>(race)</p> <p>(agegrp*race)</p> <p>(sex)</p> <p>(agegrp*sex)</p> |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------|

The agegrp dummies are (correctly) included only once.

## Interactions with continuous variables

`i.varname1*varname2` (as distinguished from `i.varname1*i.varname2`—note the second `i.`) specifies an interaction of a categorical variable with a continuous variable. For instance,

```
. xi: regress y i.agegrp*wgt
```

results in the model

|                                                                                                                                                  |                                                                                         |
|--------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------|
| $y = a + b_2 \_Iagegrp\_2 + b_3 \_Iagegrp\_3 + b_4 \_Iagegrp\_4$ $+ c \_wgt$ $+ d_2 \_IageXwgt\_2 + d_3 \_IageXwgt\_3 + d_4 \_IageXwgt\_4$ $+ u$ | <p>(agegrp dummies)</p> <p>(continuous wgt effect)</p> <p>(agegrp*wgt interactions)</p> |
|--------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------|

A variation on this notation, using `|` rather than `*`, omits the agegrp dummies. Typing

```
. xi: regress y i.agegrp|wgt
```

fits the model

|                                                                                             |                                                                 |
|---------------------------------------------------------------------------------------------|-----------------------------------------------------------------|
| $y = a' + c' \_wgt$ $+ d'_2 \_IageXwgt\_2 + d'_3 \_IageXwgt\_3 + d'_4 \_IageXwgt\_4$ $+ u'$ | <p>(continuous wgt effect)</p> <p>(agegrp*wgt interactions)</p> |
|---------------------------------------------------------------------------------------------|-----------------------------------------------------------------|

The predicted values of  $y$  are

| agegrp*wgt model                          | agegrp wgt model                       |               |
|-------------------------------------------|----------------------------------------|---------------|
| $y = a + c \text{wgt}$                    | $a' + c' \text{wgt}$                   | if agegrp = 1 |
| $a + c \text{wgt} + b_2 + d_2 \text{wgt}$ | $a' + c' \text{wgt} + d'_2 \text{wgt}$ | if agegrp = 2 |
| $a + c \text{wgt} + b_3 + d_3 \text{wgt}$ | $a' + c' \text{wgt} + d'_3 \text{wgt}$ | if agegrp = 3 |
| $a + c \text{wgt} + b_4 + d_4 \text{wgt}$ | $a' + c' \text{wgt} + d'_4 \text{wgt}$ | if agegrp = 4 |

That is, typing

```
. xi: regress y i.agegrp*wgt
```

is equivalent to typing

```
. xi: regress y i.agegrp i.agegrp|wgt
```

In either case, you do not need to specify separately the continuous variable `wgt`; it is included automatically.

## Using xi: Interpreting output

```
. xi: regress mpg i.rep78
i.rep78 _Irep78_1-5 (naturally coded; _Irep78_1 omitted)
(output from regress appears)
```

Interpretation: `i.rep78` expanded to the dummies `_Irep78_1`, `_Irep78_2`, ..., `_Irep78_5`. The numbers on the end are “natural” in the sense that `_Irep78_1` corresponds to `rep78 = 1`, `_Irep78_2` to `rep78 = 2`, and so on. Finally, the dummy for `rep78 = 1` was omitted.

```
. xi: regress mpg i.make
i.make _Imake_1-74 (_Imake_1 for make==AMC Concord omitted)
(output from regress appears)
```

Interpretation: `i.make` expanded to `_Imake_1`, `_Imake_2`, ..., `_Imake_74`. The coding is not natural because `make` is a string variable. `_Imake_1` corresponds to one `make`, `_Imake_2` to another, and so on. You can find out the coding by typing `describe`. `_Imake_1` for the AMC Concord was omitted.

## How xi names variables

By default, xi assigns to the dummy variables it creates names having the form

$$\_Istub\_groupid$$

You may subsequently refer to the entire set of variables by typing ‘*Istub\**’. For example,

| name               | =     | $\_I + stub$ | + $\_ + groupid$ | Entire set    |
|--------------------|-------|--------------|------------------|---------------|
| $\_Iagegrp\_1$     | $\_I$ | agegrp       | – 1              | $\_Iagegrp*$  |
| $\_Iagegrp\_2$     | $\_I$ | agegrp       | – 2              | $\_Iagegrp*$  |
| $\_IageXwgt\_1$    | $\_I$ | ageXwgt      | – 1              | $\_IageXwgt*$ |
| $\_IageXrac\_1\_2$ | $\_I$ | ageXrac      | – 1\_2           | $\_IageXrac*$ |
| $\_IageXrac\_2\_1$ | $\_I$ | ageXrac      | – 2\_1           | $\_IageXrac*$ |

If you specify a prefix in the `prefix(string)` option, say,  $\_S$ , then xi will name the variables starting with the prefix

$$\_Sstub\_groupid$$

## xi as a command rather than a command prefix

xi can be used as a command prefix or as a command by itself. In the latter form, xi merely creates the indicator and interaction variables. Typing

```
. xi: regress y i.agegrp*wgt
i.agegrp _Iagegrp_1-4 (naturally coded; _Iagegrp_1 omitted)
i.agegrp*wgt _IageXwgt_1-4 (coded as above)
(output from regress appears)
```

is equivalent to typing

```
. xi i.agegrp*wgt
i.agegrp _Iagegrp_1-4 (naturally coded; _Iagegrp_1 omitted)
i.agegrp*wgt _IageXwgt_1-4 (coded as above)
. regress y _Iagegrp* _IageXwgt*
(output from regress appears)
```

## Warnings

1. xi creates new variables in your dataset; most are bytes, but interactions with continuous variables will have the storage type of the underlying continuous variable. You may get the error message “no room to add more variables” or “insufficient memory”. You may need to adjust the `maxvar` setting or reset `max_memory` if it has been set too low; see [U] 6 Managing memory.
2. When using xi with an estimation command, you may get the error message “unable to allocate matrix”. This usually occurs because you attempted to create a matrix that is too large; see [R] Limits.

## Stored results

xi stores the following characteristics:

|                                                           |                   |
|-----------------------------------------------------------|-------------------|
| <code>_dta[<a href="#">__xi__Vars__Prefix__</a>]</code>   | prefix names      |
| <code>_dta[<a href="#">__xi__Vars__To__Drop__</a>]</code> | variables created |

### Description

`zinb` fits a zero-inflated negative binomial (ZINB) model to overdispersed count data with excess zero counts. The ZINB model assumes that the excess zero counts come from a logit or probit model and the remaining counts come from a negative binomial model.

### Quick start

Zero-inflated negative binomial model of  $y$  on  $x_1$  and  $x_2$  with inflation modeled using  $x_3$

```
zinb y x1 x2, inflate(x3)
```

And conduct likelihood-ratio test against ZIP model

```
zinb y x1 x2, inflate(x3) zip
```

Use a probit model instead of a logit model to predict excess zeros

```
zinb y x1 x2, inflate(x3) probit
```

### Menu

Statistics > Count outcomes > Zero-inflated negative binomial regression

## Syntax

```
zinb depvar [indepvars] [if] [in] [weight],
 inflate(varlist [, offset(varname)] | _cons) [options]
```

| <u>collinear</u>                                | keep collinear variables                                                                                                                         |
| <u>coeflegend</u>                               | display legend instead of statistics                                                                                                             |

\*inflate(*varlist* [, offset(*varname*)] | \_cons) is required.

*indepvars* and *varlist* may contain factor variables; see [U] 11.4.3 Factor variables.

bayes, bayesboot, bootstrap, by, collect, fp, jackknife, rolling, statsby, and svy are allowed; see [U] 11.1.10 Prefix commands. For more details, see [BAYES] bayes: zinb.

Weights are not allowed with the bootstrap prefix; see [R] bootstrap.

vce( ), zip, and weights are not allowed with the svy prefix; see [SVY] svy.

fweights, iweights, and pweights are allowed; see [U] 11.1.6 weight.

collinear and coeflegend do not appear in the dialog box.

See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

## Options

### Model

`inflate(varlist[, offset(varname)] | _cons)` specifies the equation that determines whether the observed count is zero. Conceptually, omitting `inflate()` would be equivalent to fitting the model with `nbreg`.

`inflate(varlist[, offset(varname)])` specifies the variables in the equation. You may optionally include an offset for this *varlist*.

`inflate(_cons)` specifies that the equation determining whether the count is zero contains only an intercept. To run a zero-inflated model of *devar* with only an intercept in both equations, type `zinb devar, inflate(_cons)`.

`noconstant`, `exposure(varnamee)`, `offset(varnameo)`, `constraints(constraints)`; see [R] **Estimation options**.

`probit` requests that a probit, instead of logit, model be used to characterize the excess zeros in the data.

### SE/Robust

`vce(vcetype)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory (`oim`, `opg`), that are robust to some kinds of misspecification (`robust`), that allow for intragroup correlation (`cluster clustvar`), and that use bootstrap or jackknife methods (`bootstrap`, `jackknife`); see [R] **vce\_option**.

### Reporting

`level(#)`; see [R] **Estimation options**.

`irr` reports estimated coefficients transformed to incidence-rate ratios, that is,  $e^{\beta_i}$  rather than  $\beta_i$ . Standard errors and confidence intervals are similarly transformed. This option affects how results are displayed, not how they are estimated or stored. `irr` may be specified at estimation or when replaying previously estimated results.

`zip` requests that a likelihood-ratio test comparing the ZINB model with the zero-inflated Poisson model be included in the output.

`nocnsreport`; see [R] **Estimation options**.

*display\_options*: `nocl`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `nolstretch`; see [R] **Estimation options**.

### Maximization

*maximize\_options*: `difficult`, `technique(algorithm_spec)`, `iterate(#)`, `[no]log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `ltolerance(#)`, `nrtolerance(#)`, `nonrtolerance`, and `from(init_specs)`; see [R] **Maximize**. These options are seldom used.

Setting the optimization type to `technique(bhhh)` resets the default *vcetype* to `vce(opg)`.

The following options are available with `zinb` but are not shown in the dialog box:

`collinear`, `coeflegend`; see [R] **Estimation options**.

## Remarks and examples

Zero-inflated negative binomial (ZINB) models are used to model count data that have a higher fraction of zeros than is likely to be generated by a standard negative binomial model. To account for excess zeros, ZINB models assume that these excess zeros come from a model other than the negative binomial model. A zero that comes from this other model is known as a “degenerate zero”.

The negative binomial overdispersion parameter,  $\alpha$ , differentiates the ZINB model from the zero-inflated Poisson (ZIP) model (see [R] [zip](#)). Here overdispersion refers to the fact that the negative binomial variance is greater than its mean, whereas the Poisson variance is equal to its mean. Thus, values of  $\alpha > 1$  indicate overdispersion. The larger the  $\alpha$ , the greater the negative binomial variance. See [Methods and formulas](#) in [R] [nbgreg](#) for further discussion of negative binomial overdispersion.

The `zinb` command fits ZINB models and provides two choices for modeling the excess zeros: the default logit function or, when the `probit` option is specified, the probit function. Both functions are symmetric about zero, but the logistic function has more area under the tails.

See [Long \(1997, 242–247\)](#) and [Cameron and Trivedi \(2005, 680–681\)](#) for a discussion of zero-modified count models.

### ▷ Example 1: Fitting a ZINB model

In [example 1](#) of [R] [zip](#), we fit a zero-inflated Poisson model using the `zip` command to the fictional data on the number of fish caught by visitors to a national park. Let’s fit a ZINB model to these data.

Just like with `zip`, we use the required the `inflate()` option to model whether a visitor fishes as a function of the number of accompanying children (`child`) and whether the visitor is camping (`camper`). Next, we assume the response variable, `count`, depends on whether the visitor used a live bait (`livebait`) and the number of persons in the party (`persons`), which includes the visitor plus other adults and children.

```

. use https://www.stata-press.com/data/r19/fish
(Fictional fishing data)
. zinz count persons livebait, inflate(child camper)
Fitting constant-only model:
Iteration 0: Log likelihood = -519.33992

| alpha    | 1.667029    | .3028685  |       |       | 1.167604             | 2.380076  |

The coefficients in the first equation of the coefficient table, labeled count, correspond to the negative binomial model for individuals who fished. For instance, among visitors who fished, using a live bait increases the expected number of caught fish by a factor of  $\exp(1.5575) \approx 4.7$ , holding other covariates constant.

The confidence interval for alpha indicates that the ZINB model is more appropriate than the ZIP model. To confirm this, you can run zinz and specify the zip option to obtain the ZIP likelihood-ratio test.

The `inflate` equation models whether the visitor does not fish. We can use `margins` to obtain a better understanding of how the `inflate` equation affects the occurrence of the excess zero counts. We specify `margins`'s options `dydx(child camper)` and `predict(pr)`. `pr` is `predict`'s option for estimating the probability of a degenerate zero or, in our example, the probability of not fishing; see the `margins` section in [R] [zibn postestimation](#).

```
. margins, dydx(child camper) predict(pr)
Average marginal effects Number of obs = 250
Model VCE: OIM
Expression: Pr(count=0), predict(pr)
dy/dx wrt: child camper
```

|        | Delta-method |           | z     | P> z  | [95% conf. interval] |           |
|--------|--------------|-----------|-------|-------|----------------------|-----------|
|        | dy/dx        | std. err. |       |       |                      |           |
| child  | .257531      | .029941   | 8.60  | 0.000 | .1988477             | .3162144  |
| camper | -.1633578    | .0503938  | -3.24 | 0.001 | -.2621277            | -.0645878 |

The `margins` output tells us that a visitor is less likely to be visiting the park to fish if accompanied by children and more likely to fish if camping.

You also may want to evaluate whether a standard negative binomial model is adequate to fit the data. This can be done using information criteria; see [example 2](#) in [R] [zip](#).

| <code>e(b)</code>            | coefficient vector                                                               |
| <code>e(Cns)</code>          | constraints matrix                                                               |
| <code>e(ilog)</code>         | iteration log (up to 20 iterations)                                              |
| <code>e(gradient)</code>     | gradient vector                                                                  |
| <code>e(V)</code>            | variance–covariance matrix of the estimators                                     |
| <code>e(V_modelbased)</code> | model-based variance                                                             |
| Functions                    |                                                                                  |
| <code>e(sample)</code>       | marks estimation sample                                                          |

In addition to the above, the following is stored in `r()`:

|                       |                                                                                                                            |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------|
| Matrices              |                                                                                                                            |
| <code>r(table)</code> | matrix containing the coefficients with their standard errors, test statistics, <i>p</i> -values, and confidence intervals |

Note that results stored in `r()` are updated when the command is replayed and will be replaced when any *r*-class command is run after the estimation command.

## Methods and formulas

The `zinz` command maximizes a likelihood function that is a mixture of the logistic (or probit) and negative binomial distributions. The logistic distribution models the unobserved process that creates the excess zeros, and the negative binomial distribution models the counts. Define

$$\xi_j^\beta = \mathbf{x}_j \boldsymbol{\beta} + \text{offset}_j^\beta$$

$$\xi_j^\gamma = \mathbf{z}_j \boldsymbol{\gamma} + \text{offset}_j^\gamma$$

$$\mu_j = \exp(\xi_j^\beta)$$

$$p_j = 1/(1 + \alpha \mu_j)$$

$$m = 1/\alpha$$

Here the vector  $\mathbf{x}_j$  contains the covariates specified in *indepvars* for the *j*th observation, and  $\mathbf{z}_j$  contains the covariates specified in the `inflate()` option. Similarly, estimates for  $\boldsymbol{\beta}$  are found in the first equation of the `zinz` coefficient table (labeled after *depvar*), and the estimates for  $\boldsymbol{\gamma}$  are found in the second equation of the coefficient table (labeled `inflate`). The parameter  $\alpha$  is the negative binomial

overdispersion parameter, and its estimate is the ancillary parameter labeled alpha in the coefficient table. Parameters  $p_j$ ,  $m$ , and  $\mu_j$  are parameters of a negative binomial distribution; see *Methods and formulas* in [R] **nbreg** for details.

The log likelihood maximized by **zinz** is

$$\begin{aligned} \ln L = & \sum_{j \in S} w_j \ln \{F_j + (1 - F_j)p_j^m\} + \\ & \sum_{j \notin S} w_j \left\{ \ln(1 - F_j) + \ln \Gamma(m + y_j) - \ln \Gamma(y_j + 1) \right. \\ & \left. - \ln \Gamma(m) + m \ln p_j + y_j \ln(1 - p_j) \right\} \end{aligned}$$

where  $w_j$  are the weights,  $S$  is the set of observations for which the observed outcome  $y_j = 0$ , and  $F_j$  is the logistic distribution function

$$F_j = F(\xi_j^\gamma) = \exp(\xi_j^\gamma) / \{1 + \exp(\xi_j^\gamma)\}$$

or, if the probit option is specified, the standard normal distribution function

$$F_j = F(\xi_j^\gamma) = \Phi(\xi_j^\gamma)$$

From Long (1997), the variance of the mixture distribution is

$$\text{Var}(y_j | \mathbf{x}_i, \mathbf{z}_i) = \mu_j(1 - F_j)\{1 + \mu_j(F_j + \alpha)\}$$

When  $F_j$  is zero, we have the variance of the negative binomial distribution; when  $F_j > 0$ , the variance can exceed that of the negative binomial distribution.

This command supports the Huber/White/sandwich estimator of the variance and its clustered version using `vce(robust)` and `vce(cluster clustvar)`, respectively. See [P] **\_robust**, particularly *Maximum likelihood estimators* and *Methods and formulas*.

**zinz** also supports estimation with survey data. For details on VCEs with survey data, see [SVY] **Variance estimation**.

## Postestimation commands

The following postestimation commands are available after `zinb`:

| Command                      | Description                                                                                                                             |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <code>contrast</code>        | contrasts and ANOVA-style joint tests of parameters                                                                                     |
| <code>estat ic</code>        | Akaike's, consistent Akaike's, corrected Akaike's, and Schwarz's Bayesian information criteria (AIC, CAIC, AICc, and BIC, respectively) |
| <code>estat summarize</code> | summary statistics for the estimation sample                                                                                            |
| <code>estat vce</code>       | variance–covariance matrix of the estimators (VCE)                                                                                      |
| <code>estat (svy)</code>     | postestimation statistics for survey data                                                                                               |
| <code>estimates</code>       | cataloging estimation results                                                                                                           |
| <code>etable</code>          | table of estimation results                                                                                                             |
| * <code>forecast</code>      | dynamic forecasts and simulations                                                                                                       |
| * <code>hausman</code>       | Hausman's specification test                                                                                                            |
| <code>lincom</code>          | point estimates, standard errors, testing, and inference for linear combinations of parameters                                          |
| * <code>lrtest</code>        | likelihood-ratio test                                                                                                                   |
| <code>margins</code>         | marginal means, predictive margins, marginal effects, and average marginal effects                                                      |
| <code>marginsplot</code>     | graph the results from <code>margins</code> (profile plots, interaction plots, etc.)                                                    |
| <code>nlcom</code>           | point estimates, standard errors, testing, and inference for nonlinear combinations of parameters                                       |
| <code>predict</code>         | number of events, incidence rates, probabilities, etc.                                                                                  |
| <code>predictnl</code>       | point estimates, standard errors, testing, and inference for generalized predictions                                                    |
| <code>pwcompare</code>       | pairwise comparisons of parameters                                                                                                      |
| <code>suest</code>           | seemingly unrelated estimation                                                                                                          |
| <code>test</code>            | Wald tests of simple and composite linear hypotheses                                                                                    |
| <code>testnl</code>          | Wald tests of nonlinear hypotheses                                                                                                      |

\*`forecast`, `hausman`, and `lrtest` are not appropriate with `svy` estimation results.

## predict

### Description for predict

`predict` creates a new variable containing predictions such as numbers of events, incidence rates, probabilities, linear predictions, and standard errors.

### Menu for predict

Statistics > Postestimation

### Syntax for predict

