`vce(unconditional)` specifies that the covariates that are not fixed be treated in a way that accounts for their having been sampled. The VCE is estimated using the linearization method. This method allows for heteroskedasticity or other violations of distributional assumptions and allows for correlation among the observations in the same manner as `vce(robust)` and `vce(cluster...)`, which may have been specified with the estimation command. This method also accounts for complex survey designs if the data are `svyset`. See [Obtaining margins with survey data and representative samples](#). When you use complex survey data, this method requires that the linearized variance estimation method be used for the model. See [SVY] [svy postestimation](#) for an example of margins with replication-based methods.

`nose` suppresses calculation of the VCE and standard errors. See [Requirements for model specification](#) for an example of the use of this option.

#### Advanced

`noweights` specifies that any weights specified on the previous estimation command be ignored by `margins`. By default, `margins` uses the weights specified on the estimator to average responses and to compute summary statistics. If weights are specified on the `margins` command, they override previously specified weights, making it unnecessary to specify `noweights`. The `noweights` option is not allowed after `svy:` estimation when the `vce(unconditional)` option is specified.

For multilevel models, such as `meglm`, the default behavior is to construct a single weight value for each observation by multiplying the corresponding multilevel weights within the given observation.

`noesample` specifies that `margins` not restrict its computations to the estimation sample used by the previous estimation command. See [Example 15: Margins evaluated out of sample](#).

With the default delta-method VCE, `noesample` margins may be estimated on samples other than the estimation sample; such results are valid under the assumption that the data used are treated as being given.

You can specify `noesample` and `vce(unconditional)` together, but if you do, you should be sure that the data in memory correspond to the original `e(sample)`. To show that you understand that, you must also specify the `force` option. Be aware that making the `vce(unconditional)` calculation on a sample different from the estimation sample would be equivalent to estimating the coefficients on one set of data and computing the scores used by the linearization on another set; see [P] [\\_robust](#).

`emptycells(strict)` and `emptycells(reweight)` are relevant only when the `asbalanced` option is also specified. `emptycells()` specifies how empty cells are handled in interactions involving factor variables that are being treated as balanced; see [Obtaining margins as though the data were balanced](#).

`emptycells(strict)` is the default; it specifies that margins involving empty cells be treated as not estimable.

`emptycells(reweight)` specifies that the effects of the observed cells be increased to accommodate any missing cells. This makes the margin estimable but changes its interpretation. `emptycells(reweight)` is implied when the `within()` option is specified.

`estimtolerance(tol)` specifies the numerical tolerance used to determine estimable functions. The default is `estimtolerance(1e-5)`.

A linear combination of the model coefficients  $z$  is found to be not estimable if

$$\text{mreldif}(z, z \times H) > \text{tol}$$

where  $H$  is defined in [Methods and formulas](#).

`noestimcheck` specifies that margins not check for estimability. By default, the requested margins are checked and those found not estimable are reported as such. Nonestimability is usually caused by empty cells. If `noestimcheck` is specified, estimates are computed in the usual way and reported even though the resulting estimates are manipulable, which is to say they can differ across equivalent models having different parameterizations. See [Estimability of margins](#).

`force` instructs margins to proceed in some situations where it would otherwise issue an error message because of apparent violations of assumptions. Do not be casual about specifying `force`. You need to understand and fully evaluate the statistical issues. For an example of the use of `force`, see [Using margins after the estimates use command](#).

`chainrule` and `nochainrule` specify whether margins uses the chain rule when numerically computing derivatives. You need not specify these options when using margins after any official Stata estimator; margins will choose the appropriate method automatically.

Specify `nochainrule` after estimation by a community-contributed command. We recommend using `nochainrule`, even though `chainrule` is usually safe and is always faster. `nochainrule` is safer because it makes no assumptions about how the parameters and covariates join to form the response.

`nochainrule` is implied when the `expression()` option is specified.

#### Reporting

`level(#)` specifies the confidence level, as a percentage, for confidence intervals. The default is `level(95)` or as set by `set level`; see [U] [20.8 Specifying the width of confidence intervals](#).

`mcompare(method)` specifies the method for computing  $p$ -values and confidence intervals that account for multiple comparisons within a factor-variable term.

Most methods adjust the comparisonwise error rate,  $\alpha_c$ , to achieve a prespecified experimentwise error rate,  $\alpha_e$ .

`mcompare(noadjust)` is the default; it specifies no adjustment.

$$\alpha_c = \alpha_e$$

`mcompare(bonferroni)` adjusts the comparisonwise error rate based on the upper limit of the Bonferroni inequality

$$\alpha_e \leq m\alpha_c$$

where  $m$  is the number of comparisons within the term.

The adjusted comparisonwise error rate is

$$\alpha_c = \alpha_e/m$$

`mcompare(sidak)` adjusts the comparisonwise error rate based on the upper limit of the probability inequality

$$\alpha_e \leq 1 - (1 - \alpha_c)^m$$

where  $m$  is the number of comparisons within the term.

The adjusted comparisonwise error rate is

$$\alpha_c = 1 - (1 - \alpha_e)^{1/m}$$

This adjustment is exact when the  $m$  comparisons are independent.

`mcompare(scheffe)` controls the experimentwise error rate using the  $F$  or  $\chi^2$  distribution with degrees of freedom equal to the rank of the term.

`mcompare(method adjustall)` specifies that the multiple-comparison adjustments count all comparisons across all terms rather than performing multiple comparisons term by term. This leads to more conservative adjustments when multiple variables or terms are specified in *marginslist*. This option is compatible only with the `bonferroni` and `sidak` methods.

`noatlegend` specifies that the legend showing the fixed values of covariates be suppressed.

`post` causes `margins` to behave like a Stata estimation (e-class) command. `margins` posts the vector of estimated margins along with the estimated variance–covariance matrix to `e()`, so you can treat the estimated margins just as you would results from any other estimation command. For example, you could use `test` to perform simultaneous tests of hypotheses on the margins, or you could use `lincom` to create linear combinations. See [Example 10: Testing margins—contrasts of margins](#).

*display\_options*: `noci`, `nopvalues`, `vsquish`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `noIstretch`.

`noci` suppresses confidence intervals from being reported in the coefficient table.

`nopvalues` suppresses  $p$ -values and their test statistics from being reported in the coefficient table.

`vsquish` specifies that the blank space separating factor-variable terms or time-series–operated variables from other variables in the model be suppressed.

`nofvlabel` displays factor-variable level values rather than attached value labels. This option overrides the `fvlabel` setting; see [\[R\] set showbaselevels](#).

`fvwrap(#)` allows long value labels to wrap the first  $\#$  lines in the coefficient table. This option overrides the `fvwrap` setting; see [\[R\] set showbaselevels](#).

`fvwrapon(style)` specifies whether value labels that wrap will break at word boundaries or break based on available space.

`fvwrapon(word)`, the default, specifies that value labels break at word boundaries.

`fvwrapon(width)` specifies that value labels break based on available space.

This option overrides the `fvwrapon` setting; see [R] [set showbaselevels](#).

`cformat(%fmt)` specifies how to format margins, standard errors, and confidence limits in the table of estimated margins.

`pformat(%fmt)` specifies how to format  $p$ -values in the table of estimated margins.

`sformat(%fmt)` specifies how to format test statistics in the table of estimated margins.

`no1stretch` specifies that the width of the table of estimated margins not be automatically widened to accommodate longer variable names. The default, `1stretch`, is to automatically widen the table of estimated margins up to the width of the Results window. Specifying `1stretch` or `no1stretch` overrides the setting given by [set 1stretch](#). If `set 1stretch` has not been set, the default is `1stretch`. `no1stretch` is not shown in the dialog box.

The following option is available with `margins` but is not shown in the dialog box:

`df(#)` specifies that the  $t$  distribution with  $\#$  degrees of freedom be used for computing  $p$ -values and confidence intervals. The default typically is to use the standard normal distribution. However, if the estimation command computes the residual degrees of freedom (`e(df_r)`) and `predict(xb)` is specified with `margins`, the default is to use the  $t$  distribution with `e(df_r)` degrees of freedom.

## Remarks and examples

Remarks are presented under the following headings:

### Introduction

#### Obtaining margins of responses

## Introduction

`margins` is a postestimation command, a command for use after you have fit a model using an estimation command such as `regress` or `logistic`, or using almost any other estimation command.

`margins` estimates and reports margins of responses and margins of derivatives of responses, also known as marginal effects. A margin is a statistic based on a fitted model in which some of or all the covariates are fixed. Marginal effects are changes in the response for change in a covariate, which can be reported as a derivative, elasticity, or semielasticity.

For a brief overview of `margins`, see [Williams \(2012\)](#).

## Obtaining margins of responses

What we call margins of responses are also known as predictive margins, adjusted predictions, and recycled predictions. When applied to [balanced data](#), margins of responses are also called [estimated marginal means](#) and least-squares means.

A margin is a statistic based on a fitted model calculated over a dataset in which some of or all the covariates are fixed at values different from what they really are. For instance, after a linear regression fit on males and females, the marginal mean (margin of mean) for males is the predicted mean of the dependent variable, where every observation is treated as if it represents a male; thus, those observations that in fact do represent males are included, as well as those observations that represent females. The marginal mean for females would be similarly obtained by treating all observations as if they represented females.

In making the calculation, `sex` is treated as male or female everywhere it appears in the model. The model might be

```
. regress y age bp i.sex sex#c.age sex#c.bp
```

and then, in making the marginal calculation of the mean for males and females, `margins` not only accounts for the direct effect of `i.sex` but also for the indirect effects of `sex#c.age` and `sex#c.bp`.

The response being margined can be any statistic produced by `[R] predict`, or any expression of those statistics.

Standard errors are obtained by the delta method, at least by default. The delta method assumes that the values at which the covariates are evaluated to obtain the marginal responses are fixed. When your sample represents a population, whether you are using `svy` or not (see `[SVY] svy`), you can specify `margins' vce(unconditional)` option and `margins` will produce standard errors that account for the sampling variability of the covariates. Some researchers reserve the term predictive margins to describe this.

The best way to understand margins is to see some examples. You can run the following examples yourself if you type

```
. use https://www.stata-press.com/data/r19/margex
(Artificial data for margins)
```

### Example 1: A simple case after regress

```
. regress y i.sex i.group
(output omitted)
. margins sex
Predictive margins Number of obs = 3,000
Model VCE: OLS
Expression: Linear prediction, predict()
```

|        | Margin   | Delta-method<br>std. err. | t      | P> t  | [95% conf. interval] |          |
|--------|----------|---------------------------|--------|-------|----------------------|----------|
| sex    |          |                           |        |       |                      |          |
| Male   | 60.56034 | .5781782                  | 104.74 | 0.000 | 59.42668             | 61.69401 |
| Female | 78.88236 | .5772578                  | 136.65 | 0.000 | 77.7505              | 80.01422 |

The numbers reported in the Margin column are average values of the linear prediction of `y`, as noted above the output table after `Expression:.` Based on a linear regression of `y` on `sex` and `group`, 60.6 would be the average value of the linear prediction of `y` if everyone in the data were treated as if they were male, and 78.9 would be the average value if everyone were treated as if they were female.

### Example 2: A simple case after logistic

`margins` may be used after almost any estimation command.

```
. logistic outcome i.sex i.group
(output omitted)
. margins sex
Predictive margins Number of obs = 3,000
Model VCE: OIM
Expression: Pr(outcome), predict()
```

|        | Margin   | Delta-method<br>std. err. | z     | P> z  | [95% conf. interval] |          |
|--------|----------|---------------------------|-------|-------|----------------------|----------|
| sex    |          |                           |       |       |                      |          |
| Male   | .1286796 | .0111424                  | 11.55 | 0.000 | .106841              | .1505182 |
| Female | .1905087 | .0089719                  | 21.23 | 0.000 | .1729241             | .2080933 |

The numbers reported in the Margin column are average predicted probabilities. Based on a logistic regression of outcome on sex and group, 0.13 would be the average probability of outcome if everyone in the data were treated as if they were male, and 0.19 would be the average probability if everyone were treated as if they were female.

margins reports average values after regress and average probabilities after logistic. By default, margins makes tables of whatever it is that predict (see [R] predict) predicts by default. Alternatively, margins can make tables of anything that predict can produce if you use margins' predict() option; see *Example 11: Margins of a specified prediction*.

### Example 3: Average response versus response at average

In *example 2*, margins reported average probabilities of outcome for sex = 0 and sex = 1. If we instead wanted the predicted probabilities evaluated at the mean of the covariates, we would specify margins' atmeans option. We previously typed

```
. logistic outcome i.sex i.group
(output omitted)
. margins sex
(output omitted)
```

and now we type

```
. margins sex, atmeans
Adjusted predictions Number of obs = 3,000
Model VCE: OIM
Expression: Pr(outcome), predict()
At: 1.group = .3996667 (mean)
 2.group = .3726667 (mean)
 3.group = .2276667 (mean)
```

|        | Delta-method |           |       |       |                      |
|--------|--------------|-----------|-------|-------|----------------------|
|        | Margin       | std. err. | z     | P> z  | [95% conf. interval] |
| sex    |              |           |       |       |                      |
| Male   | .0966105     | .0089561  | 10.79 | 0.000 | .0790569 .1141641    |
| Female | .1508362     | .0118064  | 12.78 | 0.000 | .127696 .1739764     |

The average of the predictions, which we calculated in *example 2*, is different from the prediction at the average of the covariates that we calculate here. The first is the average of the probabilities among actual persons in the data. The second is the expected probability of a person with “average” characteristics; in this case, that person is 40% in group one, 37% in group two, and 23% in group three. Such a person cannot exist because membership in each group is exclusive, but margins uses regression coefficients to calculate the predicted response of the mythical “average” individual.

When you specify the atmeans or at() option, margins reports the values used for the covariates in the legend above the table. margins lists the values for all the covariates, including values it may not use, in the results that follow. In this example, margins reported means for sex even though those means were not used. They were not used because we asked for the margins of sex, so sex was fixed first at 0 and then at 1.

If you wish to suppress this legend, specify the nolegend option.

### Example 4: Multiple margins from one command

More than one margin can be reported by just one margins command. You can type

```
. margins sex group
```

and doing that is equivalent in terms of the output to typing

```
. margins sex
. margins group
```

When multiple margins are requested on the same command, each is estimated separately. There is, however, a difference when you also specify margins' post option. Then, the variance–covariance matrix for all margins requested is posted, and that is what allows you to test, for example, equality of margins. Testing equality of margins is covered in [Example 10: Testing margins—contrasts of margins](#).

In any case, below we request margins for sex and for group.

```
. margins sex group
Predictive margins Number of obs = 3,000
Model VCE: OIM
Expression: Pr(outcome), predict()
```

|              | Delta-method |           | z     | P> z  | [95% conf. interval] |          |
|--------------|--------------|-----------|-------|-------|----------------------|----------|
|              | Margin       | std. err. |       |       |                      |          |
| <b>sex</b>   |              |           |       |       |                      |          |
| Male         | .1286796     | .0111424  | 11.55 | 0.000 | .106841              | .1505182 |
| Female       | .1905087     | .0089719  | 21.23 | 0.000 | .1729241             | .2080933 |
| <b>group</b> |              |           |       |       |                      |          |
| 1            | .2826207     | .0146234  | 19.33 | 0.000 | .2539593             | .311282  |
| 2            | .1074814     | .0094901  | 11.33 | 0.000 | .0888812             | .1260817 |
| 3            | .0291065     | .0073417  | 3.96  | 0.000 | .0147169             | .043496  |

### Example 5: Margins with interaction terms

The estimation command on which margins bases its calculations may contain interaction terms, such as an interaction of `sex` and `group`:

```
. logistic outcome i.sex i.group sex#group
 (output omitted)
. margins sex group
Predictive margins Number of obs = 3,000
Model VCE: OIM
Expression: Pr(outcome), predict()
```

|              | Delta-method |           | z     | P> z  | [95% conf. interval] |          |
|--------------|--------------|-----------|-------|-------|----------------------|----------|
|              | Margin       | std. err. |       |       |                      |          |
| <b>sex</b>   |              |           |       |       |                      |          |
| Male         | .1561738     | .0132774  | 11.76 | 0.000 | .1301506             | .182197  |
| Female       | .1983749     | .0101546  | 19.54 | 0.000 | .1784723             | .2182776 |
| <b>group</b> |              |           |       |       |                      |          |
| 1            | .3211001     | .0176403  | 18.20 | 0.000 | .2865257             | .3556744 |
| 2            | .1152127     | .0099854  | 11.54 | 0.000 | .0956417             | .1347838 |
| 3            | .0265018     | .0109802  | 2.41  | 0.016 | .0049811             | .0480226 |

We fit the model by typing `logistic outcome i.sex i.group sex#group`, but the meaning would have been the same had we typed `logistic outcome sex##group`.

As mentioned in [example 4](#), the results for `sex` and the results for `group` are calculated independently, and we would have obtained the same results had we typed `margins sex` followed by `margins group`.

The margin for male (`sex = 0`) is 0.16. The probability 0.16 is the average probability if everyone in the data were treated as if `sex = 0`, including `sex = 0` in the main effect and `sex = 0` in the interaction of `sex` with `group`.

Had we specified `margins sex, atmeans`, we would have obtained not average probabilities but the probabilities evaluated at the average. Rather than obtaining 0.16, we would have obtained 0.10 for `sex = 0`. The 0.10 is calculated by taking the fitted model, plugging in `sex = 0` everywhere, and plugging in the average value of the group indicator variables everywhere they are used. That is, rather than treating the group indicators as being (1, 0, 0), (0, 1, 0), or (0, 0, 1) depending on observation, the group indicators are treated as being (0.40, 0.37, 0.23), which are the average values of `group = 1`, `group = 2`, and `group = 3`.

**Example 6: Margins with continuous variables**

To the [above example](#), we will add the continuous covariate age to the model and then rerun margins sex group.

```
. logistic outcome i.sex i.group sex#group age
 (output omitted)
. margins sex group
Predictive margins Number of obs = 3,000
Model VCE: OIM
Expression: Pr(outcome), predict()
```

|              | Delta-method |           | z     | P> z  | [95% conf. interval] |          |
|--------------|--------------|-----------|-------|-------|----------------------|----------|
|              | Margin       | std. err. |       |       |                      |          |
| <b>sex</b>   |              |           |       |       |                      |          |
| Male         | .1600644     | .0125653  | 12.74 | 0.000 | .1354368             | .184692  |
| Female       | .1966902     | .0100043  | 19.66 | 0.000 | .1770821             | .2162983 |
| <b>group</b> |              |           |       |       |                      |          |
| 1            | .2251302     | .0123233  | 18.27 | 0.000 | .200977              | .2492834 |
| 2            | .150603      | .0116505  | 12.93 | 0.000 | .1277685             | .1734376 |
| 3            | .0736157     | .0337256  | 2.18  | 0.029 | .0075147             | .1397167 |

Compared with the results presented in [example 5](#), results for sex change little, but results for groups 1 and 3 change markedly. The tables differ because now we are adjusting for the continuous covariate age, as well as for sex and group.

We will continue examining interactions in [example 8](#). Because we have added a continuous variable, let's take a detour to explain how to obtain margins for continuous variables and to explain their interpretation.

**Example 7: Margins of continuous variables**

Continuing with our example of

```
. logistic outcome i.sex i.group sex#group age
```

let's examine the continuous covariate age.

You are not allowed to type `margins age`; doing that will produce an error:

```
. margins age
factor age not found in list of covariates
r(322);
```

The message “age not found in list of covariates” is `margins`' way of saying, “Yes, age might be in the model, but if it is, it is not included as a factor variable; it is in as a continuous variable.” Sometimes, Stata is overly terse. `margins` might also say that because age is continuous there are an infinite number of values at which it could evaluate the margins. At what value(s) should age be fixed? `margins` requires more guidance with continuous covariates. We can provide that guidance by using the `at()` option and typing

```
. margins, at(age=40)
```

To understand why that yields the desired result, let us tell you that if you were to type

```
. margins
```

`margins` would report the overall margin—the margin that holds nothing constant. Because our model is logistic, the average value of the predicted probabilities would be reported. The `at()` option fixes one or more covariates to the value(s) specified and can be used with both factor and continuous variables. Thus, if you typed `margins, at(age=40)`, then `margins` would average over the data the responses for everybody, setting `age=40`. Here is what happens when you type that:

```
. margins, at(age=40)
Predictive margins Number of obs = 3,000
Model VCE: OIM
Expression: Pr(outcome), predict()
At: age = 40
```

|       | Delta-method |           |       |       |                      |
|-------|--------------|-----------|-------|-------|----------------------|
|       | Margin       | std. err. | z     | P> z  | [95% conf. interval] |
| _cons | .1133603     | .0070731  | 16.03 | 0.000 | .0994972 .1272234    |

Reported is the margin for `age = 40`, adjusted for the other covariates in our model.

If we wanted to obtain the margins for age 30, 35, 40, 45, and 50, we could type

```
. margins, at(age=(30 35 40 45 50))
```

or, equivalently,

```
. margins, at(age=(30(5)50))
```

### Example 8: Margins of interactions

Our model is

```
. logistic outcome i.sex i.group sex#group age
```

We can obtain the margins of all possible combinations of the levels of sex and the levels of group by typing

```
. margins sex#group
Predictive margins Number of obs = 3,000
Model VCE: OIM
Expression: Pr(outcome), predict()
```

|           | Delta-method |           |       |       | [95% conf. interval] |          |
|-----------|--------------|-----------|-------|-------|----------------------|----------|
|           | Margin       | std. err. | z     | P> z  |                      |          |
| sex#group |              |           |       |       |                      |          |
| Male#1    | .2379605     | .0237178  | 10.03 | 0.000 | .1914745             | .2844465 |
| Male#2    | .0658294     | .0105278  | 6.25  | 0.000 | .0451953             | .0864636 |
| Male#3    | .0538001     | .0136561  | 3.94  | 0.000 | .0270347             | .0805656 |
| Female#1  | .2158632     | .0112968  | 19.11 | 0.000 | .1937218             | .2380045 |
| Female#2  | .2054406     | .0183486  | 11.20 | 0.000 | .1694781             | .2414032 |
| Female#3  | .085448      | .0533914  | 1.60  | 0.110 | -.0191973            | .1900932 |

The first line in the table reports the marginal probability for sex = 0 (male) and group = 1. That is, it reports the estimated probability if everyone in the data were treated as if they were sex = 0 and group = 1.

Also reported are all the other combinations of sex and group.

By the way, we could have typed margins sex#group even if our fitted model did not include sex#group. Estimation is one thing, and asking questions about the nature of the estimates is another. margins does, however, require that i.sex and i.group appear somewhere in the model, because fixing a value outside the model would just produce the grand margin, and you can separately ask for that if you want it by typing margins without arguments.

### Example 9: Decomposing margins

We have the model

```
. logistic outcome i.sex i.group sex#group age
```

In [example 6](#), we typed `margins sex` and obtained 0.160 for males and 0.197 for females. We are going to decompose each of those numbers. Let us explain:

1. The margin for males, 0.160, treats everyone as if they were male, and that amounts to simultaneously
  - (a) treating males as males and
  - (b) treating females as males.
2. The margin for females, 0.197, treats everyone as if they were female, and that amounts to simultaneously
  - (a) treating males as females and
  - (b) treating females as females.

The margins 1a and 1b are the decomposition of 1, and the margins 2a and 2b are the decomposition of 2.

We could obtain 1a and 2a by typing

```
. margins if sex==0, at(sex=(0 1))
```

because the qualifier `if sex==0` would restrict margins to running on only the males. Similarly, we could obtain 1b and 2b by typing

```
. margins if sex==1, at(sex=(0 1))
```

We run these examples below:

```
. margins if sex==0, at(sex=(0 1))
```

```
Predictive margins Number of obs = 1,498
Model VCE: OIM
Expression: Pr(outcome), predict()
1._at: sex = 0
2._at: sex = 1
```

|     | Delta-method |           |       |       |                      |
|-----|--------------|-----------|-------|-------|----------------------|
|     | Margin       | std. err. | z     | P> z  | [95% conf. interval] |
| _at |              |           |       |       |                      |
| 1   | .0794393     | .0062147  | 12.78 | 0.000 | .0672586 .0916199    |
| 2   | .1335584     | .0127351  | 10.49 | 0.000 | .1085981 .1585187    |

```
. margins if sex==1, at(sex=(0 1))
Predictive margins Number of obs = 1,502
Model VCE: OIM
Expression: Pr(outcome), predict()
1. _at: sex = 0
2. _at: sex = 1
```

|     | Delta-method |           |       |       | [95% conf. interval] |          |
|-----|--------------|-----------|-------|-------|----------------------|----------|
|     | Margin       | std. err. | z     | P> z  |                      |          |
| _at |              |           |       |       |                      |          |
| 1   | .2404749     | .0199709  | 12.04 | 0.000 | .2013326             | .2796171 |
| 2   | .2596538     | .0104756  | 24.79 | 0.000 | .2391219             | .2801857 |

Putting together the results from [example 6](#) and the results above, we have

|                                           |       |
|-------------------------------------------|-------|
| Margin treating individuals as themselves | 0.170 |
| Margin treating individuals as male       | 0.160 |
| Margin treating male as male              | 0.079 |
| Margin treating female as male            | 0.240 |
| Margin treating individuals as female     | 0.197 |
| Margin treating male as female            | 0.134 |
| Margin treating female as female          | 0.260 |

### Example 10: Testing margins—contrasts of margins

Continuing with the previous example, it would be interesting to test the equality of [2b](#) and [1b](#), to test whether the average probability of a positive outcome for females treated as females is equal to that for females treated as males. That test would be different from testing the overall significance of `sex` in our model. The test performed on our model would be a test of whether the probability of a positive outcome differs between males and females when they have equal values of the other covariates. The test of equality of margins is a test of whether the *average* probabilities differ given the different pattern of values of the other covariates that the two sexes have in our data.

We can also perform such tests by treating the results from `margins` as estimation results. There are three steps required to perform tests on margins. First, you must arrange it so that all the margins of interest are reported by just one `margins` command. Second, you must specify `margins`' post option. Third, you perform the test with the `test` command.

Such tests and comparisons can be readily performed by contrasting margins; see [\[R\] margins, contrast](#). Also see *Contrasts of margins—effects (discrete marginal effects)* in [\[R\] marginsplot](#).

In the [previous example](#), we used two commands to obtain our results, namely,

```
. margins if sex==0, at(sex=(0 1))
. margins if sex==1, at(sex=(0 1))
```

We could, however, have obtained the same results by typing just one command:

```
. margins, over(sex) at(sex=(0 1))
```

Performing `margins, over(sex)` first restricts the sample to `sex==0` and then restricts it to `sex==1`, and that is equivalent to the two different `if` conditions that we specified before.

To test whether females treated as females is equal to females treated as males, we will need to type

```
. margins, over(sex) at(sex=(0 1)) post
. test _b[2._at#1.sex] = _b[1._at#1.sex]
```

We admit that the second command may seem to have come out of nowhere. When we specify `post` on the `margins` command, `margins` behaves as if it were an estimation command, which means that 1) it posts its estimates and full VCE to `e()`, 2) it gains the ability to replay results just as any estimation command can, and 3) it gains access to the standard postestimation commands. Item 3 explains why we could use `test`. We learned that we wanted to test `_b[2._at#1.sex]` and `_b[1._at#1.sex]` by replaying the estimation results, but this time with the standard estimation command `coeflegend` option. So, what we typed was

```
. margins, over(sex) at(sex=(0 1)) post
. margins, coeflegend
. test _b[2._at#1.sex] = _b[1._at#1.sex]
```

We will let you try `margins`, `coeflegend` for yourself. The results of running the other two commands are

```
. margins, over(sex) at(sex=(0 1)) post
Predictive margins Number of obs = 3,000
Model VCE: OIM
Expression: Pr(outcome), predict()
Over: sex
1._at: 0.sex
 sex = 0
 1.sex
 sex = 0
2._at: 0.sex
 sex = 1
 1.sex
 sex = 1
```

|          | Delta-method |           |       |       | [95% conf. interval] |          |
|----------|--------------|-----------|-------|-------|----------------------|----------|
|          | Margin       | std. err. | z     | P> z  |                      |          |
| _at#sex  |              |           |       |       |                      |          |
| 1#Male   | .0794393     | .0062147  | 12.78 | 0.000 | .0672586             | .0916199 |
| 1#Female | .2404749     | .0199709  | 12.04 | 0.000 | .2013326             | .2796171 |
| 2#Male   | .1335584     | .0127351  | 10.49 | 0.000 | .1085981             | .1585187 |
| 2#Female | .2596538     | .0104756  | 24.79 | 0.000 | .2391219             | .2801857 |

```
. test _b[2._at#1.sex] = _b[1._at#1.sex]
(1) - 1bn._at#1.sex + 2._at#1.sex = 0
 chi2(1) = 0.72
 Prob > chi2 = 0.3951
```

We can perform the same test in one command using contrasts of margins:

```
. logistic outcome i.sex i.group sex#group age
(output omitted)
. margins, over(sex) at(sex=(0 1)) contrast(atcontrast(r._at) wald)
Contrasts of predictive margins Number of obs = 3,000
Model VCE: OIM
Expression: Pr(outcome), predict()
Over: sex
1._at: 0.sex
 sex = 0
 1.sex
 sex = 0
2._at: 0.sex
 sex = 1
 1.sex
 sex = 1
```

|                 | df | chi2  | P>chi2 |
|-----------------|----|-------|--------|
| ._at@sex        |    |       |        |
| (2 vs 1) Male   | 1  | 14.59 | 0.0001 |
| (2 vs 1) Female | 1  | 0.72  | 0.3951 |
| Joint           | 2  | 16.13 | 0.0003 |

|                 | Delta-method |           |                      |          |
|-----------------|--------------|-----------|----------------------|----------|
|                 | Contrast     | std. err. | [95% conf. interval] |          |
| ._at@sex        |              |           |                      |          |
| (2 vs 1) Male   | .0541192     | .0141706  | .0263453             | .081893  |
| (2 vs 1) Female | .0191789     | .0225516  | -.0250215            | .0633793 |

We refit our logistic model because its estimation results were replaced when we posted our margins. The syntax to perform the contrast we want is admittedly not obvious. Contrasting (testing) across at() groups is more difficult than contrasting across the margins themselves or across over() groups, because we have no natural place for the contrast operators (r., in our case). We also explicitly requested Wald tests of the contrasts, which are not provided by default. Nevertheless, the  $\chi^2$  statistic and its *p*-value for (2 vs 1) for female matches the results of our test command. We also obtain the test of whether the response of males treated as males is equal to the response of males treated as females.

For a gentler introduction to contrasts of margins, see [\[R\] margins, contrast](#).

### Example 11: Margins of a specified prediction

We will fit the model

```
. use https://www.stata-press.com/data/r19/margex
. tobit ycn i.sex i.group sex#group age, ul(90)
```

and we will tell the following story about the variables: We run a peach orchard where we allow people to pick their own peaches. A person receives one empty basket in exchange for \$20, along with the right to enter the orchard. There is no official limit on how many peaches a person can pick, but only 90 peaches will fit into a basket. The dependent variable in the above tobit model, ycn, is the number of peaches picked. We use tobit, a special case of censored-normal regression, because ycn is censored at 90.