```
predict [type] newvar [if] [in] [, statistic nooffset]
```

```
predict [type] stub* [if] [in] , scores
```

| <i>statistic</i> | Description |
|------------------|-------------|
|------------------|-------------|

Main

|                                    |                                         |
|------------------------------------|-----------------------------------------|
| <code>n</code>                     | number of events; the default           |
| <code>ir</code>                    | incidence rate                          |
| <code>pr</code>                    | probability of a degenerate zero        |
| <code>pr(<i>n</i>)</code>          | probability $\Pr(y_j = n)$              |
| <code>pr(<i>a</i>,<i>b</i>)</code> | probability $\Pr(a \leq y_j \leq b)$    |
| <code>xb</code>                    | linear prediction                       |
| <code>stdp</code>                  | standard error of the linear prediction |

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

### Options for predict

Main

`n`, the default, calculates the predicted number of events, which is  $(1 - F_j) \exp(\mathbf{x}_j \boldsymbol{\beta})$  if neither `offset()` nor `exposure()` was specified when the model was fit, where  $F_j$  is the predicted probability of a zero outcome;  $(1 - F_j) \exp(\mathbf{x}_j \boldsymbol{\beta} + \text{offset}_j^\beta)$  if `offset()` was specified; or  $(1 - F_j) \{ \exp(\mathbf{x}_j \boldsymbol{\beta}) \times \text{exposure}_j \}$  if `exposure()` was specified.

`ir` calculates the incidence rate, which is the predicted number of events when exposure is 1. This is equivalent to specifying both the `n` and the `nooffset` options.

`pr` calculates the probability of a degenerate zero, predicted from the fitted degenerate distribution  $F_j = F(\mathbf{z}_j \boldsymbol{\gamma})$ . If `offset()` was specified within the `inflate()` option, then  $F_j = F(\mathbf{z}_j \boldsymbol{\gamma} + \text{offset}_j^\gamma)$  is calculated.

`pr(n)` calculates the probability  $\Pr(y_j = n)$ , where *n* is a nonnegative integer that may be specified as a number or a variable. Note that `pr` is not equivalent to `pr(0)`.

`pr(a, b)` calculates the probability  $\Pr(a \leq y_j \leq b)$ , where  $a$  and  $b$  are nonnegative integers that may be specified as numbers or variables;

$b$  missing ( $b \geq .$ ) means  $+\infty$ ;

`pr(20, .)` calculates  $\Pr(y_j \geq 20)$ ;

`pr(20, b)` calculates  $\Pr(y_j \geq 20)$  in observations for which  $b \geq .$  and calculates

$\Pr(20 \leq y_j \leq b)$  elsewhere.

`pr(., b)` produces a syntax error. A missing value in an observation of the variable  $a$  causes a missing value in that observation for `pr(a, b)`.

`xb` calculates the linear prediction, which is  $\mathbf{x}_j\boldsymbol{\beta}$  if neither `offset()` nor `exposure()` was specified;

$\mathbf{x}_j\boldsymbol{\beta} + \text{offset}_j^\beta$  if `offset()` was specified; or  $\mathbf{x}_j\boldsymbol{\beta} + \ln(\text{exposure}_j)$  if `exposure()` was specified; see `nooffset` below.

`stdp` calculates the standard error of the linear prediction.

`nooffset` is relevant only if you specified `offset()` or `exposure()` when you fit the model. It modifies the calculations made by `predict` so that they ignore the offset or exposure variable; the linear prediction is treated as  $\mathbf{x}_j\boldsymbol{\beta}$  rather than as  $\mathbf{x}_j\boldsymbol{\beta} + \text{offset}_j^\beta$  or  $\mathbf{x}_j\boldsymbol{\beta} + \ln(\text{exposure}_j)$ . Specifying `predict . . . , nooffset` is equivalent to specifying `predict . . . , ir`.

`scores` calculates equation-level score variables.

The first new variable will contain  $\partial \ln L / \partial (\mathbf{x}_j\boldsymbol{\beta})$ .

The second new variable will contain  $\partial \ln L / \partial (\mathbf{z}_j\boldsymbol{\gamma})$ .

The third new variable will contain  $\partial \ln L / \partial \ln \alpha$ .

# margins

## Description for margins

`margins` estimates margins of response for number of events, incidence rates, probabilities, and linear predictions.

## Menu for margins

Statistics > Postestimation

## Syntax for margins

```
margins [marginlist] [, options]
margins [marginlist] , predict(statistic ...) [predict(statistic ...) ...] [options]
```

| <i>statistic</i>             | Description                           |
|------------------------------|---------------------------------------|
| <code>n</code>               | number of events; the default         |
| <code>ir</code>              | incidence rate                        |
| <code>pr</code>              | probability of a degenerate zero      |
| <code>pr(<i>n</i>)</code>    | probability $\Pr(y_j = n)$            |
| <code>pr(<i>a, b</i>)</code> | probability $\Pr(a \leq y_j \leq b)$  |
| <code>xb</code>              | linear prediction                     |
| <code>stdp</code>            | not allowed with <code>margins</code> |

Statistics not allowed with `margins` are functions of stochastic quantities other than  $e(b)$ .

For the full syntax, see [R] [margins](#).

## Methods and formulas

See [Methods and formulas](#) in [R] [zinb](#) for the model definition and notation.

The probabilities calculated using the `pr(n)` option are the probability  $\Pr(y_j = n)$ . These are calculated using

$$\Pr(y_j = 0 | \mathbf{x}_j, \mathbf{z}_j) = F_j + (1 - F_j) p_2(0 | \mathbf{x}_j)$$

$$\Pr(y_j = n | \mathbf{x}_j, \mathbf{z}_j) = (1 - F_j) p_2(n | \mathbf{x}_j) \quad \text{for } n = 1, 2, \dots$$

where  $F_j$  is the probability of obtaining an observation from the degenerate distribution whose mass is concentrated at zero, and  $p_2(n | \mathbf{x}_j)$  is the probability of  $y_j = n$  from the nondegenerate, negative binomial distribution.  $F_j$  can be obtained by using the `pr` option.

See [Cameron and Trivedi \(2013, sec. 4.6\)](#) for further details.

## Description

`ziologit` fits a model for an ordinal outcome with excess zeros, a higher fraction of zeros than would be expected from a standard ordered logit model, also known as zero inflation. This model is known as a zero-inflated ordered logit (ZIOL) model. In the context of ZIOL models, zero is the lowest outcome category. The ZIOL model accounts for the zero inflation by assuming that the zero-valued outcomes come from both a logit model and an ordered logit model, allowing potentially different sets of covariates for each model.

## Quick start

Zero-inflated ordered logit model of `y` on `x1` and categorical variable `a` with excess zeros modeled using `x2`

```
ziologit y x1 i.a, inflate(x2)
```

Add offset `x3` to the ordered logit model

```
ziologit y x1 i.a, inflate(x2) offset(x3)
```

Model excess zeros using only a constant

```
ziologit y x1 i.a, inflate(_cons)
```

Model excess zeros with `x2`, and offset `x5` while suppressing the constant term

```
ziologit y x1 i.a, inflate(x2, offset(x5) noconstant)
```

Account for complex sampling design using `svyset` data

```
svy: ziologit y x1 i.a, inflate(x2)
```

## Menu

Statistics > Ordinal outcomes > Zero-inflated ordered logit regression

## Syntax

```
ziologit devar [indepvars] [if] [in] [weight],
 inflate(varlist [, noconstant offset(varname)] | _cons) [options]
```

| <i>options</i>                            | Description                                                                                                                                      |

| <u>coeflegend</u>                         | display legend instead of statistics                                                                                                             |

\*inflate(*varlist* [, noconstant offset(*varname*)] | \_cons) is required.

*indepvars* and *varlist* may contain factor variables; see [U] 11.4.3 Factor variables.

*bayes*, *bayesboot*, *bootstrap*, *by*, *collect*, *fp*, *jackknife*, *rolling*, *statsby*, and *svy* are allowed; see [U] 11.1.10 Prefix commands. For more details, see [BAYES] bayes: ziologit.

Weights are not allowed with the *bootstrap* prefix; see [R] bootstrap.

*vce*() and weights are not allowed with the *svy* prefix; see [SVY] svy.

*fweights*, *iweights*, and *pweights* are allowed; see [U] 11.1.6 weight.

*collinear* and *coeflegend* do not appear in the dialog box.

See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

## Options

### Model

`inflate(varlist [ , noconstant offset(varname) ] | _cons)` specifies the inflation equation for the logit model that determines the excess zero values; this option is required. Conceptually, omitting `inflate()` would be equivalent to fitting the model with `ologit`; see [R] [ologit](#).

`inflate(varlist [ , noconstant offset(varname) ])` specifies the independent variables in the inflation equation. To suppress the constant in this equation, specify the `noconstant` suboption. You may optionally include an offset for this *varlist*; see `offset(varname)` in [R] [Estimation options](#).

`inflate(_cons)` specifies that the inflation equation contains only an intercept. To run a zero-inflated model of *depvar* with only an intercept in both equations, type `ziologit depvar, inflate(_cons)`.

`offset(varname)`, `constraints(constraints)`; see [R] [Estimation options](#).

### SE/Robust

`vce(vcetype)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory (`oim`, `opg`), that are robust to some kinds of misspecification (`robust`), that allow for intragroup correlation (`cluster clustvar`), and that use bootstrap or jackknife methods (`bootstrap`, `jackknife`); see [R] [vce\\_option](#).

### Reporting

`level(#)`, `nocnsreport`; see [R] [Estimation options](#).

or reports the estimated coefficients transformed to odds ratios, that is,  $e^b$  rather than  $b$ . Standard errors and confidence intervals are similarly transformed. This option affects how results are displayed, not how they are estimated. or may be specified at estimation or when replaying previously estimated results.

*display\_options*: `nocl`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `nolstretch`; see [R] [Estimation options](#).

### Maximization

*maximize\_options*: `difficult`, `technique(algorithm_spec)`, `iterate(#)`, `[no]log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `ltolerance(#)`, `nrtolerance(#)`, `nonrtolerance`, and `from(init_specs)`; see [R] [Maximize](#). These options are seldom used.

Setting the optimization type to `technique(bhhh)` resets the default *vcetype* to `vce(opg)`.

The following options are available with `ziologit` but are not shown in the dialog box:

`collinear`, `coeflegend`; see [R] [Estimation options](#).

## Remarks and examples

ZIOL models (Kelley and Anderson 2008) are used when the outcome of interest is an ordinal response with a higher fraction of observations in the lowest level than would be expected from a standard ordered logit model. The observations in the lowest category are often referred to as zeros because they typically correspond to the absence of a behavior or trait. Examples include measurements of symptoms, diet, exercise, drug use, and other ordinal outcomes where the lowest level is “none” or “never”.

With ordinal outcomes, larger values of the response variable represent higher outcome levels, but the precise numeric value is irrelevant. For consistency, we will refer to the lowest category as zero regardless of whether that outcome takes the number 0 in the dataset.

The presence of a high fraction of zeros, also known as zero inflation, is driven by the fact that the lowest-level observations represent two latent (unobservable) groups: subjects with excess zeros and subjects with conditional zeros. Excess zeros are subjects who are not susceptible to the outcome, whereas conditional zeros are susceptible to higher outcomes even though they currently demonstrate zero response. For example, if the outcome is alcohol consumption, a teetotaler who completely abstains from alcohol would be an excess zero, whereas a drinker who chose not to drink on the day of the survey would be a conditional zero.

To determine susceptibility (that is, to identify excess zeros), ZIOL regression uses a logit model for the inflation equation. For the main regression that determines the ordinal outcome of susceptible subjects, ZIOL uses an ordered logit model. The equation for the main regression is sometimes referred to as the intensity equation. These two equations can have different sets of covariates and different offsets. Parameters can be reported as coefficients or odds ratios with the `or` option. See *Methods and formulas* for more details.

ZIOL models are similar in spirit to zero-inflated ordered probit (ZIOP) models (see [R] [zioprobit](#)), which use a probit model for the inflation equation and an ordered probit model for the intensity equation. Unlike ZIOP models, the results from ZIOL models can be presented as odds ratios. As such, ZIOL models often appeal to epidemiologists and health researchers, whereas ZIOP models are traditionally used by economists and social scientists. In general, the two types of models tend to produce similar predictions and yield similar inference.

In the context of ZIOL models, the excess-zero or “always-zero” group is often called the nonsusceptible group, and, likewise, the other group is called the susceptible group. In the context of ZIOP models, the terms “nonparticipation” and “participation” are used to refer to the groups. We will use both terminologies interchangeably depending on the context.

The ordered logit model is not nested within the ZIOL model, which means that a likelihood-ratio test cannot be used to check whether a standard ordered logit model is adequate. Instead, one can use information criteria; see [example 2](#) in [R] [zip](#).

### ▷ Example 1: Zero-inflated ordered logit model

We use the fictional data on cigarette consumption from [example 1](#) in [R] [zioprobit](#). In that example, we fit a ZIOP model to these data; here we fit a ZIOL model. Both models are appropriate for analyzing this zero-inflated ordinal outcome, but the ZIOP model is more likely to be used by an economist studying consumer purchasing patterns, while the ZIOL model is more likely to be used by an epidemiologist studying smoking behavior.

The outcome of interest, `tobacco`, represents daily cigarette consumption as an ordinal response with four levels: 0 indicates “no cigarettes”, and responses 1 through 3 indicate increasing cigarette consumption. More than half of the respondents reported no cigarette consumption, and we suspect that these respondents belong to one of two latent groups. Individuals in the first group are excess zeros, which is to say that they are genuine nonsmokers and thus are not susceptible to cigarette consumption. Individuals in the second group are would-be smokers with no current smoking activity but who might smoke, say, if the price of cigarettes falls or their income increases. These individuals are called conditional zeros because they demonstrate zero cigarette consumption, conditional on being susceptible to smoking. We suspect that these two types of zeros are driven by different patterns of behavior; hence, we choose the ZIOL model over the traditional ordered logit model.

Here the inflation (logit) equation corresponds to the decision to smoke. The intensity (ordered logit) equation corresponds to the level of cigarette consumption by a smoker or would-be smoker. The intensity equation includes covariates for education in years (`education`), annual income in tens of thousands of dollars (`income`), age in decades (`age`), and gender (`female`). The inflation equation includes all the covariates from the intensity equation, plus indicators for whether either of the respondent’s parents smoked (`parent`) and whether the respondent’s religion discourages smoking (`religion`). Covariates for the intensity equation are specified in the `ziologit` command statement directly after the dependent variable `tobacco`. Covariates for the inflation equation are specified in the required `inflate()` option.

The first section of the coefficient table, labeled `tobacco`, corresponds to the tobacco intensity equation and contains coefficients from the ordered logit model fit to susceptible subjects. The second section, labeled `inflate`, corresponds to the inflation equation and contains coefficients from the logit model for susceptibility. ZIOL models allow different sets of covariates in the inflation and intensity equations, but when a variable is included in both equations, it is possible for the coefficients to have opposite signs. The third section of the coefficient table contains the cutpoints from the ordered logit model. See [Remarks and examples](#) in [R] `ologit` for an explanation of cutpoints.

Compared with the ZIOP model from [example 1](#) in [R] [zioprobit](#), the coefficients here are larger in absolute value, but the  $z$  scores and  $p$ -values are similar. This is consistent with the fact that the logistic distribution used by ZIOL has heavier tails than the normal distribution used by ZIOP. Perhaps the most important difference between these two models is that the estimated coefficients from the ZIOP model are difficult to interpret, but the coefficients from the ZIOL model can be exponentiated and reported as odds ratios with the `or` option.

We replay our results specifying `or`:

```
. ziologit, or
Zero-inflated ordered logit regression Number of obs = 15,000
 Wald chi2(4) = 2143.69
Log likelihood = -7652.4891 Prob > chi2 = 0.0000
```

Note: Estimates are transformed only in the first 2 equations to odds ratios.

Note: `_cons` estimates baseline odds.

Examining the odds ratios from the tobacco intensity equation, we see that a one-unit increase in income, which corresponds to an increase of \$10,000 in annual income, raises a smoker's odds of increased cigarette consumption by a factor of 3.63. Looking at the inflation equation, we see that a one-unit increase in income lowers the odds of being susceptible to smoking by a factor of 0.825. This suggests that wealthier individuals are less likely to smoke (consistent with income acting as a proxy for health consciousness), but if they do decide to smoke, they tend to smoke more cigarettes (perhaps because they can afford them).

## Stored results

In addition to the above, the following is stored in `r()`:

|          |                                                                                                                       |
|----------|-----------------------------------------------------------------------------------------------------------------------|
| Matrices |                                                                                                                       |
| r(table) | matrix containing the coefficients with their standard errors, test statistics, $p$ -values, and confidence intervals |

Note that results stored in `r()` are updated when the command is replayed and will be replaced when any `r-class` command is run after the estimation command.

## Methods and formulas

The modern class of zero-inflated models was originally developed by Lambert (1992) to address the problem of excess zeros in count data (see [R] zip). This model framework has been extended to ordinal outcomes with the ZIOL model by Kelley and Anderson (2008).

The precise numeric value of an ordinal outcome is irrelevant, so without loss of generality we consider an ordinal response variable  $Y$  with levels coded as 0, 1, 2,  $\dots$ ,  $H$ . The first step in the ZIOL model is to determine susceptibility. Let  $s_j = 1$  if the  $j$ th individual is susceptible to exhibiting a nonzero response, and let  $s_j = 0$  if the  $j$ th individual is an excess zero. (Similarly, using alternative terminology, let individuals with  $s_j = 1$  belong to the participation group and those with  $s_j = 0$  belong to the nonparticipation group.) The ZIOL inflation equation uses a logit model to determine the probability of susceptibility (or participation) as

$$\Pr(s_j = 1 | \mathbf{z}_j) = F(\mathbf{z}_j \boldsymbol{\gamma}) \quad (1)$$

$\mathbf{z}_j$  is a vector of covariates that determines susceptibility,  $\boldsymbol{\gamma}$  is a vector of coefficients that have to be estimated, and  $F(\cdot)$  is the logistic distribution function:  $F(x) = e^x / (1 + e^x)$ .

Next, conditioning on  $s_j = 1$ , outcome intensity levels  $\tilde{y}_j$  are modeled using an ordered logit model whose levels may also include 0. The corresponding probabilities are given by

$$\Pr(\tilde{y}_j = h | s_j = 1, \mathbf{x}_j) = F(\kappa_h - \mathbf{x}_j \boldsymbol{\beta}) - F(\kappa_{h-1} - \mathbf{x}_j \boldsymbol{\beta}) \quad h = 0, 1, \dots, H \quad (2)$$

$\mathbf{x}_j$  is a vector of covariates that determine intensity (which can be different from  $\mathbf{z}_j$ ),  $\boldsymbol{\beta}$  is a vector of coefficients to be estimated, and cutpoints  $\kappa_h$  are boundary parameters to be estimated (subject to  $\kappa_{-1} = -\infty$ ,  $\kappa_H = +\infty$ ). These cutpoints take the place of an intercept.

The observed response variable is  $y_j = s_j \tilde{y}_j$ . Thus, a zero outcome occurs when  $s_j = 0$  (the individual is an excess zero) or when  $s_j = 1$  and  $\tilde{y}_j = 0$  (the individual is a conditional zero). To observe a positive  $y_j$ , there is a joint requirement that  $s_j = 1$  and  $\tilde{y}_j > 0$ .

The distribution of  $Y$  is given by

$$\begin{aligned} \Pr(Y) &= \begin{cases} \Pr(y_j = 0 | \mathbf{z}_j, \mathbf{x}_j) \\ \Pr(y_j = h | \mathbf{z}_j, \mathbf{x}_j) \quad h = 1, 2, \dots, H \end{cases} \\ &= \begin{cases} \Pr(s_j = 0 | \mathbf{z}_j) + \Pr(s_j = 1 | \mathbf{z}_j) \Pr(\tilde{y}_j = 0 | s_j = 1, \mathbf{x}_j) \\ \Pr(s_j = 1 | \mathbf{z}_j) \Pr(\tilde{y}_j = h | s_j = 1, \mathbf{x}_j) \quad h = 1, 2, \dots, H \end{cases} \end{aligned} \tag{3}$$

The probability of zero outcome has been inflated because it is the sum of the probability of zero intensity from the ordered logit model and the probability of nonsusceptibility from the logit model.

Substituting (1) and (2) in (3), we get

$$\begin{aligned} \Pr(Y) &= \begin{cases} \Pr(y_j = 0 | \mathbf{z}_j, \mathbf{x}_j) \\ \Pr(y_j = h | \mathbf{z}_j, \mathbf{x}_j) \quad h = 1, 2, \dots, H - 1 \\ \Pr(y_j = H | \mathbf{z}_j, \mathbf{x}_j) \end{cases} \\ &= \begin{cases} \{1 - F(\mathbf{z}_j \boldsymbol{\gamma})\} + F(\mathbf{z}_j \boldsymbol{\gamma}) F(\kappa_0 - \mathbf{x}_j \boldsymbol{\beta}) \\ F(\mathbf{z}_j \boldsymbol{\gamma}) \{F(\kappa_h - \mathbf{x}_j \boldsymbol{\beta}) - F(\kappa_{h-1} - \mathbf{x}_j \boldsymbol{\beta})\} \quad h = 1, 2, \dots, H - 1 \\ F(\mathbf{z}_j \boldsymbol{\gamma}) \{1 - F(\kappa_{H-1} - \mathbf{x}_j \boldsymbol{\beta})\} \end{cases} \end{aligned} \tag{4}$$

If the `offset()` option is specified,  $\mathbf{x}_j \boldsymbol{\beta}$  in the intensity equation is replaced with  $\mathbf{x}_j \boldsymbol{\beta} + \text{offset}_j^\beta$ . If the `offset()` suboption is specified in the `inflate()` option,  $\mathbf{z}_j \boldsymbol{\gamma}$  in the inflation equation is replaced with  $\mathbf{z}_j \boldsymbol{\gamma} + \text{offset}_j^\gamma$ .

The log-likelihood function is

$$\ln L = \sum_{j=1}^N w_j \sum_{h=0}^H I(y_j = h) \ln \{ \Pr(y_j = h | \mathbf{z}_j, \mathbf{x}_j) \}$$

where  $w_j$  is an optional weight for the  $j$ th observation and

$$I(y_j = h) = \begin{cases} 1 & \text{if } y_j = h \\ 0 & \text{otherwise} \end{cases}$$

The choice between the ZIOL model and the ordered logit model cannot be made using a likelihood-ratio test because the two hypotheses are not nested in the usual sense of parameter restrictions. The inflation effect is removed, and all subjects are deemed susceptible when  $\mathbf{z}_j \boldsymbol{\gamma} \rightarrow \infty$ , a condition that cannot be imposed. To compare the fits of nonnested models, you can use `estat ic` to display information criteria (see [R] [estat ic](#)).

This command supports the Huber/White/sandwich estimator of the variance and its clustered version with `vce(robust)` and `vce(cluster clustvar)`, respectively. See [P] [\\_robust](#), particularly *Maximum likelihood estimators* and *Methods and formulas*.

`ziologit` also supports estimation with survey data. For details on VCEs with survey data, see [SVY] [Variance estimation](#).

## Postestimation commands

The following postestimation commands are available after `ziologist`:

| Command                      | Description                                                                                                                             |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <code>contrast</code>        | contrasts and ANOVA-style joint tests of parameters                                                                                     |
| <code>estat ic</code>        | Akaike's, consistent Akaike's, corrected Akaike's, and Schwarz's Bayesian information criteria (AIC, CAIC, AICc, and BIC, respectively) |
| <code>estat summarize</code> | summary statistics for the estimation sample                                                                                            |
| <code>estat vce</code>       | variance–covariance matrix of the estimators (VCE)                                                                                      |
| <code>estat (svy)</code>     | postestimation statistics for survey data                                                                                               |
| <code>estimates</code>       | cataloging estimation results                                                                                                           |
| <code>etable</code>          | table of estimation results                                                                                                             |
| * <code>forecast</code>      | dynamic forecasts and simulations                                                                                                       |
| * <code>hausman</code>       | Hausman's specification test                                                                                                            |
| <code>lincom</code>          | point estimates, standard errors, testing, and inference for linear combinations of parameters                                          |
| * <code>lrtest</code>        | likelihood-ratio test                                                                                                                   |
| <code>margins</code>         | marginal means, predictive margins, marginal effects, and average marginal effects                                                      |
| <code>marginsplot</code>     | graph the results from <code>margins</code> (profile plots, interaction plots, etc.)                                                    |
| <code>nlcom</code>           | point estimates, standard errors, testing, and inference for nonlinear combinations of parameters                                       |
| <code>predict</code>         | probabilities, linear predictions and their SEs, etc.                                                                                   |
| <code>predictnl</code>       | point estimates, standard errors, testing, and inference for generalized predictions                                                    |
| <code>pwcompare</code>       | pairwise comparisons of parameters                                                                                                      |
| <code>suest</code>           | seemingly unrelated estimation                                                                                                          |
| <code>test</code>            | Wald tests of simple and composite linear hypotheses                                                                                    |
| <code>testnl</code>          | Wald tests of nonlinear hypotheses                                                                                                      |

\*`forecast`, `hausman`, and `lrtest` are not appropriate with `svy` estimation results.

# predict

## Description for predict

predict creates a new variable containing predictions such as probabilities, linear predictions, and standard errors.

## Menu for predict

Statistics > Postestimation

## Syntax for predict

```
predict [type] { stub* | newvar | newvarlist } [if] [in] [, statistic
outcome(outcome) nooffset]
```

```
predict [type] stub* [if] [in] , scores
```

| <i>statistic</i>      | Description                                                                     |
|-----------------------|---------------------------------------------------------------------------------|
| Main                  |                                                                                 |
| <code>pmargin</code>  | marginal probabilities of levels, $\Pr(y_j = h)$ ; the default                  |
| <code>pjoint1</code>  | joint probabilities of levels and susceptibility, $\Pr(y_j = h, s_j = 1)$       |
| <code>pcond1</code>   | probabilities of levels conditional on susceptibility, $\Pr(y_j = h   s_j = 1)$ |
| <code>ps</code>       | probability of susceptibility, $\Pr(s_j = 1)$                                   |
| <code>pns</code>      | probability of nonsusceptibility, $\Pr(s_j = 0)$                                |
| <code>xb</code>       | linear prediction                                                               |
| <code>xbinfl</code>   | linear prediction for inflation equation                                        |
| <code>stdp</code>     | standard error of the linear prediction                                         |
| <code>stdpinfl</code> | standard error of the linear prediction for inflation equation                  |

If you do not specify `outcome()`, `pmargin`, `pjoint1`, and `pcond1` (with one new variable specified) assume `outcome(#1)`.

You specify one or  $k$  new variables with `pmargin`, `pjoint1`, and `pcond1`, where  $k$  is the number of outcomes.

You specify one new variable with `ps`, `pns`, `xb`, `xbinfl`, `stdp`, and `stdpinfl`.

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

## Options for predict

Main

`pmargin`, the default, calculates the predicted marginal probabilities of outcome levels,  $\Pr(y_j = h)$ .

`pjoint1` calculates the predicted joint probabilities of outcome levels and susceptibility,  $\Pr(y_j = h, s_j = 1)$ .

`pcond1` calculates the predicted probabilities of outcome levels conditional on susceptibility,  $\Pr(y_j = h | s_j = 1)$ .

With `pmargin`, `pjoint1`, and `pcond1`, you can compute predicted probabilities for one or for all outcome levels. When you specify one new variable, `predict` computes probabilities for the first outcome level. You can specify the `outcome(#i)` option to obtain probabilities for the  $i$ th level. When you specify multiple new variables or a stub, `predict` computes probabilities for all outcome levels. The behavior of `predict` with one new variable is equivalent to specifying `outcome(#1)`.

`ps` and `pns` calculate the predicted marginal probability of susceptibility [ $\Pr(s_j = 1)$ ] and of nonsusceptibility [ $\Pr(s_j = 0)$ ], respectively.

In econometrics literature, probabilities of susceptibility and nonsusceptibility are known as probabilities of participation and nonparticipation. Similarly to `predict` after `zioprobit`, you can use options `ppar` and `pnpair` to compute these probabilities. Options `ppar` and `pnpair` produce identical results to the respective options `ps` and `pns` but label new variables as `Pr(participation)` and `Pr(nonparticipation)` instead of `Pr(susceptible)` and `Pr(nonsusceptible)`.

`xb` calculates the linear prediction for the ordered logit equation, which is  $\mathbf{x}_j\beta$  if `offset()` was not specified with `ziologit` and is  $\mathbf{x}_j\beta + \text{offset}_j^\beta$  if `offset()` was specified.

`xbinfl` calculates the linear prediction for the inflation equation, which is  $\mathbf{z}_j\gamma$  if `offset()` was not specified in `inflate()` and is  $\mathbf{z}_j\gamma + \text{offset}_j^\gamma$  if `offset()` was specified in `inflate()`.

`stdp` calculates the standard error of the linear prediction for the ordered logit equation.

`stdpinfl` calculates the standard error of the linear prediction for the inflation equation.

`outcome(outcome)` specifies the outcome for which predicted probabilities are to be calculated. `outcome()` should contain either one value of the dependent variable or one of #1, #2, ..., with #1 meaning the first category of the dependent variable, #2 meaning the second category, etc. `outcome()` is allowed only with `pmargin`, `pjoint1`, and `pcond1`.

`nooffset` is relevant only if you specified `offset(varname)` with `ziologit` or within the `inflate()` option. It modifies the calculations made by `predict` so that they ignore the offset variable; that is, the linear prediction for the main regression equation is treated as  $\mathbf{x}_j\beta$  rather than as  $\mathbf{x}_j\beta + \text{offset}_j^\beta$  and the linear prediction for the inflation equation is treated as  $\mathbf{z}_j\gamma$  rather than as  $\mathbf{z}_j\gamma + \text{offset}_j^\gamma$ .

`scores` calculates equation-level score variables.

The first new variable will contain  $\partial \ln L / \partial (\mathbf{x}_j\beta)$ . In the absence of independent variables in the main equation, this variable is not stored.

The second new variable will contain  $\partial \ln L / \partial (\mathbf{z}_j\gamma)$ .

When the dependent variable takes  $k$  different values, the third new variable through new variable  $k + 1$  will contain  $\partial \ln L / \partial (\kappa_h)$  for  $h = 0, 1, \dots, k - 2$ .

# margins

## Description for margins

`margins` estimates margins of response for probabilities and linear predictions.

## Menu for margins

Statistics > Postestimation

## Syntax for margins

```
margins [marginlist] [, options]
```

```
margins [marginlist] , predict(statistic ...) [predict(statistic ...) ...] [options]
```

| <i>statistic</i> | Description                                                                     |
|------------------|---------------------------------------------------------------------------------|
| default          | marginal probabilities for each outcome                                         |
| <u>p</u> margin  | marginal probabilities of levels, $\Pr(y_j = h)$ ; the default                  |
| <u>p</u> joint1  | joint probabilities of levels and susceptibility, $\Pr(y_j = h, s_j = 1)$       |
| <u>p</u> cond1   | probabilities of levels conditional on susceptibility, $\Pr(y_j = h   s_j = 1)$ |
| <u>p</u> s       | probability of susceptibility, $\Pr(s_j = 1)$                                   |
| <u>p</u> ns      | probability of nonsusceptibility, $\Pr(s_j = 0)$                                |
| <u>x</u> b       | linear prediction                                                               |
| <u>x</u> binfl   | linear prediction for inflation equation                                        |
| <u>s</u> tdp     | not allowed with margins                                                        |
| <u>s</u> tdpinfl | not allowed with margins                                                        |

`pmargin`, `pjoint1`, and `pcond1` default to the first outcome.

Statistics not allowed with `margins` are functions of stochastic quantities other than  $e(b)$ .

For the full syntax, see [R] [margins](#).

## Remarks and examples

The ZIOL model allows all the predictions and marginal effects available with the standard `ologit` model (see [R] [ologit postestimation](#)), along with additional predictions and marginal effects related to the inflation equation for susceptibility. The probabilities of susceptibility and nonsusceptibility can be calculated using options `ps` and `pns`, respectively. If you prefer an alternative terminology of probabilities of participation and nonparticipation, you can instead use options `ppar` and `pnpair`, which will produce identical numerical results but label variables as `Pr(participation)` and `Pr(nonparticipation)` instead of `Pr(susceptible)` and `Pr(nonsusceptible)`.

### ▷ Example 1: Average marginal effect of gender on probability of nonsusceptibility

In [example 1](#) of [R] [ziologit](#), we fit a model for levels of cigarette consumption.

```
. use https://www.stata-press.com/data/r19/tobacco
(Fictional tobacco consumption data)
. ziologit tobacco education income age i.female,
> inflate(education income age i.female i.parent i.religion)
(output omitted)
```

This model parallels the zero-inflated ordered probit (ZIOP) model that was fit in [example 1](#) of [R] [zioprobit](#).

To continue the comparison between the ZIOL and ZIOP models, we re-create [example 1](#) from [R] [zioprobit postestimation](#) by using `margins` to estimate the average marginal effect of gender on the probability of nonsusceptibility (being an excess zero) for individuals with a college degree (17 years of education) and a smoking parent.

```
. margins, predict(pns) dydx(female) at(education = 17 parent = 1)
Average marginal effects Number of obs = 15,000
Model VCE: OIM
Expression: Pr(nonsusceptible), predict(pns)
dy/dx wrt: 1.female
At: education = 17
 parent = 1
```

|        | Delta-method |           |      |       | [95% conf. interval] |          |
|--------|--------------|-----------|------|-------|----------------------|----------|
|        | dy/dx        | std. err. | z    | P> z  |                      |          |
| female | .085421      | .010096   | 8.46 | 0.000 | .0656333             | .1052087 |
| Female |              |           |      |       |                      |          |

Note: dy/dx for factor levels is the discrete change from the base level.

Despite the differences between the ZIOL and ZIOP models, the conclusion is the same: women with a college degree and a smoking parent are expected to have an approximately 8.5% higher chance of being genuine nonsmokers (excess zeros) than comparable men.

◀

### ▷ Example 2: Predicted probabilities of conditional zeros

Next, we consider the effect of income on the probability of zero tobacco consumption, conditional on susceptibility. These would-be smokers are known as conditional zeros. In [example 1](#) of [R] [ziologit](#), we saw that increasing income raises a smoker's odds of increased tobacco consumption dramatically, so we expect to see a larger fraction of conditional zeros at the lower end of the income scale.

We examine conditional probabilities of zero consumption for incomes ranging from \$10,000 to \$60,000, and we use the `noatlegend` option to suppress the default legend because we know the values 1 to 6 correspond to income in tens of thousands of dollars.

```
. margins, predict(pcond1 outcome(0)) at(income = (1/6)) noatlegend
Predictive margins Number of obs = 15,000
Model VCE: OIM
Expression: Pr(tobacco=0|susceptible=1), predict(pcond1 outcome(0))
```

|     | Delta-method |           | z      | P> z  | [95% conf. interval] |          |
|-----|--------------|-----------|--------|-------|----------------------|----------|
|     | Margin       | std. err. |        |       |                      |          |
| _at |              |           |        |       |                      |          |

| 5   | .3741538     | .0024547  | 152.42 | 0.000 | .3693427             | .3789649 |
| 6   | .3152985     | .0026294  | 119.91 | 0.000 | .3101449             | .320452  |

The influence of income is dramatic: susceptible individuals (potential smokers) who earn \$10,000 a year are almost twice as likely to refrain from smoking as potential smokers who earn \$60,000 per year (59% versus 32%).

## Methods and formulas

See *Methods and formulas* in [R] **ziologit** for the model definition and notation. Specifically, see (1) for the formula for the probability of susceptibility,  $\Pr(s_j = 1|\mathbf{z}_j)$ ; see (2) for the formula for the probabilities of outcome levels conditional on susceptibility,  $\Pr(y_j = h|s_j = 1, \mathbf{x}_j)$ ; and see (4) for the formula for the marginal probabilities of outcome levels,  $\Pr(y_j = h|\mathbf{z}_j, \mathbf{x}_j)$ .

The joint probability of susceptibility and outcome  $y_j = h$  can be expressed as

$$\Pr(y_j = h, s_j = 1|\mathbf{z}_j, \mathbf{x}_j) = \Pr(s_j = 1|\mathbf{z}_j) \Pr(y_j = h|s_j = 1, \mathbf{x}_j)$$

for  $h = 0, 1, \dots, H$ .

## Description

`zioprobit` fits a model for an ordinal outcome with excess zeros, a higher fraction of zeros than would be expected from a standard ordered probit model, also known as zero inflation. This model is known as a zero-inflated ordered probit (ZIOP) model. In the context of ZIOP models, zero is an actual 0 value or the lowest outcome category. The ZIOP model accounts for the zero inflation by assuming that the zero-valued outcomes come from both a probit model and an ordered probit model, allowing potentially different sets of covariates for each model.

## Quick start

Zero-inflated ordered probit model of `y` on `x1` and categorical variable `a` with excess zeros modeled using `x2`

```
zioprobit y x1 i.a, inflate(x2)
```

Add offset `x3` to the ordered probit model

```
zioprobit y x1 i.a, inflate(x2) offset(x3)
```

Model excess zeros using only a constant

```
zioprobit y x1 i.a, inflate(_cons)
```

Model excess zeros with `x2`, and offset `x5` while suppressing the constant term

```
zioprobit y x1 i.a, inflate(x2, offset(x5) noconstant)
```

Account for complex sampling design using `svyset` data

```
svy: zioprobit y x1 i.a, inflate(x2)
```

## Menu

Statistics > Ordinal outcomes > Zero-inflated ordered probit regression

## Syntax

```
zioprobit depvar [indepvars] [if] [in] [weight] ,
 inflate(varlist [, noconstant offset(varname)] | _cons) [options]
```

| <u>coeflegend</u> | display legend instead of statistics |

---

\*inflate(*varlist* [ , noconstant offset(*varname*) ] | \_cons) is required.

*indepvars* and *varlist* may contain factor variables; see [U] 11.4.3 **Factor variables**.

*bayes*, *bayesboot*, *bootstrap*, *by*, *collect*, *fp*, *jackknife*, *rolling*, *statsby*, and *svy* are allowed; see [U] 11.1.10 **Prefix commands**. For more details, see [BAYES] **bayes: zioprobit**.

Weights are not allowed with the *bootstrap* prefix; see [R] **bootstrap**.

*vce*() and weights are not allowed with the *svy* prefix; see [SVY] **svy**.

*fweights*, *iwweights*, and *pweights* are allowed; see [U] 11.1.6 **weight**.

*collinear* and *coeflegend* do not appear in the dialog box.

See [U] 20 **Estimation and postestimation commands** for more capabilities of estimation commands.

## Options

### Model

`inflate(varlist [ , noconstant offset(varname) ] | _cons)` specifies the inflation equation for the probit model that determines the excess zero values; this option is required. Conceptually, omitting `inflate()` would be equivalent to fitting the model with `oprobit`; see [R] [oprobit](#).

`inflate(varlist [ , noconstant offset(varname) ])` specifies the independent variables in the inflation equation. To suppress the constant in this equation, specify the `noconstant` suboption. You may optionally include an offset for this *varlist*; see `offset(varname)` in [R] [Estimation options](#).

`inflate(_cons)` specifies that the inflation equation contains only an intercept. To run a zero-inflated model of *depvar* with only an intercept in both equations, type `zioprobit depvar, inflate(_cons)`.

`offset(varname)`, `constraints(constraints)`; see [R] [Estimation options](#).

### SE/Robust

`vce(vcetype)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory (`oim`, `opg`), that are robust to some kinds of misspecification (`robust`), that allow for intragroup correlation (`cluster clustvar`), and that use bootstrap or jackknife methods (`bootstrap`, `jackknife`); see [R] [vce\\_option](#).

### Reporting

`level(#)`, `nocnsreport`; see [R] [Estimation options](#).

`display_options`: `nocl`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `nolstretch`; see [R] [Estimation options](#).

### Maximization

`maximize_options`: `difficult`, `technique(algorithm_spec)`, `iterate(#)`, `[no]log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `ltolerance(#)`, `nrtolerance(#)`, `nonrtolerance`, and `from(init_specs)`; see [R] [Maximize](#). These options are seldom used.

Setting the optimization type to `technique(bhhh)` resets the default *vcetype* to `vce(opg)`.

The following options are available with `zioprobit` but are not shown in the dialog box:

`collinear`, `coeflegend`; see [R] [Estimation options](#).

## Remarks and examples

ZIOP models are used when the outcome of interest is an ordinal response variable and the data exhibit a high fraction of observations in the lowest category or what we will refer to from now on as “zero” but without quotes. Like the ordered probit model, the actual values taken by the ordinal response variable are irrelevant. While the outcome is typically coded as 0, 1, 2, ..., *H*, `zioprobit` interprets the lowest value present in the dataset as 0 to be consistent with the original derivation of the model and subsequent applications.

Like all zero-inflated models, the ZIOP model is an alternative when the data exhibit a higher fraction of zero-valued outcomes than is likely compatible with an ordered probit model. This concentration of zeros is referred to as zero inflation. Inflation is assumed to occur in the lowest value to ensure that shifting the levels of the ordinal response variable by a constant will not affect the estimated parameters in the model. This is common in ordered probit models; see [R] [oprobit](#).

Without loss of generality, we consider an ordinal response variable with levels 0, 1, 2, ...,  $H$ . Traditional ordered probit models treat all observations with zero-valued outcomes as a homogeneous group. By contrast, ZIOP models assume that zeros could occur in the data as members of two latent (unobservable) groups. Individuals in the “always-zero” group have outcome 0 as the only possible value. This first group is often called the nonparticipation group. The second group, in addition to 0, may also assume any of the other values, 1, 2, ...,  $H$ . This group is often called the participation group. Some disciplines, such as public health and medicine, refer to the process that determines the zeros rather than the groups. In this case, there is an incidence or occurrence process that determines whether an observation belongs to the always-zero group and a severity or intensity process that determines the level in the second group. The result of having two groups or processes is an inflation in the proportion of zero-valued observations in the data.

The ZIOP model has been used in studies of international and domestic conflicts ([Bagozzi et al. 2015](#)), sports participation ([Downward, Lera-Lopez, and Rasciute 2011](#)), and the adoption of new building technologies ([Ganguly, Koebel, and Cantrell 2010](#)), to name a few. See [Kelley and Anderson \(2008\)](#) for a discussion of zero-inflated ordinal models in the context of health.

The classic application of the ZIOP model is the study of tobacco use by [Harris and Zhao \(2007\)](#). Like the zero-inflated Poisson models in the count-data literature ([Lambert 1992](#)), [Harris and Zhao](#) derived the ZIOP model using a two-stage decision process. An individual must decide whether to participate in an activity (for example, smoking or drug consumption) and, conditional on participating, must decide on the level of participation, which also includes zero participation. The first decision is a binary choice and is modeled using a probit model, while the second is an ordered choice and is modeled using an ordered probit model. In other terms, to account for the excess of zeros, [Harris and Zhao](#) allowed for zero observations to occur in two ways: as a realization of the probit model (nonparticipants) and as a realization of the ordered probit model when the binary random variable in the probit model is 1 (participant with zero activity). See [Methods and formulas](#) for more details. For a Bayesian derivation of the ZIOP model, see [Gurmu and Dagne \(2012\)](#).

You may want to check whether a standard ordered probit model is adequate to fit the data. You can do this, for instance, using information criteria; see [example 2](#) in [R] [zip](#).

### ▷ Example 1: Zero-inflated ordered probit model

We have fictional data on cigarette consumption per day for 15,000 subjects between ages 14 and 84. The outcome of interest, `tobacco`, is an ordinal response with four levels coded as 0 for “no cigarettes”, 1 for “up to 8 cigarettes/day”, 2 for “8 to 12 cigarettes/day”, and 3 for “more than 12 cigarettes/day”. The exact number of daily consumed cigarettes is unknown.

About 63% of the respondents identified themselves as current nonsmokers. We suspect that these self-identified current nonsmokers belong to one of two groups. Individuals in the first group are genuine nonsmokers (always-zero group) who have never smoked and will never smoke. Individuals in the second group are smokers with no smoking activity who could be the corner solution of a standard consumer demand problem and who may smoke, say, if the price of tobacco falls or their income increases. It is likely that these two types of zeros are driven by different patterns of consumer behavior and a ZIOP model is a good candidate in this case.

We model tobacco consumption levels for subjects who choose to smoke as a function of years of education (`education`), annual income in tens of thousands of dollars (`income`), age in tens of years (`age`), and whether the respondent is a female (`female`). In addition to education, income, age, and female, the decision to smoke is modeled as a function of whether either of the respondent's parents smoked (`parent`) and whether the respondent's religion discourages smoking (`religion`). We list all the covariates in the required `inflate()` option.

```
. use https://www.stata-press.com/data/r19/tobacco
(Fictional tobacco consumption data)
. zioprobit tobacco education income i.female age,
> inflate(education income i.parent age i.female i.religion)

Iteration 0: Log likelihood = -14820.211 (not concave)

In the output table, the first set of coefficients, labeled `tobacco`, corresponds to the participation (smoking) levels. These coefficients are interpreted in the same way as coefficients from an ordered probit model. The second set of coefficients, labeled `inflate`, corresponds to the equation for the participation decision. These are interpreted in the same way as coefficients from a binary probit model. ZIOP models do not require the variables to be the same in the participation level and decision equations. However, the same variables can appear in both. If the same variables are included, it is not uncommon for the coefficients to have opposite signs. For example, `income` and `education` in the model above have positive signs in the level equation and negative signs in the decision equation.

The estimated coefficients are not particularly informative, and as with all discrete choice models, marginal effects are better to interpret. We use `margins` to estimate the average marginal effect of having a smoking parent on the probability of being a genuine nonsmoker. Specifying `pnpar` within the `predict()` option means that we are requesting the predicted probability of nonparticipation, which in our example is equivalent to being a genuine nonsmoker.

```
. margins, predict(pnpar) dydx(parent)
Average marginal effects Number of obs = 15,000
Model VCE: OIM
Expression: Pr(nonparticipation), predict(pnpar)
dy/dx wrt: 1.parent
```

|                   | Delta-method |           |        |       |                        |
|-------------------|--------------|-----------|--------|-------|------------------------|
|                   | dy/dx        | std. err. | z      | P> z  | [95% conf. interval]   |
| parent<br>Smoking | -.1797895    | .0071967  | -24.98 | 0.000 | -.1938948    -.1656843 |

Note: dy/dx for factor levels is the discrete change from the base level.

On average, individuals whose parents are smokers are about 18% less likely to be nonsmokers themselves than individuals whose parents did not use tobacco. See [\[R\] zioprobit postestimation](#) for more information and examples.

## Stored results

| <code>e(asbalanced)</code>     | factor variables <code>fvset</code> as <code>asbalanced</code>           |
| <code>e(asobserved)</code>     | factor variables <code>fvset</code> as <code>asobserved</code>           |

### Matrices

|                              |                                              |
|------------------------------|----------------------------------------------|
| <code>e(b)</code>            | coefficient vector                           |
| <code>e(Cns)</code>          | constraints matrix                           |
| <code>e(ilog)</code>         | iteration log (up to 20 iterations)          |
| <code>e(gradient)</code>     | gradient vector                              |
| <code>e(cat)</code>          | category values                              |
| <code>e(V)</code>            | variance–covariance matrix of the estimators |
| <code>e(V_modelbased)</code> | model-based variance                         |

### Functions

|                        |                         |
|------------------------|-------------------------|
| <code>e(sample)</code> | marks estimation sample |
|------------------------|-------------------------|

In addition to the above, the following is stored in `r()`:

|                       |                                                                                                                       |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------|
| Matrices              |                                                                                                                       |
| <code>r(table)</code> | matrix containing the coefficients with their standard errors, test statistics, $p$ -values, and confidence intervals |

Note that results stored in `r()` are updated when the command is replayed and will be replaced when any `r-class` command is run after the estimation command.

## Methods and formulas

Consider an ordinal response variable  $Y$  with levels coded as  $0, 1, 2, \dots, H$ . For notational simplicity, we assume that the zeros are inflated, but the following derivation may be adapted to accommodate inflation in the lowest outcome category. Harris and Zhao (2007) derived the ZIOP model in two steps. First, the group membership (participants versus nonparticipants) can be modeled using a probit model. Let  $s_j = 1$  if the  $j$ th individual belongs to the participation group or let  $s_j = 0$  otherwise. With the probit model, the probability of participation is given by

$$\Pr(s_j = 1 | \mathbf{z}_j) = \Phi(\mathbf{z}_j \boldsymbol{\gamma}) \quad (1)$$

$\mathbf{z}_j$  is a vector of covariates that determines group membership,  $\boldsymbol{\gamma}$  is a vector of coefficients that have to be estimated, and  $\Phi(\cdot)$  is the standard normal distribution function. Next, conditioning on  $s_j = 1$ , participation levels  $\tilde{y}_j$  are modeled using an ordered probit model; these levels may also include 0. The corresponding probabilities are given by

$$\Pr(\tilde{y}_j = h | s_j = 1, \mathbf{x}_j) = \Phi(\kappa_h - \mathbf{x}_j \boldsymbol{\beta}) - \Phi(\kappa_{h-1} - \mathbf{x}_j \boldsymbol{\beta}) \quad h = 0, 1, \dots, H \quad (2)$$

where  $\kappa_{-1} = -\infty$ ,  $\kappa_H = +\infty$ , and  $\mathbf{x}_j$  is a vector of covariates that could be different from  $\mathbf{z}_j$ .  $\kappa_h$  are boundary parameters that need to be estimated in addition to the coefficients vector  $\boldsymbol{\beta}$ .

The intercept  $\beta_0$  is set equal to 0 in (2) for identification. Note that  $s_j$  and  $\tilde{y}_j$  are both unobservable in terms of the zeros. The observed response variable is  $y_j = s_j \tilde{y}_j$ . Thus, the zero outcome occurs when  $s_j = 0$  (the individual is not a participant) or occurs when  $s_j = 1$  and  $\tilde{y}_j = 0$  (the individual is a participant with zero activity). To observe a positive  $y_j$ , it is a joint requirement that  $s_j = 1$  and  $\tilde{y}_j > 0$ .

The distribution of  $Y$  is given by

$$\begin{aligned} \Pr(Y) &= \begin{cases} \Pr(y_j = 0 | \mathbf{z}_j, \mathbf{x}_j) \\ \Pr(y_j = h | \mathbf{z}_j, \mathbf{x}_j) \end{cases} \quad h = 1, 2, \dots, H \\ &= \begin{cases} \Pr(s_j = 0 | \mathbf{z}_j) + \Pr(s_j = 1 | \mathbf{z}_j) \Pr(\tilde{y}_j = 0 | s_j = 1, \mathbf{x}_j) \\ \Pr(s_j = 1 | \mathbf{z}_j) \Pr(\tilde{y}_j = h | s_j = 1, \mathbf{x}_j) \end{cases} \quad h = 1, 2, \dots, H \end{aligned} \quad (3)$$

The probability of zero outcome has been inflated because it is the sum of the probability of zero activity from the ordered probit model and the probability of nonparticipation from the probit model.

Substituting (1) and (2) in (3), we get

$$\Pr(Y) = \begin{cases} \Pr(y_j = 0 | \mathbf{z}_j, \mathbf{x}_j) \\ \Pr(y_j = h | \mathbf{z}_j, \mathbf{x}_j) & h = 1, 2, \dots, H - 1 \\ \Pr(y_j = H | \mathbf{z}_j, \mathbf{x}_j) \end{cases}$$

$$= \begin{cases} \{1 - \Phi(\mathbf{z}_j \boldsymbol{\gamma})\} + \Phi(\mathbf{z}_j \boldsymbol{\gamma}) \Phi(\kappa_0 - \mathbf{x}_j \boldsymbol{\beta}) \\ \Phi(\mathbf{z}_j \boldsymbol{\gamma}) \{ \Phi(\kappa_h - \mathbf{x}_j \boldsymbol{\beta}) - \Phi(\kappa_{h-1} - \mathbf{x}_j \boldsymbol{\beta}) \} & h = 1, 2, \dots, H - 1 \\ \Phi(\mathbf{z}_j \boldsymbol{\gamma}) \{1 - \Phi(\kappa_{H-1} - \mathbf{x}_j \boldsymbol{\beta})\} \end{cases}$$

If the respective `offset()` option is specified,  $\mathbf{x}_j \boldsymbol{\beta}$  and  $\mathbf{z}_j \boldsymbol{\gamma}$  are replaced with  $\mathbf{x}_j \boldsymbol{\beta} + \text{offset}_j^\beta$  and  $\mathbf{z}_j \boldsymbol{\gamma} + \text{offset}_j^\gamma$ , respectively.

The log-likelihood function is

$$\ln L = \sum_{j=1}^N w_j \sum_{h=0}^H I(y_j = h) \ln \{ \Pr(y_j = h | \mathbf{z}_j, \mathbf{x}_j) \}$$

where  $w_j$  is an optional weight for the  $j$ th observation and

$$I(y_j = h) = \begin{cases} 1 & \text{if } y_j = h \\ 0 & \text{otherwise} \end{cases}$$

The choice between the ZIOP model and the ordered probit model cannot be made using a likelihood-ratio test because the two hypotheses are not nested in the usual sense of parameter restrictions. The restriction  $\boldsymbol{\gamma} = 0$  does not eliminate the inflation effect; it makes the group membership probabilities both equal to 0.5 [see (1)]. What is needed to remove the inflation effect is  $\mathbf{z}_j \boldsymbol{\gamma} \rightarrow \infty$ , which cannot be imposed. Because ZIOP and ordered probit models are not nested, you can compare the fits of the two models using information criteria.

This command supports the Huber/White/sandwich estimator of the variance and its clustered version with `vce(robust)` and `vce(cluster clustvar)`, respectively. See [P] [\\_robust](#), particularly *Maximum likelihood estimators* and *Methods and formulas*.

`zioprobit` also supports estimation with survey data. For details on VCEs with survey data, see [SVY] [Variance estimation](#).