After fitting this model, if we typed

```
. margins sex
```

we would obtain the margins for males and for females of the uncensored number of peaches picked. We would obtain that because `predict` after `tobit` produces the uncensored number by default. To obtain the censored prediction, we would have to specify `predict's ystar(.,90)` option. If we want the margins based on that response, we type

```
. margins sex, predict(ystar(.,90))
```

The results of typing that are

```
. tobit ycn i.sex i.group sex#group age, ul(90)
(output omitted)
```

```
. margins sex, predict(ystar(.,90))
```

```
Predictive margins
```

```
Number of obs = 3,000
```

```
Model VCE: OIM
```

```
Expression: E(ycn|ycn<90), predict(ystar(.,90))
```

|        | Delta-method |           |        |       | [95% conf. interval] |          |
|--------|--------------|-----------|--------|-------|----------------------|----------|
|        | Margin       | std. err. | z      | P> z  |                      |          |
| sex    |              |           |        |       |                      |          |
| Male   | 62.21804     | .5996952  | 103.75 | 0.000 | 61.04266             | 63.39342 |
| Female | 78.34272     | .4555278  | 171.98 | 0.000 | 77.4499              | 79.23553 |

In our previous examples, `sex = 1` has designated females, so evidently the females visiting our orchard are better at filling baskets than the men.

### Example 12: Margins of a specified expression

Continuing with our peach orchard example and the previously fit model

```
. use https://www.stata-press.com/data/r19/margex
```

```
. tobit ycn i.sex i.group sex#group age, ul(90)
```

let's examine how well our baskets are working for us. What is the proportion of the number of peaches actually picked to the number that would have been picked were the baskets larger? As mentioned in [example 11](#), `predict, ystar(.,90)` produces the expected number picked given the limit of basket size. `predict, xb` would predict the expected number without a limit. We want the ratio of those two predictions. That ratio will measure as a proportion how well the baskets work. Thus, we could type

```
. margins sex, expression(predict(ystar(.,90))/predict(xb))
```

That would give us the proportion for everyone treated as male and everyone treated as female, but what we want to know is how well baskets work for true males and true females, so we will type

```
. margins, over(sex) expression(predict(ystar(0,90))/predict(xb))
Predictive margins Number of obs = 3,000
Model VCE: OIM
Expression: predict(ystar(0,90))/predict(xb)
Over: sex
```

|        | Delta-method |           |        |       |                      |
|--------|--------------|-----------|--------|-------|----------------------|
|        | Margin       | std. err. | z      | P> z  | [95% conf. interval] |
| sex    |              |           |        |       |                      |
| Male   | .9811785     | .0013037  | 752.60 | 0.000 | .9786233 .9837338    |
| Female | .9419962     | .0026175  | 359.88 | 0.000 | .9368659 .9471265    |

By the way, we could count the number of peaches saved by the limited basket size during the period of data collection by typing

```
. count
3,000
. margins, expression(3000*(predict(xb)-predict(ystar(.,90))))
(output omitted)
```

The number of peaches saved turns out to be 9,183.

### Example 13: Margins with multiple outcomes (responses)

Estimation commands such as `mlogit` and `mprobit` (see [R] [mlogit](#) and [R] [mprobit](#)) calculate multiple responses, and those multiple responses are reflected in the options available with `predict` after estimation. Obtaining margins for such estimators is thus the same as obtaining margins of a specified prediction, which was demonstrated in [example 11](#). The solution is to include the `predict_opt` that selects the desired response in margins' `predict(predict_opt)` option.

If we fit the multinomial logistic model

```
. mlogit group i.sex age
```

then to obtain the margins for the probability that `group = 1`, we would type

```
. margins sex, predict(outcome(1))
```

and to obtain the margins for the probability that `group = 3`, we would type

```
. margins sex, predict(outcome(3))
```

To obtain the margins for each of these outcomes simultaneously, type

```
. margins sex, predict(outcome(1)) predict(outcome(3))
```

We learned about the `outcome(1)` and `outcome(3)` options by looking in [R] [mlogit postestimation](#). For an example using margins with a multiple-outcome estimator, see [example 4](#) in [R] [mlogit postestimation](#).

**Example 14: Margins with multiple equations**

Estimation commands such as `mvreg`, `manova`, `sureg`, and `reg3` (see [\[MV\] mvreg](#), [\[MV\] manova](#), [\[R\] sureg](#), and [\[R\] reg3](#)) fit multiple equations. Obtaining margins for such estimators is the same as obtaining margins with multiple outcomes (see [example 13](#)), which in turn is the same as obtaining margins of a specified prediction (see [example 11](#)). You place the relevant option from the estimator's `predict` command into `margins'` `predict(predict_opt)` option.

If we fit the seemingly unrelated regression model

```
. sureg (y = i.sex age) (distance = i.sex i.group)
```

we can obtain the marginal means of `y` for males and females by typing

```
. margins sex, predict(equation(y))
```

and we can obtain the marginal means of `distance` by typing

```
. margins sex, predict(equation(distance))
```

We could obtain the difference between the margins of `y` and `distance` by typing

```
. margins sex, expression(predict(equation(y)) -
> predict(equation(distance)))
```

More examples can be found in [\[MV\] manova](#) and [\[MV\] manova postestimation](#).

**Example 15: Margins evaluated out of sample**

You can fit your model on one dataset and use `margins` on another if you specify `margins'` `noesample` option. Remember that `margins` reports estimated average responses, and, unless you lock all the covariates at fixed values by using the `at()` option, the remaining variables are allowed to vary as they are observed to vary in the data. That is indeed the point of using `margins`. The fitted model provides the basis for adjusting for the remaining variables, and the data provide their values. The predictions produced by `margins` are of interest assuming the data used by `margins` are in some sense interesting or representative. In some cases, you might need to fit your model on one set of data and perform `margins` on another.

In [example 11](#), we fit the model

```
. tobit ycn i.sex i.group sex#group age, ul(90)
```

and we told a story about our peach orchard in which we charged people \$20 to collect a basket of peaches, where baskets could hold at most 90 peaches. Let us now tell you that we believe the data on which we estimated those margins were unrepresentative, or at least, we have a more representative sample stored in another `.dta` file. That dataset includes the demographics of our customers but does not include counts of peaches picked. It is a lot of work counting those peaches.

Thus, we will fit our model just as we did previously using the detailed data, but we will bring the other, more representative dataset into memory before issuing the margins sex, predict(ystar(.,90)) command, and we will add noesample to it.

```
. use https://www.stata-press.com/data/r19/margex
(Artificial data for margins)
. tobit ycn i.sex i.group sex#group age, ul(90)
(output omitted)
. use https://www.stata-press.com/data/r19/peach
. margins sex, predict(ystar(.,90)) noesample
Predictive margins Number of obs = 2,727
Model VCE: OIM
Expression: E(ycn*|ycn<90), predict(ystar(.,90))
```

|     | Delta-method |           |        |       | [95% conf. interval] |          |
|-----|--------------|-----------|--------|-------|----------------------|----------|
|     | Margin       | std. err. | z      | P> z  |                      |          |
| sex |              |           |        |       |                      |          |
| 0   | 56.79774     | 1.003731  | 56.59  | 0.000 | 54.83046             | 58.76502 |
| 1   | 75.02146     | .6437446  | 116.54 | 0.000 | 73.75974             | 76.28317 |

In [example 12](#), we produced an estimate of the number of peaches saved by the limited-size baskets. We can update that estimate using the new demographic data by typing

```
. count
2,727
. margins, exp(2727*(predict(xb)-predict(ystar(.,90)))) noesample
(output omitted)
```

By running the above, we find that the updated number of peaches saved is 6,408.

### Obtaining margins of derivatives of responses (a.k.a. marginal effects)

Derivatives of responses are themselves responses, so everything said above in [Obtaining margins of responses](#) is equally true of derivatives of responses, and every example above could be repeated here substituting the derivative of the response for the response.

Derivatives are of interest because they are an informative way of summarizing fitted results. The change in a response for a change in the covariate is easy to understand and to explain. In simple models, one hardly needs margins to assist in obtaining such margins. Consider the simple linear regression

$$y = \beta_0 + \beta_1 \times \text{sex} + \beta_2 \times \text{age} + \epsilon$$

The derivatives of the responses are

$$dy/d(\text{sex}) = \beta_1$$

$$dy/d(\text{age}) = \beta_2$$

margins computes these derivatives using  $\hat{\beta}_1$  and  $\hat{\beta}_2$ , the coefficients from the linear predictor of  $y$ . How does the linear predictor  $\hat{y}$  change between males and females? It changes by  $\hat{\beta}_1$ . How does  $\hat{y}$  change with age? It changes by  $\hat{\beta}_2$  per year.

If you make the model a little more complicated, however, the need for margins arises. Consider the model

$$y = \beta_0 + \beta_1 \times \text{sex} + \beta_2 \times \text{age} + \beta_3 \times \text{age}^2 + \epsilon$$

Now, the derivative with respect to age is

$$dy/d(\text{age}) = \beta_2 + 2 \times \beta_3 \times \text{age}$$

The change in  $y$  for a change in age itself changes with age, and so to better understand the fitted results, you might want to make a table of the change in  $y$  for a change in age for age = 30, age = 40, and age = 50. `margins` can do that.

Consider an even more complicated model, such as

$$y = \beta_0 + \beta_1 \times \text{sex} + \beta_2 \times \text{age} + \beta_3 \times \text{age}^2 + \beta_4 \times \text{bp} + \beta_5 \times \text{sex} \times \text{bp} + \beta_6 \times \text{tmt} + \beta_7 \times \text{tmt} \times \text{age} + \beta_8 \times \text{tmt} \times \text{age}^2 + \epsilon \quad (1)$$

The derivatives are

$$dy/d(\text{sex}) = \beta_1 + \beta_5 \times \text{bp}$$

$$dy/d(\text{age}) = \beta_2 + 2 \times \beta_3 \times \text{age} + \beta_7 \times \text{tmt} + 2 \times \beta_8 \times \text{tmt} \times \text{age}$$

$$dy/d(\text{bp}) = \beta_4 + \beta_5 \times \text{sex}$$

$$dy/d(\text{tmt}) = \beta_6 + \beta_7 \times \text{age} + \beta_8 \times \text{age}^2$$

At this point, `margins` becomes indispensable.

### Use at() freely, especially with continuous variables

An option one tends to use frequently with derivatives of responses is `at()`. Such use is often to better understand or to communicate how the response varies, or, in technical jargon, to explore the nature of the response surface.

For instance, the effect  $dy/d(\text{tmt})$  in (1) is equal to  $\beta_6 + \beta_7 \times \text{age} + \beta_8 \times \text{age}^2$ , and so simply to understand how treatment varies with age, we may want to fix age at various values. We might type

```
. margins, dydx(tmt) at(age=(30 40 50))
```

### Expressing derivatives as elasticities

You specify the `dydx(varname)` option on the `margins` command to use  $dy/d(\text{varname})$  as the response variable. If you want that derivative expressed as an elasticity, you can specify `eyex(varname)`, `eydx(varname)`, or `dyex(varname)`. You substitute `e` for `d` where you want an elasticity. In the discussion below, when we talk about  $y$ , we are referring to the linear predictions from the model.

The formulas are

$$\text{dydx}() = dy/dx$$

$$\text{eyex}() = dy/dx \times (x/y)$$

$$\text{eydx}() = dy/dx \times (1/y) = d \ln(y)/dx$$

$$\text{dyex}() = dy/dx \times (x) = dy/d \ln(x)$$

and the interpretations are

|                       |              |                     |              |               |
|-----------------------|--------------|---------------------|--------------|---------------|
| <code>dydx()</code> : |              | change in $y$ for a |              | change in $x$ |
| <code>eyex()</code> : | proportional | change in $y$ for a | proportional | change in $x$ |
| <code>eydx()</code> : | proportional | change in $y$ for a |              | change in $x$ |
| <code>dyex()</code> : |              | change in $y$ for a | proportional | change in $x$ |

As `margins` always does with response functions, calculations are made at the observational level and are then averaged. Let's assume that in observation 5,  $dy/dx = 0.5$ ,  $y = 15$ , and  $x = 30$ ; then

$$\begin{aligned} \text{dydx}() &= 0.5 \\ \text{eyex}() &= 1.0 \\ \text{eydx}() &= 0.03 \\ \text{dyex}() &= 15.0 \end{aligned}$$

Many social scientists would informally explain the meaning of  $\text{eyex}() = 1$  as “ $y$  increases 100% when  $x$  increases 100%” or as “ $y$  doubles when  $x$  doubles”, although neither statement is literally true.  $\text{eyex}()$ ,  $\text{eydx}()$ , and  $\text{dyex}()$  are rates evaluated at a point, just as  $\text{dydx}()$  is a rate, and all such interpretations are valid only for small (infinitesimal) changes in  $x$ . It is true that  $\text{eyex}() = 1$  means  $y$  increases with  $x$  at a rate such that, if the rate were constant,  $y$  would double if  $x$  doubled. This issue of casual interpretation is no different from casually interpreting  $\text{dydx}()$  as if it represents the response to a unit change. It is not necessarily true that  $\text{dydx}() = 0.5$  means that “ $y$  increases by 0.5 if  $x$  increases by 1”. It is true that “ $y$  increases with  $x$  at a rate such that, if the rate were constant,  $y$  would increase by 0.5 if  $x$  increased by 1”.

$\text{dydx}()$ ,  $\text{eyex}()$ ,  $\text{eydx}()$ , and  $\text{dyex}()$  may be used with continuous  $x$  variables.  $\text{dydx}()$  and  $\text{eydx}()$  may also be used with factor variables. For  $\text{eydx}()$ , effects are based on  $d \ln(y)/dx$  for continuous covariates and on differences of  $\ln(y)$  for discrete covariates. Estimates based on logarithms have better computational properties and allow us to think of semielasticities as coefficients in a regression with log dependent variables. As we discuss next, when we are analyzing marginal effects of categorical variables, we think in terms of discrete differences instead of derivatives.

## Derivatives versus discrete differences

In (1),

$$y = \beta_0 + \beta_1 \times \text{sex} + \beta_2 \times \text{age} + \beta_3 \times \text{age}^2 + \beta_4 \times \text{bp} + \beta_5 \times \text{sex} \times \text{bp} + \beta_6 \times \text{tmt} + \beta_7 \times \text{tmt} \times \text{age} + \beta_8 \times \text{tmt} \times \text{age}^2 + \epsilon$$

Let us call your attention to the derivatives of  $y$  with respect to age and sex:

$$dy/d(\text{age}) = \beta_2 + 2 \times \beta_3 \times \text{age} + \beta_7 \times \text{tmt} + 2 \times \beta_8 \times \text{tmt} \times \text{age} \quad (2)$$

$$dy/d(\text{sex}) = \beta_1 + \beta_5 \times \text{bp} \quad (3)$$

`age` is presumably a continuous variable, and (2) is precisely how `margins` calculates its derivatives when you type `margins, dydx(age)`. `sex`, however, is presumably a factor variable, and `margins` does not necessarily make the calculation using (3) were you to type `margins, dydx(sex)`. We will explain, but let us first clarify what we mean by a continuous and a factor variable. Say that you fit (1) by typing

```
. regress y i.sex age c.age#c.age i.bp bp#sex
> i.tmt tmt#c.age tmt#c.age#c.age
```

It is important that `sex` entered the model as a factor variable. It would not do to type `regress y sex ...` because then `sex` would be a continuous variable, or at least it would be a continuous variable from Stata's point of view. The model estimates would be the same, but `margins`' understanding of those estimates would be a little different. With the model fit using `i.sex`, `margins` understands that either `sex` is 0 or `sex` is 1. With the model fit using `sex`, `margins` thinks `sex` is continuous and, for instance, `sex = 1.5` is a possibility.

`margins` calculates `dydx()` differently for continuous and for factor variables. For continuous variables, `margins` calculates  $dy/dx$  using the fitted values from `regress`. For factor variables, `margins` calculates the discrete first difference from the base category. To obtain that for `sex`, write down the model and then subtract from it the model evaluated at the base category for `sex`, which is `sex = 0`. If you do that, you will get the same formula as we obtained for the derivative, namely,

$$\text{discrete difference}\{(\text{sex} = 1) - (\text{sex} = 0)\} = \beta_1 + \beta_5 \times \text{bp}$$

We obtain the same formula because our model is linear regression. Outside of linear regression, and outside of linear response functions generally, the discrete difference is not equal to the derivative. The discrete difference is not equal to the derivative for logistic regression, probit, etc. The discrete difference calculation is generally viewed as better for factor variables than the derivative calculation because the discrete difference is what would actually be observed.

If you want the derivative calculation for your factor variables, specify the `continuous` option on the `margins` command.

### Example 16: Average marginal effect (partial effects)

Concerning the title of this example, the way we use the term marginal effect, the effects of factor variables are calculated using discrete first differences. If you wanted the continuous calculation, you would specify `margins`' `continuous` option in what follows.

```
. use https://www.stata-press.com/data/r19/margex
(Artificial data for margins)
. logistic outcome treatment##group age c.age#c.age treatment#c.age
(output omitted)
. margins, dydx(treatment)
Average marginal effects Number of obs = 3,000
Model VCE: OIM
Expression: Pr(outcome), predict()
dy/dx wrt: 1.treatment
```

|             | Delta-method |           |      |       |                      |          |
|-------------|--------------|-----------|------|-------|----------------------|----------|
|             | dy/dx        | std. err. | z    | P> z  | [95% conf. interval] |          |
| 1.treatment | .0385625     | .0162848  | 2.37 | 0.018 | .0066449             | .0704801 |

Note: `dy/dx` for factor levels is the discrete change from the base level.

The average marginal effect of treatment on the probability of a positive outcome is 0.039.

**Example 17: Average marginal effect of all covariates**

We will continue with the model

```
. logistic outcome treatment##group age c.age#c.age treatment#c.age
```

if we wanted the average marginal effects for all covariates, we would type margins, dydx(\*) or margins, dydx(\_all); they mean the same thing. This is probably the most common way margins, dydx() is used.

```
. margins, dydx(*)
```

Average marginal effects Number of obs = 3,000  
 Model VCE: OIM

Expression: Pr(outcome), predict()  
 dy/dx wrt: 1.treatment 2.group 3.group age

|             | Delta-method |           | z     | P> z  | [95% conf. interval] |           |
|-------------|--------------|-----------|-------|-------|----------------------|-----------|
|             | dy/dx        | std. err. |       |       |                      |           |
| 1.treatment | .0385625     | .0162848  | 2.37  | 0.018 | .0066449             | .0704801  |
| group       |              |           |       |       |                      |           |
| 2           | -.0776906    | .0181584  | -4.28 | 0.000 | -.1132805            | -.0421007 |
| 3           | -.1505652    | .0400882  | -3.76 | 0.000 | -.2291366            | -.0719937 |
| age         | .0095868     | .0007796  | 12.30 | 0.000 | .0080589             | .0111148  |

Note: dy/dx for factor levels is the discrete change from the base level.

**Example 18: Evaluating marginal effects over the response surface**

Continuing with the model

```
. logistic outcome treatment##group age c.age#c.age treatment#c.age
```

What follows maps out the entire response surface of our fitted model. We report the marginal effect of treatment evaluated at age = 20, 30, . . . , 60, by each level of group.

```
. margins group, dydx(treatment) at(age=(20(10)60))
Conditional marginal effects Number of obs = 3,000
Model VCE: OIM
Expression: Pr(outcome), predict()
dy/dx wrt: 1.treatment
1._at: age = 20
2._at: age = 30
3._at: age = 40
4._at: age = 50
5._at: age = 60
```

|             | Delta-method   |           |       |       |                      |
|-------------|----------------|-----------|-------|-------|----------------------|
|             | dy/dx          | std. err. | z     | P> z  | [95% conf. interval] |
| 0.treatment | (base outcome) |           |       |       |                      |
| 1.treatment |                |           |       |       |                      |
| _at#group   |                |           |       |       |                      |
| 1 1         | -.0208409      | .0152862  | -1.36 | 0.173 | -.0508013 .0091196   |
| 1 2         | .009324        | .0059896  | 1.56  | 0.120 | -.0024155 .0210635   |
| 1 3         | .0006558       | .0048682  | 0.13  | 0.893 | -.0088856 .0101972   |
| 2 1         | -.0436964      | .0279271  | -1.56 | 0.118 | -.0984325 .0110397   |
| 2 2         | .0382959       | .0120405  | 3.18  | 0.001 | .014697 .0618949     |
| 2 3         | .0064564       | .0166581  | 0.39  | 0.698 | -.0261929 .0391057   |
| 3 1         | -.055676       | .0363191  | -1.53 | 0.125 | -.1268601 .015508    |
| 3 2         | .1152235       | .0209858  | 5.49  | 0.000 | .074092 .156355      |
| 3 3         | .0284808       | .0471293  | 0.60  | 0.546 | -.0638908 .1208524   |
| 4 1         | -.027101       | .0395501  | -0.69 | 0.493 | -.1046177 .0504158   |
| 4 2         | .2447682       | .0362623  | 6.75  | 0.000 | .1736954 .315841     |
| 4 3         | .0824401       | .1025028  | 0.80  | 0.421 | -.1184616 .2833418   |
| 5 1         | .0292732       | .0587751  | 0.50  | 0.618 | -.0859239 .1444703   |
| 5 2         | .3757777       | .0578106  | 6.50  | 0.000 | .2624709 .4890844    |
| 5 3         | .1688268       | .1642191  | 1.03  | 0.304 | -.1530368 .4906904   |

Note: dy/dx for factor levels is the discrete change from the base level.

## Obtaining margins with survey data and representative samples

The standard errors and confidence intervals produced by `margins` are based by default on the delta method applied to the VCE of the current estimates. Delta-method standard errors treat the covariates at which the response is evaluated as given or fixed. Such standard errors are appropriate if you specify `at()` to fix the covariates, and they are appropriate when you are making inferences about groups exactly like your sample whether you specify `at()` or not.

On the other hand, if you have a representative sample of the population or if you have complex survey data and if you want to make inferences about the underlying population, you need to account for the variation in the covariates that would arise in repeated sampling. You do that using `vce(unconditional)`, which invokes a different standard error calculation based on [Korn and Graubard \(1999\)](#). Syntactically, there are three cases. They all involve specifying `vce(unconditional)` on the `margins` command:

1. *You have a representative random sample, and you have not svyset your data.*  
When you fit the model, you need to specify the `vce(robust)` or `vce(cluster clustvar)` option. When you issue the `margins` command, you need to specify the `vce(unconditional)` option.
2. *You have a weighted sample, and you have not svyset your data.*  
You need to specify `[pw=weight]` when you fit the model and, of course, specify the `vce(unconditional)` option on the `margins` command. You do not need to specify the weights on the `margins` command because `margins` will obtain them from the estimation results.
3. *You have svyset your data, whether it be a simple random sample or something more complex including weights, strata, sampling units, or poststratification, and you are using the linearized variance estimator.*  
You need to use the `svy` prefix when you fit the model. You need to specify `vce(unconditional)` when you issue the `margins` command. You do not need to respecify the weights.  
Even though the data are `svyset`, and even though the estimation was `svy` estimation, `margins` does not default to `vce(unconditional)`. It does not default to `vce(unconditional)` because there are valid reasons to want the data-specific, `vce(delta)` standard-error estimates. Whether you specify `vce(unconditional)` or not, `margins` uses the weights, so you do not need to respecify them even if you are using `vce(unconditional)`.

`vce(unconditional)` is allowed only after estimation with `vce(robust)`, `vce(cluster ...)`, or the `svy` prefix with the linearized variance estimator. If the VCE of the current estimates was specified as clustered, so will be the VCE estimates of `margins`. If the estimates were from a survey estimation, the survey settings in the dataset will be used by `margins`.

When you use `vce(unconditional)`, never specify `if exp` or `in range` on the `margins` command; instead, specify the `subpop(if exp)` option. You do that for the usual reasons; see [\[SVY\] Subpopulation estimation](#). If you specify `over(varlist)` to examine subgroups, the subgroups will automatically be treated as subpopulations.

If you are using a replication-based variance estimator, you may want to use this method to estimate the variance of your margins; see [\[SVY\] svy postestimation](#).

**Example 19: Inferences for populations, margins of response**

In [example 6](#), we fit the model

```
. logistic outcome i.sex i.group sex#group age
```

and we obtained margins by sex and margins by group,

```
. margins sex group
```

If our data were randomly drawn from the population of interest and we wanted to account for this, we would have typed

```
. logistic outcome i.sex i.group sex#group age, vce(robust)
. margins sex group, vce(unconditional)
```

We do that below:

```
. logistic outcome i.sex i.group sex#group age, vce(robust)
 (output omitted)
. margins sex group, vce(unconditional)
```

Predictive margins Number of obs = 3,000  
 Expression: Pr(outcome), predict()

|              | Unconditional |           | z     | P> z  | [95% conf. interval] |          |
|--------------|---------------|-----------|-------|-------|----------------------|----------|
|              | Margin        | std. err. |       |       |                      |          |
| <b>sex</b>   |               |           |       |       |                      |          |
| Male         | .1600644      | .0131685  | 12.16 | 0.000 | .1342546             | .1858743 |
| Female       | .1966902      | .0104563  | 18.81 | 0.000 | .1761963             | .2171841 |
| <b>group</b> |               |           |       |       |                      |          |
| 1            | .2251302      | .0127069  | 17.72 | 0.000 | .200225              | .2500354 |
| 2            | .150603       | .0118399  | 12.72 | 0.000 | .1273972             | .1738088 |
| 3            | .0736157      | .0343188  | 2.15  | 0.032 | .0063522             | .1408793 |

The estimated margins are the same as they were in [example 6](#), but the standard errors and confidence intervals differ, although not by much. Given that we have 3,000 observations in our randomly drawn sample, we should expect this.

### Example 20: Inferences for populations, marginal effects

In [example 17](#), we fit a logistic model and then obtained the average marginal effects for all covariates by typing

```
. logistic outcome treatment##group age c.age#c.age treatment#c.age
. margins, dydx(*)
```

To repeat that and also obtain standard errors for our population, we would type

```
. logistic outcome treatment##group age c.age#c.age treatment#c.age, vce(robust)
 (output omitted)
. margins, dydx(*) vce(unconditional)
```

```
Average marginal effects Number of obs = 3,000
Expression: Pr(outcome), predict()
dy/dx wrt: 1.treatment 2.group 3.group age
```

|             | dy/dx     | Unconditional<br>std. err. | z     | P> z  | [95% conf. interval] |           |
|-------------|-----------|----------------------------|-------|-------|----------------------|-----------|
| 1.treatment | .0385625  | .0163872                   | 2.35  | 0.019 | .0064442             | .0706808  |
| group       |           |                            |       |       |                      |           |
| 2           | -.0776906 | .0179573                   | -4.33 | 0.000 | -.1128863            | -.0424949 |
| 3           | -.1505652 | .0411842                   | -3.66 | 0.000 | -.2312848            | -.0698456 |
| age         | .0095868  | .0007814                   | 12.27 | 0.000 | .0080553             | .0111183  |

Note: dy/dx for factor levels is the discrete change from the base level.

### Example 21: Inferences for populations with svyset data

See [example 3](#) in [\[SVY\] svy postestimation](#).

## Standardizing margins

A standardized margin is the margin calculated on data different from the data used to fit the model. Typically, the word standardized is reserved for situations in which the alternate population is a reference population, which may be real or artificial, and which is treated as fixed.

Say that you work for a hospital and have fit a model of mortality on the demographic characteristics of the hospital's patients. At this stage, were you to type

```
. margins
```

you would obtain the mortality rate for your hospital. You have another dataset, `hstandard.dta`, that contains demographic characteristics of patients across all hospitals along with the population of each hospital recorded in the `pop` variable. You could obtain the expected mortality rate at your hospital if your patients matched the characteristics of the standard population by typing

```
. use https://www.stata-press.com/data/r19/hstandard, clear
. margins [fw=pop], noesample
```

You specified `noesample` because the margin is being calculated on data other than the data used to fit the model. You specified `[fw=pop]` because the reference dataset you are using included population counts, as many reference datasets do.

## Obtaining margins as though the data were balanced

Here we discuss what are commonly called estimated marginal means or least-squares means. These are margins that assume that the design is **balanced**, which means all levels of factor variables are equally likely. The seminal reference on these margins is [Searle, Speed, and Milliken \(1980\)](#).

In designed experiments, observations are often allocated in a balanced way so that the variances can be easily compared and decomposed. At the Acme Portable Widget Company, they are experimenting with a new machine. The machine has three temperature settings and two pressure settings; a combination of settings will be optimal on any particular day, determined by the weather. At start-up, one runs a quick test and chooses the optimal setting for the day. Across different days, each setting will be used about equally, says the manufacturer.

In experiments with the machine, 10 widgets were collected for stress testing at each of the settings over a six-week period. We wish to know the average stress-test value that can be expected from these machines over a long period.

## Balancing using asbalanced

The data were intended to be balanced, but unfortunately some samples were destroyed before the stress could be measured, rendering the data unbalanced. To estimate the margins as if the data were balanced, specify the `asbalanced` option.

```
. use https://www.stata-press.com/data/r19/acmemanuf
. regress y pressure##temp
 (output omitted)
. margins, asbalanced
Adjusted predictions Number of obs = 49
Model VCE: OLS
Expression: Linear prediction, predict()
At: pressure (asbalanced)
 temp (asbalanced)
```

|       | Delta-method |           |       |       |                      |
|-------|--------------|-----------|-------|-------|----------------------|
|       | Margin       | std. err. | t     | P> t  | [95% conf. interval] |
| _cons | 115.3758     | 1.530199  | 75.40 | 0.000 | 112.2899 118.4618    |

If we had omitted the `asbalanced` option, our calculations would have been different:

```
. margins
Predictive margins Number of obs = 49
Model VCE: OLS
Expression: Linear prediction, predict()
```

|       | Delta-method |           |       |       |                      |
|-------|--------------|-----------|-------|-------|----------------------|
|       | Margin       | std. err. | t     | P> t  | [95% conf. interval] |
| _cons | 109.9214     | 1.422629  | 77.27 | 0.000 | 107.0524 112.7904    |

To see what margins, asbalanced is doing, first recall that pressure and temp are categorical variables that take values {1, 2} and {1, 2, 3}, respectively. To re-create the asbalanced calculations using the at() option, we set each level of pressure equal to 1/2 and each level of temp equal to 1/3.

```
. margins, at(1.pressure=0.5 2.pressure=0.5
> 1.temp=0.333333 2.temp=0.333333 3.temp=0.333333)
Adjusted predictions Number of obs = 49
Model VCE: OLS
Expression: Linear prediction, predict()
At: 1.pressure = .5
 2.pressure = .5
 1.temp = .333333
 2.temp = .333333
 3.temp = .333333
```

|       | Margin   | Delta-method<br>std. err. | t     | P> t  | [95% conf. interval] |          |
|-------|----------|---------------------------|-------|-------|----------------------|----------|
| _cons | 115.3758 | 1.530199                  | 75.40 | 0.000 | 112.2899             | 118.4618 |

□ Technical note

Concerning how asbalanced calculations are performed, if a factor variable has  $l$  levels, then each level’s coefficient contributes to the response weighted by  $1/l$ . If two factors,  $a$  and  $b$ , interact, then each coefficient associated with their interaction is weighted by  $1/(l_a \times l_b)$ .

If a balanced factor interacts with a continuous variable, then each coefficient in the interaction is applied to the value of the continuous variable, and the results are weighted equally. So, if the factor being interacted has  $l_a$  levels, the effect of each coefficient on the value of the continuous covariate is weighted by  $1/l_a$ .

**Balancing by standardization**

To better understand the balanced results, we can perform the balancing ourselves by using the standardizing method shown in *Standardizing margins*. To do that, we will input a balanced dataset and then type margins, noesample.

```
. use https://www.stata-press.com/data/r19/acmemanuf
. regress y pressure##temp
 (output omitted)
. drop _all
```

```

. input pressure temp
 pressure temp
1. 1 1
2. 1 2
3. 1 3
4. 2 1
5. 2 2
6. 2 3
7. end

. margins, noesample
Predictive margins Number of obs = 6
Model VCE: OLS
Expression: Linear prediction, predict()

```

|       | Delta-method |           | t     | P> t  | [95% conf. interval] |          |
|-------|--------------|-----------|-------|-------|----------------------|----------|
|       | Margin       | std. err. |       |       |                      |          |
| _cons | 115.3758     | 1.530199  | 75.40 | 0.000 | 112.2899             | 118.4618 |

We obtain the same results as previously.

## Balancing nonlinear responses

If our testing had produced a binary outcome, say, acceptable/unacceptable, rather than a continuous variable, we would type

```

. use https://www.stata-press.com/data/r19/acmemanuf, clear
. logistic acceptable pressure##temp
. margins, asbalanced

```

The result of doing that would be 0.680. If we omitted the `asbalanced` option, the result would have been 0.667. The two results are so similar because `acmemanuf.dta` is nearly balanced.

Even though the `asbalanced` option can be used on both linear and nonlinear responses, such as probabilities, there is an issue of which you should be aware. The most widely used formulas for balancing responses apply the balancing to the linear prediction, average that as if it were balanced, and then apply the nonlinear transform. That is the calculation that produced 0.680.

An alternative would be to apply the standardization method. That amounts to making the linear predictions observation by observation, applying the nonlinear transform to each, and then averaging the nonlinear result as if it were balanced. You could do that by typing

```

. use https://www.stata-press.com/data/r19/acmemanuf, clear
. logistic acceptable pressure##temp
. clear
. input pressure temp
 (see above for entered data)
. margins, noesample

```

The result from the standardization procedure would be 0.672. These two ways of averaging nonlinear responses are discussed in detail in [Lane and Nelder \(1982\)](#) within the context of general linear models.

Concerning the method used by the `asbalanced` option, if your data start balanced and you have a nonlinear response, you will get different results with and without the `asbalanced` option!

## Treating a subset of covariates as balanced

So far, we have treated all the covariates as if they were balanced. `margins` will allow you to treat a subset of the covariates as balanced, too. For instance, you might be performing an experiment in which you are randomly allocating patients to a treatment arm and so want to balance on arm, but you do not want to balance the other characteristics.

In this example, we will imagine that the outcome of the experiment is continuous. We type

```
. use https://www.stata-press.com/data/r19/margex, clear
. regress y arm##sex sex##agegroup
. margins, at((asbalanced) arm)
```

If we wanted results balanced on `agegroup` as well, we could type

```
. margins, at((asbalanced) arm agegroup)
```

If we wanted results balanced on all three covariates, we could type

```
. margins, at((asbalanced) arm agegroup sex)
```

or we could type

```
. margins, at((asbalanced) _factor)
```

or we could type

```
. margins, asbalanced
```

## Balancing in the presence of continuous covariates

So far, we have considered only factor variables because the concept of balancing is applicable only to factor covariates. If your model contains both factor and continuous covariates, the `asbalanced` option will treat the factor covariates as if they were balanced, but it will not affect the continuous covariates.

Here we imagine that the outcome of the experiment is binary and that we have two factor covariates (`arm` and `sex`) and two continuous covariates (`distance` and `ycn`). We could type

```
. use https://www.stata-press.com/data/r19/margex, clear
. logistic outcome i.arm i.sex c.distance c.ycn
. margins, asbalanced
```

This calculates the marginal probability of `outcome = 1` while treating factor covariates `arm` and `sex` as balanced, but continuous covariates `distance` and `ycn` are left as observed, which is the default behavior.

If we set continuous covariates equal to their means while maintaining a balanced treatment of factor covariates, the resulting margin is called an **adjusted treatment mean**. To calculate this margin, we could type

```
. margins, asbalanced atmeans
```

or we could type

```
. margins, at((asbalanced) _factor (mean) _continuous)
```

## Using fvset design

As a convenience feature, equivalent to

```
. regress y arm##sex sex##agegroup
. margins, at((asbalanced) arm sex)
```

is

```
. fvset design asbalanced arm sex
. regress y arm##sex sex##agegroup
. margins
```

The advantage of the latter is that you have to set the variables as balanced only once. This is useful when balancing is a design characteristic of certain variables and you wish to avoid accidentally treating them as unbalanced.

If you save your data after `fvsetting`, the settings will be remembered in future sessions. If you want to clear the setting(s), type

```
. fvset clear varlist
```

See [R] [fvset](#).

## Balancing in the presence of empty cells

The issue of empty cells is not exclusively an issue of balancing, but there are special considerations when balancing. Empty cells are discussed generally in *Estimability of margins*.

An empty cell is an interaction of levels of two or more factor variables for which you have no data. Usually, margins involving empty cells cannot be estimated. When balancing, there is an alternate definition of the margin that allows the margin to be estimated. `margins` makes the alternate calculation when you specify the `emptycells(reweight)` option. By default, `margins` uses the `emptycells(strict)` option.

If you have empty cells in your data and you request margins involving the empty cells, those margins will be marked as not estimable even if you specify the `asbalanced` option.

```
. use https://www.stata-press.com/data/r19/estimability, clear
(margins estimability)
. regress y sex##group
(output omitted)
. margins sex, asbalanced
```

```
Adjusted predictions Number of obs = 69
Model VCE: OLS
Expression: Linear prediction, predict()
At: group (asbalanced)
```

|        | Delta-method |                 |       |       |                      |
|--------|--------------|-----------------|-------|-------|----------------------|
|        | Margin       | std. err.       | t     | P> t  | [95% conf. interval] |
| sex    |              |                 |       |       |                      |
| Male   | 21.91389     | 1.119295        | 19.58 | 0.000 | 19.67572 24.15206    |
| Female | .            | (not estimable) |       |       |                      |

This example is discussed in *Estimability of margins*, although without the `asbalanced` option. What is said there is equally relevant to the `asbalanced` case. For reasons explained there, the margin for `sex = 1` (female) cannot be estimated.

The margin for `sex = 1` can be estimated in the `asbalanced` case if you are willing to make an assumption. Remember that `margins` makes the balanced calculation by summing the responses associated with the levels and then dividing by the number of levels. If you specify `emptycells(reweight)`, `margins` sums what is available and divides by the number available. Thus, you are assuming that, whatever the responses in the empty cells, those responses are such that they would not change the overall mean of what is observed.

The results of specifying `emptycells(reweight)` are

```
. margins sex, asbalanced emptycells(reweight)
Adjusted predictions Number of obs = 69
Model VCE: OLS
Expression: Linear prediction, predict()
Empty cells: reweight
At: group (asbalanced)
```

|        | Delta-method |           |       |       |                      |
|--------|--------------|-----------|-------|-------|----------------------|
|        | Margin       | std. err. | t     | P> t  | [95% conf. interval] |
| sex    |              |           |       |       |                      |
| Male   | 21.91389     | 1.119295  | 19.58 | 0.000 | 19.67572 24.15206    |
| Female | 24.85185     | 1.232304  | 20.17 | 0.000 | 22.38771 27.316      |

## Obtaining margins with nested designs

### Introduction to nested designs

Factors whose meaning depends on other factors are called nested factors, and the factors on which their meaning depends are called the nesting factors. For instance, assume that we have a sample of patients and each patient is assigned to one doctor. Then, patient is nested within doctor. Let the identifiers of the first 5 observations of our data be

| Doctor | Patient | Name  |
|--------|---------|-------|
| 1      | 1       | Fred  |
| 1      | 2       | Mary  |
| 1      | 3       | Bob   |
| 2      | 1       | Karen |
| 2      | 2       | Hank  |

The first patient on one doctor’s list has nothing whatsoever to do with the first patient on another doctor’s list. The meaning of `patient = 1` is defined only when the value of `doctor` is supplied.

Nested factors enter into models as interactions of nesting and nested; the nested factor does not appear by itself. We might estimate a model such as

```
. regress y ... i.doctor doctor#patient ...
```

You do not include `i.patient` because the coding for patient has no meaning except within doctor. Patient 1 is Fred for doctor 1 and Karen for doctor 2, etc.

`margins` provides an option to help account for the structure of nested models. The `within(varlist)` option specifies that margins estimate and report a set of margins for the value combinations of `varlist`. We might type

```
. margins, within(doctor)
```

Margin calculations are performed first for `doctor = 1`, then for `doctor = 2`, and so on.

Sometimes you need to specify `within()`, and other times you do not. Let's consider the particular model

```
. regress y i.doctor doctor#patient i.sex sex#doctor#patient
```

The guidelines are the following:

1. You may compute overall margins by typing `margins`.
2. You may compute overall margins within levels of a nesting factor by typing `margins, within(doctor)`.
3. You may compute margins of a nested factor within levels of its nesting factor by typing `margins patient, within(doctor)`.
4. You may compute margins of factors in your model, as long as the factor does not nest other factors and is not nested within other factors, by typing `margins sex`.
5. You may not compute margins of a nesting factor, such as `margins doctor`, because they are not estimable.

For examples using `within()`, see [\[R\] anova](#).

### Margins with nested designs as though the data were balanced

To obtain margins with nested designs as though the data were balanced, the guidelines are the same as above except that 1) you add the `asbalanced` option and 2) whenever you do not specify `within()`, you specify `emptycells(reweight)`. The updated guidelines are

1. You may compute overall margins by typing `margins, asbalanced emptycells(reweight)`.
2. You may compute overall margins within levels of a nesting factor by typing `margins, asbalanced within(doctor)`.
3. You may compute margins of a nested factor within levels of its nesting factor by typing `margins patient, asbalanced within(doctor)`.
4. You may compute margins of factors in your model, as long as the factor does not nest other factors and is not nested within other factors, by typing `margins sex, asbalanced emptycells(reweight)`.
5. You may not compute margins of a nesting factor, such as `margins doctor`, because they are not estimable.

Just as explained in *Using fvset design*, rather than specifying the `asbalanced` option, you may set the balancing characteristic on the factor variables once and for all by using the command `fvset design asbalanced varlist`.

#### □ Technical note

Specifying either `emptycells(reweight)` or `within(varlist)` causes margins to rebalance over all empty cells in your model. If you have interactions in your model that are not involved in the nesting, margins will lose its ability to detect estimability. □

#### □ Technical note

Careful readers will note that the description of `within(varlist)` matches closely the description of `over(varlist)`. The concept of nesting is similar to the concept of subpopulations. `within()` differs from `over()` in that it gracefully handles the missing cells when margins are computed as balanced. □

### Coding of nested designs

In the *Introduction* to this section, we showed a coding of the nested variable `patient`, where the coding started over with each doctor:

| Doctor | Patient | Name  |
|--------|---------|-------|
| 1      | 1       | Fred  |
| 1      | 2       | Mary  |
| 1      | 3       | Bob   |
| 2      | 1       | Karen |
| 2      | 2       | Hank  |

That coding style is not required. The data could just as well have been coded

| Doctor | Patient | Name  |
|--------|---------|-------|
| 1      | 1       | Fred  |
| 1      | 2       | Mary  |
| 1      | 3       | Bob   |
| 2      | 4       | Karen |
| 2      | 5       | Hank  |

or even

| Doctor | Patient | Name  |
|--------|---------|-------|
| 1      | 1037239 | Fred  |
| 1      | 2223942 | Mary  |
| 1      | 0611393 | Bob   |
| 2      | 4433329 | Karen |
| 2      | 6110271 | Hank  |

Actually, either of the above two alternatives is better than the first one because margins will be better able to give you feedback about estimability should you make a mistake following the guidelines. On the other hand, both of these alternatives require more memory at the estimation step. If you run short of memory, you will need to recode your patient ID to the first coding style, which you could do by typing

```
. sort doctor patient
. by doctor: generate newpatient = _n
```

Alternatively, you can set `emptycells drop` and continue to use your patient ID variable just as it is coded. If you do this, we recommend that you remember to type `set emptycells keep` when you are finished; margins is better able to determine estimability that way. If you regularly work with large nested models, you can set `emptycells keep`, permanently so that the setting persists across sessions. See [R] [set emptycells](#).

## Special topics

### Requirements for model specification

The results that margins reports are based on the most recently fit model or, in Stata jargon, the most recently issued estimation command. Here we discuss 1) mechanical requirements for how you specify that estimation command, 2) workarounds to use when those restrictions prove impossible, and 3) requirements for margins' `predict(pred_opt)` option to work.

Concerning 1, when you specify the estimation command, covariates that are logically factor variables must be Stata factor variables, and that includes indicator variables, binary variables, and dummies. It will not do to type

```
. regress y ... sex ...
```

even if `sex` is a 0/1 variable. You must type

```
. regress y ... i.sex ...
```

If you violate this rule, you will not get incorrect results, but you will discover that you will be unable to obtain margins on `sex`:

```
. margins sex
factor sex not found in list of covariates
r(111);
```

It is also important that if the same continuous variable appears in your model more than once, differently transformed, those transforms be performed via Stata's factor-variable notation. It will not do to type

```
. generate age2 = age^2
. regress y ... age age2 ...
```

You must type

```
. regress y ... age c.age#c.age ...
```

You must do that because margins needs to know everywhere that variable appears in the model if it is to be able to set covariates to fixed values.

Concerning 2, sometimes the transformations you desire may not be achievable using the factor-variable notation; in those situations, there is a workaround. Let's assume you wish to estimate

```
. generate age1_5 = age^1.5
. regress y ... age age1_5 ...
```

There is no factor-variable notation for including `age` and `age1.5` in a model, so obviously you are going to obtain the estimates by typing just what we have shown. In what follows, it would be okay if there are interactions of `age` and `age1_5` with other variables specified by the factor-variable notation, so the model could just as well be

```
. regress y ... age age1_5 sex#c.age sex#c.age1_5 ...
```

Let's assume you have fit one of these two models. On any subsequent `margins` command where you leave `age` free to vary, there will be no issue. You can type

```
. margins sex
```

and results will be correct. Issues arise when you attempt to fix `age` at predetermined values. The following would produce incorrect results:

```
. margins sex, at(age=20)
```

The results would be incorrect because they leave `age1_5` free to vary, and, logically, fixing `age` implies that `age1_5` should also be fixed. Because we were unable to state the relationship between `age` and `age1_5` using the factor-variable notation, `margins` does not know to fix `age1_5` at `201.5` when it fixes `age` at 20. To get the correct results, you must fix the value of `age1_5` yourself:

```
. margins sex, at(age=20 age1_5=89.442719)
```

That command produces correct results. In the command, `89.442719` is `201.5`.

In summary, when there is a functional relationship between covariates of your model and that functional relationship is not communicated to `margins` via the factor-variable notation, then it becomes your responsibility to ensure that all variables that are functionally related are set to the appropriate fixed values when any one of them is set to a fixed value.

Concerning 3, we wish to amend our claim that you can calculate margins for anything that `predict` will produce. We need to add a qualifier. Let us show you an example where the statement is not true. After `regress`, `predict` will predict something it calls `pr(a, b)`, which is the probability  $a \leq y \leq b$ . Yet if we attempted to use `pr()` with `margins` after estimation by `regress`, we would obtain

```
. margins sex, predict(pr(10,20))
prediction is a function of possibly stochastic quantities other than e(b)
r(498);
```

What we should have stated was that you can calculate margins for anything that `predict` will produce for which all the estimated quantities used in its calculation appear in  $e(V)$ , the estimated VCE. `pr()` is a function of  $\beta$ , the estimated coefficients, and of  $s^2$ , the estimated variance of the residual. `regress` does not post the variance of the residual variance (`sic`) in  $e(V)$ , or even estimate it, and therefore, `predict(pr(10, 20))` cannot be specified with `margins` after estimation by `regress`.

It is unlikely that you will ever encounter these kinds of problems because there are so few predictions where the components are not posted to  $e(V)$ . If you do encounter the problem, the solution may be to specify `nose` to suppress the standard error calculation. If the problem is not with computing the margin, but with computing its standard error, `margins` will report the result:

```
. margins sex, predict(pr(10,20)) nose
(output appears with SEs, tests, and CIs left blank)
```

□ Technical note

Programmers: If you run into this after running an estimation command that you have written, be aware that as of Stata 11, you are supposed to set in `e(marginsok)` the list of options allowed with `predict` that are okay to use with `margins`. When that list is not set, `margins` looks for violations of its assumptions and, if it finds any, refuses to proceed. □

**Estimability of margins**

Sometimes `margins` will report that a margin cannot be estimated:

```
. use https://www.stata-press.com/data/r19/estimability, clear
(margins estimability)
. regress y sex##group
(output omitted)
. margins sex
Predictive margins Number of obs = 69
Model VCE: OLS
Expression: Linear prediction, predict()
```

|        | Delta-method |                 |       |       |                      |
|--------|--------------|-----------------|-------|-------|----------------------|
|        | Margin       | std. err.       | t     | P> t  | [95% conf. interval] |
| sex    |              |                 |       |       |                      |
| Male   | 21           | .8500245        | 24.71 | 0.000 | 19.30027 22.69973    |
| Female | .            | (not estimable) |       |       |                      |

In the above output, the margin for `sex = 0` (male) is estimated, but the margin for `sex = 1` (female) is not estimable. This occurs because of empty cells. An empty cell is an interaction of levels of two or more factor variables for which you have no data. In the example, the lack of estimability arises because we have two empty cells:

```
. table sex group, nototals
```

|        | Group |   |    |   |   |
|--------|-------|---|----|---|---|
|        | 1     | 2 | 3  | 4 | 5 |
| Sex    |       |   |    |   |   |
| Male   | 2     | 9 | 27 | 8 | 2 |
| Female | 9     | 9 | 3  |   |   |

To calculate the marginal mean response for `sex = 1`, we have no responses to average over for `group = 4` and `group = 5`. We obviously could calculate that mean for the observations that really are `sex = 1`, but remember, the marginal calculation for `sex = 1` treats everyone as if female, and we will thus have 8 and 2 observations for which we have no basis for estimating the response.

There is no solution for this problem unless you are willing to treat the data as if it were balanced and adjust your definition of a margin; see *Balancing in the presence of empty cells*.

## Manipulability of tests

Manipulability is a problem that arises with some tests, and in particular, arises with Wald tests. Tests of margins are based on Wald tests, hence our interest. This is a generic issue and not specific to the `margins` command.

Let's understand the problem. Consider performing a test of whether some statistic  $\phi$  is 0. Whatever the outcome of that test, it would be desirable if the outcome were the same were we to test whether the  $\sqrt{\phi}$  were 0, or whether  $\phi^2$  were 0, or whether any other monotonic transform of  $\phi$  were 0 (for  $\phi^2$ , we were considering only the positive half of the number line). If a test does not have that property, it is manipulable.

Wald tests are manipulable, and that means the tests produced by `margins` are manipulable. You can see this for yourself by typing

```
. use https://www.stata-press.com/data/r19/margex, clear
. replace y = y - 65
. regress y sex##group
. margins, df(.)
. margins, expression(predict(xb)^2)
```

To compare the results from the two `margins` commands, we added the `df(.)` option to the first one, forcing it to report a  $z$  statistic even though a  $t$  statistic would have been appropriate in this case. We would prefer if the test against zero produced by `margins, df(.)` was equal to the test produced by `margins, expression(predict(xb)^2)`. But alas, they produce different results. The first produces  $z = 12.93$ , and the second produces  $z = 12.57$ .

The difference is not much in our example, but behind the scenes, we worked to make it small. We subtracted 65 from `y` so that the experiment would be for a case where it might be reasonable that you would be testing against 0. One does not typically test whether the mean income in the United States is zero or whether the mean blood pressure of live patients is zero. Had we left `y` as it was originally, we would have obtained  $z = 190$  and  $z = 96$ . We did not want to show that comparison to you first because the mean of `y` is so far from 0 that you probably would never be testing it. The corresponding difference in  $\phi$  is tiny.

Regardless of the example, it is important that you base your tests in the metric where the likelihood surface is most quadratic. For further discussion on manipulability, see [Manipulability in \[R\] predictnl](#).

This manipulability is not limited to Wald tests after estimation; you can also see the manipulability of results produced by linear regression just by applying nonlinear transforms to a covariate (Phillips and Park 1988; Gould 1996).

## Using margins after the estimates use command

Assume you fit and used `estimates save` (see [\[R\] estimates save](#)) to save the estimation results:

```
. regress y sex##group age c.age*c.age if site==1
. ...
. estimates save mymodel
file mymodel.ster saved
```

Later, perhaps in a different Stata session, you reload the estimation results by typing

```
. estimates use mymodel
```

You plan to use margins with the reloaded results. You must remember that margins bases its results not only on the current estimation results but also on the current data in memory. Before you can use margins, you must reload the dataset on which you fit the model or, if you wish to produce standardized margins, some other dataset.

```
. use mydata, clear
(data for fitting models)
```

If the dataset you loaded contained the data for standardization, you can stop reading; you know that to produce standardized margins, you need to specify the noesample option.

We reloaded the original data and want to produce margins for the estimation sample. In addition to the data, margins requires that e(sample) be set, as margins will remind us:

```
. margins sex
e(sample) does not identify the estimation sample
r(322);
```

The best solution is to use estimates esample to rebuild e(sample):

```
. estimates esample: y sex group age if site==1
```

If we knew we had no missing values in y and the covariates, we could type

```
. estimates esample: if site==1
```

Either way, margins would now work:

```
. margins sex
(usual output appears)
```

There is an alternative. We do not recommend it, but we admit that we have used it. Rather than rebuilding e(sample), you can use margins' noesample option to tell margins to skip using e(sample). You could then specify the appropriate if statement (if necessary) to identify the estimation sample:

```
. estimates use mymodel
. use mydata, clear
. margins sex if !missing(y, sex, group age) & site==1, noesample
```

In the above, we are not really running on a sample different from the estimation sample; we are merely using noesample to fool margins, and then we are specifying on the margins command the conditions equivalent to re-create e(sample).

If we wish to obtain vce(unconditional) results, however, noesample will be insufficient. We must also specify the force option,

```
. margins sex if !missing(y, sex, group age) & site==1,
> vce(unconditional) noesample force
(usual output appears)
```

Regardless of the approach you choose—resetting e(sample) or specifying noesample and possibly force—make sure you are right. In the vce(delta) case, you want to be right to ensure that you obtain the results you want. In the vce(unconditional) case, you need to be right because otherwise results will be statistically invalid.

## Syntax of at()

In `at(atspec)`, `atspec` may contain one or more of the following specifications:

```
varlist
(stat) varlist
varname = #
varname = (numlist)
varname = generate(exp)
```

where

1. `varnames` must be covariates in the previously fit model (estimation command).
2. Variable names (whether in `varname` or `varlist`) may be continuous variables, factor variables, or specific level variables, such as `age`, `group`, or `3.group`.
3. `varlist` may also be one of three standard lists:
  - (a) `_all` (all covariates),
  - (b) `_factor` (all factor-variable covariates), or
  - (c) `_continuous` (all continuous covariates).
4. `stat` can be any of the following:

| <i>stat</i>        | Description                                | Variables allowed |
|--------------------|--------------------------------------------|-------------------|
| <u>as</u> observed | at observed values in the sample (default) | all               |
| mean               | means (default for <i>varlist</i> )        | all               |
| median             | medians                                    | continuous        |
| p1                 | 1st percentile                             | continuous        |
| p2                 | 2nd percentile                             | continuous        |
| ...                | 3rd–49th percentiles                       | continuous        |
| p50                | 50th percentile (same as median)           | continuous        |
| ...                | 51st–97th percentiles                      | continuous        |
| p98                | 98th percentile                            | continuous        |
| p99                | 99th percentile                            | continuous        |
| min                | minimums                                   | continuous        |
| max                | maximums                                   | continuous        |
| zero               | fixed at zero                              | continuous        |
| base               | base level                                 | factors           |
| <u>as</u> balanced | all levels equally probable and sum to 1   | factors           |

Any *stat* except `zero`, `base`, and `asbalanced` may be prefixed with an `o` to get the overall statistic—the sample over all `over()` groups. For example, `omean`, `omedian`, and `op25`. Overall statistics differ from their correspondingly named statistics only when the `over()` or `within()` option is specified. When no *stat* is specified, `mean` is assumed. If *stat* is not followed by a *varlist*, *stat* is ignored.

*atspec* can involve multiple settings for one covariate as well as settings for multiple covariates. The following rules are applied when more than one covariate or value is included:

1. When more than one covariate is referenced in *atspec* but each covariate is set to only one value, all settings are applied in combination. For example, `at(x1=5 x2=0)` results in *margins* being estimated under one scenario, with *x1* set to 5, *x2* set to 0, and all other covariates set to their observed values (the default).
2. When multiple values are specified for a covariate, the covariate will be set to each of the values in turn. For example, `at(x1=5 x1=10)` or, equivalently, `at(x1=(5 10))` specifies that *x1* be set first to 5 and then to 10.
3. When multiple values are specified for more than one covariate, all possible combinations of settings are applied in turn. For example, `at(x1=(5 10) x2=(0 1))` results in *margins* being estimated under four scenarios: (*x1* = 5 *x2* = 0), (*x1* = 5 *x2* = 1), (*x1* = 10 *x2* = 0), and (*x1* = 10 *x2* = 1).
4. Settings may be specified for groups of covariates using three general varlists—`_all`, `_factor`, and `_continuous`. When *atspec* includes both specifications with general varlists and specifications with named covariates, the specifications for named covariates take precedence over general ones. For example, `at(x1=10 (means) _all)` sets *x1* to 10 while setting all other covariates to their means.
5. Only one (*stat*) varlist specification can be applied to a covariate. If more than one is specified, the rightmost specification is respected. For example, `at((means) x1 x2 (medians) x1 x2)` sets both *x1* and *x2* to their medians.
6. When both a (*stat*) specification and another specification are included for a named covariate, the other specification takes precedence. For example, `at(x1=5 (means) x1)` sets *x1* to 5.

In addition, `at()` can be repeated. When multiple `at()` options are specified, *atspecs* are processed sequentially. For instance, `at(x1=5) at(x2=0)` results in *margins* being estimated under two scenarios. The first sets *x1* to 5 and all other covariates, including *x2*, to their observed values. The second sets *x2* to 0 and all other covariates to their observed values. Note that this is different from the single `at(x1=5 x2=0)` specification, which sets *x1* and *x2* to the specified values simultaneously.

### Estimation commands that may be used with margins

*margins* may be used after most estimation commands.

*margins* cannot be used after estimation commands that do not produce full variance matrices, such as `exlogistic` and `expoisson` (see [R] [exlogistic](#) and [R] [expoisson](#)).

*margins* is all about covariates and cannot be used after estimation commands that do not post the covariates, which eliminates `gmm` (see [R] [gmm](#)).

*margins* cannot be used after some estimation commands that have an odd data organization, such as `nlogit`. However, *margins* has been specially adapted to work with many choice model estimation commands; see [CM] [margins](#).

Introduction to margins, part 3: Interactions

## Glossary

**adjusted mean.** A *margin* when the response is the linear predictor from linear regression, ANOVA, etc. For some authors, adjusting also implies adjusting for unbalanced data. See *Obtaining margins of responses* and see *Obtaining margins as though the data were balanced*.

**adjusted treatment mean.** When calculating *estimated marginal means* (also known as least-squares means) in the presence of continuous covariates, some authors recommend setting the continuous covariates equal to their means. This yields an estimated marginal mean that *Searle, Speed, and Milliken (1980)* refer to as an adjusted treatment mean. Adjusted treatment means are obtained using option `at((asbalanced) _factor (mean) _continuous)` or, equivalently, options `asbalanced` and `atmeans` together.

**average marginal effect.** See *marginal effect and average marginal effect*.

**average partial effect.** See *partial effect and average partial effect*.

**balanced data.** When a dataset contains an equal number of observations at each level of a factor variable, it is said to be balanced with respect to that variable. The concept of balanced data is only applicable to factor variables, not continuous variables. Balancing is common in designed experiments, but even if the data are not balanced, the `asbalanced` option allows margins to be calculated as though the data were balanced. Also see *Obtaining margins as though the data were balanced*.

**conditional margin.** A *margin* when the response is evaluated at fixed values of all the covariates. If any covariates are left as observed, the margin is called a predictive margin.

**effect.** The effect of  $x$  is the derivative of the *response* with respect to covariate  $x$ , or it is the difference in responses caused by a discrete change in  $x$ . Also see *marginal effect*.

The effect of  $x$  measures the change in the response for a change in  $x$ . Derivatives or differences might be reported as elasticities. If  $x$  is continuous, the effect is measured continuously. If  $x$  is a factor, the effect is measured with respect to each level of the factor and may be calculated as a discrete difference or as a continuous change, as measured by the derivative. `margins` calculates the discrete difference by default and calculates the derivative if the `continuous` option is specified.

**elasticity and semielasticity.** The elasticity of  $y$  with respect to  $x$  is  $d(\ln y)/d(\ln x) = (x/y) \times (dy/dx)$ , which is approximately equal to the proportional change in  $y$  for a proportional change in  $x$ .

The semielasticity of  $y$  with respect to  $x$  is either 1)  $dy/d(\ln x) = x \times (dy/dx)$  or 2)  $d(\ln y)/dx = (1/y) \times (dy/dx)$ , which is approximately 1) the change in  $y$  for a proportional change in  $x$  or 2) the proportional change in  $y$  for a change in  $x$ .

`margins` uses model predictions or user-specified statistics in `expression()` in place of  $y$  above.

**empty cell.** An interaction of levels of two or more factor variables for which you have no data. For instance, you have `sex` interacted with `group` in your model, and in your data there are no females in group 1. Empty cells affect which margins can be estimated; see *Estimability of margins*.

**estimability.** Estimability concerns whether a margin can be uniquely estimated (identified); see *Estimability of margins*.

**estimated marginal mean.** An estimated marginal mean, as defined by Searle, Speed, and Milliken (1980), is a margin assuming the levels of each factor covariate are balanced (equally likely), including interaction terms. This is obtained using the `asbalanced` option.

If the model includes continuous covariates, setting them equal to their sample means yields a type of estimated marginal mean known as an *adjusted treatment mean*.