## Postestimation commands

The following postestimation commands are available after `zioprobit`:

| Command                      | Description                                                                                                                             |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <code>contrast</code>        | contrasts and ANOVA-style joint tests of parameters                                                                                     |
| <code>estat ic</code>        | Akaike's, consistent Akaike's, corrected Akaike's, and Schwarz's Bayesian information criteria (AIC, CAIC, AICc, and BIC, respectively) |
| <code>estat summarize</code> | summary statistics for the estimation sample                                                                                            |
| <code>estat vce</code>       | variance–covariance matrix of the estimators (VCE)                                                                                      |
| <code>estat (svy)</code>     | postestimation statistics for survey data                                                                                               |
| <code>estimates</code>       | cataloging estimation results                                                                                                           |
| <code>etable</code>          | table of estimation results                                                                                                             |
| * <code>forecast</code>      | dynamic forecasts and simulations                                                                                                       |
| * <code>hausman</code>       | Hausman's specification test                                                                                                            |
| <code>lincom</code>          | point estimates, standard errors, testing, and inference for linear combinations of parameters                                          |
| * <code>lrtest</code>        | likelihood-ratio test                                                                                                                   |
| <code>margins</code>         | marginal means, predictive margins, marginal effects, and average marginal effects                                                      |
| <code>marginsplot</code>     | graph the results from margins (profile plots, interaction plots, etc.)                                                                 |
| <code>nlcom</code>           | point estimates, standard errors, testing, and inference for nonlinear combinations of parameters                                       |
| <code>predict</code>         | probabilities, linear predictions and their SEs, etc.                                                                                   |
| <code>predictnl</code>       | point estimates, standard errors, testing, and inference for generalized predictions                                                    |
| <code>pwcompare</code>       | pairwise comparisons of parameters                                                                                                      |
| <code>suest</code>           | seemingly unrelated estimation                                                                                                          |
| <code>test</code>            | Wald tests of simple and composite linear hypotheses                                                                                    |
| <code>testnl</code>          | Wald tests of nonlinear hypotheses                                                                                                      |

\*`forecast`, `hausman`, and `lrtest` are not appropriate with `svy` estimation results.

# predict

## Description for predict

`predict` creates a new variable containing predictions such as probabilities, linear predictions, and standard errors.

## Menu for predict

Statistics > Postestimation

## Syntax for predict

```
predict [type] { stub* | newvar | newvarlist } [if] [in] [, statistic
outcome(outcome) nooffset]
```

```
predict [type] stub* [if] [in] , scores
```

| <i>statistic</i> | Description |
|------------------|-------------|
|------------------|-------------|

Main

|                       |                                                                                |
|-----------------------|--------------------------------------------------------------------------------|
| <code>pmargin</code>  | marginal probabilities of levels, $\Pr(y_j = h)$ ; the default                 |
| <code>pjoint1</code>  | joint probabilities of levels and participation, $\Pr(y_j = h, s_j = 1)$       |
| <code>pcond1</code>   | probabilities of levels conditional on participation, $\Pr(y_j = h   s_j = 1)$ |
| <code>ppar</code>     | probability of participation, $\Pr(s_j = 1)$                                   |

If you do not specify `outcome()`, `pmargin`, `pjoint1`, and `pcond1` (with one new variable specified) assume `outcome(#1)`.

You specify one or  $k$  new variables with `pmargin`, `pjoint1`, and `pcond1`, where  $k$  is the number of outcomes.

You specify one new variable with `ppar`, `pnpar`, `xb`, `xbinfl`, `stdp`, and `stdpinfl`.

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

## Options for predict

Main

`pmargin`, the default, calculates the predicted marginal probabilities of outcome levels,  $\Pr(y_j = h)$ .

`pjoint1` calculates the predicted joint probabilities of outcome levels and participation,  $\Pr(y_j = h, s_j = 1)$ .

`pcond1` calculates the predicted probabilities of outcome levels conditional on participation,  $\Pr(y_j = h | s_j = 1)$ .

With `pmargin`, `pjoint1`, and `pcond1`, you can compute predicted probabilities for one or for all outcome levels. When you specify one new variable, `predict` computes probabilities for the first outcome level. You can specify the `outcome(#i)` option to obtain probabilities for the  $i$ th level. When you specify multiple new variables or a stub, `predict` computes probabilities for all outcome levels. The behavior of `predict` with one new variable is equivalent to specifying `outcome(#1)`.

`ppar` and `pnpair` calculate the predicted marginal probability of participation [ $\Pr(s_j = 1)$ ] and of nonparticipation [ $\Pr(s_j = 0)$ ], respectively.

In health-related fields, probabilities of participation and nonparticipation are known as probabilities of susceptibility and nonsusceptibility. Similarly to `predict` after `ziologit`, you can use options `ps` and `pns` to compute these probabilities. Options `ps` and `pns` produce identical results to the respective options `ppar` and `pnpair` but label new variables as `Pr(susceptible)` and `Pr(nonsusceptible)` instead of `Pr(participation)` and `Pr(nonparticipation)`.

`xb` calculates the linear prediction for the ordered probit equation, which is  $\mathbf{x}_j\beta$  if `offset()` was not specified with `zioprobit` and is  $\mathbf{x}_j\beta + \text{offset}_j^\beta$  if `offset()` was specified.

`xbinfl` calculates the linear prediction for the inflation equation, which is  $\mathbf{z}_j\gamma$  if `offset()` was not specified in `inflate()` and is  $\mathbf{z}_j\gamma + \text{offset}_j^\gamma$  if `offset()` was specified in `inflate()`.

`stdp` calculates the standard error of the linear prediction for the ordered probit equation.

`stdpinfl` calculates the standard error of the linear prediction for the inflation equation.

`outcome(outcome)` specifies the outcome for which predicted probabilities are to be calculated. `outcome()` should contain either one value of the dependent variable or one of `#1`, `#2`, ..., with `#1` meaning the first category of the dependent variable, `#2` meaning the second category, etc. `outcome()` is allowed only with `pmargin`, `pjoint1`, and `pcond1`.

`nooffset` is relevant only if you specified `offset(varname)` with `zioprobit` or within the `inflate()` option. It modifies the calculations made by `predict` so that they ignore the offset variable; that is, the linear prediction for the main regression equation is treated as  $\mathbf{x}_j\beta$  rather than as  $\mathbf{x}_j\beta + \text{offset}_j^\beta$  and the linear prediction for the inflation equation is treated as  $\mathbf{z}_j\gamma$  rather than as  $\mathbf{z}_j\gamma + \text{offset}_j^\gamma$ .

`scores` calculates equation-level score variables.

The first new variable will contain  $\partial \ln L / \partial (\mathbf{x}_j\beta)$ . In the absence of independent variables in the main equation, this variable is not stored.

The second new variable will contain  $\partial \ln L / \partial (\mathbf{z}_j\gamma)$ .

When the dependent variable takes  $k$  different values, the third new variable through new variable  $k + 1$  will contain  $\partial \ln L / \partial (\kappa_h)$  for  $h = 0, 1, \dots, k - 2$ .

# margins

## Description for margins

`margins` estimates margins of response for probabilities and linear predictions.

## Syntax for margins

```
margins [marginlist] [, options]
```

```
margins [marginlist] , predict(statistic ...) [predict(statistic ...) ...] [options]
```

| <i>statistic</i> | Description                                                                    |
|------------------|--------------------------------------------------------------------------------|
| default          | marginal probabilities for each outcome                                        |
| <u>p</u> margin  | marginal probabilities of levels, $\Pr(y_j = h)$ ; the default                 |
| pjoint1          | joint probabilities of levels and participation, $\Pr(y_j = h, s_j = 1)$       |
| pcond1           | probabilities of levels conditional on participation, $\Pr(y_j = h   s_j = 1)$ |
| ppar             | probability of participation, $\Pr(s_j = 1)$                                   |
| pnpar            | probability of nonparticipation, $\Pr(s_j = 0)$                                |
| xb               | linear prediction                                                              |
| xbinfl           | linear prediction for inflation equation                                       |
| stdp             | not allowed with margins                                                       |
| stdpinfl         | not allowed with margins                                                       |

`pmargin`, `pjoint1`, and `pcond1` default to the first outcome.

Statistics not allowed with `margins` are functions of stochastic quantities other than  $e(b)$ .

For the full syntax, see [\[R\] margins](#).

## Remarks and examples

Various sets of predictions and marginal effects may be of interest for the ZIOP model. For instance, we may want to investigate the marginal effects of a covariate on the probability of participation, or on the probabilities for levels of consumption conditional on participation, or on the overall probabilities for different consumption levels. We explore these options in greater detail in the following examples.

### ▷ Example 1: Average marginal effects on probability of nonparticipation

In [example 1](#) of [\[R\] zioprobit](#), we fit a model for level of cigarette consumption.

```
. use https://www.stata-press.com/data/r19/tobacco
(Fictional tobacco consumption data)

. zioprobit tobacco education income i.female age,
> inflate(education income i.parent age i.female i.religion)
(output omitted)
```

We can use `margins` to estimate the expected marginal effect of gender for individuals with a college degree (17 years of education) and a smoking parent on the probability of nonparticipation (being a genuine nonsmoker). To do this, we specify `predict(pnpar)` with `margins` as follows:

```
. margins, predict(pnpar) dydx(female) at(education = 17 parent = 1)
Average marginal effects Number of obs = 15,000
Model VCE: OIM
Expression: Pr(nonparticipation), predict(pnpar)
dy/dx wrt: 1.female
At: education = 17
 parent = 1
```

|        | dy/dx    | Delta-method<br>std. err. | z    | P> z  | [95% conf. interval] |         |
|--------|----------|---------------------------|------|-------|----------------------|---------|
| female | .0855995 | .0100239                  | 8.54 | 0.000 | .0659531             | .105246 |
| Female |          |                           |      |       |                      |         |

Note: dy/dx for factor levels is the discrete change from the base level.

Women with a college degree and a smoking parent are expected to have about an 8.5% higher chance of being genuine nonsmokers than do men.

### ▷ Example 2: Predicted probabilities of zero-valued outcomes

In [example 1](#) of [\[R\] zioprobit](#), we found that the coefficient on `income` was positive in the level equation but negative in the participation equation. In the case of our tobacco consumption example, economic theory offers a reasonable interpretation for this. Higher income may act as an indicator for health awareness, which accounts for its association with an increased probability of being a genuine nonsmoker. However, if cigarettes are a normal good—that is, something for which demand increases when income increases—then smokers with higher income should have a lower probability of having zero consumption at the time of the survey.

We first consider the effect of `income` at six prespecified values ranging from \$10,000 to \$60,000 on the probability of being a genuine nonsmoker (nonparticipation). Because we know the values 1 to 6 correspond to income in tens of thousands, we conserve space and suppress the default legend by using the `noatlegend` option.

```
. margins, predict(pnpar) at(income = (1/6)) noatlegend
Predictive margins Number of obs = 15,000
Model VCE: OIM
Expression: Pr(nonparticipation), predict(pnpar)
```

|     | Delta-method |           |       |       |                      |
|-----|--------------|-----------|-------|-------|----------------------|
|     | Margin       | std. err. | z     | P> z  | [95% conf. interval] |
| _at |              |           |       |       |                      |
| 1   | .1727928     | .0056963  | 30.33 | 0.000 | .1616283 .1839573    |
| 2   | .1944564     | .0055236  | 35.20 | 0.000 | .1836304 .2052824    |
| 3   | .2176787     | .0052981  | 41.09 | 0.000 | .2072945 .2280629    |
| 4   | .2424141     | .0050413  | 48.09 | 0.000 | .2325333 .2522948    |
| 5   | .2685948     | .0047857  | 56.12 | 0.000 | .259215 .2779745     |
| 6   | .2961309     | .0045767  | 64.70 | 0.000 | .2871607 .3051011    |

The probability of being a genuine nonsmoker increases with income. For instance, for individuals who earn \$10,000 a year, the expected increase in the probability of being a genuine nonsmoker is about  $(0.1945 - 0.1728) \times 100\% = 2.17\%$  if they earn an additional \$10,000.

We next investigate the effect of income on the joint probability of being a smoker (participation equals 1) with zero consumption. We do this by specifying `predict(pjoint1 outcome(0))` with `margins`:

```
. margins, predict(pjoint1 outcome(0)) at(income = (1/6)) noatlegend
Predictive margins Number of obs = 15,000
Model VCE: OIM
Expression: Pr(tobacco=0, participation=1), predict(pjoint1 outcome(0))
```

|     | Delta-method |           |        |       |                      |
|-----|--------------|-----------|--------|-------|----------------------|
|     | Margin       | std. err. | z      | P> z  | [95% conf. interval] |
| _at |              |           |        |       |                      |
| 1   | .5595131     | .0040167  | 139.30 | 0.000 | .5516405 .5673856    |
| 2   | .5080066     | .0037793  | 134.42 | 0.000 | .5005993 .5154139    |
| 3   | .4558656     | .0035553  | 128.22 | 0.000 | .4488975 .4628338    |
| 4   | .4029089     | .0033683  | 119.62 | 0.000 | .3963072 .4095106    |
| 5   | .3485692     | .0032481  | 107.32 | 0.000 | .3422031 .3549352    |
| 6   | .2929155     | .00317    | 92.40  | 0.000 | .2867023 .2991287    |

For individuals who are smokers, the probability of zero consumption decreases as income increases, suggesting that tobacco is like a normal good for smokers. For example, for individuals who earn \$10,000 a year, earning an additional \$10,000 will decrease their probability of being a smoker with zero consumption by about  $(0.5595 - 0.5080) \times 100\% = 5.15\%$ .

If we wanted to compute the effect of income on the overall probability of zero consumption instead of the probability of zero consumption among smokers, we would omit `pjoint1` from within the `predict` option.

```
. margins, predict(outcome(0)) at(income = (1/6)) noatlegend
(output omitted)
```

This version of the `margins` command gives the sum of the probability of nonparticipation and the joint probability of participation with zero consumption.

## Methods and formulas

The participation equation is

$$s_j = I(\mathbf{z}_j\boldsymbol{\gamma} + u_{1j} > 0) \quad j = 1, 2, \dots, n$$

where  $s_j$  is 1 if the  $j$ th subject belongs to the participation group (for example, smokers) and is 0 if the subject belongs to the nonparticipation group (for example, genuine nonsmokers),  $\mathbf{z}_j$  are the covariates used to model the group membership,  $\boldsymbol{\gamma}$  is a vector of coefficients, and  $u_{1j}$  is a random-error term following a standard normal distribution.

The ordinal outcome equation is

$$\tilde{y}_j = \sum_{h=0}^H hI(\kappa_{h-1} < \mathbf{x}_j\boldsymbol{\beta} + u_{2j} \leq \kappa_h)$$

where  $\tilde{y}_j$  is the ordinal outcome conditional on participation,  $\mathbf{x}_j$  are the outcome covariates,  $\boldsymbol{\beta}$  are the coefficients, and  $u_{2j}$  is a random-error term following a standard normal distribution. The observed outcome values are 0, 1, ...,  $H$ .  $\kappa_0, \kappa_1, \dots, \kappa_{H-1}$  are real numbers such that  $\kappa_i < \kappa_m$  for  $i < m$ .  $\kappa_{-1}$  is taken as  $-\infty$  and  $\kappa_H$  is taken as  $+\infty$ . We assume that the error terms  $u_{1j}$  and  $u_{2j}$  are independent. We observe  $y_j = s_j\tilde{y}_j$ .

The probability of participation is

$$\Pr(s_j = 1|\mathbf{z}_j) = \Phi(\mathbf{z}_j\boldsymbol{\gamma}) \quad (1)$$

where  $\Phi(\cdot)$  is the standard normal distribution function.

The probability of nonparticipation is

$$\Pr(s_j = 0|\mathbf{z}_j) = 1 - \Phi(\mathbf{z}_j\boldsymbol{\gamma}) \quad (2)$$

The probability of outcome  $y_j = h$  given that the  $j$ th subject belongs to the participation group is

$$\begin{aligned} \Pr(y_j = h|s_j = 1, \mathbf{x}_j) &= \Pr(\tilde{y}_j = h|\mathbf{x}_j) \\ &= \Phi(\kappa_h - \mathbf{x}_j\boldsymbol{\beta}) - \Phi(\kappa_{h-1} - \mathbf{x}_j\boldsymbol{\beta}) \end{aligned} \quad (3)$$

for  $h = 0, 1, \dots, H$ , where  $\Phi(\kappa_{-1} - \mathbf{x}_j\boldsymbol{\beta}) = 0$  and  $\Phi(\kappa_H - \mathbf{x}_j\boldsymbol{\beta}) = 1$ .

The joint probability of outcome  $y_j = h$  and participation can be expressed as

$$\Pr(y_j = h, s_j = 1|\mathbf{z}_j, \mathbf{x}_j) = \Pr(s_j = 1|\mathbf{z}_j) \Pr(y_j = h|s_j = 1, \mathbf{x}_j)$$

for  $h = 0, 1, \dots, H$ , and computed using (1) and (3).

The marginal probabilities of the outcome  $y_j$  are

$$\begin{aligned} \Pr(y_j = 0|\mathbf{z}_j, \mathbf{x}_j) &= \Pr(s_j = 0|\mathbf{z}_j) + \Pr(s_j = 1|\mathbf{z}_j) \Pr(\tilde{y}_j = 0|\mathbf{x}_j) \\ \Pr(y_j = h|\mathbf{z}_j, \mathbf{x}_j) &= \Pr(s_j = 1|\mathbf{z}_j) \Pr(\tilde{y}_j = h|\mathbf{x}_j) \quad h = 1, 2, \dots, H-1 \\ \Pr(y_j = H|\mathbf{z}_j, \mathbf{x}_j) &= \Pr(s_j = 1|\mathbf{z}_j) \Pr(\tilde{y}_j = H|\mathbf{x}_j) \end{aligned}$$

and can be computed using (1), (2), and (3).

If the `offset()` option is specified with `zioprobit`,  $\mathbf{x}_j\boldsymbol{\beta}$  is replaced with  $\mathbf{x}_j\boldsymbol{\beta} + \text{offset}_j^\beta$ . If the `offset()` option is specified within the `inflate()` option,  $\mathbf{z}_j\boldsymbol{\gamma}$  is replaced with  $\mathbf{z}_j\boldsymbol{\gamma} + \text{offset}_j^\gamma$ .

## Description

`zip` fits a zero-inflated Poisson (ZIP) model to count data with excess zero counts. The ZIP model assumes that the excess zero counts come from a logit or probit model and the remaining counts come from a Poisson model.

## Quick start

Zero-inflated Poisson model of  $y$  on  $x_1$  and  $x_2$  with inflation modeled using  $x_3$

```
zip y x1 x2, inflate(x3)
```

Use a probit model instead of a logit model to predict excess zeros

```
zip y x1 x2, inflate(x3) probit
```

## Menu

Statistics > Count outcomes > Zero-inflated Poisson regression

## Syntax

```
zip depvar [indepvars] [if] [in] [weight],
 inflate(varlist [, offset(varname)] | _cons) [options]
```

\*inflate(*varlist* [, offset(*varname*)] | \_cons) is required.