When some cells are empty, it is impossible to estimate their marginal means. To get around this limitation, Searle, Speed, and Milliken introduced the concept of modified estimated marginal means, in which margins involving empty cells are redefined so that they become estimable. This is invoked by the `emptycells(reweight)` option. See *Balancing in the presence of empty cells*.

**least-squares mean.** Synonym for estimated marginal mean.

**margin.** A statistic calculated from predictions or other statistics of a previously fit model at fixed values of some covariates and averaging or otherwise integrating over the remaining covariates. The prediction or other statistic on which the margin is based is called the response.

If all the covariates are fixed, then the margin is called a conditional margin. If any covariates are left to vary, the margin is called a predictive margin.

In this documentation, we divide margins on the basis of whether the statistic is a response or a derivative of a response; see *Obtaining margins of responses* and *Obtaining margins of derivatives of responses*.

**marginal effect and average marginal effect.** The marginal effect of  $x$  is the *margin* of the *effect* of  $x$ . The term is popular with social scientists, and because of that, you might think the word marginal in marginal effect means derivative because of terms like marginal cost and marginal revenue. Marginal used in that way, however, refers to the derivative of revenue and the derivative of cost; it refers to the numerator, whereas marginal effect refers to the denominator. Moreover, *effect* is already a derivative or difference.

Some researchers interpret marginal in marginal effect to mean instantaneous, and thus a marginal effect is the instantaneous derivative rather than the discrete first difference, corresponding to margins' continuous option. Researchers who use marginal in this way refer to the discrete difference calculation of an effect as a partial effect.

Other researchers define marginal effect to be the margin when all covariates are held fixed and the average marginal effect when some covariates are not fixed.

**out-of-sample prediction.** Predictions made in one dataset using the results from a model fit on another. Sample here refers to the sample on which the model was fit, and out-of-sample refers to the dataset on which the predictions are made.

**partial effect and average partial effect.** Some authors restrict the term *marginal effect* to mean derivatives and use the term partial effect to denote discrete differences; see *marginal effect and average marginal effect*.

**population marginal mean.** The theoretical (true) value that is estimated by *estimated marginal mean*. We avoid this term because it can be confused with the concept of a population in survey statistics, with which the population marginal mean has no connection.

**posting results, posting margins.** A Stata concept having to do with storing the results from the `margins` command in `e()` so that those results can be used as if they were estimation results, thus allowing the subsequent use of postestimation commands, such as `test`, `testnl`, `lincom`, and `nlcom` (see [R] [test](#), [R] [testnl](#), [R] [lincom](#), and [R] [nlcom](#)). This is achieved by specifying `margins' post` option. See [Example 10: Testing margins—contrasts of margins](#).

**predictive margin.** A *margin* in which all the covariates are not fixed. When all covariates are fixed, it is called a *conditional margin*.

**recycled prediction.** A synonym for *predictive margin*.

**response.** A prediction or other statistic derived from combining the parameter estimates of a fitted model with data or specified values on covariates. Derivatives of responses are themselves responses. Responses are what we take *margins* of.

**standardized margin.** The margin calculated on data different from the data used to fit the model. The term *standardized* is usually reserved for situations in which the alternate population is a reference population, which may be real or artificial, and which is treated as fixed.

**subpopulation.** A subset of your sample that represents a subset of the population, such as the males in a sample of people. In survey contexts when it is desired to account for sampling of the covariates, standard errors for marginal statistics and effects need to account for both the population and the subpopulation. This is accomplished by specifying the `vce(unconditional)` option and one of the `subpop()` or `over()` options. In fact, the above is allowed even when your data are not `svyset` because `vce(unconditional)` implies that the sample represents a population.

## Stored results

`margins` stores the following in `r()`:

### Scalars

|                              |                                               |
|------------------------------|-----------------------------------------------|
| <code>r(N)</code>            | number of observations                        |
| <code>r(N_sub)</code>        | subpopulation observations                    |
| <code>r(N_clust)</code>      | number of clusters                            |
| <code>r(N_psu)</code>        | number of sampled PSUs, survey data only      |

|------------------------|-------------------------|

## Methods and formulas

Margins are statistics calculated from predictions of a previously fit model at fixed values of some covariates and averaging or otherwise integrating over the remaining covariates. There are many names for the different statistics that margins can compute: estimates marginal means (see Searle, Speed, and Milliken [1980]), predictive margins (see Graubard and Korn [2004]), marginal effects (see Greene [2018]), and average marginal/partial effects (see Wooldridge [2010] and Bartus [2005]).

Methods and formulas are presented under the following headings:

- Notation*
- Marginal effects*
- Fixing covariates and balancing factors*
- Estimable functions*
- Standard errors conditional on the covariates*
- Unconditional standard errors*

## Notation

Let  $\theta$  be the vector of parameters in the current model fit, let  $\mathbf{z}$  be a vector of covariate values, and let  $f(\mathbf{z}, \theta)$  be a scalar-valued function returning the value of the predictions of interest. The following table illustrates the parameters and default prediction for several of Stata's estimation commands.

| Command  | $\theta$                           | $\mathbf{z}$                 | $f(\mathbf{z}, \theta)$                                  |
|----------|------------------------------------|------------------------------|----------------------------------------------------------|
| regress  | $\beta$                            | $\mathbf{x}$                 | $\mathbf{x}\beta$                                        |
| cloglog  | $\beta$                            | $\mathbf{x}$                 | $1 - e^{-e^{x\beta}}$                                    |
| logit    | $\beta$                            | $\mathbf{x}$                 | $1/(1 + e^{-x\beta})$                                    |
| poisson  | $\beta$                            | $\mathbf{x}$                 | $e^{x\beta}$                                             |
| probit   | $\beta$                            | $\mathbf{x}$                 | $\Phi(\mathbf{x}\beta)$                                  |
| biprobit | $\beta_1, \beta_2, \rho$           | $\mathbf{x}_1, \mathbf{x}_2$ | $\Phi_2(\mathbf{x}_1\beta_1, \mathbf{x}_2\beta_2, \rho)$ |
| mlogit   | $\beta_1, \beta_2, \dots, \beta_k$ | $\mathbf{x}$                 | $e^{-x\beta_1} / (\sum_i e^{-x\beta_i})$                 |
| nbreg    | $\beta, \ln\alpha$                 | $\mathbf{x}$                 | $e^{x\beta}$                                             |

$\Phi()$  and  $\Phi_2()$  are cumulative distribution functions:  $\Phi()$  for the standard normal distribution and  $\Phi_2()$  for the standard bivariate normal distribution.

margins computes estimates of

$$p(\theta) = \frac{1}{M_{S_p}} \sum_{j=1}^M \delta_j(S_p) f(\mathbf{z}_j, \theta)$$

where  $\delta_j(S_p)$  identifies elements within the subpopulation  $S_p$  (for the prediction of interest),

$$\delta_j(S_p) = \begin{cases} 1, & j \in S_p \\ 0, & j \notin S_p \end{cases}$$

$M_{S_p}$  is the subpopulation size,

$$M_{S_p} = \sum_{j=1}^M \delta_j(S_p)$$

and  $M$  is the population size.

Let  $\hat{\theta}$  be the vector of parameter estimates. Then, margins estimates  $p(\theta)$  via

$$\hat{p} = \frac{1}{w.} \sum_{j=1}^N \delta_j(S_p) w_j f(\mathbf{z}_j, \hat{\theta})$$

where

$$w. = \sum_{j=1}^N \delta_j(S_p) w_j$$

$\delta_j(S_p)$  indicates whether observation  $j$  is in subpopulation  $S_p$ ,  $w_j$  is the weight for the  $j$ th observation, and  $N$  is the sample size.

## Marginal effects

margins also computes marginal and partial effects. For the marginal effect of continuous covariate  $x$ , margins computes

$$\hat{p} = \frac{1}{w.} \sum_{j=1}^N \delta_j(S_p) w_j h(\mathbf{z}_j, \hat{\theta})$$

where

$$h(\mathbf{z}, \theta) = \frac{\partial f(\mathbf{z}, \theta)}{\partial x}$$

The marginal effect for level  $k$  of factor variable  $A$  is the simple contrast (also known as difference) comparing its margin with the margin at the base level.

$$h(\mathbf{z}, \theta) = f(\mathbf{z}, \theta|A = k) - f(\mathbf{z}, \theta|A = \text{base})$$

Elasticities and semielasticities given by `eyex()` and `dyex()` are only available for continuous covariates. Elasticities are computed using

$$h(\mathbf{z}, \theta) = \frac{\partial \ln\{f(\mathbf{z}, \theta)\}}{\partial \ln(x)}$$

and semielasticities, `dyex()`, using

$$h(\mathbf{z}, \theta) = \frac{\partial f(\mathbf{z}, \theta)}{\partial \ln(x)}$$

Semielasticities of the form `eydx()` for continuous covariates are computed using

$$h(\mathbf{z}, \theta) = \frac{\partial \ln\{f(\mathbf{z}, \theta)\}}{\partial x}$$

and for discrete covariates using

$$h(\mathbf{z}, \theta) = \ln\{f(\mathbf{z}, \theta|A = k)\} - \ln\{f(\mathbf{z}, \theta|A = \text{base})\}$$

## Fixing covariates and balancing factors

`margins` controls the values in each  $\mathbf{z}$  vector through the `marginlist`, the `at()` option, the `atmeans` option, and the `asbalanced` and `emptycells()` options. Suppose  $\mathbf{z}$  is composed of the elements from the equation specification

$$A\#B\ x$$

where  $A$  is a factor variable with  $a$  levels,  $B$  is a factor variable with  $b$  levels, and  $x$  is a continuous covariate. To simplify the notation for this discussion, assume the levels of  $A$  and  $B$  start with 1 and are contiguous. Then

$$\mathbf{z} = (A_1, \dots, A_a, B_1, \dots, B_b, A_1B_1, A_1B_2, \dots, A_aB_b, x, 1)$$

where  $A_i$ ,  $B_j$ , and  $A_iB_j$  represent the indicator values for the factor variables  $A$  and  $B$  and the interaction  $A\#B$ .

When factor  $A$  is in the `marginlist`, `margins` replaces  $A$  with  $i$  and then computes the mean of the subsequent prediction, for  $i = 1, \dots, a$ . When the interaction term  $A\#B$  is in the `marginlist`, `margins` replaces  $A$  with  $i$  and  $B$  with  $j$ , and then computes the mean of the subsequent prediction, for all combinations of  $i = 1, \dots, a$  and  $j = 1, \dots, b$ .

The `at()` option sets model covariates to fixed values. For example, `at(x=15)` causes `margins` to temporarily set  $x$  to 15 for each observation in the dataset before computing any predictions. Similarly, `at((median) x)` causes `margins` to temporarily set  $x$  to the median of  $x$  using the current dataset.

When factor variable  $A$  is specified as `asbalanced`, `margins` sets each  $A_i$  to  $1/a$ . Thus, each  $\mathbf{z}$  vector will look like

$$\mathbf{z} = (1/a, \dots, 1/a, B_1, \dots, B_b, B_1/a, B_2/a, \dots, B_b/a, x, 1)$$

If  $B$  is also specified as `asbalanced`, then each  $B_j$  is set to  $1/b$ , and each  $\mathbf{z}$  vector will look like

$$\mathbf{z} = (1/a, \dots, 1/a, 1/b, \dots, 1/b, 1/ab, 1/ab, \dots, 1/ab, x, 1)$$

If `emptycells(reweight)` is also specified, then `margins` uses a different balancing weight for each element of  $\mathbf{z}$ , depending on how many empty cells the element is associated with. Let  $\delta_{ij}$  indicate that the  $ij$ th cell of  $A\#B$  was observed in the estimation sample.

$$\delta_{ij} = \begin{cases} 0, & A = i \text{ and } B = j \text{ was an empty cell} \\ 1, & \text{otherwise} \end{cases}$$

For the grand margin, the affected elements of  $\mathbf{z}$  and their corresponding balancing weights are

$$A_i = \frac{\sum_j \delta_{ij}}{\sum_k \sum_j \delta_{kj}}$$

$$B_j = \frac{\sum_i \delta_{ij}}{\sum_i \sum_k \delta_{ik}}$$

$$A_iB_j = \frac{\delta_{ij}}{\sum_k \sum_l \delta_{kl}}$$

For the  $j$ th margin of  $B$ , the affected elements of  $\mathbf{z}$  and their corresponding balancing weights are

$$A_i = \frac{\delta_{ij}}{\sum_k \delta_{kj}}$$

$$B_l = \begin{cases} 1, & \text{if } l = j \text{ and not all } \delta_{ij} \text{ are zero} \\ 0, & \text{otherwise} \end{cases}$$

$$A_i B_l = \frac{\delta_{il}}{\sum_k \delta_{kl}} B_l$$

## Estimable functions

The fundamental idea behind estimable functions is clearly defined in the statistical literature for linear models; see [Searle and Gruber \(2017\)](#). Assume that we are working with the following linear model:

$$\mathbf{y} = \mathbf{X}\mathbf{b} + \mathbf{e}$$

where  $\mathbf{y}$  is an  $N \times 1$  vector of responses,  $\mathbf{X}$  is an  $N \times p$  matrix of covariate values,  $\mathbf{b}$  is a  $p \times 1$  vector of coefficients, and  $\mathbf{e}$  is a vector of random errors. Assuming a constant variance for the random errors, the normal equations for the least-squares estimator,  $\hat{\mathbf{b}}$ , are

$$\mathbf{X}'\mathbf{X}\hat{\mathbf{b}} = \mathbf{X}'\mathbf{y}$$

When  $\mathbf{X}$  is not of full column rank, we will need a generalized inverse (g-inverse) of  $\mathbf{X}'\mathbf{X}$  to solve for  $\hat{\mathbf{b}}$ . Let  $\mathbf{G}$  be a g-inverse of  $\mathbf{X}'\mathbf{X}$ .

[Searle and Gruber \(2017\)](#) defines a linear function of the parameters as *estimable* if it is identically equal to some linear function of the expected values of the  $\mathbf{y}$  vector. Let  $\mathbf{H} = \mathbf{G}\mathbf{X}'\mathbf{X}$ . Then this definition simplifies to the following rule:

$$\mathbf{z}\mathbf{b} \text{ is estimable if } \mathbf{z} = \mathbf{z}\mathbf{H}$$

`margins` generalizes this to nonlinear functions by assuming the prediction function  $f(\mathbf{z}, \boldsymbol{\theta})$  is a function of one or more of the linear predictions from the equations in the model that  $\boldsymbol{\theta}$  represents.

$$f(\mathbf{z}, \boldsymbol{\theta}) = h(\mathbf{z}_1\boldsymbol{\beta}_1, \mathbf{z}_2\boldsymbol{\beta}_2, \dots, \mathbf{z}_k\boldsymbol{\beta}_k)$$

$\mathbf{z}_i\boldsymbol{\beta}_i$  is considered estimable if  $\mathbf{z}_i = \mathbf{z}_i\mathbf{H}_i$ , where  $\mathbf{H}_i = \mathbf{G}_i\mathbf{X}'_i\mathbf{X}_i$ ,  $\mathbf{G}_i$  is a g-inverse for  $\mathbf{X}'_i\mathbf{X}_i$ , and  $\mathbf{X}_i$  is the matrix of covariates from the  $i$ th equation of the fitted model. `margins` considers  $p(\boldsymbol{\theta})$  to be estimable if every  $\mathbf{z}_i\boldsymbol{\beta}_i$  is estimable.

## Standard errors conditional on the covariates

By default, `margins` uses the delta method to estimate the variance of  $\hat{p}$ .

$$\widehat{\text{Var}}(\hat{p} | \mathbf{z}) = \mathbf{v}'\mathbf{V}\mathbf{v}$$

where  $\mathbf{V}$  is a variance estimate for  $\hat{\boldsymbol{\theta}}$  and

$$\mathbf{v} = \left. \frac{\partial \hat{p}}{\partial \boldsymbol{\theta}} \right|_{\boldsymbol{\theta}=\hat{\boldsymbol{\theta}}}$$

This variance estimate is conditional on the  $\mathbf{z}$  vectors used to compute the marginalized predictions.

## Unconditional standard errors

margins with the vce(unconditional) option uses linearization to estimate the unconditional variance of  $\hat{\theta}$ . Linearization uses the variance estimator for the total of a score variable for  $\hat{p}$  as an approximate estimator for  $\text{Var}(\hat{p})$ ; see [SVY] **Variance estimation**. margins requires that the model was fit using some form of linearized variance estimator and that predict, scores computes the appropriate score values for the linearized variance estimator.

The score for  $\hat{p}$  from the  $j$ th observation is given by

$$s_j = \frac{\partial \hat{p}}{\partial w_j} = -\frac{\delta_j(S_p)}{w} \hat{p} + \frac{\delta_j(S_p)}{w} f(\mathbf{z}_j, \hat{\theta}) + \frac{1}{w} \sum_{i=1}^N \delta_i(S_p) w_i \frac{\partial f(\mathbf{z}_i, \hat{\theta})}{\partial w_j}$$

The remaining partial derivative can be decomposed using the chain rule.

$$\frac{\partial f(\mathbf{z}_i, \hat{\theta})}{\partial w_j} = \left( \frac{\partial f(\mathbf{z}_i, \theta)}{\partial \theta} \Big|_{\theta=\hat{\theta}} \right) \left( \frac{\partial \hat{\theta}}{\partial w_j} \right)'$$

This is the inner product of two vectors, the second of which is not a function of the  $i$  index. Thus, the score is

$$s_j = -\frac{\delta_j(S_p)}{w} \hat{p} + \frac{\delta_j(S_p)}{w} f(\mathbf{z}_j, \hat{\theta}) + \left( \frac{\partial \hat{p}}{\partial \theta} \Big|_{\theta=\hat{\theta}} \right) \left( \frac{\partial \hat{\theta}}{\partial w_j} \right)'$$

If  $\hat{\theta}$  was derived from a system of equations (such as in linear regression or maximum likelihood estimation), then  $\hat{\theta}$  is the solution to

$$\mathbf{G}(\theta) = \sum_{j=1}^N \delta_j(S_m) w_j \mathbf{g}(\theta, \mathbf{y}_j, \mathbf{x}_j) = \mathbf{0}$$

where  $S_m$  identifies the subpopulation used to fit the model,  $\mathbf{g}()$  is the model's gradient function, and  $\mathbf{y}_j$  and  $\mathbf{x}_j$  are the values of the dependent and independent variables for the  $j$ th observation. We can use linearization to derive a first-order approximation for  $\partial \hat{\theta} / \partial w_j$ .

$$\mathbf{G}(\hat{\theta}) \approx \mathbf{G}(\theta_0) + \frac{\partial \mathbf{G}(\theta)}{\partial \theta} \Big|_{\theta=\theta_0} (\hat{\theta} - \theta_0)$$

Let  $\mathbf{H}$  be the Hessian matrix

$$\mathbf{H} = \frac{\partial \mathbf{G}(\theta)}{\partial \theta} \Big|_{\theta=\theta_0}$$

Then

$$\hat{\theta} \approx \theta_0 + (-\mathbf{H})^{-1} \mathbf{G}(\theta_0)$$

and

$$\frac{\partial \hat{\theta}}{\partial w_j} \approx (-\mathbf{H})^{-1} \frac{\partial \mathbf{G}(\theta)}{\partial w_j} \Big|_{\theta=\hat{\theta}} = (-\mathbf{H})^{-1} \delta_j(S_m) \mathbf{g}(\hat{\theta}, \mathbf{y}_j, \mathbf{x}_j)$$

The computed value of the score for  $\hat{p}$  for the  $j$ th observation is

$$s_j = \mathbf{v}' \mathbf{u}_j$$

where

$$\mathbf{v} = \begin{bmatrix} -\frac{\hat{p}}{w_j} \\ \frac{1}{w_j} \\ \frac{\partial \hat{p}}{\partial \boldsymbol{\theta}} (-\mathbf{H})^{-1} \end{bmatrix}$$

and

$$\mathbf{u}_j = \begin{bmatrix} \delta_j(S_p) \\ \delta_j(S_p) f(\mathbf{z}_j, \hat{\boldsymbol{\theta}}) \\ \delta_j(S_m) \mathbf{g}(\hat{\boldsymbol{\theta}}, \mathbf{y}_j, \mathbf{x}_j) \end{bmatrix}$$

Thus, the variance estimate for  $\hat{p}$  is

$$\widehat{\text{Var}}(\hat{p}) = \mathbf{v}' \widehat{\text{Var}}(\widehat{\mathbf{U}}) \mathbf{v}$$

where

$$\widehat{\mathbf{U}} = \sum_{j=1}^N w_j \mathbf{u}_j$$

margins uses the model-based variance estimates for  $(-\mathbf{H})^{-1}$  and the scores from predict for  $\mathbf{g}(\hat{\boldsymbol{\theta}}, \mathbf{y}_j, \mathbf{x}_j)$ .

## Postestimation commands

The following standard postestimation command is available after `margins`:

| Command                  | Description                                                                         |
|--------------------------|-------------------------------------------------------------------------------------|
| <code>marginsplot</code> | graph the results from <code>margins</code> —profile plots, interaction plots, etc. |

For information on `marginsplot`, see [R] [marginsplot](#).

The following standard postestimation commands are available after `margins`, `post`:

| Command                      | Description                                                                                       |
|------------------------------|---------------------------------------------------------------------------------------------------|
| <code>contrast</code>        | contrasts and ANOVA-style joint tests of parameters                                               |
| <code>estat summarize</code> | summary statistics for the estimation sample                                                      |
| <code>estat vce</code>       | variance–covariance matrix of the estimators (VCE)                                                |
| <code>estimates</code>       | cataloging estimation results                                                                     |
| <code>etable</code>          | table of estimation results                                                                       |
| <code>lincom</code>          | point estimates, standard errors, testing, and inference for linear combinations of parameters    |
| <code>nlcom</code>           | point estimates, standard errors, testing, and inference for nonlinear combinations of parameters |
| <code>pwcompare</code>       | pairwise comparisons of parameters                                                                |
| <code>test</code>            | Wald tests of simple and composite linear hypotheses                                              |
| <code>testnl</code>          | Wald tests of nonlinear hypotheses                                                                |

## Remarks and examples

Continuing with the example from *Example 8: Margins of interactions* in [R] [margins](#), we use the dataset and refit the logistic model of outcome:

```
. use https://www.stata-press.com/data/r19/margex
(Artificial data for margins)
. logistic outcome sex##group age
(output omitted)
```

We then estimate the margins for males and females and post the margins as estimation results with a full VCE.

```
. margins sex, post
Predictive margins Number of obs = 3,000
Model VCE: OIM
Expression: Pr(outcome), predict()
```

|        | Delta-method |           | z     | P> z  | [95% conf. interval] |          |
|--------|--------------|-----------|-------|-------|----------------------|----------|
|        | Margin       | std. err. |       |       |                      |          |
| sex    |              |           |       |       |                      |          |
| Male   | .1600644     | .0125653  | 12.74 | 0.000 | .1354368             | .184692  |
| Female | .1966902     | .0100043  | 19.66 | 0.000 | .1770821             | .2162983 |

We can now use nlcom (see [R] [nlcom](#)) to estimate a risk ratio of females to males using the average probabilities for females and males posted by margins:

```
. nlcom (risk_ratio: _b[1.sex] / _b[0.sex])
 risk_ratio: _b[1.sex] / _b[0.sex]
```

|            | Coefficient | Std. err. | z     | P> z  | [95% conf. interval] |          |
|------------|-------------|-----------|-------|-------|----------------------|----------|
| risk_ratio | 1.228819    | .1149538  | 10.69 | 0.000 | 1.003514             | 1.454124 |

We could similarly estimate the average risk difference between females and males:

```
. nlcom (risk_diff: _b[1.sex] - _b[0.sex])
 risk_diff: _b[1.sex] - _b[0.sex]
```

|           | Coefficient | Std. err. | z    | P> z  | [95% conf. interval] |         |
|-----------|-------------|-----------|------|-------|----------------------|---------|
| risk_diff | .0366258    | .0160632  | 2.28 | 0.023 | .0051425             | .068109 |

## Description

`margins` with the `contrast` option or with contrast operators performs contrasts of margins. This extends the capabilities of `contrast` to any of the nonlinear responses, predictive margins, or other margins that can be estimated by `margins`.

## Quick start

Reference category contrasts of the predictive margins for `a` after `logit y a##b x1`  
`margins r.a`

Contrasts of predictive margins for `a` with the previous level  
`margins ar.a`

Test the equality of predictive margins for `a`  
`margins a, contrast`

Reference category contrasts of predictive margins for `x1 = 10` and `x1 = 20` with `x1 = 0`  
`margins, at(x1=(0 10 20)) contrast(atcontrast(r))`

Average partial effect of increasing `x1` by 100 for each observation after `probit y x1 x2`  
`margins, at((asobserved) _all) at(x1=generate(x1+100)) ///  
contrast(atcontrast(r))`

## Menu

Statistics > Postestimation

## Syntax

```
margins [marginlist] [if] [in] [weight] [, contrast margins_options]
```

```
margins [marginlist] [if] [in] [weight] [, contrast(suboptions) margins_options]
```

where *marginlist* is a list of factor variables or interactions that appear in the current estimation results. The variables may be typed with or without [contrast operators](#), and you may use any factor-variable syntax:

```
. margins sex##group, contrast
. margins sex##g.group, contrast
. margins sex@group, contrast
```

See the [operators \(\*op.\*\)](#) table in [\[R\] contrast](#) for the list of contrast operators. Contrast operators may also be specified on the variables in `margins's` `over()` and `within()` options to perform contrasts across the levels of those variables.

| <i>suboptions</i>                                         | Description                                                                                                      |
|-----------------------------------------------------------|------------------------------------------------------------------------------------------------------------------|
| Contrast                                                  |                                                                                                                  |
| <code>overall</code>                                      | add a joint hypothesis test for all specified contrasts                                                          |
| <code>lincom</code>                                       | treat user-defined contrasts as linear combinations                                                              |
| <code>predict(<i>op</i>[ <code>._predict</code> ])</code> | apply the <i>op.</i> contrast operator to the groups defined by multiple <code>predict()</code> options          |
| <code>atcontrast(<i>op</i>[ <code>._at</code> ])</code>   | apply the <i>op.</i> contrast operator to the groups defined by <code>at()</code>                                |
| <code>predictjoint</code>                                 | test jointly across all groups defined by multiple <code>predict()</code> options                                |
| <code>atjoint</code>                                      | test jointly across all groups defined by <code>at()</code>                                                      |
| <code>overjoint</code>                                    | test jointly across all levels of the unoperated <code>over()</code> variables                                   |
| <code>withinjoint</code>                                  | test jointly across all levels of the unoperated <code>within()</code> variables                                 |
| <code>marginswithin</code>                                | perform contrasts within the levels of the unoperated terms in <i>marginlist</i>                                 |
| <code>cieffects</code>                                    | show effects table with confidence intervals                                                                     |
| <code>pveffects</code>                                    | show effects table with <i>p</i> -values                                                                         |
| <code>effects</code>                                      | show effects table with confidence intervals and <i>p</i> -values                                                |
| <code>nowald</code>                                       | suppress table of Wald tests                                                                                     |
| <code>noatlevels</code>                                   | report only the overall Wald test for terms that use the <code>within @</code> or nested <code> </code> operator |
| <code>nosvyadjust</code>                                  | compute unadjusted Wald tests for survey results                                                                 |

`collect` is allowed; see [\[U\] 11.1.10 Prefix commands](#).

`fweights`, `awweights`, `iweights`, and `pweights` are allowed; see [\[U\] 11.1.6 weight](#).

## Suboptions

### Contrast

`overall` specifies that a joint hypothesis test over all terms be performed.

`lincom` specifies that user-defined contrasts be treated as linear combinations. The default is to require that all user-defined contrasts sum to zero. (Summing to zero is part of the definition of a contrast.)

`predict` (`op` [`._predict`]) specifies that the `op` contrast operator be applied to the groups defined by multiple specifications of `margins`'s `predict()` option. The default behavior, by comparison, is to perform tests and contrasts within these groups.

`atcontrast` (`op` [`._at`]) specifies that the `op` contrast operator be applied to the groups defined by the `at()` option(s). The default behavior, by comparison, is to perform tests and contrasts within the groups defined by the `at()` option(s).

See [example 6](#) in *Remarks and examples*.

`predictjoint` specifies that joint tests be performed across all groups defined by multiple specifications of `margins`'s `predict()` option. The default behavior, by comparison, is to perform contrasts and tests within each group.

`atjoint` specifies that joint tests be performed across all groups defined by the `at()` option. The default behavior, by comparison, is to perform contrasts and tests within each group.

See [example 5](#) in *Remarks and examples*.

`overjoint` specifies how unoperated variables in the `over()` option are treated.

Each variable in the `over()` option may be specified either with or without a contrast operator. For contrast-operated variables, the specified contrast comparisons are always performed.

`overjoint` specifies that joint tests be performed across all levels of the unoperated variables. The default behavior, by comparison, is to perform contrasts and tests within each combination of levels of the unoperated variables.

See [example 3](#) in *Remarks and examples*.

`withinjoint` specifies how unoperated variables in the `within()` option are treated.

Each variable in the `within()` option may be specified either with or without a contrast operator. For contrast-operated variables, the specified contrast comparisons are always performed.

`withinjoint` specifies that joint tests be performed across all levels of the unoperated variables. The default behavior, by comparison, is to perform contrasts and tests within each combination of levels of the unoperated variables.

`marginswithin` specifies how unoperated variables in `marginlist` are treated.

Each variable in `marginlist` may be specified either with or without a contrast operator. For contrast-operated variables, the specified contrast comparisons are always performed.

`marginswithin` specifies that contrasts and tests be performed within each combination of levels of the unoperated variables. The default behavior, by comparison, is to perform joint tests across all levels of the unoperated variables.

See [example 4](#) in *Remarks and examples*.

`ci effects` specifies that a table containing a confidence interval for each individual contrast be reported.

`pveffects` specifies that a table containing a  $p$ -value for each individual contrast be reported.

`effects` specifies that a single table containing a confidence interval and  $p$ -value for each individual contrast be reported.

`nowald` suppresses the table of Wald tests.

`noatlevels` indicates that only the overall Wald test be reported for each term containing within or nested (@ or |) operators.

`nosvyadjust` is for use with `svy` estimation commands. It specifies that the Wald test be carried out without the default adjustment for the design degrees of freedom. That is to say the test is carried out as  $W/k \sim F(k, d)$  rather than as  $(d - k + 1)W/(kd) \sim F(k, d - k + 1)$ , where  $k$  is the dimension of the test and  $d$  is the total number of sampled PSUs minus the total number of strata.