*indepvars* and *varlist* may contain factor variables; see [U] 11.4.3 **Factor variables**.

bayes, bayesboot, bootstrap, by, collect, fp, jackknife, rolling, statsby, and svy are allowed; see [U] 11.1.10 **Prefix commands**. For more details, see [BAYES] **bayes: zip**.

Weights are not allowed with the bootstrap prefix; see [R] **bootstrap**.

vce() and weights are not allowed with the svy prefix; see [SVY] **svy**.

fweights, iweights, and pweights are allowed; see [U] 11.1.6 **weight**.

collinear and coeflegend do not appear in the dialog box.

See [U] 20 **Estimation and postestimation commands** for more capabilities of estimation commands.

## Options

### Model

`inflate(varlist [, offset(varname)] | _cons)` specifies the equation that determines whether the observed count is zero. Conceptually, omitting `inflate()` would be equivalent to fitting the model with `poisson`; see [R] [poisson](#).

`inflate(varlist [, offset(varname)])` specifies the variables in the equation. You may optionally include an offset for this *varlist*.

`inflate(_cons)` specifies that the equation determining whether the count is zero contains only an intercept. To run a zero-inflated model of *depvar* with only an intercept in both equations, type `zip depvar, inflate(_cons)`.

`noconstant`, `exposure(varnamee)`, `offset(varnameo)`, `constraints(constraints)`; see [R] [Estimation options](#).

`probit` requests that a probit, instead of logit, model be used to characterize the excess zeros in the data.

### SE/Robust

`vce(vcetype)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory (`oim`, `opg`), that are robust to some kinds of misspecification (`robust`), that allow for intragroup correlation (`cluster clustvar`), and that use bootstrap or jackknife methods (`bootstrap`, `jackknife`); see [R] [vce\\_option](#).

### Reporting

`level(#)`; see [R] [Estimation options](#).

`irr` reports estimated coefficients transformed to incidence-rate ratios, that is,  $e^b$  rather than  $b$ . Standard errors and confidence intervals are similarly transformed. This option affects how results are displayed, not how they are estimated or stored. `irr` may be specified at estimation or when replaying previously estimated results.

`nocnsreport`; see [R] [Estimation options](#).

*display\_options*: `nocl`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `nolstretch`; see [R] [Estimation options](#).

### Maximization

*maximize\_options*: `difficult`, `technique(algorithm_spec)`, `iterate(#)`, `[no]log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `ltolerance(#)`, `nrtolerance(#)`, `nonrtolerance`, and `from(init_specs)`; see [R] [Maximize](#). These options are seldom used.

Setting the optimization type to `technique(bhhh)` resets the default *vcetype* to `vce(opg)`.

The following options are available with `zip` but are not shown in the dialog box:

`collinear`, `coeflegend`; see [R] [Estimation options](#).

## Remarks and examples

Zero-inflated Poisson (ZIP) models address the case when the data contain a higher fraction of zeros than is likely to be generated from a Poisson model. Having a large proportion of zero observations, in itself, does not necessarily mean that we have the excess zeros problem. For instance, a Poisson model with a mean value of 0.2 predicts that  $P(Y = 0) = \exp(-0.2) \approx 0.82$ . However, the range of possible outcomes is restricted because of the small variance, 0.2 (mean and variance are equal for a Poisson model), as shown by  $P(Y > 3) \approx 0.00006$ . Unlike Poisson models, ZIP models allow us to have a large fraction of zeros without restricting the range of outcomes.

ZIP models assume that an observation is 0 with a probability  $p$  or is a realization of a Poisson random variable, which can also be 0, with a probability  $1 - p$ . For instance, you might count how many fish each visitor to a park catches. Many visitors may catch zero, because they do not fish (as opposed to being unsuccessful). Using a logit or probit model, you may model the probability  $p$  of whether a person does not fish depending on several covariates related to fishing. Using a Poisson distribution, you may model how many fish a person catches depending on several covariates having to do with the success of catching fish (type of lure or bait, time of day, temperature, season, etc.). This is the type of data for which the `zip` command is useful.

See [Long \(1997, 242–247\)](#) and [Cameron and Trivedi \(2005, 680–681\)](#) for a discussion of the ZIP model and other zero-modified count models.

### ▷ Example 1: Fitting a ZIP model

We have fictional data on the number of fish caught (`count`) by visitors to a national park on a particular day. Some of the visitors do not fish, but we do not have the data on whether a person fished; we merely have data on how many fish were caught together with several covariates.

Variable `count` exhibits an excess of zero observations (142 of 250 observations), beyond what would be expected from a Poisson model. We suspect that the number of zeros may be inflated because many visitors are not fishing. That is, a zero observation may be the result of a visitor who was unfortunate and caught no fish but may also be because the visitor did not fish. A standard Poisson model (see [\[R\] poisson](#)) treats these two types of zero observations as a homogeneous group, which typically leads to biased statistical results. We would like to distinguish between the two types of zeros and possibly draw inference for them separately (see [example 1](#) in [\[R\] zip postestimation](#)).

The `zip` command allows us to model the two types of zeros. First, using the required the `inflate()` option, we model whether a visitor fishes as a function of the number of children accompanying him or her (`child`) and whether he or she is camping (`camper`). Next, we assume the response variable, `count`, depends on whether the visitor used a live bait (`livebait`) and the number of persons (`persons`), which includes the visitor and any adults or children accompanying him. Note that `persons` is always greater than `child`.

```

. use https://www.stata-press.com/data/r19/fish
(Fictional fishing data)
. zip count persons livebait, inflate(child camper)
Fitting constant-only model:
Iteration 0: Log likelihood = -1347.807
Iteration 1: Log likelihood = -1305.3245
Iteration 2: Log likelihood = -1104.3005
Iteration 3: Log likelihood = -1103.9426
Iteration 4: Log likelihood = -1103.9425
Fitting full model:
Iteration 0: Log likelihood = -1103.9425
Iteration 1: Log likelihood = -896.2346
Iteration 2: Log likelihood = -851.61723
Iteration 3: Log likelihood = -850.70435
Iteration 4: Log likelihood = -850.70142
Iteration 5: Log likelihood = -850.70142
Zero-inflated Poisson regression
Inflation model: logit
Number of obs = 250
Nonzero obs = 108
Zero obs = 142
LR chi2(2) = 506.48
Prob > chi2 = 0.0000
Log likelihood = -850.7014

```

| count    | Coefficient | Std. err. | z     | P> z  | [95% conf. interval] |           |
|----------|-------------|-----------|-------|-------|----------------------|-----------|
| count    |             |           |       |       |                      |           |
| persons  | .8068853    | .0453288  | 17.80 | 0.000 | .7180424             | .8957281  |
| livebait | 1.757289    | .2446082  | 7.18  | 0.000 | 1.277866             | 2.236713  |
| _cons    | -2.178472   | .2860289  | -7.62 | 0.000 | -2.739078            | -1.617865 |
| inflate  |             |           |       |       |                      |           |
| child    | 1.602571    | .2797719  | 5.73  | 0.000 | 1.054228             | 2.150913  |
| camper   | -1.015698   | .365259   | -2.78 | 0.005 | -1.731593            | -.2998038 |
| _cons    | -.4922872   | .3114562  | -1.58 | 0.114 | -1.10273             | .1181558  |

Coefficients in the upper half of the table correspond to the Poisson model for individuals who fished. For instance, among visitors who fished, using a live bait increases the expected number of caught fish by a factor of  $\exp(1.7572) \approx 5.8$ , holding other covariates constant.

◀

## ▶ Example 2: Comparing model fit

When you have count data, you may want to test whether a conventional count data model or a zero-inflated count data model is preferable. The classical likelihood-ratio test cannot be used here because the models are not nested. But we can use information criteria such as the AIC and BIC to check whether the standard or zero-inflated model is more appropriate.

Continuing with our fishing example, let's check whether the standard Poisson or ZIP model is more appropriate for our data. First, we store the estimation results from the previous ZIP model by typing

```
. estimates store zip
```

Next, we fit the Poisson model corresponding to the main equation of the ZIP model and store its results as `pois`:

```
. poisson count persons livebait
(output omitted)
. estimates store pois
```

We use `estimates stats` to display the AIC and BIC values for the two models.

```
. estimates stats pois zip
Akaike's information criterion and Bayesian information criterion
```

| Model | N   | ll(null)  | ll(model) | df | AIC      | BIC      |
|-------|-----|-----------|-----------|----|----------|----------|
| pois  | 250 | -1647.716 | -1312.178 | 3  | 2630.356 | 2640.92  |
| zip   | 250 | -1103.942 | -850.7014 | 6  | 1713.403 | 1734.532 |

Note: BIC uses  $N$  = number of observations. See [\[R\] IC note](#).

The ZIP model has smaller AIC and BIC values; we thus conclude that it fits our data better than the standard Poisson model.

◀

## Stored results

`zip` stores the following in `e()`:

### Scalars

|                            |                                           |

| e(asobserved) | factor variables fvset as asobserved                                     |

## Matrices

|                 |                                              |
|-----------------|----------------------------------------------|
| e(b)            | coefficient vector                           |
| e(Cns)          | constraints matrix                           |
| e(ilog)         | iteration log (up to 20 iterations)          |
| e(gradient)     | gradient vector                              |
| e(V)            | variance–covariance matrix of the estimators |
| e(V_modelbased) | model-based variance                         |

## Functions

|           |                         |
|-----------|-------------------------|
| e(sample) | marks estimation sample |
|-----------|-------------------------|

In addition to the above, the following is stored in `r()`:

## Matrices

|          |                                                                                                                       |
|----------|-----------------------------------------------------------------------------------------------------------------------|
| r(table) | matrix containing the coefficients with their standard errors, test statistics, $p$ -values, and confidence intervals |
|----------|-----------------------------------------------------------------------------------------------------------------------|

Note that results stored in `r()` are updated when the command is replayed and will be replaced when any  $r$ -class command is run after the estimation command.

## Methods and formulas

Consider the formulation of a zero-inflated model as presented in [Lambert \(1992\)](#). Define

$$\xi_j^\beta = \mathbf{x}_j \boldsymbol{\beta} + \text{offset}_j^\beta$$

$$\xi_j^\gamma = \mathbf{z}_j \boldsymbol{\gamma} + \text{offset}_j^\gamma$$

$$\lambda_j = \exp(\xi_j^\beta)$$

$$F_j = F(\xi_j^\gamma)$$

where  $F(\cdot)$  is the inverse of the logit function or, if the `probit` option was specified, the inverse of the probit function (or the standard normal cumulative distribution function). All subjects are assumed to be independent with the  $j$ th response determined as follows:

$$Y_j = 0 \quad \text{with probability } F_j$$

$$Y_j \sim \text{Poisson}(\lambda_j) \quad \text{with probability } 1 - F_j$$

In other words,

$$\Pr(Y_j = 0 | \mathbf{x}_j, \mathbf{z}_j) = F_j + (1 - F_j) \exp(-\lambda_j)$$

$$\Pr(Y_j = n | \mathbf{x}_j, \mathbf{z}_j) = (1 - F_j) \exp(-\lambda_j) \frac{\lambda_j^n}{n!} \quad \text{for } n = 1, 2, \dots$$

The `zip` command maximizes the log-likelihood  $\ln L$ , defined by

$$\begin{aligned} \ln L = & \sum_{j \in S} w_j \ln \{ F_j + (1 - F_j) \exp(-\lambda_j) \} \\ & + \sum_{j \notin S} w_j \{ \ln(1 - F_j) - \lambda_j + \xi_j y_j - \ln(y_j!) \} \end{aligned}$$

where  $w_j$  are the weights and  $S$  is the set of observations for which the observed outcome  $y_j = 0$ .

This command supports the Huber/White/sandwich estimator of the variance and its clustered version using `vce(robust)` and `vce(cluster clustvar)`, respectively. See [P] [\\_robust](#), particularly *Maximum likelihood estimators* and *Methods and formulas*.

`zip` also supports estimation with survey data. For details on VCEs with survey data, see [SVY] [Variance estimation](#).

## Postestimation commands

The following postestimation commands are available after `zip`:

| Command                      | Description                                                                                                                             |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <code>contrast</code>        | contrasts and ANOVA-style joint tests of parameters                                                                                     |
| <code>estat ic</code>        | Akaike's, consistent Akaike's, corrected Akaike's, and Schwarz's Bayesian information criteria (AIC, CAIC, AICc, and BIC, respectively) |
| <code>estat summarize</code> | summary statistics for the estimation sample                                                                                            |
| <code>estat vce</code>       | variance–covariance matrix of the estimators (VCE)                                                                                      |
| <code>estat (svy)</code>     | postestimation statistics for survey data                                                                                               |
| <code>estimates</code>       | cataloging estimation results                                                                                                           |
| <code>etable</code>          | table of estimation results                                                                                                             |
| * <code>forecast</code>      | dynamic forecasts and simulations                                                                                                       |
| * <code>hausman</code>       | Hausman's specification test                                                                                                            |
| <code>lincom</code>          | point estimates, standard errors, testing, and inference for linear combinations of parameters                                          |
| * <code>lrtest</code>        | likelihood-ratio test                                                                                                                   |
| <code>margins</code>         | marginal means, predictive margins, marginal effects, and average marginal effects                                                      |
| <code>marginsplot</code>     | graph the results from <code>margins</code> (profile plots, interaction plots, etc.)                                                    |
| <code>nlcom</code>           | point estimates, standard errors, testing, and inference for nonlinear combinations of parameters                                       |
| <code>predict</code>         | number of events, incidence rates, probabilities, etc.                                                                                  |
| <code>predictnl</code>       | point estimates, standard errors, testing, and inference for generalized predictions                                                    |
| <code>pwcompare</code>       | pairwise comparisons of parameters                                                                                                      |
| <code>suest</code>           | seemingly unrelated estimation                                                                                                          |
| <code>test</code>            | Wald tests of simple and composite linear hypotheses                                                                                    |
| <code>testnl</code>          | Wald tests of nonlinear hypotheses                                                                                                      |

\*`forecast`, `hausman`, and `lrtest` are not appropriate with `svy` estimation results.

# predict

## Description for predict

`predict` creates a new variable containing predictions such as numbers of events, incidence rates, probabilities, linear predictions, and standard errors.

## Menu for predict

Statistics > Postestimation

## Syntax for predict

```
predict [type] newvar [if] [in] [, statistic nooffset]
```

```
predict [type] stub* [if] [in] , scores
```

| <i>statistic</i> | Description |
|------------------|-------------|
|------------------|-------------|

Main

|                                    |                                         |
|------------------------------------|-----------------------------------------|
| <code>n</code>                     | number of events; the default           |
| <code>ir</code>                    | incidence rate                          |
| <code>pr</code>                    | probability of a degenerate zero        |
| <code>pr(<i>n</i>)</code>          | probability $\Pr(y_j = n)$              |
| <code>pr(<i>a</i>,<i>b</i>)</code> | probability $\Pr(a \leq y_j \leq b)$    |
| <code>xb</code>                    | linear prediction                       |
| <code>stdp</code>                  | standard error of the linear prediction |

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

## Options for predict

Main

`n`, the default, calculates the predicted number of events, which is  $(1 - F_j) \exp(\mathbf{x}_j\boldsymbol{\beta})$  if neither `offset()` nor `exposure()` was specified when the model was fit, where  $F_j$  is the predicted probability of a zero outcome;  $(1 - F_j) \exp(\mathbf{x}_j\boldsymbol{\beta} + \text{offset}_j^\beta)$  if `offset()` was specified; or  $(1 - F_j) \{ \exp(\mathbf{x}_j\boldsymbol{\beta}) \times \text{exposure}_j \}$  if `exposure()` was specified.

`ir` calculates the incidence rate, which is the predicted number of events when exposure is 1. This is equivalent to specifying both the `n` and the `nooffset` options.

`pr` calculates the probability of a degenerate zero, predicted from the fitted degenerate distribution  $F_j = F(\mathbf{z}_j\boldsymbol{\gamma})$ . If `offset()` was specified within the `inflate()` option, then  $F_j = F(\mathbf{z}_j\boldsymbol{\gamma} + \text{offset}_j^\gamma)$  is calculated.

`pr(n)` calculates the probability  $\Pr(y_j = n)$ , where  $n$  is a nonnegative integer that may be specified as a number or a variable. Note that `pr` is not equivalent to `pr(0)`.

`pr(a, b)` calculates the probability  $\Pr(a \leq y_j \leq b)$ , where  $a$  and  $b$  are nonnegative integers that may be specified as numbers or variables;

$b$  missing ( $b \geq .$ ) means  $+\infty$ ;

`pr(20, .)` calculates  $\Pr(y_j \geq 20)$ ;

`pr(20, b)` calculates  $\Pr(y_j \geq 20)$  in observations for which  $b \geq .$  and calculates  $\Pr(20 \leq y_j \leq b)$  elsewhere.

`pr(. , b)` produces a syntax error. A missing value in an observation of the variable  $a$  causes a missing value in that observation for `pr(a, b)`.

`xb` calculates the linear prediction, which is  $\mathbf{x}_j\boldsymbol{\beta}$  if neither `offset()` nor `exposure()` was specified;  $\mathbf{x}_j\boldsymbol{\beta} + \text{offset}_j^\beta$  if `offset()` was specified; or  $\mathbf{x}_j\boldsymbol{\beta} + \ln(\text{exposure}_j)$  if `exposure()` was specified; see `nooffset` below.

`stdp` calculates the standard error of the linear prediction.

`nooffset` is relevant only if you specified `offset()` or `exposure()` when you fit the model. It modifies the calculations made by `predict` so that they ignore the offset or exposure variable; the linear prediction is treated as  $\mathbf{x}_j\boldsymbol{\beta}$  rather than as  $\mathbf{x}_j\boldsymbol{\beta} + \text{offset}_j^\beta$  or  $\mathbf{x}_j\boldsymbol{\beta} + \ln(\text{exposure}_j)$ . Specifying `predict . . . , nooffset` is equivalent to specifying `predict . . . , ir`.

`scores` calculates equation-level score variables.

The first new variable will contain  $\partial \ln L / \partial (\mathbf{x}_j\boldsymbol{\beta})$ .

The second new variable will contain  $\partial \ln L / \partial (\mathbf{z}_j\boldsymbol{\gamma})$ .

# margins

## Description for margins

`margins` estimates margins of response for the numbers of events, incidence rates, probabilities, and linear predictions.