## Remarks and examples

Remarks are presented under the following headings:

*Contrasts of margins*

*Contrasts and the `over()` option*

*The overjoint suboption*

*The marginswithin suboption*

*Contrasts and the `at()` option*

*Estimating treatment effects with margins*

*Conclusion*

## Contrasts of margins

### ▷ Example 1

Estimating contrasts of margins is as easy as adding a contrast operator to the variable name. Let's review [Example 2: A simple case after logistic](#) of [R] **margins**. Variable `sex` is coded 0 for males and 1 for females.

```
. use https://www.stata-press.com/data/r19/margex
(Artificial data for margins)

. logistic outcome i.sex i.group
(output omitted)

. margins sex

Predictive margins Number of obs = 3,000
Model VCE: OIM

Expression: Pr(outcome), predict()
```

|        | Delta-method |           |       |       |                      |
|--------|--------------|-----------|-------|-------|----------------------|
|        | Margin       | std. err. | z     | P> z  | [95% conf. interval] |
| sex    |              |           |       |       |                      |
| Male   | .1286796     | .0111424  | 11.55 | 0.000 | .106841 .1505182     |
| Female | .1905087     | .0089719  | 21.23 | 0.000 | .1729241 .2080933    |

The first margin, 0.13, is the average probability of a positive outcome, treating everyone as if they were male. The second margin, 0.19, is the average probability of a positive outcome, treating everyone as if they were female. We can compare females with males by rerunning `margins` and adding a contrast operator:

```
. margins r.sex
Contrasts of predictive margins Number of obs = 3,000
Model VCE: OIM
Expression: Pr(outcome), predict()
```

|     | df | chi2  | P>chi2 |
|-----|----|-------|--------|
| sex | 1  | 16.61 | 0.0000 |

|                         | Delta-method |           |                      |
|-------------------------|--------------|-----------|----------------------|
|                         | Contrast     | std. err. | [95% conf. interval] |
| sex<br>(Female vs Male) | .0618291     | .0151719  | .0320927 .0915656    |

The `r.` prefix for `sex` is the reference-category contrast operator—see [R] [contrast](#). (The default reference category is zero, the lowest value of `sex`.) Contrast operators in a *marginlist* work just as they do in the *termlist* of a `contrast` command.

The contrast estimate of 0.06 says that unconditional on group, females on average are about 6% more likely than males to have a positive outcome. The  $\chi^2$  statistic of 16.61 shows that the contrast is significantly different from zero.

You may be surprised that we did not need to include the `contrast` option to estimate our contrast. If we had included the option, our output would not have changed:

```
. margins r.sex, contrast
Contrasts of predictive margins Number of obs = 3,000
Model VCE: OIM
Expression: Pr(outcome), predict()
```

|     | df | chi2  | P>chi2 |
|-----|----|-------|--------|
| sex | 1  | 16.61 | 0.0000 |

|                         | Delta-method |           |                      |
|-------------------------|--------------|-----------|----------------------|
|                         | Contrast     | std. err. | [95% conf. interval] |
| sex<br>(Female vs Male) | .0618291     | .0151719  | .0320927 .0915656    |

The contrast option is useful mostly for its suboptions, which control the output and how contrasts are estimated in more complicated situations. But contrast may be specified on its own (without contrast operators or suboptions) if we do not need estimates or confidence intervals:

```
. margins sex group, contrast
Contrasts of predictive margins Number of obs = 3,000
Model VCE: OIM
Expression: Pr(outcome), predict()
```

|       | df | chi2   | P>chi2 |
|-------|----|--------|--------|
| sex   | 1  | 16.61  | 0.0000 |
| group | 2  | 225.76 | 0.0000 |

Each  $\chi^2$  statistic is a joint test of constituent contrasts. The test for group has two degrees of freedom because group has three levels.

## Contrasts and the over() option

### ▷ Example 2

It is common to estimate margins at combinations of factor levels, and margins, contrast includes several suboptions for contrasting such margins. Let's fit a model with two categorical predictors and their interaction:

```
. logistic outcome agegroup##group
Logistic regression Number of obs = 3,000
 LR chi2(8) = 520.64
 Prob > chi2 = 0.0000
Log likelihood = -1105.7504 Pseudo R2 = 0.1906
```

| outcome   | Odds ratio | Std. err. | z     | P> z  | [95% conf. interval] |          |
|-----------|------------|-----------|-------|-------|----------------------|----------|
| agegroup  |            |           |       |       |                      |          |
| 30-39     | 3.54191    | 2.226951  | 2.01  | 0.044 | 1.032882             | 12.14576 |
| 40+       | 16.23351   | 9.611879  | 4.71  | 0.000 | 5.086452             | 51.80955 |
| group     |            |           |       |       |                      |          |
| 2         | .834507    | .5663738  | -0.27 | 0.790 | .2206611             | 3.15598  |
| 3         | .2146739   | .1772903  | -1.86 | 0.062 | .042541              | 1.083306 |
| agegroup# |            |           |       |       |                      |          |
| group     |            |           |       |       |                      |          |
| 30-39#2   | .4426927   | .3358505  | -1.07 | 0.283 | .1000772             | 1.958257 |
| 30-39#3   | 1.16088    | 1.103521  | 0.16  | 0.875 | .1801538             | 7.480508 |
| 40+#2     | .440672    | .3049393  | -1.18 | 0.236 | .1135259             | 1.711055 |
| 40+#3     | .4407892   | .4034666  | -0.89 | 0.371 | .0732998             | 2.650693 |
| _cons     | .0379747   | .0223371  | -5.56 | 0.000 | .0119897             | .1202762 |

Note: **\_cons** estimates baseline odds.

Each of agegroup and group has three levels. To compare each age group with the reference category on the probability scale, we can again use margins with the r. contrast operator.

```
. margins r.agegroup
Contrasts of predictive margins Number of obs = 3,000
Model VCE: OIM
Expression: Pr(outcome), predict()
```

|                  | df | chi2   | P>chi2 |  |
|------------------|----|--------|--------|--|
| agegroup         |    |        |        |  |
| (30-39 vs 20-29) | 1  | 10.04  | 0.0015 |  |
| (40+ vs 20-29)   | 1  | 224.44 | 0.0000 |  |
| Joint            | 2  | 238.21 | 0.0000 |  |

|                  | Contrast | Delta-method<br>std. err. | [95% conf. interval] |          |
|------------------|----------|---------------------------|----------------------|----------|
| agegroup         |          |                           |                      |          |
| (30-39 vs 20-29) | .044498  | .0140448                  | .0169706             | .0720253 |
| (40+ vs 20-29)   | .2059281 | .0137455                  | .1789874             | .2328688 |

Our model includes an interaction, though, so it would be nice to estimate the contrasts separately for each value of group. We need the `over()` option:

```
. margins r.agegroup, over(group)
Contrasts of predictive margins Number of obs = 3,000
Model VCE: OIM
Expression: Pr(outcome), predict()
Over: group
```

|                    | df | chi2   | P>chi2 |  |
|--------------------|----|--------|--------|--|
| agegroup@group     |    |        |        |  |
| (30-39 vs 20-29) 1 | 1  | 6.94   | 0.0084 |  |
| (30-39 vs 20-29) 2 | 1  | 1.18   | 0.2783 |  |
| (30-39 vs 20-29) 3 | 1  | 3.10   | 0.0783 |  |
| (40+ vs 20-29) 1   | 1  | 173.42 | 0.0000 |  |
| (40+ vs 20-29) 2   | 1  | 57.77  | 0.0000 |  |
| (40+ vs 20-29) 3   | 1  | 5.12   | 0.0236 |  |
| Joint              | 6  | 266.84 | 0.0000 |  |

|                    | Contrast | Delta-method<br>std. err. | [95% conf. interval] |          |
|--------------------|----------|---------------------------|----------------------|----------|
| agegroup@group     |          |                           |                      |          |
| (30-39 vs 20-29) 1 | .0819713 | .0311208                  | .0209757             | .142967  |

| (30-39 vs 20-29) 3 | .0243462 | .0138291                  | -.0027584            | .0514507 |
| (40+ vs 20-29) 1   | .3447797 | .0261811                  | .2934658             | .3960937 |
| (40+ vs 20-29) 2   | .1540882 | .0202722                  | .1143554             | .193821  |
| (40+ vs 20-29) 3   | .0470319 | .0207774                  | .006309              | .0877548 |

The effect of agegroup appears to be greatest for the first level of group.

Including a variable in the `over()` option is not equivalent to including the variable in the main *marginlist*. The variables in the *marginlist* are manipulated in the analysis, so that we can measure, for example, the effect of being in age group 3 and not age group 1. (The manipulation could be mimicked by running `replace` and then `predict`, but the manipulations actually performed by `margins` do not change the data in memory.) The variables in the `over()` option are not so manipulated—the values of the `over()` variables are left as they were observed, and the *marginlist* variables are manipulated separately for each observed `over()` group.

### The overjoint suboption

#### ▷ Example 3

Each variable in an `over()` option may be specified with or without contrast operators. Our `over(group)` option did not include a contrast operator, so `margins` estimated the contrasts separately for each level of group. If we had instead specified `over(r.group)`, we would have received differences of the contrasts:

```
. margins r.agegroup, over(r.group)
Contrasts of predictive margins Number of obs = 3,000
Model VCE: OIM
Expression: Pr(outcome), predict()
Over: group
```

|                           | df | chi2  | P>chi2 |
|---------------------------|----|-------|--------|
| group#agegroup            |    |       |        |
| (2 vs 1) (30-39 vs 20-29) | 1  | 3.55  | 0.0596 |
| (2 vs 1) (40+ vs 20-29)   | 1  | 33.17 | 0.0000 |
| (3 vs 1) (30-39 vs 20-29) | 1  | 2.86  | 0.0906 |
| (3 vs 1) (40+ vs 20-29)   | 1  | 79.36 | 0.0000 |
| Joint                     | 4  | 83.88 | 0.0000 |

|                           | Delta-method |           |                      |
|---------------------------|--------------|-----------|----------------------|
|                           | Contrast     | std. err. | [95% conf. interval] |
| group#agegroup            |              |           |                      |
| (2 vs 1) (30-39 vs 20-29) | -.0653508    | .0346921  | -.133346 .0026445    |
| (2 vs 1) (40+ vs 20-29)   | -.1906915    | .0331121  | -.25559 -.1257931    |
| (3 vs 1) (30-39 vs 20-29) | -.0576252    | .0340551  | -.1243719 .0091216   |
| (3 vs 1) (40+ vs 20-29)   | -.2977479    | .0334237  | -.3632572 -.2322386  |

The contrasts are double differences: the estimate of  $-0.19$ , for example, says that the difference in the probability of success between age group 3 and age group 1 is smaller in group 2 than in group 1. We can jointly test pairs of the double differences with the `overjoint` suboption:

```
. margins r.agegroup, over(group) contrast(overjoint)
Contrasts of predictive margins Number of obs = 3,000
Model VCE: OIM
Expression: Pr(outcome), predict()
Over: group
```

|                          | df | chi2  | P>chi2 |
|--------------------------|----|-------|--------|
| group#agegroup           |    |       |        |
| (joint) (30-39 vs 20-29) | 2  | 3.62  | 0.1641 |
| (joint) (40+ vs 20-29)   | 2  | 79.45 | 0.0000 |
| Joint                    | 4  | 83.88 | 0.0000 |

The `contrast(overjoint)` option overrides the default behavior of `over()` and requests joint tests over the levels of the unoperated variable `group`. The  $\chi^2$  statistic of 3.62 tests that the first and third contrasts from the previous table are jointly zero. The  $\chi^2$  statistic of 79.45 jointly tests the other pair of contrasts.

### The marginswithin suboption

#### ➤ Example 4

Another suboption that may usefully be combined with `over()` is `marginswithin`. `marginswithin` requests that contrasts be performed within the levels of unoperated variables in the main *marginlist*, instead of performing them jointly across the levels. `marginswithin` affects only unoperated variables because contrast operators take precedence over suboptions.

Let's first look at the default behavior, which occurs when marginswithin is not specified:

```
. margins agegroup, over(r.group) contrast(effects)
Contrasts of predictive margins Number of obs = 3,000
Model VCE: OIM
Expression: Pr(outcome), predict()
Over: group
```

|                  | df | chi2  | P>chi2 |
|------------------|----|-------|--------|
| group#agegroup   |    |       |        |
| (2 vs 1) (joint) | 2  | 33.94 | 0.0000 |
| (3 vs 1) (joint) | 2  | 83.38 | 0.0000 |
| Joint            | 4  | 83.88 | 0.0000 |

|                                                         | Delta-method |           |       |       | [95% conf. interval] |           |
|---------------------------------------------------------|--------------|-----------|-------|-------|----------------------|-----------|
|                                                         | Contrast     | std. err. | z     | P> z  |                      |           |
| group#<br>agegroup<br>(2 vs 1)<br>(30-39<br>vs<br>base) | -.0653508    | .0346921  | -1.88 | 0.060 | -.133346             | .0026445  |
| (2 vs 1)<br>(40+<br>vs<br>base)                         | -.1906915    | .0331121  | -5.76 | 0.000 | -.25559              | -.1257931 |
| (3 vs 1)<br>(30-39<br>vs<br>base)                       | -.0576252    | .0340551  | -1.69 | 0.091 | -.1243719            | .0091216  |
| (3 vs 1)<br>(40+<br>vs<br>base)                         | -.2977479    | .0334237  | -8.91 | 0.000 | -.3632572            | -.2322386 |

Here agegroup in the main *marginlist* is an unoperated variable, so margins by default performs joint tests across the levels of agegroup: the  $\chi^2$  statistic of 33.94, for example, jointly tests whether the first two contrast estimates in the lower table differ significantly from zero.

When we specify marginswithin, the contrasts will instead be performed within the levels of agegroup:

```
. margins agegroup, over(r.group) contrast(marginswithin effects)
Contrasts of predictive margins Number of obs = 3,000
Model VCE: OIM
Expression: Pr(outcome), predict()
Over: group
```

|                | df | chi2   | P>chi2 |
|----------------|----|--------|--------|
| group@agegroup |    |        |        |
| (2 vs 1) 20-29 | 1  | 0.06   | 0.7991 |
| (2 vs 1) 30-39 | 1  | 7.55   | 0.0060 |
| (2 vs 1) 40+   | 1  | 68.39  | 0.0000 |
| (3 vs 1) 20-29 | 1  | 1.80   | 0.1798 |
| (3 vs 1) 30-39 | 1  | 10.47  | 0.0012 |
| (3 vs 1) 40+   | 1  | 159.89 | 0.0000 |
| Joint          | 6  | 186.87 | 0.0000 |

|                | Delta-method |           |        |       |           | [95% conf. interval] |  |
|----------------|--------------|-----------|--------|-------|-----------|----------------------|--|
|                | Contrast     | std. err. | z      | P> z  |           |                      |  |
| group@agegroup |              |           |        |       |           |                      |  |
| (2 vs 1) 20-29 | -.0058686    | .0230533  | -0.25  | 0.799 | -.0510523 | .039315              |  |
| (2 vs 1) 30-39 | -.0712194    | .0259246  | -2.75  | 0.006 | -.1220308 | -.0204081            |  |
| (2 vs 1) 40+   | -.1965602    | .0237688  | -8.27  | 0.000 | -.2431461 | -.1499742            |  |
| (3 vs 1) 20-29 | -.0284991    | .0212476  | -1.34  | 0.180 | -.0701436 | .0131454             |  |
| (3 vs 1) 30-39 | -.0861243    | .0266137  | -3.24  | 0.001 | -.1382862 | -.0339624            |  |
| (3 vs 1) 40+   | -.326247     | .0258009  | -12.64 | 0.000 | -.3768159 | -.2756781            |  |

The joint tests in the top table have been replaced by one-degree-of-freedom tests, one for each combination of the two reference comparisons and three levels of agegroup. The reference-category contrasts for group have been performed within levels of agegroup.

## Contrasts and the at() option

### ► Example 5

The `at()` option of `margins` is used to set predictors to particular values. When `at()` is used, contrasts are by default performed within each `at()` level:

```
. margins r.agegroup, at(group=(1/3))
Contrasts of adjusted predictions Number of obs = 3,000
Expression: Pr(outcome), predict()
1._at: group = 1
2._at: group = 2
3._at: group = 3
```

|                    | df | chi2   | P>chi2 |
|--------------------|----|--------|--------|
| agegroup@_at       |    |        |        |
| (30-39 vs 20-29) 1 | 1  | 6.94   | 0.0084 |
| (30-39 vs 20-29) 2 | 1  | 1.18   | 0.2783 |
| (30-39 vs 20-29) 3 | 1  | 3.10   | 0.0783 |
| (40+ vs 20-29) 1   | 1  | 173.42 | 0.0000 |
| (40+ vs 20-29) 2   | 1  | 57.77  | 0.0000 |
| (40+ vs 20-29) 3   | 1  | 5.12   | 0.0236 |
| Joint              | 6  | 266.84 | 0.0000 |

|                    | Delta-method |           |                      |          |
|--------------------|--------------|-----------|----------------------|----------|
|                    | Contrast     | std. err. | [95% conf. interval] |          |
| agegroup@_at       |              |           |                      |          |
| (30-39 vs 20-29) 1 | .0819713     | .0311208  | .0209757             | .142967  |
| (30-39 vs 20-29) 2 | .0166206     | .0153309  | -.0134275            | .0466686 |
| (30-39 vs 20-29) 3 | .0243462     | .0138291  | -.0027584            | .0514507 |
| (40+ vs 20-29) 1   | .3447797     | .0261811  | .2934658             | .3960937 |
| (40+ vs 20-29) 2   | .1540882     | .0202722  | .1143554             | .193821  |
| (40+ vs 20-29) 3   | .0470319     | .0207774  | .006309              | .0877548 |

Our `at(group=(1/3))` option manipulates the values of `group` and is therefore not equivalent to `over(group)`. We see that the reference-category contrasts for `agegroup` have been performed within each `at()` level. For a similar example that uses the `._at` operator instead of the `at()` option, see *Contrasts of at() groups—discrete effects* in [R] [marginsplot](#).

The default within behavior of `at()` may be changed to joint behavior with the `atjoint` suboption:

```
. margins r.agegroup, at(group=(1/3)) contrast(atjoint)
Contrasts of adjusted predictions Number of obs = 3,000
Model VCE: OIM
Expression: Pr(outcome), predict()
1._at: group = 1
2._at: group = 2
3._at: group = 3
```

|                          | df | chi2  | P>chi2 |
|--------------------------|----|-------|--------|
| _at#agegroup             |    |       |        |
| (joint) (30-39 vs 20-29) | 2  | 3.62  | 0.1641 |
| (joint) (40+ vs 20-29)   | 2  | 79.45 | 0.0000 |
| Joint                    | 4  | 83.88 | 0.0000 |

Now, the tests are performed jointly over the levels of `group`, the `at()` variable. The `atjoint` suboption is the analogue for `at()` of the `overjoint` suboption from [example 3](#).

### ▷ Example 6

What if we would like to apply a contrast operator, like `r.`, to the `at()` levels? It is not possible to specify the operator inside the `at()` option. Instead, we need a new suboption, `atcontrast()`:

```
. margins r.agegroup, at(group=(1/3)) contrast(atcontrast(r))
Contrasts of adjusted predictions Number of obs = 3,000
Model VCE: OIM
Expression: Pr(outcome), predict()
1._at: group = 1
2._at: group = 2
3._at: group = 3
```

|                           | df | chi2  | P>chi2 |
|---------------------------|----|-------|--------|
| _at#agegroup              |    |       |        |
| (2 vs 1) (30-39 vs 20-29) | 1  | 3.55  | 0.0596 |
| (2 vs 1) (40+ vs 20-29)   | 1  | 33.17 | 0.0000 |
| (3 vs 1) (30-39 vs 20-29) | 1  | 2.86  | 0.0906 |
| (3 vs 1) (40+ vs 20-29)   | 1  | 79.36 | 0.0000 |
| Joint                     | 4  | 83.88 | 0.0000 |

|                           | Delta-method |           |                        |
|---------------------------|--------------|-----------|------------------------|
|                           | Contrast     | std. err. | [95% conf. interval]   |
| _at#agegroup              |              |           |                        |
| (2 vs 1) (30-39 vs 20-29) | -.0653508    | .0346921  | -.133346    .0026445   |
| (2 vs 1) (40+ vs 20-29)   | -.1906915    | .0331121  | -.25559    -.1257931   |
| (3 vs 1) (30-39 vs 20-29) | -.0576252    | .0340551  | -.1243719    .0091216  |
| (3 vs 1) (40+ vs 20-29)   | -.2977479    | .0334237  | -.3632572    -.2322386 |

When we specify `contrast(atcontrast(r))`, `margins` will apply the `r.` reference-category operator to the levels of `group`, the variable specified inside `at()`. The default reference category is 1, the lowest level of `group`.

## Estimating treatment effects with margins

margins with the contrast option can also be used to estimate treatment effects in certain cases. A treatment effect represents the change in an outcome variable that is attributable to a particular event, controlling for all other factors that could affect the outcome. For example, we might want to know how a person’s wage changes as a result of being in a union. Here the outcome variable is the person’s wage, and the “event” is membership in a union. The treatment effect measures the difference in a person’s wage as a result of being or not being in a union once we control for the person’s educational background, level of experience, industry, and other factors.

In fact, Stata has an entire manual dedicated to estimators designed specifically for estimating treatment effects; see the *Stata Causal Inference and Treatment-Effects Estimation Reference Manual*. Here we show how margins can be used to estimate treatment effects using the regression-adjustment estimator when the conditional independence assumption is met; see [CAUSAL] [teffects intro](#). Regression adjustment simply means that we are going to use a regression model to predict the outcome variable, controlling for treatment status and other characteristics. The conditional independence assumption implies that we have enough variables in our dataset so that once we control for them in our regression model, the outcomes one would obtain with and without treatment are independent of how treatment status is determined.

### ▷ Example 7: Regression adjustment with a binary treatment variable

nlsw88.dta contains women’s wages (wage) in dollars per hour, a binary variable indicating their union status (union), years of experience (ttl\_exp), and a variable, grade, indicating the number of years of schooling completed. We want to know how being in a union (the treatment) affects women’s wages. Traditionally, a wage equation of the form

$$\ln \text{wage}_i = \beta_0 + \beta_1 \text{union}_i + \beta_2 \text{grade}_i + \beta_3 \text{ttl\_exp} + \beta_4 \text{ttl\_exp}^2 + \epsilon_i$$

would be fit. However, there are two shortcomings that we will improve upon. First, to avoid the problem of predicting the level of a log-transformed dependent variable, we will use poisson with the vce(robust) option to fit an exponential regression model; see [Wooldridge \(2010, sec. 18.2\)](#) for background on this approach. Second, the previous equation implies that factors other than union status have the same impact on wages for both union and nonunion workers. Regression-adjustment estimators allow all the variables to have different impacts depending on the level of the treatment variable, and we can accomplish that here using factor-variable notation. In Stata, we fit our model by typing

```
. use https://www.stata-press.com/data/r19/nlsw88
(NLSW, 1988 extract)

. poisson wage i.union##(c.grade c.ttl_exp##c.ttl_exp), vce(robust)
note: noncount dependent variable encountered; results correspond to an
 exponential-mean model rather than a poisson model.

| Union      | .0011808    | .0008428            | 1.40  | 0.161 | -.0004711            | .0028327  |
| _cons      | .017488     | .0893602            | 0.20  | 0.845 | -.1576547            | .1926308  |

To see how union status affects wages, we can use margins:

```
. margins r.union, vce(unconditional)
Contrasts of predictive margins
Expression: Predicted number of events, predict()
Number of obs = 1,876
```

|       | df | chi2  | P>chi2 |
|-------|----|-------|--------|
| union | 1  | 26.22 | 0.0000 |

|                              | Contrast | Unconditional<br>std. err. | [95% conf. interval] |          |
|------------------------------|----------|----------------------------|----------------------|----------|
| union<br>(Union vs Nonunion) | 1.004119 | .1960944                   | .6197815             | 1.388457 |

The estimated contrast 1.004 indicates that on average, belonging to a union causes a woman’s wage to be slightly more than a dollar higher than if she were not in the union. This estimated contrast is called the average treatment effect (ATE). Conceptually, we predicted the wage of each woman in the estimation sample assuming she was in a union and obtained the sample mean. We then predicted each woman’s wage assuming she was not in a union and obtained that sample mean. The difference between these two sample means represents the ATE.

We obtain essentially the same results by using `teffects ra`:

```
. teffects ra (wage c.grade c.ttl_exp##c.ttl_exp, poisson) (union)
Iteration 0: EE criterion = 2.611e-13
Iteration 1: EE criterion = 1.112e-26
Treatment-effects estimation Number of obs = 1,876
Estimator : regression adjustment
Outcome model : Poisson
Treatment model: none
```

|        |                                    | Robust      |           | z     | P> z  | [95% conf. interval] |          |
|--------|------------------------------------|-------------|-----------|-------|-------|----------------------|----------|
| wage   |                                    | Coefficient | std. err. |       |       |                      |          |
| ATE    |                                    |             |           |       |       |                      |          |
|        | union<br>(Union<br>vs<br>Nonunion) | 1.004119    | .1960421  | 5.12  | 0.000 | .619884              | 1.388355 |
| POmean |                                    |             |           |       |       |                      |          |
|        | union<br>Nonunion                  | 7.346493    | .1096182  | 67.02 | 0.000 | 7.131645             | 7.561341 |

The point estimates of the ATE are identical to those we obtained using `margins`, though the standard errors differ slightly from those reported by `margins`. The standard errors from the two estimators are, however, asymptotically equivalent, meaning they would coincide with a sufficiently large dataset. The last statistic in this output table indicates the untreated potential-outcome mean (untreated POM), which is the mean predicted wage assuming each woman did not belong to a union.

If we specify the `pomeans` option with `teffects ra`, we can obtain both the treated and the untreated POMs, which represent the predicted mean wages assuming all women were or were not in the union:

```
. teffects ra (wage c.grade c.ttl_exp##c.ttl_exp, poisson) (union), pomeans
Iteration 0: EE criterion = 2.611e-13
Iteration 1: EE criterion = 1.112e-26
Treatment-effects estimation Number of obs = 1,876
Estimator : regression adjustment
Outcome model : Poisson
Treatment model: none
```

|         |                   | Robust      |           | z     | P> z  | [95% conf. interval] |          |
|---------|-------------------|-------------|-----------|-------|-------|----------------------|----------|
| wage    |                   | Coefficient | std. err. |       |       |                      |          |
| POmeans |                   |             |           |       |       |                      |          |
|         | union<br>Nonunion | 7.346493    | .1096182  | 67.02 | 0.000 | 7.131645             | 7.561341 |
|         | Union             | 8.350612    | .1757346  | 47.52 | 0.000 | 8.006179             | 8.695046 |

Notice that the difference between these two POMs equals 1.004119, which is the ATE we obtained earlier.

In some applications, the average treatment effect of the treated (ATET) is more germane than the ATE. For example, if the untreated subjects in the sample could not possibly receive treatment (perhaps because a medical condition precludes their taking an experimental drug), then considering the counterfactual outcome had those subjects taken the drug may not be relevant. In these cases, the ATET is a better statistic because it measures the effect of the treatment only for those subjects who actually did receive treatment. Like the ATE, the ATET involves computing predicted outcomes for each treatment level, obtaining the sample means, and computing the difference between those two means. Unlike the ATE, however, we use only observations corresponding to treated subjects.

▷ Example 8: Regression adjustment with a binary treatment variable (continued)

Here we calculate the ATET of union membership, first using margins. Because teffects ra overwrote our estimation results, we first quietly refit our poisson model. We then call margins to obtain the ATET:

```
. quietly poisson wage i.union##(c.grade c.ttl_exp##c.ttl_exp), vce(robust)
. margins r.union, subpop(union) vce(unconditional)
Contrasts of predictive margins Number of obs = 1,876
 Subpop. no. obs = 460
```

Expression: Predicted number of events, predict()

|       | df | chi2  | P>chi2 |
|-------|----|-------|--------|
| union | 1  | 18.86 | 0.0000 |

|                              | Unconditional |           |                      |
|------------------------------|---------------|-----------|----------------------|
|                              | Contrast      | std. err. | [95% conf. interval] |
| union<br>(Union vs Nonunion) | .901419       | .2075863  | .4945574 1.308281    |

The key here was specifying the subpop(union) option to restrict margin's computations to those women who are union members. The results indicate that being in the union causes the union members' wages to be about 90 cents higher than they would otherwise be.

To replicate these results using `teffects ra`, we include the `atet` option to obtain ATETs:

```
. teffects ra (wage c.grade c.ttl_exp#c.ttl_exp, poisson) (union), atet
Iteration 0: EE criterion = 2.611e-13
Iteration 1: EE criterion = 9.347e-27
Treatment-effects estimation Number of obs = 1,876
Estimator : regression adjustment
Outcome model : Poisson
Treatment model: none
```

|        |                                    | Robust      |           | z     | P> z  | [95% conf. interval] |          |
|--------|------------------------------------|-------------|-----------|-------|-------|----------------------|----------|
| wage   |                                    | Coefficient | std. err. |       |       |                      |          |
| ATET   |                                    |             |           |       |       |                      |          |
|        | union<br>(Union<br>vs<br>Nonunion) | .901419     | .2075309  | 4.34  | 0.000 | .4946658             | 1.308172 |
| P0mean |                                    |             |           |       |       |                      |          |
|        | union<br>Nonunion                  | 7.776417    | .162121   | 47.97 | 0.000 | 7.458665             | 8.094168 |

We obtain the same point estimate of the effect of union status as with `margins`. As before, the standard errors differ slightly between the two estimators, but they are asymptotically equivalent. The output also indicates that among the women who are in a union, their average wage would be \$7.78 if they were not in a union.

□ Technical note

One advantage of the ATET over the ATE is that the ATET can be consistently estimated with slightly weaker assumptions than are required to consistently estimate the ATE. See [Comparing the ATE and ATET in Remarks and examples of \[CAUSAL\] teffects intro advanced](#).

Both `margins` and `teffects` can estimate treatment effects using regression adjustment, so which should you use? In addition to regression adjustment, the `teffects` command implements other estimators of treatment effects; some of these estimators possess desirable robustness properties that we cannot replicate using `margins`. Moreover, all the `teffects` estimators use a common syntax and automatically present the estimated treatment effects, whereas we must first fit our own regression model and then call `margins` to obtain the treatment effects.

On the other hand, particularly with the `at()` option, `margins` gives us more flexibility in specifying our scenarios. The `teffects` commands allow us to measure the effect of a single binary or multinomial treatment, but we can have `margins` compute the effects of arbitrary interventions, as we illustrate in the next example.

## ► Example 9: Interventions involving multiple variables

Suppose we want to see how women's wages would be affected if we could increase each woman's education level by one year. That is, we want to measure the treatment effect of an additional year of schooling. We assume that if a woman attains another year of schooling, she cannot simultaneously work. Thus, an additional year of education implies her total work experience must decrease by a year. The flexible `at()` option of `margins` allows us to manipulate both variables at once:

```
. quietly poisson wage i.union##(c.grade c.ttl_exp##c.ttl_exp), vce(robust)
. margins, at((asobserved) _all)
> at(grade=generate(grade+1) ttl_exp=generate(ttl_exp-1))
> contrast(atcontrast(r._at))