## Menu for margins

Statistics > Postestimation

## Syntax for margins

```
margins [marginlist] [, options]
```

```
margins [marginlist] , predict(statistic ...) [predict(statistic ...) ...] [options]
```

| <i>statistic</i>                   | Description                           |
|------------------------------------|---------------------------------------|
| <code>n</code>                     | number of events; the default         |
| <code>ir</code>                    | incidence rate                        |
| <code>pr</code>                    | probability of a degenerate zero      |
| <code>pr(<i>n</i>)</code>          | probability $\Pr(y_j = n)$            |
| <code>pr(<i>a</i>,<i>b</i>)</code> | probability $\Pr(a \leq y_j \leq b)$  |
| <code>xb</code>                    | linear prediction                     |
| <code>stdp</code>                  | not allowed with <code>margins</code> |

Statistics not allowed with `margins` are functions of stochastic quantities other than `e(b)`.

For the full syntax, see [R] [margins](#).

## Remarks and examples

### ▷ Example 1: Obtaining predicted counts

Continuing with [example 1](#) from [\[R\] zip](#), we will use `predict` to compute the predicted number of fish captured by each individual.

```
. use https://www.stata-press.com/data/r19/fish
(Fictional fishing data)
. zip count persons livebait, inflate(child camper)
(output omitted)
. predict numfish
(option n assumed; predicted number of events)
. summarize numfish
```

| Variable | Obs | Mean     | Std. dev. | Min     | Max      |
|----------|-----|----------|-----------|---------|----------|
| numfish  | 250 | 2.770999 | 3.269588  | .079269 | 13.55015 |

The average predicted number of fish caught by all visitors, regardless of whether or not they fished, is 2.77 fish.

### ▷ Example 2: Obtaining predicted probabilities

`predict` with the `pr` option computes the probability that an individual does not fish.

```
. predict pr, pr
```

On the other hand, `predict` with the `pr(n)` option computes the probability of catching *n* fish; particularly, the probability of catching zero fish will be

```
. predict pr0, pr(0)
. list pr pr0 in 1
```

|    | pr       | pr0      |
|----|----------|----------|
| 1. | .3793549 | .8609267 |

Notice that `pr0` is always equal to or greater than `pr`. For example, for the first individual, the probability of not fishing is 0.38; on the other hand, the probability of catching zero fish (0.86) is equal to the sum of the probability of not fishing and the probability of fishing but not catching any fish. `pr0` can be also computed as one minus the probability of catching at least one fish, that is:

```
. predict pr_catch, pr(1,.)
. gen pr0b = 1-pr_catch
```

## Methods and formulas

See *Methods and formulas* in [R] [zip](#) for the model definition and notation.

The probabilities calculated using the `pr(n)` option are the probability  $\Pr(y_j = n)$ . These are calculated using

$$\Pr(y_j = 0 | \mathbf{x}_j, \mathbf{z}_j) = F_j + (1 - F_j) \exp(-\lambda_j)$$

$$\Pr(y_j = n | \mathbf{x}_j, \mathbf{z}_j) = (1 - F_j) \frac{\lambda_j^n \exp(-\lambda_j)}{n!} \quad \text{for } n = 1, 2, \dots$$

where  $F_j$  is the probability of obtaining an observation from the degenerate distribution whose mass is concentrated at zero.  $F_j$  can be obtained by using the `pr` option.

See [Cameron and Trivedi \(2013, sec. 4.6\)](#) for further details.

## Description

`ztest` performs  $z$  tests on the equality of means, assuming known variances. The test can be performed for one sample against a hypothesized population value or for no difference in population means estimated from two samples. Two-sample tests can be conducted for paired and unpaired data. Clustered data are also supported.

`ztesti` is the immediate form of `ztest`; see [\[U\] 19 Immediate commands](#).

For the comparison of means when variances are unknown, use `ttest`; see [\[R\] ttest](#).

## Quick start

One-sample test that the mean of `v1` is 3 at the 90% confidence level

```
ztest v1 == 3, level(90)
```

Same as above, and adjust for clustering with clusters defined by `cvar` and an intraclass correlation of 0.5

```
ztest v1 == 3, level(90) cluster(cvar) rho(0.5)
```

Unpaired  $z$  test that the mean of `v1` is equal between two groups defined by `catvar`

```
ztest v1, by(catvar)
```

Same as above, and adjust for clustering with clusters defined by `cvar` and an intraclass correlation of 0.5 in the two groups

```
ztest v1, by(catvar) cluster(cvar) rho(0.5)
```

Unpaired test of equality of the means of `v2` and `v3`

```
ztest v2 == v3, unpaired
```

Paired test of equality of the means of `v2` and `v3` with standard deviation of the differences between paired observations of 2.4

```
ztest v2 == v3, sddiff(2.4)
```

Same as above, specified using a common standard deviation of 2 and correlation between observations of 0.28

```
ztest v2 == v3, sd(2) corr(0.28)
```

Immediate form unpaired test of  $\mu_1 = \mu_2$  if  $\bar{x}_1 = 3.2$ ,  $sd_1 = 0.1$ ,  $\bar{x}_2 = 3.4$ , and  $sd_2 = 0.15$  with  $n_1 = n_2 = 120$

```
ztesti 120 3.2 0.1 120 3.4 0.15
```

## Menu

### ztest

Statistics > Summaries, tables, and tests > Classical tests of hypotheses > z test (mean-comparison test, known variance)

### ztesti

Statistics > Summaries, tables, and tests > Classical tests of hypotheses > z test calculator

## Syntax

### One-sample z test

```
ztest varname == # [if] [in] [, onesampleopts]
```

### Two-sample z test using groups

```
ztest varname [if] [in], by(groupvar) [twosamplegopts]
```

### Two-sample z test using variables

```
ztest varname1 == varname2 [if] [in], unpaired [twosamplevaropts]
```

### Paired z test

```
ztest varname1 == varname2 [if] [in], sddiff(#) [level(#)]
```

```
ztest varname1 == varname2 [if] [in], corr(#) [pairedopts]
```

### Immediate form of one-sample z test

```
ztesti #_obs #_mean #_sd #_val [, level(#)]
```

### Immediate form of two-sample unpaired z test

```
ztesti #_obs1 #_mean1 #_sd1 #_obs2 #_mean2 #_sd2 [, level(#)]
```

### onesampleopts          Description

## Options

### Main

`by(groupvar)` specifies the *groupvar* that defines the two groups that `ztest` will use to test the hypothesis that their means are equal. Specifying `by(groupvar)` implies an unpaired (two-sample) *z* test. Do not confuse the `by()` option with the `by prefix`; you can specify both.

`unpaired` specifies that the data be treated as unpaired. The `unpaired` option is used when the two sets of values to be compared are in different variables.

`sddiff(#)` specifies the population standard deviation of the differences between paired observations for a paired *z* test. For this kind of test, either `sddiff()` or `corr()` must be specified.

`corr(#)` specifies the correlation between paired observations for a paired *z* test. This option along with `sd1()` and `sd2()` or with `sd()` is used to compute the standard deviation of the differences between paired observations unless that standard deviation is supplied directly in the `sddiff()` option. For a paired *z* test, either `sddiff()` or `corr()` must be specified.

`sd(#)` specifies the population standard deviation for a one-sample *z* test or the common population standard deviation for a two-sample *z* test. The default is `sd(1)`. `sd()` may not be combined with `sd1()`, `sd2()`, or `sddiff()`.

`sd1(#)` specifies the standard deviation of the first population or group. When `sd1()` is specified with `by(groupvar)`, the first group is defined by the first category of the sorted *groupvar*. `sd1()` requires `sd2()` and may not be combined with `sd()` or `sddiff()`.

`sd2(#)` specifies the standard deviation of the second population or group. When `sd2()` is specified with `by(groupvar)`, the second group is defined by the second category of the sorted *groupvar*. `sd2()` requires `sd1()` and may not be combined with `sd()` or `sddiff()`.

`level(#)` specifies the confidence level, as a percentage, for confidence intervals. The default is `level(95)` or as set by `set level`; see [\[U\] 20.8 Specifying the width of confidence intervals](#).

`cluster(varname)` specifies the variable that identifies clusters. The `cluster()` option is required to adjust the computation for clustering.

`rho(#)` specifies the intraclass correlation for a one-sample test or the common intraclass correlation for a two-sample test. The `rho()` option is required to adjust the computation for clustering for a one-sample test.

`rho1(#)` specifies the intraclass correlation of the first group for a two-sample test using groups. The `rho()` option or both `rho1()` and `rho2()` options are required to adjust the computation for clustering.

`rho2(#)` specifies the intraclass correlation of the second group for a two-sample test using groups. The `rho()` option or both `rho1()` and `rho2()` options are required to adjust the computation for clustering.

When `by()` is used, `sd1()` and `sd2()` or `sd()` is used to specify the population standard deviations of the two groups defined by *groupvar* for an unpaired two-sample *z* test (using groups). By default, a common standard deviation of one, `sd(1)`, is assumed.

When `unpaired` is used, `sd1()` and `sd2()` or `sd()` is used to specify the population standard deviations of *varname*<sub>1</sub> and *varname*<sub>2</sub> for an unpaired two-sample *z* test (using variables). By default, a common standard deviation of one, `sd(1)`, is assumed.

Options `corr()`, `sd1()`, and `sd2()` or `corr()` and `sd()` are used for a paired  $z$  test to compute the standard deviation of the differences between paired observations. By default, a common standard deviation of one, `sd(1)`, is assumed for both populations. Alternatively, the standard deviation of the differences between paired observations may be supplied directly with the `sddiff()` option.

## Remarks and examples

Remarks are presented under the following headings:

*One-sample z test*  
*Two-sample z test*  
*Paired z test*  
*Adjust for clustering*  
*Immediate form*

For the purpose of illustration, we assume that variances are known in all the examples below.

### One-sample z test

#### ▷ Example 1

In the first form, `ztest` tests whether the mean of the sample is equal to a known constant under the assumption of known variance. Assume that we have a sample of 74 automobiles. We know each automobile's average mileage rating and wish to test whether the overall average for the sample is 20 miles per gallon. We also assume that the population standard deviation is 6.

```
. use https://www.stata-press.com/data/r19/auto
(1978 automobile data)
. ztest mpg==20, sd(6)
```

One-sample z test

| Variable | Obs | Mean    | Std. err. | Std. dev. | [95% conf. interval] |          |
|----------|-----|---------|-----------|-----------|----------------------|----------|
| mpg      | 74  | 21.2973 | .6974858  | 6         | 19.93025             | 22.66434 |

```
mean = mean(mpg) z = 1.8600
HO: mean = 20
Ha: mean < 20 Ha: mean != 20 Ha: mean > 20
Pr(Z < z) = 0.9686 Pr(|Z| > |z|) = 0.0629 Pr(Z > z) = 0.0314
```

The  $p$ -value for the two-sided test is 0.0629, so we do not have statistical evidence to reject the null hypothesis that the mean equals 20 at a 5% significance level, but we would reject the null hypothesis at a 10% level.

## Two-sample z test

### ▷ Example 2: Two-sample z test using groups

We are testing the effectiveness of a new fuel additive. We run an experiment in which 12 cars are given the fuel treatment and 12 cars are not. The results of the experiment are as follows:

| treated | mpg |
|---------|-----|
| 0       | 20  |
| 0       | 23  |
| 0       | 21  |
| 0       | 25  |
| 0       | 18  |
| 0       | 17  |
| 0       | 18  |
| 0       | 24  |
| 0       | 20  |
| 0       | 24  |
| 0       | 23  |
| 0       | 19  |
| 1       | 24  |
| 1       | 25  |
| 1       | 21  |
| 1       | 22  |
| 1       | 23  |
| 1       | 18  |
| 1       | 17  |
| 1       | 28  |
| 1       | 24  |
| 1       | 27  |
| 1       | 21  |
| 1       | 23  |

The treated variable is coded as 1 if the car received the fuel treatment and 0 otherwise.

We can test the equality of means of the treated and untreated group by typing

```
. use https://www.stata-press.com/data/r19/fuel3
. ztest mpg, by(treated) sd(3)
```

Two-sample z test

| Group | Obs | Mean  | Std. err. | Std. dev. | [95% conf. interval] |          |
|-------|-----|-------|-----------|-----------|----------------------|----------|
| 0     | 12  | 21    | .8660254  | 3         | 19.30262             | 22.69738 |
| 1     | 12  | 22.75 | .8660254  | 3         | 21.05262             | 24.44738 |
| diff  |     | -1.75 | 1.224745  |           | -4.150456            | .6504558 |

```
diff = mean(0) - mean(1) z = -1.4289
HO: diff = 0
Ha: diff < 0 Ha: diff != 0 Ha: diff > 0
Pr(Z < z) = 0.0765 Pr(|Z| > |z|) = 0.1530 Pr(Z > z) = 0.9235
```

We do not have evidence to reject the null hypothesis that the means of the two groups are equal at a 5% significance level.

In the above, we assumed that the two groups have the same standard deviation of 3. If the standard deviations for the two groups are different, we can specify group-specific standard deviations in options `sd1()` and `sd2()`:

```
. ztest mpg, by(treated) sd1(2.7) sd2(3.2)
Two-sample z test
```

| Group | Obs | Mean  | Std. err. | Std. dev. | [95% conf. interval] |          |
|-------|-----|-------|-----------|-----------|----------------------|----------|
| 0     | 12  | 21    | .7794229  | 2.7       | 19.47236             | 22.52764 |
| 1     | 12  | 22.75 | .9237604  | 3.2       | 20.93946             | 24.56054 |
| diff  |     | -1.75 | 1.208649  |           | -4.118909            | .6189093 |

```
diff = mean(0) - mean(1) z = -1.4479
HO: diff = 0
Ha: diff < 0 Ha: diff != 0 Ha: diff > 0
Pr(Z < z) = 0.0738 Pr(|Z| > |z|) = 0.1476 Pr(Z > z) = 0.9262
```

### □ Technical note

In two-sample randomized designs, subjects will sometimes refuse the assigned treatment but still be measured for an outcome. In this case, take care to specify the group properly. You might be tempted to let *varname* contain missing where the subject refused and thus let `ztest` drop such observations from the analysis. [Zelen \(1979\)](#) argues that it would be better to specify that the subject belongs to the group in which he or she was randomized, even though such inclusion will dilute the measured effect.

### ▷ Example 3: Two-sample z test using variables

There is a second, inferior way to organize the data in the preceding example. We ran a test on 24 cars, 12 without the additive and 12 with. We now create two new variables, `mpg1` and `mpg2`.

| mpg1 | mpg2 |
|------|------|
| 20   | 24   |
| 23   | 25   |
| 21   | 21   |
| 25   | 22   |
| 18   | 23   |
| 17   | 18   |
| 18   | 17   |
| 24   | 28   |
| 20   | 24   |
| 24   | 27   |
| 23   | 21   |
| 19   | 23   |

This method is inferior because it suggests a connection that is not there. There is no link between the car with 20 mpg and the car with 24 mpg in the first row of the data. Each column of data could be arranged in any order. Nevertheless, if our data are organized like this, `ztest` can accommodate us.

```
. use https://www.stata-press.com/data/r19/fuel
. ztest mpg1==mpg2, unpaired sd(3)
```

Two-sample z test

| Variable | Obs | Mean  | Std. err. | Std. dev. | [95% conf. interval] |          |
|----------|-----|-------|-----------|-----------|----------------------|----------|
| mpg1     | 12  | 21    | .8660254  | 3         | 19.30262             | 22.69738 |
| mpg2     | 12  | 22.75 | .8660254  | 3         | 21.05262             | 24.44738 |
| diff     |     | -1.75 | 1.224745  |           | -4.150456            | .6504558 |

```
diff = mean(mpg1) - mean(mpg2) z = -1.4289
H0: diff = 0
Ha: diff < 0 Ha: diff != 0 Ha: diff > 0
Pr(Z < z) = 0.0765 Pr(|Z| > |z|) = 0.1530 Pr(Z > z) = 0.9235
```

## Paired z test

### ▷ Example 4

Suppose that the preceding data were actually collected by running a test on 12 cars. Each car was run once with the fuel additive and once without. Our data are stored in the same manner as in [example 3](#), but this time, there is most certainly a connection between the mpg values that appear in the same row. These come from the same car. The variables mpg1 and mpg2 represent mileage without and with the treatment, respectively. Suppose that the two variables have a common standard deviation of 2 and the correlation between them is 0.4.

```
. use https://www.stata-press.com/data/r19/fuel
. ztest mpg1==mpg2, sd(2) corr(0.4)
```

Paired z test

| Variable | Obs | Mean  | Std. err. | Std. dev. | [95% conf. interval] |           |
|----------|-----|-------|-----------|-----------|----------------------|-----------|
| mpg1     | 12  | 21    | .5773503  | 2         | 19.86841             | 22.13159  |
| mpg2     | 12  | 22.75 | .5773503  | 2         | 21.61841             | 23.88159  |
| diff     | 12  | -1.75 | .6324555  | 2.19089   | -2.98959             | -.5104099 |

```
mean(diff) = mean(mpg1 - mpg2) z = -2.7670
H0: mean(diff) = 0
Ha: mean(diff) < 0 Ha: mean(diff) != 0 Ha: mean(diff) > 0
Pr(Z < z) = 0.0028 Pr(|Z| > |z|) = 0.0057 Pr(Z > z) = 0.9972
```

The *p*-value for the two-sided test is 0.0057, so we reject, for example, the null hypothesis that the two means are equal at a 5% significance level.

Equivalently, we could specify directly the standard deviation of the differences between paired observations with the `sddiff()` option:

```
. ztest mpg1==mpg2, sddiff(2.191)
Paired z test
```

| Variable | Obs | Mean  | Std. err. | Std. dev. | [95% conf. interval] |           |
|----------|-----|-------|-----------|-----------|----------------------|-----------|
| diff     | 12  | -1.75 | .6324872  | 2.191     | -2.989652            | -.5103478 |

```

 mean(diff) = mean(mpg1 - mpg2) z = -2.7669
HO: mean(diff) = 0
Ha: mean(diff) < 0 Ha: mean(diff) != 0 Ha: mean(diff) > 0
Pr(Z < z) = 0.0028 Pr(|Z| > |z|) = 0.0057 Pr(Z > z) = 0.9972

```

◀

## Adjust for clustering

When observations are not independent and can be grouped into clusters, we need to adjust for clustering in a  $z$  test. For example, in a cluster randomized design, groups of individuals are randomized instead of individuals. To adjust for clustering, we need to specify the cluster identifier variable in the `cluster()` option. In the case of a one-sample  $z$  test, we need to also specify the intraclass correlation in the `rho()` option. In the case of a two-sample  $z$  test, we need to also specify the common population intraclass correlation in the `rho()` option or group-specific population intraclass correlations in the `rho1()` and `rho2()` options.