Contrasts of predictive margins Number of obs = 1,876
Model VCE: Robust

Expression: Predicted number of events, predict()
1._at: (asobserved)
2._at: grade = grade+1
 ttl_exp = ttl_exp-1
```

|      | df | chi2  | P>chi2 |  |
|------|----|-------|--------|--|
| ._at | 1  | 58.53 | 0.0000 |  |

|                  | Delta-method |           |                      |          |
|------------------|--------------|-----------|----------------------|----------|
|                  | Contrast     | std. err. | [95% conf. interval] |          |
| ._at<br>(2 vs 1) | .3390392     | .0443161  | .2521813             | .4258971 |

The first `at()` option instructs `margins` to obtain predicted wages for all women in the sample using their existing values for `grade` and `ttl_exp` and to record the mean of those predictions. The second `at()` option instructs `margins` to obtain the mean predicted wage under the counterfactual scenario where each woman's education level is increased by one year and total work experience is simultaneously decreased by one year. The `contrast()` option instructs `margins` to compute the difference between the two means. The output indicates that increasing education by one year, which will necessarily decrease work experience by the same amount, will cause the average wage to increase by about 34 cents per hour, a statistically significant amount.

◀

## Conclusion

`margins, contrast` is a powerful command, and its abundance of suboptions may seem daunting. The suboptions are in the service of only three goals, however. There are three things that `margins, contrast` can do with a factor variable or a set of `at()` definitions:

1. Perform contrasts across the levels of the factor or set (as in [example 1](#)).
2. Perform a joint test across the levels of the factor or set (as in [example 5](#)).
3. Perform other tests and contrasts within each level of the factor or set (as in [example 4](#)).

The default behavior for variables specified inside `at()`, `over()`, and `within()` is to perform contrasts within groups; the default behavior for variables in the *marginalist* is to perform joint tests across groups.

◀

## Stored results

`margins`, `contrast` stores the following additional results in `r()`:

### Scalars

`r(k_terms)`                      number of terms participating in contrasts

### Macros

`r(cmd)`                              `contrast`  
`r(cmd2)`                             `margins`  
`r(overall)`                         `overall` or empty

### Matrices

`r(L)`                                 matrix of contrasts applied to the margins  
`r(chi2)`                              vector of  $\chi^2$  statistics  
`r(p)`                                 vector of  $p$ -values corresponding to `r(chi2)`  
`r(df)`                                vector of degrees of freedom corresponding to `r(p)`

`margins`, `contrast` with the `post` option also stores the following additional results in `e()`:

### Scalars

`e(k_terms)`                         number of terms participating in contrasts

### Macros

`e(cmd)`                              `contrast`  
`e(cmd2)`                             `margins`  
`e(overall)`                         `overall` or empty

### Matrices

`e(L)`                                 matrix of contrasts applied to the margins  
`e(chi2)`                              vector of  $\chi^2$  statistics  
`e(p)`                                 vector of  $p$ -values corresponding to `e(chi2)`  
`e(df)`                                vector of degrees of freedom corresponding to `e(p)`

## Description

`margins` with the `pwcompare` option performs pairwise comparisons of margins. `margins, pwcompare` extends the capabilities of `pwcompare` to any of the nonlinear responses, predictive margins, or other margins that can be estimated by `margins`.

## Quick start

All pairwise comparisons of the predictive margins for `a` after `logit y a##b x1`  
`margins a, pwcompare`

Same as above, but report both tests and confidence intervals for differences in predictive margins  
`margins a, pwcompare(effects)`

Same as above, but adjust  $p$ -values and confidence intervals for multiple comparisons using Bonferroni's method  
`margins a, pwcompare(effects) mcompare(bonferroni)`

Report predictive margins for the levels of `a`, and group those that are not significantly different  
`margins a, pwcompare(groups)`

All pairwise comparisons of the predictive margins for combinations of levels of `a` and `b`  
`margins a#b, pwcompare`

## Menu

Statistics > Postestimation

## Syntax

```
margins [marginlist] [if] [in] [weight] [, pwcompare margins_options]
```

```
margins [marginlist] [if] [in] [weight] [, pwcompare(suboptions) margins_options]
```

where *marginlist* is a list of factor variables or interactions that appear in the current estimation results. The variables may be typed with or without the `i.` prefix, and you may use any factor-variable syntax:

```
. margins i.sex i.group i.sex#i.group, pwcompare
. margins sex group sex#i.group, pwcompare
. margins sex##group, pwcompare
```

| <i>suboptions</i> | Description |

| <code>cieffects</code> | show effects table with confidence intervals; the default         |
| <code>pveffects</code> | show effects table with <i>p</i> -values                          |
| <code>effects</code>   | show effects table with confidence intervals and <i>p</i> -values |
| <code>cimargins</code> | show table of margins and confidence intervals                    |
| <code>groups</code>    | show table of margins and group codes                             |
| <code>sort</code>      | sort the margins or contrasts in each term                        |

`collect` is allowed; see [\[U\] 11.1.10 Prefix commands](#).

`fweights`, `awweights`, `iweights`, and `pweights` are allowed; see [\[U\] 11.1.6 weight](#).

## Suboptions

Pairwise comparisons

`cieffects` specifies that a table of the pairwise comparisons with their standard errors and confidence intervals be reported. This is the default.

`pveffects` specifies that a table of the pairwise comparisons with their standard errors, test statistics, and *p*-values be reported.

`effects` specifies that a table of the pairwise comparisons with their standard errors, test statistics, *p*-values, and confidence intervals be reported.

`cimargins` specifies that a table of the margins with their standard errors and confidence intervals be reported.

`groups` specifies that a table of the margins with their standard errors and group codes be reported. Margins with the same letter in the group code are not significantly different at the specified significance level.

`sort` specifies that the reported tables be sorted on the margins or contrasts in each term.

## Remarks and examples

You should be familiar with the concepts and syntax of both `margins` and `pwcompare` before using the `pwcompare` option of `margins`. These remarks build on those in [R] [margins](#) and [R] [pwcompare](#).

`margins` can perform pairwise comparisons of any of the margins that it estimates.

We begin by fitting a logistic regression model using the NHANES II dataset, ignoring the complex survey nature of the data. Our dependent variable is `highbp`, an indicator for whether a person has high blood pressure. We fit an interacted model including two factor variables representing the region of the country as well as the continuous covariate `bmi`.

```
. use https://www.stata-press.com/data/r19/nhanes2
. logistic highbp region#c.bmi
 (output omitted)
```

By default, `margins` will compute the predictive margins of the probability of a positive outcome for each of the terms in `marginlist` after logistic regression. We will `margin` on `region` so that `margins` will estimate the average predicted probabilities of having high blood pressure conditional on being in each of the four regions and unconditional on BMI. We can specify the `pwcompare` option to obtain all possible pairwise comparisons of these predictive margins:

```
. margins region, pwcompare
Pairwise comparisons of predictive margins Number of obs = 10,351
Model VCE: OIM
Expression: Pr(highbp), predict()
```

|          | Delta-method |           | Unadjusted           |          |
|----------|--------------|-----------|----------------------|----------|
|          | Contrast     | std. err. | [95% conf. interval] |          |
| region   |              |           |                      |          |
| MW vs NE | -.0377194    | .0133571  | -.0638987            | -.01154  |
| S vs NE  | -.0156843    | .0133986  | -.041945             | .0105764 |
| W vs NE  | -.006873     | .0136595  | -.0336451            | .019899  |
| S vs MW  | .0220351     | .0124564  | -.0023789            | .0464492 |
| W vs MW  | .0308463     | .0127366  | .0058831             | .0558096 |
| W vs S   | .0088112     | .0127801  | -.0162373            | .0338598 |

This table gives each of the pairwise differences with confidence intervals. We can see that the confidence interval in the row labeled `MW vs NE` does not include 0. At the 5% level, the predictive margins for the first and second regions, the Northeast and the Midwest, are significantly different. The same is true of the second and fourth regions, the Midwest and the West. With many pairwise comparisons, output in this format can be difficult to sort through. We can organize it by adding the `group` suboption:

```
. margins region, pwcompare(group)
Pairwise comparisons of predictive margins Number of obs = 10,351
Model VCE: OIM
Expression: Pr(highbp), predict()
```

|        | Delta-method Unadjusted |           |        |
|--------|-------------------------|-----------|--------|
|        | Margin                  | std. err. | groups |
| region |                         |           |        |
| NE     | .4388358                | .010069   | B      |
| MW     | .4011164                | .0087764  | A      |
| S      | .4231516                | .0088395  | AB     |
| W      | .4319628                | .0092301  | B      |

Note: Margins sharing a letter in the group label are not significantly different at the 5% level.

The group output includes the predictive margins for each region and letters denoting margins that are not significantly different from one another. In this case, the Northeast (NE), South (S), and West (W) regions have the letter B in the “Unadjusted Groups” column. The letter B indicates that the average predicted probability for the Northeast region is not significantly different from the average predicted probabilities for the South and West regions at the 5% significance level. The Midwest (MW) region does not share a letter with the Northeast region nor the West region, which indicates that the average predicted probability for the Midwest region is significantly different for each of the other two regions at our 5% level.

We can also include the `mcompare(bonferroni)` option to perform tests using Bonferroni’s method to account for making multiple comparisons.

```
. margins region, pwcompare(group) mcompare(bonferroni)
Pairwise comparisons of predictive margins Number of obs = 10,351
Model VCE: OIM
Expression: Pr(highbp), predict()
```

|        | Number of comparisons |
|--------|-----------------------|
| region | 6                     |

|        | Delta-method Bonferroni |           |        |
|--------|-------------------------|-----------|--------|
|        | Margin                  | std. err. | groups |
| region |                         |           |        |
| NE     | .4388358                | .010069   | B      |
| MW     | .4011164                | .0087764  | A      |
| S      | .4231516                | .0088395  | AB     |
| W      | .4319628                | .0092301  | AB     |

Note: Margins sharing a letter in the group label are not significantly different at the 5% level.

We now see the letter A on the row corresponding to the West region. At the 5% level and with Bonferroni’s adjustment, the predictive margins for the probability in the Midwest and West regions are not significantly different.

## Stored results

`margins`, `pwcompare` stores the following additional results in `r()`:

### Scalars

`r(k_terms)` number of terms participating in pairwise comparisons

### Macros

`r(cmd)` `pwcompare`  
`r(cmd2)` `margins`  
`r(group#)` group code for the #th margin in `r(b)`  
`r(mcmethod_vs)` *method* from `mcompare()`  
`r(mctitle_vs)` title for *method* from `mcompare()`  
`r(mcadjustall_vs)` `adjustall` or empty

### Matrices

`r(b)` margin estimates  
`r(V)` variance-covariance matrix of the margin estimates  
`r(b_vs)` margin difference estimates  
`r(V_vs)` variance-covariance matrix of the margin difference estimates  
`r(error_vs)` margin difference estimability codes;  
 0 means estimable,  
 8 means not estimable  
`r(table_vs)` matrix containing the margin differences with their standard errors, test statistics, *p*-values, and confidence intervals  
`r(L)` matrix that produces the margin differences

`margins`, `pwcompare` with the `post` option also stores the following additional results in `e()`:

### Scalars

`e(k_terms)` number of terms participating in pairwise comparisons

### Macros

`e(cmd)` `pwcompare`  
`e(cmd2)` `margins`

### Matrices

`e(b)` margin estimates  
`e(V)` variance-covariance matrix of the margin estimates  
`e(b_vs)` margin difference estimates  
`e(V_vs)` variance-covariance matrix of the margin difference estimates  
`e(error_vs)` margin difference estimability codes;  
 0 means estimable,  
 8 means not estimable  
`e(L)` matrix that produces the margin differences

## Description

`marginsplot` graphs the results of the immediately preceding `margins` command; see [R] [margins](#). Common names for some of the graphs that `marginsplot` can produce are profile plots and interaction plots.

`marginsplot` is also available after `estat lcp` and `estat lcmean`; see [SEM] [estat lcp](#), [SEM] [estat lcmean](#), [FMM] [estat lcp](#), and [FMM] [estat lcmean](#).

where *dimlist* may be any of the dimensions across which margins were computed in the immediately preceding `margins` command; see [R] [margins](#). That is to say, *dimlist* may be any variable used in the `margins` command, including variables specified in the `at()`, `over()`, and `within()` options. More advanced specifications of *dimlist* are covered in [Addendum: Advanced uses of dimlist](#).

| <i>dimopts</i>                           | Description                                                                 |
|------------------------------------------|-----------------------------------------------------------------------------|
| <code>labels</code> ( <i>lablist</i> )   | list of quoted strings to label each level of the dimension                 |
| <code>elabels</code> ( <i>elablist</i> ) | list of enumerated labels                                                   |
| <code>no labels</code>                   | label groups with their values, not their labels                            |
| <code>all simple labels</code>           | forgo variable name and equal signs in all labels                           |
| <code>no simple labels</code>            | include variable name and equal signs in all labels                         |
| <code>separator</code> ( <i>string</i> ) | separator for labels when multiple variables are specified in the dimension |
| <code>no separator</code>                | do not use a separator                                                      |

where *lablist* is defined as

```
"label" ["label" [...]]
```

*elablist* is defined as

```
"label" [# "label" [...]]
```

and the #s are the indices of the levels of the dimension—1 is the first level, 2 is the second level, and so on.

## Options

### Main

`xdimension()`, `plotdimension()`, `bydimension()`, and `graphdimension()` specify the variables from the preceding `margins` command whose group levels will be used for the graph's  $x$  axis, plots, `by()` subgraphs, and graphs.

`marginsplot` chooses default dimensions based on the `margins` command. In most cases, the first variable appearing in an `at()` option and evaluated over more than one value is used for the  $x$  axis. If no `at()` variable meets this condition, the first variable in the *marginlist* is usually used for the  $x$  axis and the remaining variables determine the plotted lines or markers. Pairwise comparisons and graphs of marginal effects (derivatives) have different defaults. In all cases, you may override the defaults and explicitly control which variables are used on each dimension of the graph by using these dimension options.

Each of these options supports [suboptions](#) that control the labeling of the dimension—axis labels for `xdimension()`, plot labels for `plotdimension()`, subgraph titles for `bydimension()`, and graph titles for `graphdimension()` titles.

For examples using the dimension options, see [Controlling the graph's dimensions](#).

`xdimension(dimlist [ , dimopts ])` specifies the variables for the  $x$  axis in *dimlist* and controls the content of those labels with *dimopts*.

`plotdimension(dimlist [ , dimopts ])` specifies in *dimlist* the variables whose group levels determine the plots and optionally specifies in *dimopts* the content of the plots' labels.

`bydimension(dimlist [ , dimopts ])` specifies in *dimlist* the variables whose group levels determine the `by()` subgraphs and optionally specifies in *dimopts* the content of the subgraphs' titles. For an example using `by()`, see [Three-way interactions](#).

`graphdimension(dimlist [ , dimopts ])` specifies in *dimlist* the variables whose group levels determine the graphs and optionally specifies in *dimopts* the content of the graphs' titles.

`horizontal` reverses the default  $x$  and  $y$  axes. By default, the  $y$  axis represents the estimates of the margins and the  $x$  axis represents one or more factors or continuous covariates. Specifying `horizontal` swaps the axes so that the  $x$  axis represents the estimates of the margins. This option can be useful if the labels on the factor or continuous covariates are long.

The `horizontal` option is discussed in [Horizontal is sometimes better](#).

`noci` removes plots of the pointwise confidence intervals. The default is to plot the confidence intervals.

`derivlabels` specifies that variable labels attached to marginal-effects variables be used in place of the variable names in titles and legends. Marginal-effects variables are the ones specified in `margins`'s option `dydx()`, `dyex()`, `eydx()`, or `eyex()`.

`name(name | stub [ , replace ])` specifies the name of the graph or graphs. If the `graphdimension()` option is specified, or if the default action is to produce multiple graphs, then the argument of `name()` is taken to be `stub` and graphs named `stub1`, `stub2`, ... are created.

The `replace` suboption causes existing graphs with the specified name or names to be replaced.

If `name()` is not specified, default names are used and the graphs may be replaced by subsequent `marginsplot` or other graphing commands.

### Labels

With the exception of `allxlabels`, all of these options may be specified either directly as options or as *dimopts* within options `xdimension()`, `plotdimension()`, `bydimension()`, and `graphdimension()`. When specified in one of the dimension options, only the labels for that dimension are affected. When specified outside the dimension options, all labels on all dimensions are affected. Specifications within the dimension options take precedence.

`allxlabels` specifies that tick marks and labels be placed on the  $x$  axis for each value of the  $x$ -dimension variables. By default, if there are more than 25 ticks, default graph axis labeling rules are applied. Labeling may also be specified using the standard graph `twoway`  $x$ -axis label rules and options—`xlabel()`; see [G-3] *axis\_label\_options*.

`nolabels` specifies that value labels not be used to construct graph labels and titles for the group levels in the dimension. By default, if a variable in a dimension has value labels, those labels are used to construct labels and titles for axis ticks, plots, subgraphs, and graphs.

Graphs of contrasts and pairwise comparisons are an exception to this rule and are always labeled with values rather than value labels.

`allsimplelabels` and `nosimplelabels` control whether graphs' labels and titles include just the values of the variables or include variable names and equal signs. The default is to use just the value label for variables that have value labels and to use variable names and equal signs for variables that do not have value labels. An example of the former is “Female” and the latter is “country=2”.

Sometimes, value labels are universally descriptive, and sometimes they have meaning only when considered in relation to their variable. For example, “Male” and “Female” are typically universal, regardless of the variable from which they are taken. “High” and “Low” may not have meaning unless you know they are in relation to a specific measure, say, blood-pressure level. The `allsimplelabels` and `nosimplelabels` options let you override the default labeling.

`allsimplelabels` specifies that all titles and labels use just the value or value label of the variable.

`nosimplelabels` specifies that all titles and labels include `varname=` before the value or value label of the variable.

`separator(string)` and `noseparator` control the separator between label sections when more than one variable is used to specify a dimension. The default separator is a comma followed by a space, but no separator may be requested with `noseparator` or the default may be changed to any string with `separator()`.

For example, if `plotdimension(a b)` is specified, the plot labels in our graph legend might be “a=1, b=1”, “a=1, b=2”, .... Specifying `separator(:)` would create labels “a=1:b=1”, “a=1:b=2”, ....

## Plot

`plotopts(plot_options)` affects the rendition of all margin plots. The `plot_options` can affect the size and color of markers, whether and how the markers are labeled, and whether and how the points are connected; see [G-3] [marker\\_options](#), [G-3] [marker\\_label\\_options](#), and [G-3] [cline\\_options](#).

These settings may be overridden for specific plots by using the `plot#opts()` option.

`plot#opts(plot_options)` affects the rendition of the #th margin plot. The `plot_options` can affect the size and color of markers, whether and how the markers are labeled, and whether and how the points are connected; see [G-3] [marker\\_options](#), [G-3] [marker\\_label\\_options](#), and [G-3] [cline\\_options](#).

`recast(plottype)` specifies that margins be plotted using `plottype`. `plottype` may be `scatter`, `line`, `connected`, `bar`, `area`, `spike`, `dropline`, or `dot`; see [G-2] [graph twoway](#). When `recast()` is specified, the plot-rendition options appropriate to the specified `plottype` may be used in lieu of `plot_options`. For details on those options, follow the appropriate link from [G-2] [graph twoway](#).

For an example using `recast()`, see [Continuous covariates](#).

You may specify `recast()` within a `plotopts()` or `plot#opts()` option. It is better, however, to specify it as documented here, outside those options. When specified outside those options, you have greater access to the plot-specific rendition options of your specified `plottype`.

## CI plot

`ciopts(rcap_options)` affects the rendition of all confidence interval plots; see [G-3] [rcap\\_options](#).

These settings may be overridden for specific confidence interval plots with the `ci#opts()` option.

`ci#opts(rcap_options)` affects the rendition of the #th confidence interval; see [G-3] [rcap\\_options](#).

`recastci(plottype)` specifies that confidence intervals be plotted using `plottype`. `plottype` may be `rarea`, `rbar`, `rspike`, `rcap`, `rcapsym`, `rline`, `rconnected`, or `rscatter`; see [G-2] [graph twoway](#). When `recastci()` is specified, the plot-rendition options appropriate to the specified `plottype` may be used in lieu of `rcap_options`. For details on those options, follow the appropriate link from [G-2] [graph twoway](#).

For an example using `recastci()`, see [Continuous covariates](#).

You may specify `recastci()` within a `ciopts()` or `ci#opts()` option. It is better, however, to specify it as documented here, outside those options. When specified outside those options, you have greater access to the plot-specific rendition options of your specified `plottype`.

`mcompare(method)` specifies the method for confidence intervals that account for multiple comparisons within a factor-variable term. The default is determined by the margins results stored in `r()`. If `marginsplot` is working from margins results stored in `e()`, the default is `mcompare(noadjust)`.

`level(#)` specifies the confidence level, as a percentage, for confidence intervals. The default is determined by the margins results stored in `r()`. If `marginsplot` is working from margins results stored in `e()`, the default is `level(95)` or as set by `set level`; see [U] [20.8 Specifying the width of confidence intervals](#).

## Pairwise

These options have an effect only when the `pwcompare` option was specified on the preceding `margins` command.

`unique` specifies that only unique pairwise comparisons be plotted. The default is to plot all pairwise comparisons, including those that are mirror images of each other—“male” versus “female” and “female” versus “male”. `margins` reports only the unique pairwise comparisons. `unique` also changes the default `xdimension()` for graphs of pairwise comparisons from the reference categories (`_pw0`) to the comparisons of each pairwise category (`_pw`).

Unique comparisons are often preferred with horizontal graphs that put all pairwise comparisons on the  $x$  axis, whereas including the full matrix of comparisons is preferred for charts showing the reference groups on an axis and the comparison groups as plots; see *Pairwise comparisons* and *Horizontal is sometimes better*.

`csort` specifies that comparison categories are sorted first, and then reference categories are sorted within comparison category. The default is to sort reference categories first, and then sort comparison categories within reference categories. This option has an observable effect only when `_pw` is also specified in one of the dimension options. It then determines the order of the labeling in the dimension where `_pw` is specified.

## Add plots

`addplot(plot)` provides a way to add other plots to the generated graph; see [G-3] *addplot\_option*.

For an example using `addplot()`, see *Adding scatterplots of the data*.

If multiple graphs are drawn by a single `marginsplot` command or if `plot` specifies plots with multiple  $y$  variables, for example, `scatter y1 y2 x`, then the graph’s legend will not clearly identify all the plots and will require customization using the `legend()` option; see [G-3] *legend\_options*.

## Y axis, X axis, Titles, Legend, Overall, By

*twoway\_options* are any of the options documented in [G-3] *twoway\_options*. These include options for titling the graph (see [G-3] *title\_options*); for saving the graph to disk (see [G-3] *saving\_option*); for controlling the labeling and look of the axes (see [G-3] *axis\_options*); for controlling the look, contents, position, and organization of the legend (see [G-3] *legend\_options*); for adding lines (see [G-3] *added\_line\_options*) and text (see [G-3] *added\_text\_options*); and for controlling other aspects of the graph’s appearance (see [G-3] *twoway\_options*).

The `label()` suboption of the `legend()` option has no effect on `marginsplot`. Use the `order()` or `lastlabel()` suboptions instead.

`byopts(byopts)` affects the appearance of the combined graph when `bydimension()` is specified or when the default graph has subgraphs, including the overall graph title, the position of the legend, and the organization of subgraphs. See [G-3] *by\_option*.

## Remarks and examples

Remarks are presented under the following headings:

- Introduction*
- Dataset*
- Profile plots*
- Interaction plots*
- Contrasts of margins—effects (discrete marginal effects)*
- Three-way interactions*
- Continuous covariates*
- Plots at every value of a continuous covariate*
- Contrasts of at() groups—discrete effects*
- Controlling the graph's dimensions*
- Pairwise comparisons*
- Horizontal is sometimes better*
- Marginal effects*
- Plotting a subset of the results from margins*
- Advanced usage*
  - Plots with multiple terms*
  - Plots with multiple at() options*
  - Adding scatterplots of the data*
- Video examples*

## Introduction

`marginsplot` is a post-`margins` command. It graphs the results of the `margins` command, whether those results are marginal means, predictive margins, marginal effects, contrasts, pairwise comparisons, or other statistics; see [R] [margins](#).

By default, the margins are plotted on the  $y$  axis, and all continuous and factor covariates specified in the `margins` command will usually be placed on the  $x$  axis or used to identify plots. Exceptions are discussed in the following sections and in *Addendum: Advanced uses of `dimlist`* below.

`marginsplot` produces classic plots, such as profile plots and interaction plots. Beyond that, anything that `margins` can compute, `marginsplot` can graph.

We will be using some relatively complicated `margins` commands with little explanation of the syntax. We will also avoid lengthy interpretations of the results of `margins`. See [R] [margins](#) for the complete syntax of `margins` and discussions of its results.

All graphs in this entry were drawn using the `s2gcolor` scheme; see [G-4] [Scheme s2](#).

[Mitchell \(2021\)](#) and [Baldwin \(2019\)](#) show in many examples how to use `marginsplot` to understand a fitted model.

## Dataset

For continuity, we will use one dataset for most examples—the Second National Health and Nutrition Examination Survey (NHANES II) ([McDowell et al. 1981](#)). NHANES II is part of a study to assess the health and nutritional status of adults and children in the United States. It is designed to be a nationally representative sample of the US population. This particular sample is from 1976 to 1980.

The survey nature of the dataset—weights, strata, and sampling units—will be ignored in our analyses. We are discussing graphing, not survey statistics. If you would like to see the results with the appropriate adjustments for the survey design, just add `svy:` before each estimation command, and if you wish, add `vce(unconditional)` as an option to each `margins` command. See [R] [margins](#), particularly the discussion and examples under *Obtaining margins with survey data and representative samples*, for reasons why you probably would want to add `vce(unconditional)` when analyzing survey data. For the most part, adjusting for survey design produces moderately larger confidence intervals and relatively small changes in point estimates.

## Profile plots

What does my estimation say about how my response varies as one (or more) of my covariates changes? That is the question that is answered by profile plots. Profile plots are also referred to as plots of estimated (or expected, or least-squares) means, though that is unnecessarily restrictive when considering models of binary, count, and ordered outcomes. In the latter cases, we might prefer to say they plot conditional expectations of responses, where a response might be a probability.

What we do with the other covariates depends on the questions we wish to answer. Sometimes, we wish to hold other covariates at fixed values, and sometimes we wish to average the response over their values. `margins` can do either, so you can graph either.

We can fit a fully factorial two-way ANOVA of systolic blood pressure on age group and sex using the NHANES II data.

```
. use https://www.stata-press.com/data/r19/nhanes2
. anova bpsystol agegrp##sex
```

|            | Number of obs = | 10,351  | R-squared =     | 0.2497 |        |
|------------|-----------------|---------|-----------------|--------|--------|
|            | Root MSE =      | 20.2209 | Adj R-squared = | 0.2489 |        |
| Source     | Partial SS      | df      | MS              | F      | Prob>F |
| Model      | 1407229.3       | 11      | 127929.93       | 312.88 | 0.0000 |
| agegrp     | 1243037.8       | 5       | 248607.56       | 608.02 | 0.0000 |
| sex        | 27728.379       | 1       | 27728.379       | 67.81  | 0.0000 |
| agegrp#sex | 88675.043       | 5       | 17735.009       | 43.37  | 0.0000 |
| Residual   | 4227440.7       | 10,339  | 408.88294       |        |        |
| Total      | 5634670         | 10,350  | 544.41256       |        |        |

If you are more comfortable with regression than ANOVA, then type

```
. regress bpsystol agegrp##sex
```

The `anova` and `regress` commands fit identical models. The output from `anova` displays all the terms in the model and thus tends to be more conducive to exploration with `margins` and `marginsplot`.

We estimate the predictive margins of systolic blood pressure for each age group using margins.

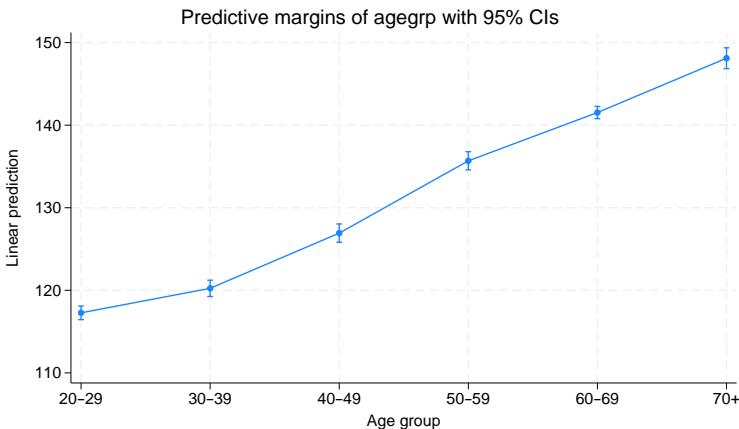

```
. margins agegrp
Predictive margins Number of obs = 10,351
Expression: Linear prediction, predict()
```

|        | Delta-method |           | t      | P> t  | [95% conf. interval] |          |
|--------|--------------|-----------|--------|-------|----------------------|----------|
|        | Margin       | std. err. |        |       |                      |          |
| agegrp |              |           |        |       |                      |          |
| 20-29  | 117.2684     | .419845   | 279.31 | 0.000 | 116.4454             | 118.0914 |
| 30-39  | 120.2383     | .5020813  | 239.48 | 0.000 | 119.2541             | 121.2225 |
| 40-49  | 126.9255     | .56699    | 223.86 | 0.000 | 125.8141             | 128.0369 |
| 50-59  | 135.682      | .5628593  | 241.06 | 0.000 | 134.5787             | 136.7853 |
| 60-69  | 141.5285     | .3781197  | 374.30 | 0.000 | 140.7873             | 142.2696 |
| 70+    | 148.1096     | .6445073  | 229.80 | 0.000 | 146.8463             | 149.373  |

The six predictive margins are just the averages of the predictions over the estimation sample, holding agegrp to each of its six levels. If this were a designed experiment rather than survey data, we might wish to assume the cells are balanced—that they have the same number of observations—and thus estimate what are often called expected means or least-squares means. To do that, we would simply add the `asbalanced` option to the `margins` command. The NHANES II data are decidedly unbalanced over `sex#agegrp` cells. So much so that it is unreasonable to assume the cells are balanced.

We graph the results:

```
. marginsplot
Variables that uniquely identify margins: agegrp
```

Profile plots are often drawn without confidence intervals (CIs). The CIs may be removed by adding the `noc1` option. We prefer to see the CIs.

Disciplines vary widely in their use of the term profile plot. Some disciplines consider any connected plot of a response over values of other variables to be a profile plot. By that definition, most graphs in this entry are profile plots.

## Interaction plots

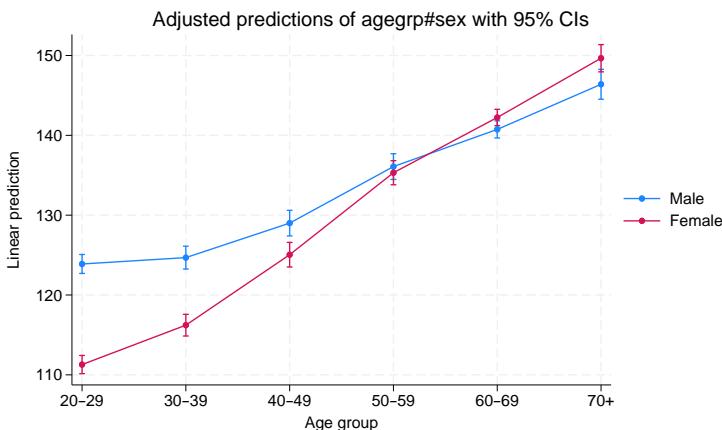

Interaction plots are often used to explore the form of an interaction. The interaction term in our ANOVA results is highly significant. Are the interaction effects also large enough to matter? What form do they take? We can answer these questions by fixing `agegrp` and `sex` to each possible combination of the two covariates and estimating the margins for those cells.