### ► Example 5: One-sample $z$ test, adjusting for clusters

Consider data on the SAT score of 75 students from 15 classes, with 5 students in each class. We want to test whether the mean verbal SAT score is different from 600. We assume a known standard deviation of 132 and a known intraclass correlation of 0.7. To perform the test, we specify the options `cluster(class)`, `rho(0.7)`, and `sd(132)`:

```
. use https://www.stata-press.com/data/r19/sat
(Fictional SAT data)
. ztest score == 600, cluster(class) rho(0.7) sd(132)
```

|                         |                      |        |
|-------------------------|----------------------|--------|
| One-sample z test       | Number of clusters = | 15     |
| Cluster variable: class | Cluster size =       | 5      |
|                         | Intraclass corr. =   | 0.7000 |

| Variable | Obs | Mean  | Std. err. | Std. dev. | [95% conf. interval] |          |
|----------|-----|-------|-----------|-----------|----------------------|----------|
| score    | 75  | 504.8 | 29.71222  | 132       | 446.5651             | 563.0349 |

```

 mean = mean(score) z = -3.2041
HO: mean = 600
Ha: mean < 600 Ha: mean != 600 Ha: mean > 600
Pr(Z < z) = 0.0007 Pr(|Z| > |z|) = 0.0014 Pr(Z > z) = 0.9993

```

We find statistical evidence to reject the null hypothesis of  $H_0: \mu_{\text{SAT}} = 600$  versus a two-sided alternative  $H_a: \mu_{\text{SAT}} \neq 600$  at the 5% significance level; the  $p$ -value =  $0.0014 < 0.05$ .

◀

### ▷ Example 6: Two-sample $z$ test using groups, adjusting for clusters

Consider a cluster randomized control trial that studies the effect of additional training of nurses and general practitioners in patient-centered care on the well-being and future disease risk of patients with type 2 diabetes (Kinmonth et al. [1998] and Campbell and Walters [2014]). Practices (practice) are randomly allocated to two groups—one trained to give patient-centered care (intervention group) and another trained to give routine care (comparison or control group). In our analysis, we transform the original bmi using the formula  $\ln(\text{bmi} - 14.67355)$  to obtain a variable that is approximately normally distributed, lbmi. We want to test the equality of the means of lbmi for the two groups. We assume a known common standard deviation of 0.35 and a known common intraclass correlation of 0.028.

To perform the test, we need to specify the `rho(0.028)` and `sd(0.35)` options. We also need to specify the cluster identifier `practice` in the `cluster()` option and the group identifier `group` in the `by()` option.

```
. use https://www.stata-press.com/data/r19/dcfdf_trial
(BMI data from Diabetes Care from Diagnosis trial (Kinmonth et al., 1998))
. ztest lbmi, by(group) cluster(practice) rho(0.028) sd(0.35)
```

Two-sample z test  
Cluster variable: practice

| Group: Control       |        | Group: Interv.       |        |
|----------------------|--------|----------------------|--------|
| Number of clusters = | 20     | Number of clusters = | 18     |
| Avg. cluster size =  | 5.10   | Avg. cluster size =  | 7.67   |
| CV cluster size =    | 0.5330 | CV cluster size =    | 0.5126 |
| Intraclass corr. =   | 0.0280 | Intraclass corr. =   | 0.0280 |

| Group   | Obs | Mean      | Std. err. | Std. dev. | [95% conf. interval] |           |
|---------|-----|-----------|-----------|-----------|----------------------|-----------|
| Control | 102 | 2.62954   | .0372502  | .35       | 2.556531             | 2.702549  |
| Interv. | 138 | 2.749023  | .0332182  | .35       | 2.683916             | 2.81413   |
| diff    |     | -.1194831 | .0499102  |           | -.2173054            | -.0216608 |

```
diff = mean(Control) - mean(Interv.) z = -2.3940
HO: diff = 0
Ha: diff < 0 Ha: diff != 0 Ha: diff > 0
Pr(Z < z) = 0.0083 Pr(|Z| > |z|) = 0.0167 Pr(Z > z) = 0.9917
```

We find statistical evidence to reject the null hypothesis of  $H_0: \mu_{\text{diff}} = 0$  versus a two-sided alternative  $H_a: \mu_{\text{diff}} \neq 0$  at the 5% significance level; the  $p$ -value = 0.0167 < 0.05.

◀

## Immediate form

### ▷ Example 7: One-sample $z$ test

`ztesti` is like `ztest`, except that we specify summary statistics rather than variables as arguments. For instance, we are reading an article that reports the mean number of sunspots per month as 62.6 with a standard deviation of 15.8. We assume this standard deviation is the population standard deviation. There are 24 months of data. We wish to test whether the mean is 75:

```
. zttesti 24 62.6 15.8 75
```

One-sample z test

|   | Obs | Mean | Std. err. | Std. dev. | [95% conf. interval] |         |
|---|-----|------|-----------|-----------|----------------------|---------|
| x | 24  | 62.6 | 3.225161  | 15.8      | 56.2788              | 68.9212 |

```
mean = mean(x) z = -3.8448
HO: mean = 75
Ha: mean < 75 Ha: mean != 75 Ha: mean > 75
Pr(Z < z) = 0.0001 Pr(|Z| > |z|) = 0.0001 Pr(Z > z) = 0.9999
```

### ▷ Example 8: Two-sample z test

There is no immediate form of `zttest` with paired data because the test is also a function of the covariance, a number unlikely to be reported in any published source. For unpaired data, however, we might type

```
. zttesti 20 20 5 32 15 4
```

Two-sample z test

|      | Obs | Mean | Std. err. | Std. dev. | [95% conf. interval] |          |
|------|-----|------|-----------|-----------|----------------------|----------|
| x    | 20  | 20   | 1.118034  | 5         | 17.80869             | 22.19131 |
| y    | 32  | 15   | .7071068  | 4         | 13.6141              | 16.3859  |
| diff |     | 5    | 1.322876  |           | 2.407211             | 7.592789 |

```
diff = mean(x) - mean(y) z = 3.7796
HO: diff = 0
Ha: diff < 0 Ha: diff != 0 Ha: diff > 0
Pr(Z < z) = 0.9999 Pr(|Z| > |z|) = 0.0002 Pr(Z > z) = 0.0001
```

## Stored results

One-sample `zttest` and `zttesti` store the following in `r()`:

Scalars

- `r(N)` sample size
- `r(mu)` sample mean
- `r(sd)` standard deviation
- `r(se)` standard error
- `r(lb)` lower confidence bound of one-sample mean
- `r(ub)` upper confidence bound of one-sample mean
- `r(z)` z statistic
- `r(p_l)` lower one-sided p-value
- `r(p)` two-sided p-value
- `r(p_u)` upper one-sided p-value
- `r(level)` confidence level

Cluster-adjusted one-sample `ztest` also stores the following in `r()`:

Scalars

|                            |                                            |
|----------------------------|--------------------------------------------|
| <code>r(K)</code>          | number of clusters $K$                     |
| <code>r(M)</code>          | cluster size $M$                           |
| <code>r(rho)</code>        | intraclass correlation                     |
| <code>r(CV_cluster)</code> | coefficient of variation for cluster sizes |

Two-sample `ztest` and `ztesti` store the following in `r()`:

Scalars

|                         |                                                                                         |
|-------------------------|-----------------------------------------------------------------------------------------|
| <code>r(N1)</code>      | sample size of population one                                                           |
| <code>r(N2)</code>      | sample size of population two                                                           |
| <code>r(mu1)</code>     | sample mean for population one                                                          |
| <code>r(mu2)</code>     | sample mean for population two                                                          |
| <code>r(mu_diff)</code> | difference of means                                                                     |
| <code>r(corr)</code>    | correlation between paired observations; if the <code>corr()</code> option is specified |
| <code>r(sd)</code>      | common standard deviation                                                               |
| <code>r(sd1)</code>     | standard deviation for population one                                                   |
| <code>r(sd2)</code>     | standard deviation for population two                                                   |
| <code>r(sd_diff)</code> | standard deviation of the differences between paired observations                       |
| <code>r(se1)</code>     | standard error of population-one sample mean                                            |
| <code>r(se2)</code>     | standard error of population-two sample mean                                            |
| <code>r(se_diff)</code> | standard error of the difference of means                                               |
| <code>r(lb1)</code>     | lower confidence bound of population-one sample mean                                    |
| <code>r(ub1)</code>     | upper confidence bound of population-one sample mean                                    |
| <code>r(lb2)</code>     | lower confidence bound of population-two sample mean                                    |
| <code>r(ub2)</code>     | upper confidence bound of population-two sample mean                                    |
| <code>r(lb_diff)</code> | lower confidence bound of the difference of means                                       |
| <code>r(ub_diff)</code> | upper confidence bound of the difference of means                                       |
| <code>r(z)</code>       | $z$ statistic                                                                           |
| <code>r(p_1)</code>     | lower one-sided $p$ -value                                                              |
| <code>r(p)</code>       | two-sided $p$ -value                                                                    |
| <code>r(p_u)</code>     | upper one-sided $p$ -value                                                              |
| <code>r(level)</code>   | confidence level                                                                        |

Cluster-adjusted two-sample `ztest` using the `by()` option also stores the following in `r()`:

Scalars

|                             |                                                           |
|-----------------------------|-----------------------------------------------------------|
| <code>r(K1)</code>          | population-one number of clusters $K_1$                   |
| <code>r(K2)</code>          | population-two number of clusters $K_2$                   |
| <code>r(M1)</code>          | population-one cluster size $M_1$                         |
| <code>r(M2)</code>          | population-two cluster size $M_2$                         |
| <code>r(rho)</code>         | common intraclass correlation                             |
| <code>r(rho1)</code>        | population-one intraclass correlation                     |
| <code>r(rho2)</code>        | population-two intraclass correlation                     |
| <code>r(CV_cluster1)</code> | population-one coefficient of variation for cluster sizes |
| <code>r(CV_cluster2)</code> | population-two coefficient of variation for cluster sizes |

## Methods and formulas

Methods and formulas are presented under the following headings:

*One-sample  $z$  test*

*Two-sample unpaired  $z$  test*

*Paired  $z$  test*

For all the tests below, the test statistic  $z$  is distributed as standard normal, and the  $p$ -value is computed as

$$p = \begin{cases} 1 - \Phi(z) & \text{for an upper one-sided test} \\ \Phi(z) & \text{for a lower one-sided test} \\ 2\{1 - \Phi(|z|)\} & \text{for a two-sided test} \end{cases}$$

where  $\Phi(\cdot)$  is the cdf of a standard normal distribution and  $|z|$  is an absolute value of  $z$ .

Also see, for instance, [Hoel \(1984, 140–161\)](#), [Dixon and Massey \(1983, 100–130\)](#), and [Tamhane and Dunlop \(2000, 237–290\)](#) for more information about  $z$  tests.

## One-sample $z$ test

Suppose that we observe a random sample  $x_1, x_2, \dots, x_n$  of size  $n$ , which follows a normal distribution with mean  $\mu$  and standard deviation  $\sigma$ . We are interested in testing the null hypothesis  $H_0: \mu = \mu_0$  versus the two-sided alternative hypothesis  $H_a: \mu \neq \mu_0$ , the upper one-sided alternative  $H_a: \mu > \mu_0$ , or the lower one-sided alternative  $H_a: \mu < \mu_0$ . Assuming a known standard deviation  $\sigma$ , we use the following test statistic,

$$z = \frac{(\bar{x} - \mu_0)}{s}$$

where  $\bar{x} = (\sum_{i=1}^n x_i)/n$  is the sample mean and  $s = \sigma/\sqrt{n}$  is the standard error of  $\bar{x}$ .

The  $100(1 - \alpha)\%$  confidence interval for  $\bar{x}$  is given by

$$\bar{x} \pm z_{1-\alpha/2}s$$

where  $z_{1-\alpha/2}$  is the  $(1 - \alpha/2)$ th quantile of the standard normal distribution.

With clustered data, suppose that there are  $K$  clusters. The  $i$ th cluster of size  $M_i$  contains the observations  $x_{i1}, x_{i2}, \dots, x_{iM_i}$ , such that  $n = \sum_{i=1}^K M_i$  and  $\bar{x} = \frac{1}{n} \sum_{i=1}^K \sum_{j=1}^{M_i} x_{ij}$ . Let  $\rho$  be the intraclass correlation. Following [Ahn, Heo, and Zhang \(2015\)](#), we assume that the cluster sizes  $M_i$  are independent and identically distributed. Let  $C_{\text{adj}}$  be the adjustment to the standard error for clustered data,

$$C_{\text{adj}} = \sqrt{\sum_{i=1}^K M_i \{1 + \rho(M_i - 1)\} / n}$$

such that  $s_{\text{cl}} = C_{\text{adj}}s$ .

$C_{\text{adj}}$  can be equivalently written as

$$C_{\text{adj}} = \sqrt{1 + \rho(\bar{M} - 1) + \rho\bar{M}CV_{\text{cl}}^2}$$

where  $\bar{M} = \sum_{i=1}^K M_i/K$  is the average cluster size and  $CV_{\text{cl}}$  is the coefficient of variation for cluster sizes:

$$CV_{\text{cl}} = \frac{\sqrt{\sum_{i=1}^K (M_i - \bar{M})^2 / K}}{\bar{M}}$$

To adjust the test statistic  $z$  and the confidence interval for clustering, replace  $s$  with  $s_{\text{cl}}$  in the corresponding formulas. In the presence of clustering, the test statistic  $z$  is asymptotically normally distributed conditional on the empirical distribution of  $M_i$ 's.

## Two-sample unpaired z test

Suppose that we observe a random sample  $x_{11}, x_{12}, \dots, x_{1n_1}$  of size  $n_1$ , which follows a normal distribution with mean  $\mu_1$  and standard deviation  $\sigma_1$ , and another random sample  $x_{21}, x_{22}, \dots, x_{2n_2}$  of size  $n_2$ , which follows a normal distribution with mean  $\mu_2$  and standard deviation  $\sigma_2$ . We are interested in testing the null hypothesis  $H_0: \mu_2 = \mu_1$  versus the two-sided alternative hypothesis  $H_a: \mu_2 \neq \mu_1$ , the upper one-sided alternative  $H_a: \mu_2 > \mu_1$ , or the lower one-sided alternative  $H_a: \mu_2 < \mu_1$ . Assuming known standard deviations  $\sigma_1$  and  $\sigma_2$ , we use the following test statistic,

$$z = \frac{\bar{x}_2 - \bar{x}_1}{\sqrt{s_1^2 + s_2^2}}$$

where  $\bar{x}_1 = (\sum_{i=1}^{n_1} x_{1i})/n_1$  and  $\bar{x}_2 = (\sum_{i=1}^{n_2} x_{2i})/n_2$  are the two sample means and  $s_1 = \sigma_1/\sqrt{n_1}$  and  $s_2 = \sigma_2/\sqrt{n_2}$  are the corresponding two standard errors.

The  $100(1 - \alpha)\%$  confidence intervals for  $\bar{x}_1$  and  $\bar{x}_2$  are given by

$$\begin{aligned} \bar{x}_1 \pm z_{1-\alpha/2} s_1 \\ \bar{x}_2 \pm z_{1-\alpha/2} s_2 \end{aligned}$$

where  $z_{1-\alpha/2}$  is the  $(1 - \alpha/2)$ th quantile of the standard normal distribution.

The  $100(1 - \alpha)\%$  confidence interval for  $\bar{x}_1 - \bar{x}_2$  is given by

$$\bar{x}_1 - \bar{x}_2 \pm z_{1-\alpha/2} \sqrt{s_1^2 + s_2^2}$$

With clustered data, similar to the discussion for the one-sample test, suppose that population one has  $K_1$  clusters and population two has  $K_2$  clusters. Let  $\rho_1$  and  $\rho_2$  be the intraclass correlations,  $\bar{M}_1$  and  $\bar{M}_2$  be the average cluster sizes,  $\bar{x}_1 = (1/n_1) \sum_{i=1}^{K_1} \sum_{j=1}^{M_{1i}} x_{1ij}$  and  $\bar{x}_2 = (1/n_2) \sum_{i=1}^{K_2} \sum_{j=1}^{M_{2i}} x_{2ij}$  be the sample means, and  $\text{CV}_{\text{cl},1}$  and  $\text{CV}_{\text{cl},2}$  be the coefficients of variation for cluster sizes for population one and population two. Let  $s_{1,\text{cl}} = C_{\text{adj},1} s_1$  and  $s_{2,\text{cl}} = C_{\text{adj},2} s_2$  be the standard errors of the population-specific sample means adjusted for clustered data, where the population-specific adjustment factors are defined as described for the one-sample test. To adjust the two-sample test statistic and the confidence intervals for clustering, replace  $s_1$  with  $s_{1,\text{cl}}$  and  $s_2$  with  $s_{2,\text{cl}}$  in the corresponding formulas.

## Paired z test

Some experiments have paired observations (also known as matched observations, correlated pairs, or permanent components). Consider a sequence of  $n$  paired observations denoted by  $x_{ij}$  for subjects  $i = 1, 2, \dots, n$  and groups  $j = 1, 2$ . An individual observation corresponds to the pair  $(x_{i1}, x_{i2})$ , and inference is made on the differences within the pairs. Let  $\mu_d = \mu_2 - \mu_1$  denote the mean difference, where  $\mu_j$  is the population mean of group  $j$ , and let  $D_i = x_{i2} - x_{i1}$  denote the difference between individual observations.  $D_i$  follows a normal distribution with mean  $\mu_2 - \mu_1$  and standard deviation  $\sigma_d$ , where  $\sigma_d = \sqrt{\sigma_1^2 + \sigma_2^2 - 2\rho_{\text{pair}}\sigma_1\sigma_2}$ ,  $\sigma_j$  is the population standard deviation of group  $j$  and  $\rho_{\text{pair}}$  is the correlation between paired observations.

We are interested in testing the null hypothesis  $H_0: \mu_2 = \mu_1$  versus the two-sided alternative hypothesis  $H_a: \mu_2 \neq \mu_1$ , the upper one-sided alternative  $H_a: \mu_2 > \mu_1$ , or the lower one-sided alternative  $H_a: \mu_2 < \mu_1$ . Assuming the standard deviation of the differences  $\sigma_d$  is known, we use the following test statistic,

$$z = \frac{\bar{d}}{s_d}$$

where  $\bar{d} = (\sum_{i=1}^n D_i)/n$  is the sample mean of the differences between paired observations and  $s_d = \sigma_d/\sqrt{n}$  is the standard error of  $\bar{d}$ .

The  $100(1 - \alpha)\%$  confidence interval for  $\bar{d}$  is given by

$$\bar{d} \pm z_{1-\alpha/2} s_d$$