```
. margins agegrp#sex
```

Then, we can graph the results:

```
. marginsplot
```

```
Variables that uniquely identify margins: agegrp sex
```

It is clear that the effect of age differs by sex—there is an interaction. If there were no interaction, then the two lines would be parallel.

While males start out with higher systolic blood pressure, females catch up to the males as age increases and may even surpass males in the upper age groups. We say “may” because we cannot tell if the differences are statistically significant. The CIs overlap for the top three age groups. It is tempting to conclude from this overlap that the differences are not statistically significant. Do not fall into this trap. Likewise, do not fall into the trap that the first three age groups are different because their CIs do not overlap. The CIs are for the point estimates, not the differences. There is a covariance between the differences that we must consider if we are to make statements about those differences.

## Contrasts of margins—effects (discrete marginal effects)

To assess the differences, all we need to do is ask `margins` to contrast the sets of effects that we just estimated; see [\[R\] margins, contrast](#). With only two groups in sex, it does not matter much which contrast operator we choose. We will use the reference contrast. It will compare the difference between males and females, with males (the first category) as the reference category.

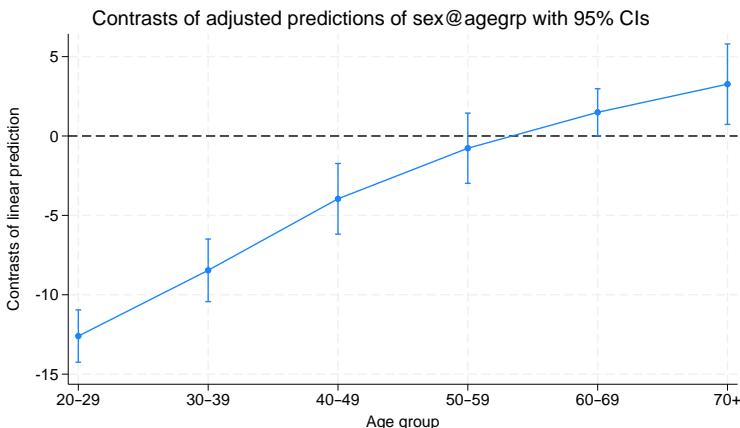

```
. margins r.sex@agegrp
Contrasts of adjusted predictions Number of obs = 10,351
Expression: Linear prediction, predict()
```

|                        | df    | F      | P>F    |
|------------------------|-------|--------|--------|
| sex@agegrp             |       |        |        |
| (Female vs Male) 20-29 | 1     | 224.92 | 0.0000 |
| (Female vs Male) 30-39 | 1     | 70.82  | 0.0000 |
| (Female vs Male) 40-49 | 1     | 12.15  | 0.0005 |
| (Female vs Male) 50-59 | 1     | 0.47   | 0.4949 |
| (Female vs Male) 60-69 | 1     | 3.88   | 0.0488 |
| (Female vs Male) 70+   | 1     | 6.37   | 0.0116 |
| Joint                  | 6     | 53.10  | 0.0000 |
| Denominator            | 10339 |        |        |

|                        | Delta-method |           |                      |
|------------------------|--------------|-----------|----------------------|
|                        | Contrast     | std. err. | [95% conf. interval] |
| sex@agegrp             |              |           |                      |
| (Female vs Male) 20-29 | -12.60132    | .8402299  | -14.24833 -10.9543   |
| (Female vs Male) 30-39 | -8.461161    | 1.005448  | -10.43203 -6.490288  |
| (Female vs Male) 40-49 | -3.956451    | 1.134878  | -6.181031 -1.731871  |
| (Female vs Male) 50-59 | -.7699782    | 1.128119  | -2.981309 1.441353   |
| (Female vs Male) 60-69 | 1.491684     | .756906   | .0080022 2.975367    |
| (Female vs Male) 70+   | 3.264762     | 1.293325  | .729594 5.79993      |

Because we are looking for effects that are different from 0, we will add a reference line at 0 to our graph.

```
. marginsplot, yline(0)
Variables that uniquely identify margins: agegrp
```

We can now say that females' systolic blood pressure is substantially and significantly lower than males' in the first three age groups but is significantly higher in the last two age groups. Despite the overlapping CIs for the last two age groups in the interaction graph, the effect of sex is significant in these age groups.

The terminology for what we just estimated and graphed varies widely across disciplines. Those versed in design of experiments refer to these values as contrasts or effects. Economists and some other social scientists call them marginal or partial effects. The latter groups might be more comfortable if we avoided the whole concept of contrasts and instead estimated the effects by typing

```
. margins agegrp, dydx(sex)
```

This will produce estimates that are identical to those shown above, and we can graph them by typing `marginsplot`.

The advantage of using the contrast notation and thinking in contrasts is most evident when we take marginal effects with respect to a categorical covariate with more than two levels. Marginal effects for each level of the covariate will be taken with respect to a specified base level. Contrasts are much more flexible. Using the `r.` operator, we can reproduce the marginal-effects results by taking derivatives with respect to a reference level (as we saw above.) We can also estimate the marginal effect of first moving from level 1 to level 2, then from level 2 to level 3, then from level 3 to level 4, ... using the `ar.` or “reverse adjacent” operator. Adjacent effects (marginal effects) can be valuable when evaluating an ordinal covariate, such as `agegrp` in our current model. For a discussion of contrasts, see [R] [contrast](#) and [R] [margins, contrast](#).

### Three-way interactions

`marginsplot` can handle any number of covariates in your `margins` command. Consider the three-way ANOVA model that results from adding an indicator for whether an individual has been diagnosed with diabetes. We will fully interact the new covariate with the others in the model.

```
. anova bpsystol agegrp##sex##diabetes
```

| Source              | Partial SS | df     | MS        | F      | Prob>F |
|---------------------|------------|--------|-----------|--------|--------|
| Model               | 1448983.2  | 23     | 62999.268 | 155.45 | 0.0000 |
| agegrp              | 107963.58  | 5      | 21592.716 | 53.28  | 0.0000 |
| sex                 | 1232.7927  | 1      | 1232.7927 | 3.04   | 0.0812 |
| agegrp#sex          | 11679.592  | 5      | 2335.9185 | 5.76   | 0.0000 |
| diabetes            | 7324.9892  | 1      | 7324.9892 | 18.07  | 0.0000 |
| agegrp#diabetes     | 5484.5462  | 5      | 1096.9092 | 2.71   | 0.0189 |
| sex#diabetes        | 102.98824  | 1      | 102.98824 | 0.25   | 0.6142 |
| agegrp#sex#diabetes | 4863.1497  | 5      | 972.62994 | 2.40   | 0.0349 |
| Residual            | 4184296.9  | 10,325 | 405.25878 |        |        |
| Total               | 5633280    | 10,348 | 544.38346 |        |        |

The three-way interaction is significant, as is the main effect of `diabetes` and its interaction with `agegrp`.

Again, if you are more comfortable with regression than ANOVA, you may type

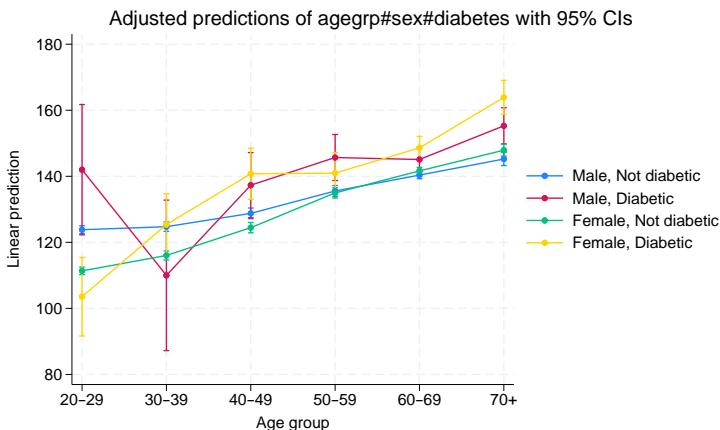

```
. regress bpsystol agegrp##sex##diabetes
```

The `margins` and `marginsplot` results will be the same.

We estimate the expected cell means for each combination of agegrp, sex, and diabetes, and then graph the results by typing

```
. margins agegrp#sex#diabetes
 (output omitted)
. marginsplot
```

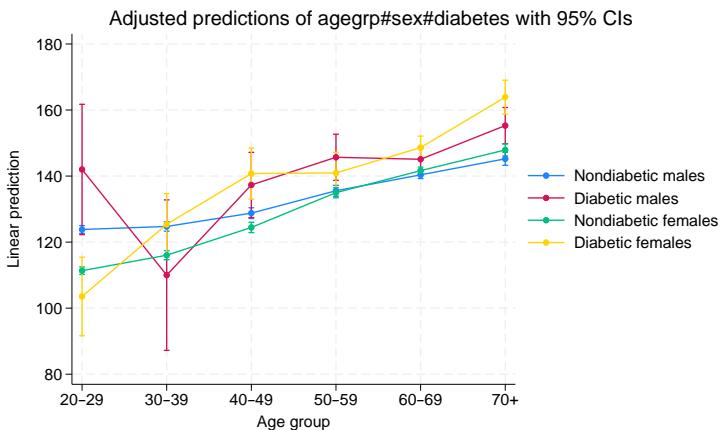

Variables that uniquely identify margins: **agegrp sex diabetes**

We wish to modify the text in the legend, and we can do so with the `lastlabel()` suboption of `legend()`. We label the first key as “Nondiabetic males”, the second as “Diabetic males”, and so on.

```
. marginsplot, legend(lastlabel(1 "Nondiabetic males")
> lastlabel(2 "Diabetic males") lastlabel(3 "Nondiabetic females")
> lastlabel(4 "Diabetic females"))
```

Variables that uniquely identify margins: **agegrp sex diabetes**

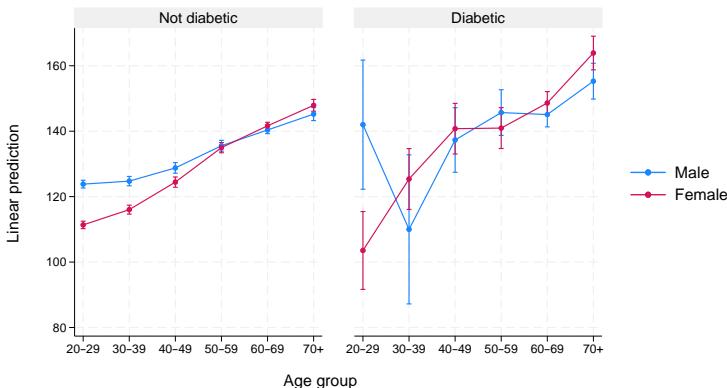

The last two graphs are busy and difficult to interpret.

We can make it better by putting those with diabetes on one subgraph and those without on another:

```
. marginsplot, by(diabetes)
Variables that uniquely identify margins: agegrp sex diabetes
```

Adjusted predictions of agegrp#sex#diabetes with 95% CIs

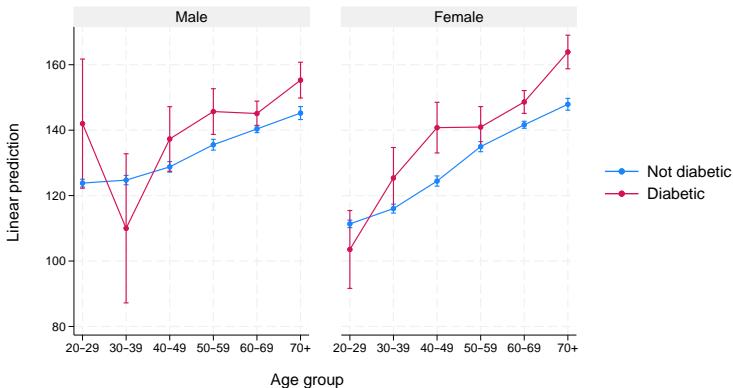

We notice much larger CIs for diabetics. That is not surprising because our sample contains only 499 diabetics compared with 9,850 nondiabetics.

A more interesting way to arrange the plots is by grouping the subgraphs on sex:

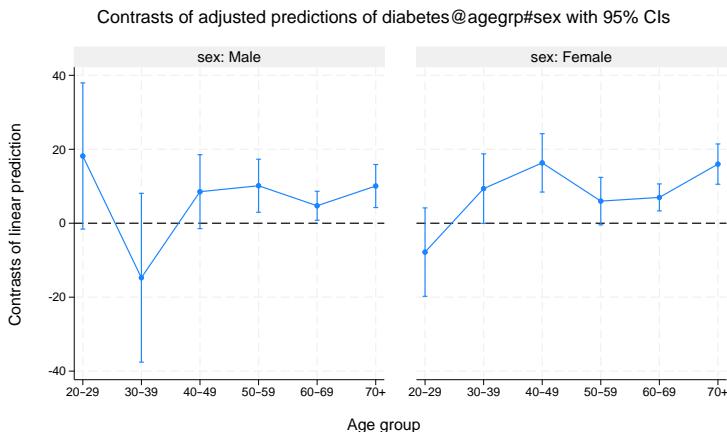

```
. marginsplot, by(sex)
Variables that uniquely identify margins: agegrp sex diabetes
```

Adjusted predictions of agegrp#sex#diabetes with 95% CIs

Aside from increased systolic blood pressure in the upper-age groups, which we saw earlier, it appears that those with diabetes are at greater risk of higher systolic blood pressure for many upper-age groups. We can check that by having `margins` estimate the differences between diabetics and nondiabetics, and graphing the results.

```
. margins r.diabetes@agegrp#sex
 (output omitted)
. marginsplot, by(sex) yline(0)
Variables that uniquely identify margins: agegrp sex
```

With CIs above 0 for six of eight age groups over 40, this graph provides evidence that diabetes is related to higher blood pressure in those over 40.

## Continuous covariates

`margins` and `marginsplot` are just as useful with continuous covariates as they are with factor variables. As a variation on our ANOVA/regression models, let's move to a logistic regression, using as our dependent variable an indicator for whether a person has high blood pressure. We introduce a continuous covariate—body mass index (BMI), a measure of weight relative to height. High BMI is often associated with high blood pressure. We will allow the effect of BMI to vary across sexes, age groups, and sex/age combinations by fully interacting the covariates.

```
. logistic highbp sex##agegrp##c.bmi
```

If we wished, we could perform all the analyses above on this model. Instead of estimating margins, contrasts, and marginal effects on the level of systolic blood pressure, we would be estimating margins, contrasts, and marginal effects on the probability of having high blood pressure. You can see those results by repeating any of the prior commands that involve `sex` and `agegrp`. In this section, we will focus on the continuous covariate `bmi`.

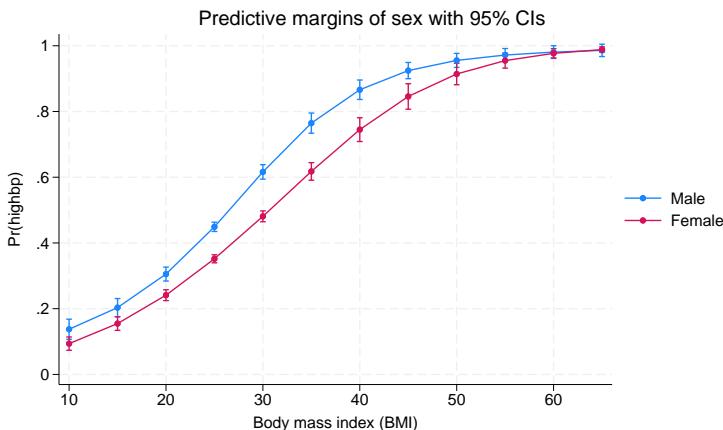

With continuous covariates, rather than specify them in the `marginlist` of `margins`, we specify the specific values at which we want the covariate evaluated in an `at()` option. `at()` options are very flexible, and there are many ways to specify values; see [Syntax of `at\(\)` in \[R\] margins](#).

BMI in our sample ranges from 12.4 to 61.1. Let's estimate the predictive margins for males and females at levels of BMI from 10 through 65 at intervals of 5 and graph the results:

```
. margins sex, at(bmi=(10(5)65))
(output omitted)
```

```
. marginsplot, xlabel(10(10)60)
```

Variables that uniquely identify margins: **bmi sex**

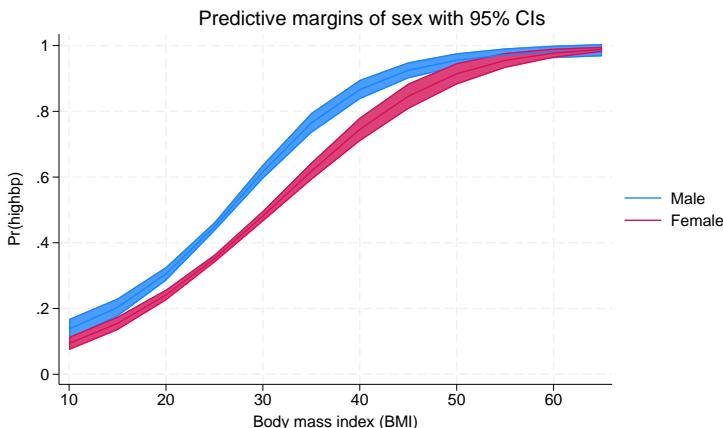

We added the `xlabel(10(10)60)` option to improve the labeling of the  $x$  axis. You may add any *twoway\_options* (see [G-3] *twoway\_options*) to the `marginsplot` command.

For a given BMI, males are generally more susceptible to high blood pressure, though the effect is attenuated by the logistic response when the probabilities approach 0 or 1.

Because `bmi` is continuous, we might prefer to see the response graphed using a line. We might also prefer that the CIs be plotted as areas. We change the plottype of the response by using the `recast()` option and the plottype of the CI by using the `recastci()` option:

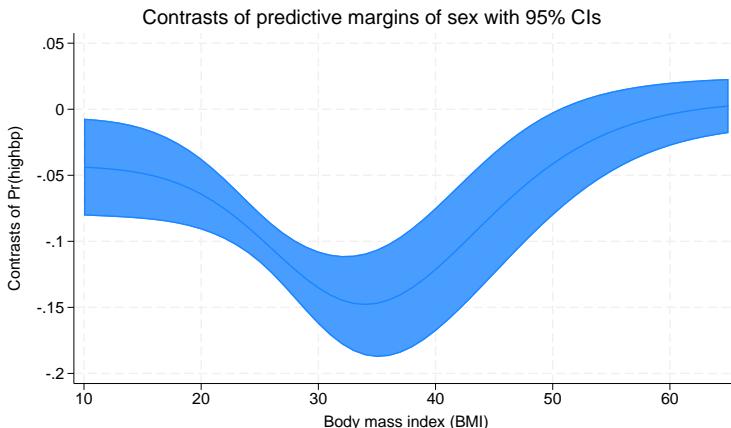

```
. marginsplot, xlabel(10(10)60) recast(line) recastci(rarea)
Variables that uniquely identify margins: bmi sex
```

The CIs are a little dark for our tastes. You can dim them a bit by reducing the intensity of their color. Adding `ciopts(color(*.8))` to our `marginsplot` command will do that. Any plot option accepted by `twoway rarea` (see [\[G-2\] graph twoway rarea](#)) may be specified in a `ciopts()` option.

Given their confidence regions, the male and female profiles appear to be statistically different over most of the range of BMI. As with the profiles of categorical covariates, we can check that assertion by contrasting the two profiles on `sex` and graphing the results. Let's improve the smoothness of the response by specifying intervals of 1 instead of 5.

```
. margins r.sex, at(bmi=(10(1)65))
(output omitted)
. marginsplot, xlabel(10(10)60) recast(line) recastci(rarea)
Variables that uniquely identify margins: bmi
```

We see that the difference between the sexes is largest at a BMI of about 35 and that the sexes respond more similarly with very high and very low BMI. This shape is largely determined by the response of the logistic function, which is attenuated near probabilities 0 and 1, combined with the fact that the lowest measured BMIs are associated with low probabilities of high blood pressure and the highest measured BMIs are associated with high probabilities of high blood pressure.

As when we contrasted profiles of categorical variables, different disciplines will think of this graph differently. Those familiar with designed experiments will be comfortable with the terms used above—this is a contrast of profiles, or a profile of effects, or a profile of a contrast. Many social scientists will prefer to think of this as a graph of marginal or partial effects. For them, this is a plot of the discrete marginal effect of being female for various levels of BMI. They can obtain an identical graph, with labeling more appropriate for the marginal effect's interpretation, by typing

```
. margins, at(bmi=(10(1)65)) dydx(sex)
. marginsplot, xlabel(10(10)60) recast(line) recastci(rarea)
```

We can also plot profiles of the response of BMI by levels of another continuous covariate (rather than by the categorical variable `sex`). To do so, we will need another continuous variable in our model. We have been using age groups as a covariate to emphasize the treatment of categorical variables and to allow the effect of age to be flexible. Our dataset also has age recorded in integer years. We replace `agegrp` with continuous `age` in our logistic regression.

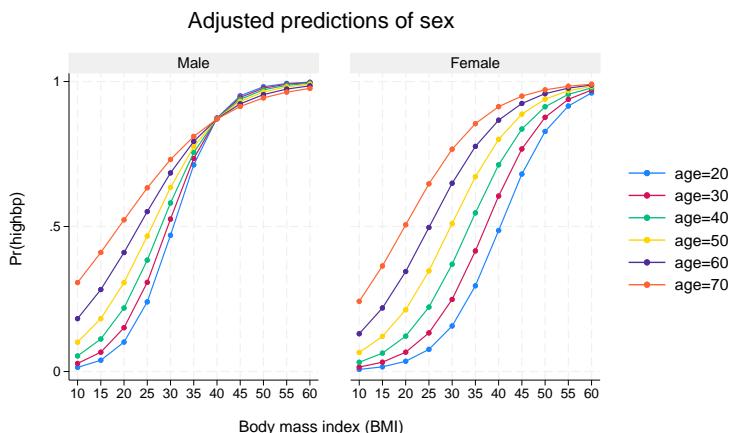

```
. logistic highbp sex##c.age##c.bmi
```

We can now obtain profiles of BMI for different ages by specifying ranges for both `bmi` and `age` in a single `at()` option on the `margins` command:

```
. margins sex, at(bmi=(10(5)60) age=(20(10)70))
```

With six ages specified, we have many profiles, so we will dispense with the CIs by adding the `nocl` option:

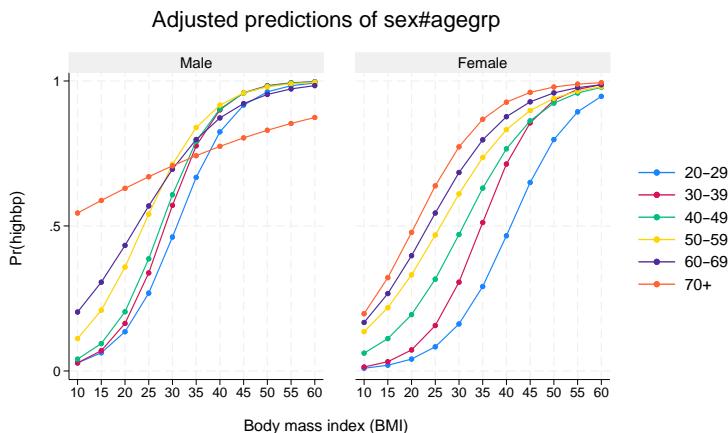

```
. marginsplot, noci by(sex)
Variables that uniquely identify margins: bmi age sex
```

Our model seems to indicate that males have a sharper reaction to body mass indices than do females. Likewise, younger subjects display a sharper response, while older subjects have a more gradual response with earlier onset. That interpretation might be a result of our parametric treatment of age. As it turns

out, the interpretation holds if we allow age to take more flexible forms or return to our use of age groups, which allows each of seven age groups to have unique BMI profiles. Here are the commands to perform that analysis:

```
. logistic highbp sex##agegrp##c.bmi
(output omitted)
. margins sex##agegrp, at(bmi=(10(5)60))
(output omitted)
. marginsplot, noci by(sex)
Variables that uniquely identify margins: bmi sex agegrp
```

## Plots at every value of a continuous covariate

In some cases, the specific values of a continuous covariate are important, and we want to plot the response at those specific values. Return to our logistic example with age treated as a continuous covariate.

```
. logistic highbp sex##c.age##c.bmi
```

We can use a programming trick to extract all the values of age and then supply them in an `at()` option, just as we would any list of values.

```
. levelsof age
. margins sex, at(age=('r(levels)'))
```

See [\[P\] levelsof](#) for a discussion of the `levelsof` command. `levelsof` returns in `r(levels)` the sorted list of unique values of the specified *varlist*, in our case, `age`.

We can then plot the results using `marginsplot`.

This is not a very interesting trick when using our `age` variable, which is recorded as integers from 20 to 74, but the approach will work with almost any continuous variable. In our model, `bmi` might seem more interesting, but there are 9,941 unique values of `bmi` in our dataset. A graph cannot resolve so many different values. For that reason, we usually recommend against plotting at every value of a covariate. Instead, graph at reasonable values over the range of the covariate by using the `at()` option, as we did earlier. This trick is best reserved for variables with a few, or at most a few dozen, unique values.

## Contrasts of at() groups—discrete effects

We have previously contrasted across the values of factor variables in our model. Put another way, we have estimated the discrete marginal effects of factor variables. We can do the same for the levels of variables in `at()` specifications and across separate `at()` specifications.

Returning to one of our logistic models and its margins, we earlier estimated the predictive margins of BMI at 5-unit intervals for both sexes. These are the commands we typed:

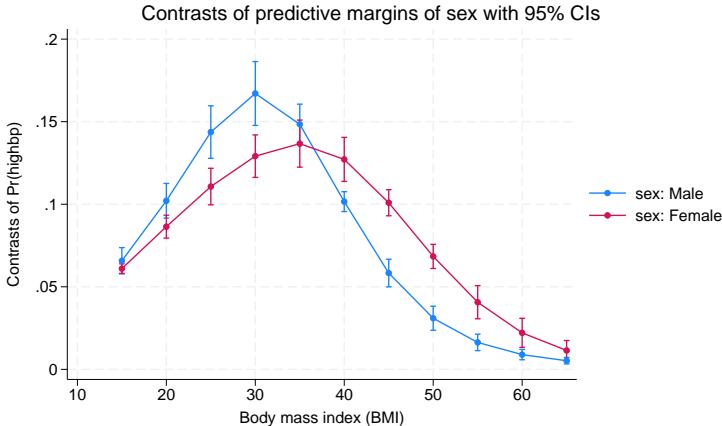

```
. logistic highbp sex##agegrp##c.bmi
. margins sex, at(bmi=(10(5)65))
. marginplot, xlabel(10(10)60)
```

We can estimate the discrete effects by sex of bmi moving from 10 to 15, then from 15 to 20, ..., and then from 60 to 65 by contrasting the levels of the `at()` groups using the reverse-adjacent contrast operator (`ar.`). We specify the operator within the `atcontrast()` suboption of the `contrast()` option. We need to specify one other option. By default, margins, contrast will apply a contrast to all variables in its *marginlist* when a contrast has been requested. In this case, we do not want to contrast across sexes but rather to contrast across the levels of BMI within each sex. To prevent margins from contrasting across the sexes, we specify the `marginswithin` option. Our margins command is

```
. margins sex, at(bmi=(10(5)65)) contrast(atcontrast(ar._at) marginswithin)
```

And we graph the results using `marginplot`:

```
. marginplot
Variables that uniquely identify margins: bmi sex
```

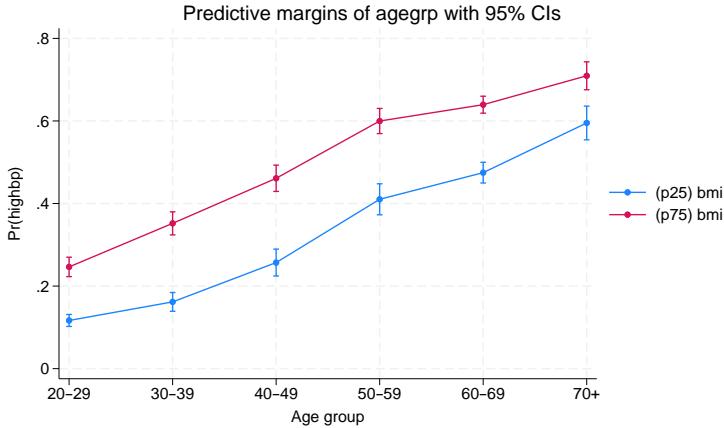

The graph shows the contrasts (or if you prefer, discrete changes) in the probability of high blood pressure by sex as one increases BMI in 5-unit increments.

We can even estimate contrasts (discrete effects) across `at()` options. To start, let's compare the age-group profiles of the probability of high blood pressure for those in the 25th and 75th percentile of BMI.

```
. margins agegrp, at((p25) bmi) at((p75) bmi)
 (output omitted)

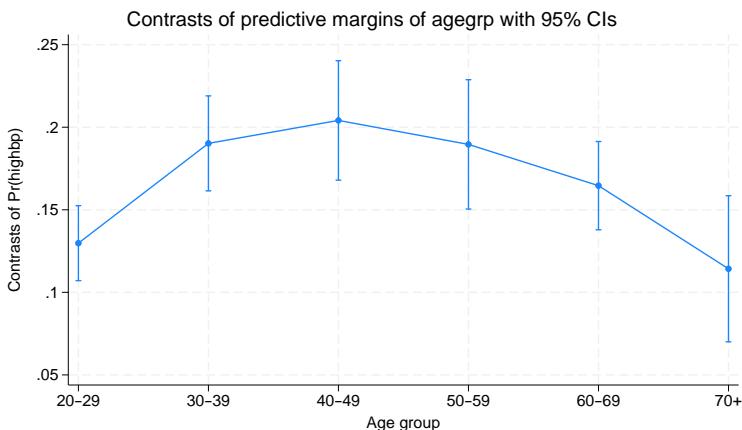

. marginsplot
Variables that uniquely identify margins: agegrp _atopt
Multiple at() options specified:
 _atoption=1: (p25) bmi
 _atoption=2: (p75) bmi
```

For each age group, people whose BMI is at the 75th percentile have a much higher probability of high blood pressure than those at the 25th percentile. What is that difference in probability and its CI? To contrast across the percentiles of BMI within age groups, we again specify a contrast operator on the `at()` groups using `atcontrast()`, and we also tell `margins` to perform that contrast within the levels of the *marginlist* by using the `marginswithin` option.

```
. margins agegrp, at((p25) bmi) at((p75) bmi)
> contrast(atcontrast(r._at) marginswithin)
(output omitted)
```

```
. marginsplot
Variables that uniquely identify margins: agegrp _atopt
Multiple at() options specified:
 _atoption=1: (p25) bmi
 _atoption=2: (p75) bmi
```

The differences in probability between 25th and 75th BMI percentiles are clearly significantly greater than 0. The differences appear to be smallest for those in the youngest and oldest age groups.

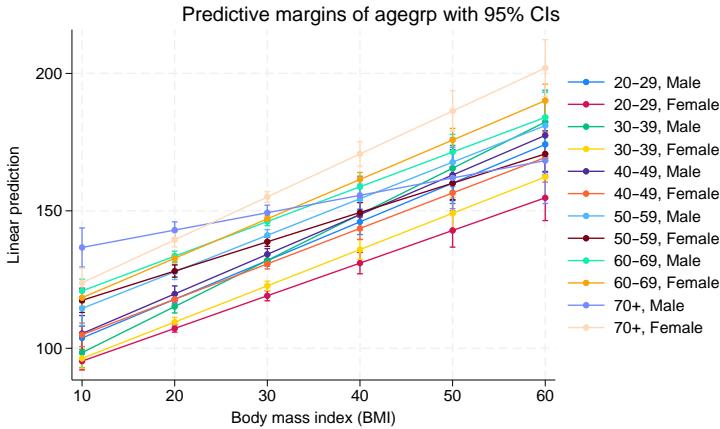

## Controlling the graph's dimensions

Thus far, `marginsplot` has miraculously done almost exactly what we want in most cases. The things we want on the  $x$  axis have been there, the choice of plots has made sense, etc. Some of that luck sprang from the relatively simple analyses we were performing, and some was from careful specification of our `margins` command. Sometimes, we will not be so lucky.

Consider the following `regress`, `margins`, and `marginsplot` commands:

```
. regress bpsystol agegrp##sex##c.bmi
(output omitted)
. margins agegrp, over(sex) at(bmi=(10(10)60))
(output omitted)
```

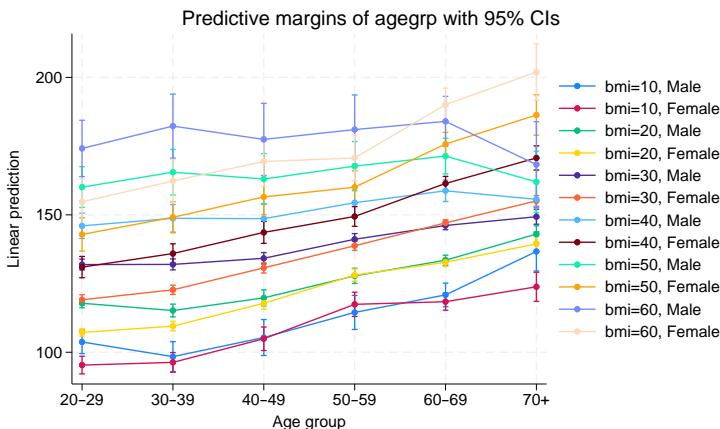

```
. marginsplot
Variables that uniquely identify margins: agegrp _atopt
Multiple at() options specified:
 _atoption=1: (p25) bmi
 _atoption=2: (p75) bmi
```

By default, `marginsplot` places the levels of the first multilevel `at()` specification on the  $x$  axis and then usually plots the levels of all remaining variables as connected lines. That is what we see in the graph above—`bmi`, the `at()` variable, is on the  $x$  axis, and each combination of `agegrp` and `sex` is plotted as a separate connected line. If there is no multilevel `at()` specification, then the first variable in `marginlist` becomes the  $x$  axis. There are many more rules, but it is usually best to simply type `marginsplot` and see what happens. If you do not like `marginsplot`'s choices, change them.

What if we wanted `agegrp` on the  $x$  axis instead of `BMI`? We tell `marginsplot` to make that change by specifying `agegrp` in the `xdimension()` option:

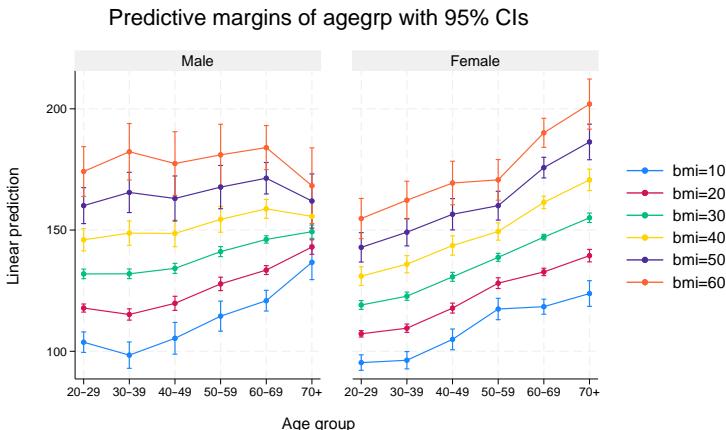

```
. marginsplot, xdimension(agegrp)
Variables that uniquely identify margins: bmi agegrp sex
```

We have been suppressing the Results window output for marginsplot, but that output is helpful if we want to change how things are plotted. You may specify any variable used in your margins command in any of the dimension options—`xdimension()`, `plotdimension()`, `bydimension()`, and `graphdimension()`. (In fact, there are some pseudovariables that you may also specify in some cases; see *Addendum: Advanced uses of dimlist* for details.) `marginsplot` tries to help you narrow your choices by listing a set of variables that uniquely identify all your margins. You are not restricted to this list.

We have a different *x* axis and a different set of plots, but our graph is still busy and difficult to read. We can make it better by creating separate graph panels for each sex. We do that by adding a `bydimension()` option with `sex` as the argument.

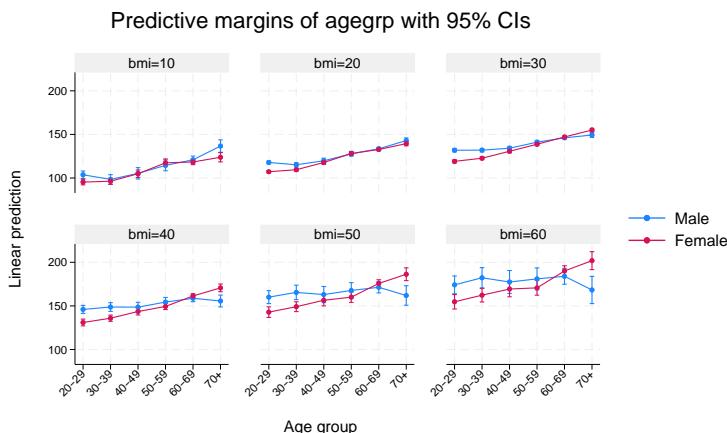

```
. marginsplot, xdimension(agegrp) bydimension(sex)
Variables that uniquely identify margins: bmi agegrp sex
```

The patterns and the differences between males and females are now easier to see.

If our interest is in comparing males and females, we might even choose to create a separate panel for each level of BMI:

```
. marginsplot, xdimension(agegrp) bydimension(bmi) xlabel(, angle(45))
Variables that uniquely identify margins: bmi agegrp sex
```

The  $x$ -axis labels did not fit, so we angled them.

We leave you to explore the use of the `graphdimension()` option. It is much like `bydimension()` but creates separate graphs rather than separate panels. Operationally, the `plotdimension()` option is rarely used. All variables not in the  $x$  dimension and not specified elsewhere become the plotted connected lines.

You will likely use the dimension options frequently. This is one of the rare cases where we recommend using the minimal abbreviations of the options—`x()` for `xdimension()`, `plot()` for `plotdimension()`, `by()` for `bydimension()`, and `graph()` for `graphdimension()`. The abbreviations are easy to read and just as meaningful as the full option names. The full names exist to reinforce the relationship between the dimension options.

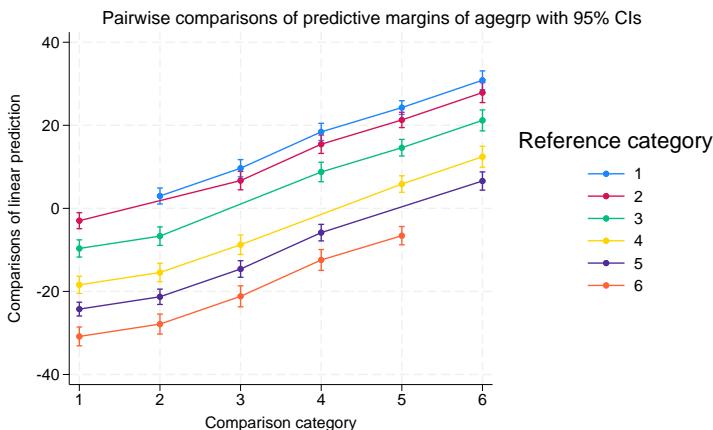

## Pairwise comparisons

`marginsplot` can graph the results of `margins`, `pwcompare`; see [R] [margins](#), [pwcompare](#). We return to one of our ANOVA examples. Here we request pairwise comparisons with the `pwcompare` option of `margins`, and we request Bonferroni-adjusted CIs with the `mcompare()` option:

```
. anova bpsystol agegrp##sex
(output omitted)
. margins agegrp, pwcompare mcompare(bonferroni)
(output omitted)
. marginsplot
```

Variables that uniquely identify margins: `_pw1` `_pw0`

`i_pw` enumerates all pairwise comparisons; `_pw0` enumerates the reference categories; `_pw1` enumerates the comparison categories.

Each connected line plot in the graph represents a reference age-group category for the pairwise comparison. The ticks on the  $x$  axis represent comparison age-group categories. So, each plot is a profile for a reference category showing its comparison to each other category.

## Horizontal is sometimes better

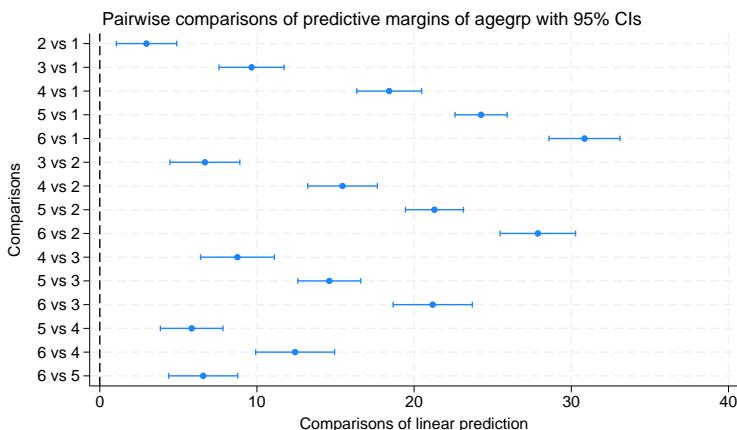

Another interesting way to graph pairwise comparisons is to simply plot each comparison and label the two categories being compared. This type of graph works better if it is oriented horizontally rather than vertically.

Continuing with the example above, we will switch the graph to horizontal. We will also make several changes to display the graph better. We specify that only unique comparisons be plotted. The graph above plotted both 1 versus 2 and 2 versus 1, which are the same comparison with opposite signs. We add a reference line at 0 because we are interested in comparisons that differ from 0. This graph looks better without the connecting lines, so we add the `recast(scatter)` option. We also reverse the  $y$  scale so that the smallest levels of age group appear at the top of the axis.

```
. marginsplot, horizontal unique xline(0) recast(scatter) yscale(reverse)
```

Variables that uniquely identify margins: `_pw1 _pw0`

`i_pw` enumerates all pairwise comparisons; `_pw0` enumerates the reference categories; `_pw1` enumerates the comparison categories.

All the comparisons differ from 0, so all our age groups are statistically different from each other.

The `horizontal` option can be useful outside of pairwise comparisons. Profile plots are usually oriented vertically. However, when your covariates have long labels or there are many levels at which the margins are being evaluated, the graph may be easier to read when rendered horizontally.

## Marginal effects

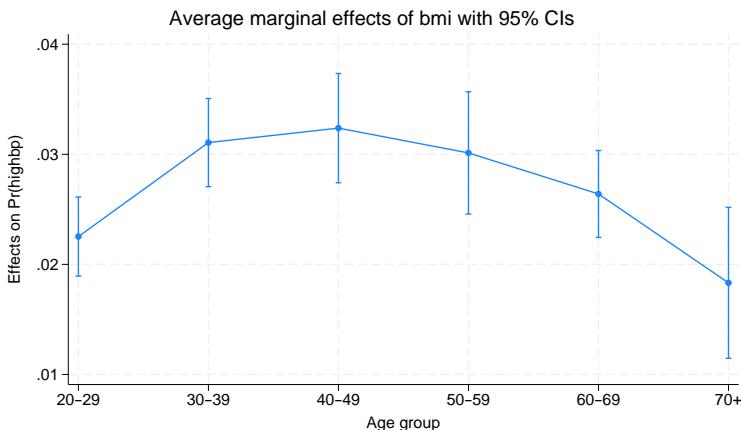

We have seen how to graph discrete effects for factor variables and continuous variables by using contrasts, and optionally by using the `dydx()` option of `margins`: [Contrasts of margins—effects \(discrete marginal effects\)](#) and [Continuous covariates](#). Let's now consider graphing instantaneous marginal effects for continuous covariates. Begin by refitting our logistic model of high blood pressure as a function of sex, age, and BMI:

```
. logistic highbp sex##agegrp##c.bmi
```

We estimate the average marginal effect of BMI on the probability of high blood pressure for each age group and then graph the results by typing

```
. margins agegrp, dydx(bmi)
 (output omitted)
. marginsplot
```

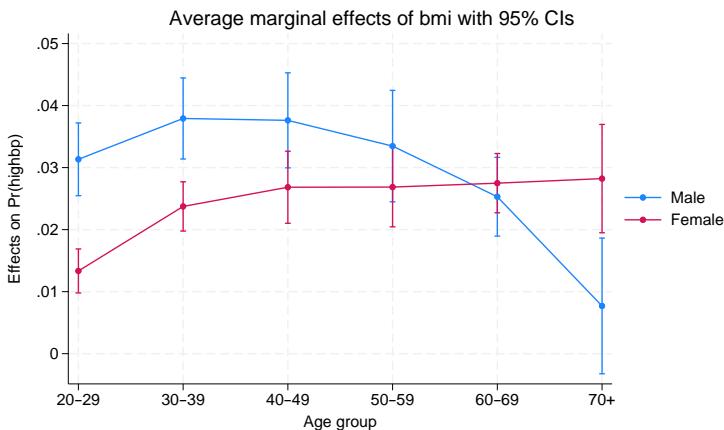

Variables that uniquely identify margins: **agegrp**

These are the conditional expectations of the marginal effects treating everyone in the sample as though they were in each age group. We can estimate fully conditional marginal effects that do not depend on averaging over the sample by also margining on our one remaining covariate—sex.

```
. margins agegrp#sex, dydx(bmi)
 (output omitted)
. marginsplot
```

Variables that uniquely identify margins: **agegrp sex**

The effect of BMI on the probability of high blood pressure looks to increase with age for females. The marginal effect is higher for males than females in the younger age groups but then decreases with age for males after the 40–49 age group.

You may want to test for differences in the marginal effect of BMI for males and females by contrasting across sexes within agegrp:

```
. margins r.sex@agegrp, dydx(bmi)
```

## Plotting a subset of the results from margins

`marginsplot` plots all the margins produced by the preceding `margins` command. If you want a graph that does not include all the margins, then enter a `margins` command that produces a reduced set of margins. Obvious ways to reduce the number of margins include not specifying some factors or interactions in the *marginlist* of `margins`, not specifying some `at()` or `over()` options, or reducing the values specified in an `at()` option. A less obvious technique uses selection lists in factor operators to select specific sets of levels from factor variables specified in the *marginlist*.

Instead of typing

```
. margins agegrp
```

which will give you margins for all six age groups in our sample, type

```
. margins i(2/4).agegrp
```

which will give you only three margins—those for groups 2, 3, and 4. See [\[U\] 11.4.3.4 Selecting levels](#).

## Advanced usage

`margins` is incredibly flexible in the statistics it can estimate and in the grouping of those estimates. Many of the estimates that `margins` can produce do not make convincing graphs. `marginsplot` plots the results of any `margins` command, regardless of whether the resulting graph is easily interpreted. Here we demonstrate some options that can make complicated `margins` into graphs that are somewhat more useful than those produced by `marginsplot`'s defaults. Others may find truly useful applications for these approaches.

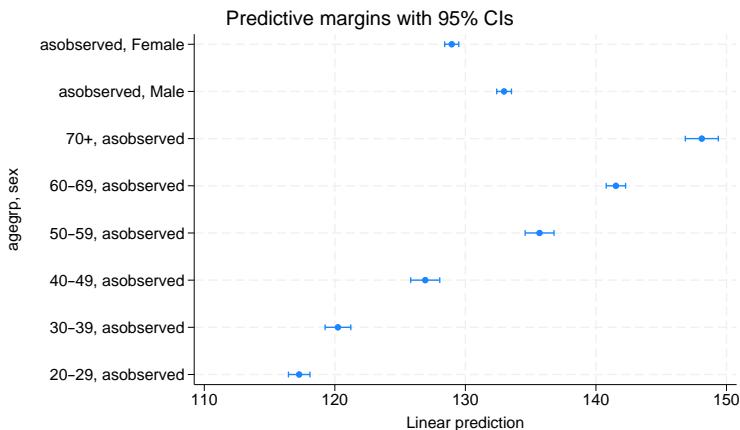

## Plots with multiple terms

Margins plots are rarely interesting when you specify multiple terms on your `margins` command, for example, `margins a b`. Such plots often compare things that are not comparable. The defaults for `marginsplot` rarely produce useful plots with multiple terms. Perhaps the most interesting graph in such cases puts all the levels of all the terms together on the vertical axis and plots their margins on the horizontal axis. We do that by including the *marginlist* from `margins` in an `xdimension()` option on `marginsplot`. The long labels on such graphs look better with a horizontal orientation, and there is no need to connect the margin estimates, so we specify the `recast(scatter)` option.

Using one of our ANOVA examples from earlier,

```
. anova bpsystol agegrp##sex
 (output omitted)
. margins agegrp sex
 (output omitted)
. marginsplot, xdimension(agegrp sex) horizontal recast(scatter)
```

Variables that uniquely identify margins: **agegrp sex**

The “asobserved” notations in the  $y$ -axis labels are informing us that, for example, when the margin for females is evaluated, the values of age group are taken as they are observed in the dataset. The margin is computed as an average over those values.

### Plots with multiple at() options

Some disciplines like to compute margins at the means of other covariates in their model and others like to compute the response for each observation and then take the means of the response. These correspond to the margins options `at((mean) _all)` and `at((asobserved) _all)`. For responses that are linear functions of the coefficients, such as `predict` after `regress`, the two computations yield identical results. For responses that are nonlinear functions of the coefficients, the two computations estimate different things.

Using one of our logistic models of high blood pressure,

```
. logistic highbp sex##agegrp##c.bmi
```

and computing both sets of margins for each age group,

```
. margins agegrp, at((mean) _all) at((asobserved) _all)
```

we can use marginsplot to compare the approaches:

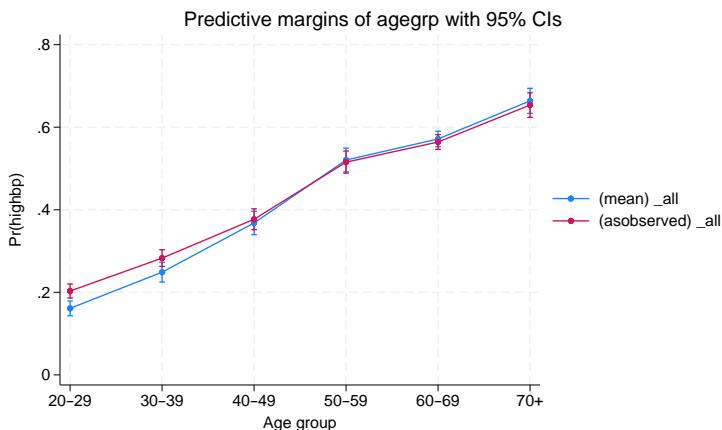

```
. marginsplot
```

Variables that uniquely identify margins: **agegrp \_atopt**

Multiple **at()** options specified:

\_atoption=1: (mean)\_all

\_atoption=2: (asobserved)\_all

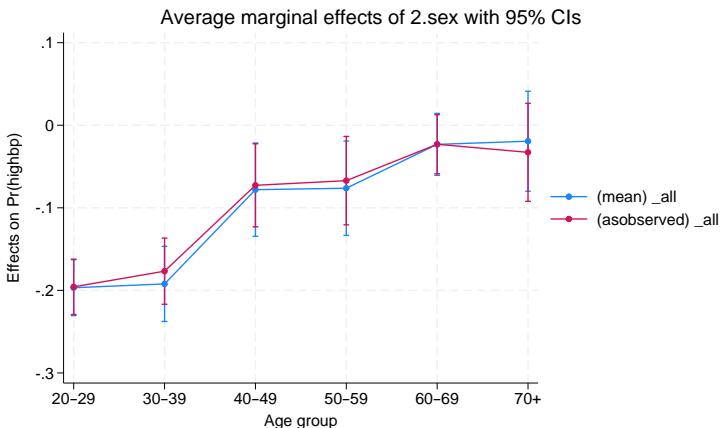

For the first three age groups, the probabilities of high blood pressure are lower at the means of sex and bpi than are the mean probabilities of high blood pressure averaged over the observed values of sex and bpi. The reverse is true for the last three age groups, although the values are very similar in these older age groups.

Such comparisons come up even more frequently when evaluating marginal effects. We can estimate the marginal effects of sex at each age group and graph the results by adding `dydx(sex)` to our `margins` command:

```
. margins agegrp, at((mean) _all) at((asobserved) _all) dydx(sex)
(output omitted)
```

```
. marginsplot
Variables that uniquely identify margins: agegrp _atopt
Multiple at() options specified:
 _atoption=1: (mean)_all
 _atoption=2: (asobserved) _all
```

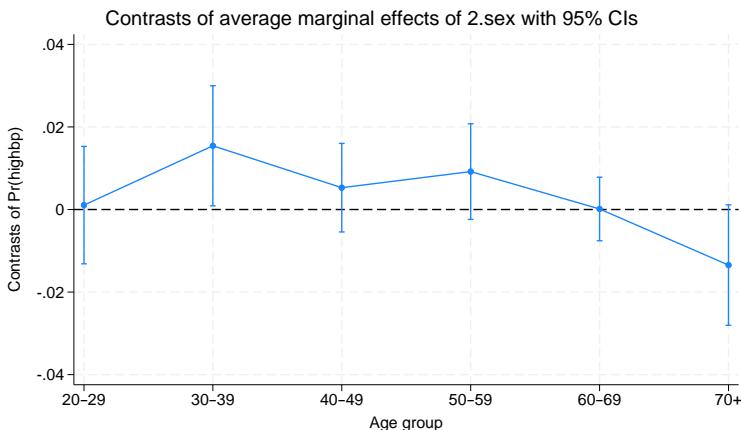

The average marginal effect is smaller for most age groups, but the CIs for both sets of estimates are wide. Can we tell the difference between the estimates? To answer that, we use the now-familiar tactic of taking the contrast of our estimated marginal-effects profiles. That means adding `contrast(atjoint marginswithin)` to our `margins` command. We will also add `mcompare(bonferroni)` to account for the fact that we will be comparing six contrasts.

```
. margins agegrp, at((mean) _all) at((asobserved) _all) dydx(sex)
> contrast(atjoint marginswithin) mcompare(bonferroni)
```

We will also add the familiar reference line at 0 to our graph of the contrasts.

```
. marginsplot, yline(0)
Variables that uniquely identify margins: agegrp _atopt
Multiple at() options specified:
 _atoption=1: (mean)_all
 _atoption=2: (asobserved)_all
```

While the difference in the estimates of marginal effects is not large, we can distinguish the estimates for the 30–39 and 70+ age groups.

The `at()` option of `margins` provides far more flexibility than demonstrated above. It can be used to evaluate a response or marginal effect at almost any point of interest or combinations of such points. See *Syntax of at()* in [R] `margins`.

## Adding scatterplots of the data

We can add scatterplots of the observed data to our plots of the margins. The NHANES II dataset is too large for this to be interesting, so for this example, we will use `auto.dta`. We fit mileage on whether the care is foreign and on a quadratic in the weight of the car. We convert the weight into tons (US definition) to improve the scaling, and we format the new tons variable to improve its labels on the graph. For our graph, we create separate variables for mileage of domestic and of foreign cars. We fit a fully interacted model so that the effect of weight on mileage can be different for foreign and for domestic cars.

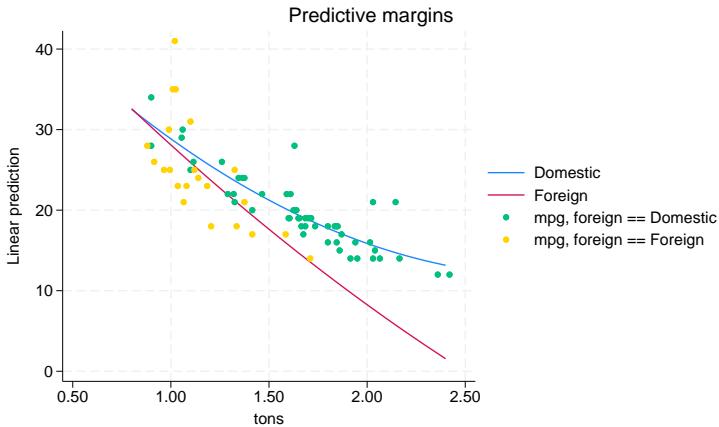

```
. use https://www.stata-press.com/data/r19/auto
. generate tons = weight/2000
. format tons %6.2f
. separate mpg, by(foreign)
. regress mpg foreign##c.tons##c.tons
```

We then estimate the margins over the range of tons, using the option `over(foreign)` to obtain separate estimates for foreign and domestic cars.

```
. margins, at(tons=(.8(.05)2.4)) over(foreign)
```

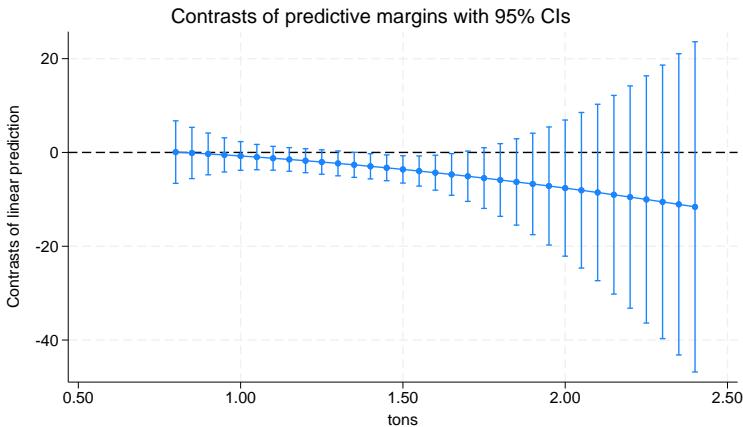

Adding scatterplots of mileage for domestic and foreign cars is easy. We insert into an `addplot()` option of `marginsplot` the same scatterplot syntax for `twoway` that we would type to produce a scatterplot of the data:

```
. marginsplot, addplot(scatter mpg0 tons || scatter mpg1 tons) recast(line) noci
Variables that uniquely identify margins: tons foreign
```

Many will be surprised that the mileage profile is higher in 1978 for domestic (US built) cars. Is the difference significant?

```
. margins, at(tons=(.8(.05)2.4)) over(r.for)
(output omitted)
. marginsplot, yline(0)
Variables that uniquely identify margins: tons
```

As we did earlier, we contrast the two profiles. We can discern some difference between the two profiles for midweight vehicles, but otherwise there is insufficient information to believe mileage differs across domestic and foreign cars.

## Addendum: Advanced uses of dimlist

*dimlist* specifies the dimensions from the immediately preceding *margins* command that are to be used for the *marginsplot*'s *x* axis, plots, subgraphs, and graphs. *dimlist* may contain:

| <i>dim</i>         | Description                                                                                                                                                                                                                                                                       |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>varname</i>     | Any variable referenced in the preceding <i>margins</i> command.                                                                                                                                                                                                                  |
| <i>_equation</i>   | If the estimation command being analyzed is multivariate and <i>margins</i> automatically produced estimates for more than one dependent-variable equation, then <i>dimlist</i> may contain <i>_equation</i> to enumerate those equations.                                        |
| <i>_outcome</i>    | If the estimation command being analyzed is ordinal and <i>margins</i> automatically produced estimates for more than one outcome level, then <i>dimlist</i> may contain <i>_outcome</i> to enumerate those outcomes.                                                             |
| <i>_predict</i>    | If the preceding <i>margins</i> command included multiple <i>predict()</i> options, then <i>dimlist</i> may contain <i>_predict</i> to enumerate those <i>predict()</i> options.                                                                                                  |
| <i>at(varname)</i> | If a variable is specified in both the <i>marginlist</i> or the <i>over()</i> option and in the <i>at()</i> option of <i>margins</i> , then the two uses can be distinguished in <i>marginsplot</i> by typing the <i>at()</i> variables as <i>at(varname)</i> in <i>dimlist</i> . |
| <i>_deriv</i>      | If the preceding <i>margins</i> command included a <i>dydx()</i> , <i>eyex()</i> , <i>dyex()</i> , or <i>eydx()</i> option, <i>dimlist</i> may also contain <i>_deriv</i> to specify all the variables over which derivatives were taken.                                         |
| <i>_term</i>       | If the preceding <i>margins</i> command included multiple terms (for example, <i>margins a b</i> ), then <i>dimlist</i> may contain <i>_term</i> to enumerate those terms.                                                                                                        |
| <i>_atopt</i>      | If the preceding <i>margins</i> command included multiple <i>at()</i> options, then <i>dimlist</i> may contain <i>_atopt</i> to enumerate those <i>at()</i> options.                                                                                                              |

When the *pairwise* option is specified on *margins*, you may specify dimensions that enumerate the pairwise comparisons.

|             |                                                         |
|-------------|---------------------------------------------------------|
| <i>_pw</i>  | enumerates all the pairwise comparisons                 |
| <i>_pw0</i> | enumerates the reference categories of the comparisons  |
| <i>_pw1</i> | enumerates the comparison categories of the comparisons |

## Description

All Stata commands maximize likelihood functions using `moptimize()` and `optimize()`; see *Methods and formulas* below. Commands use the Newton–Raphson method with step halving and special fixes when they encounter nonconcave regions of the likelihood. For details, see [M-5] `moptimize()` and [M-5] `optimize()`. For more information about programming maximum likelihood estimators in ado-files and Mata, see [R] `ml` and Pitblado, Poi, and Gould (2024).

## Syntax

`mle_cmd ... [ , options ]`

| <i>options</i>                                | Description                                                                                                                                                                                                                                                  |
|-----------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>difficult</code>                        | use a different stepping algorithm in nonconcave regions                                                                                                                                                                                                     |
| <code>technique(<i>algorithm_spec</i>)</code> | maximization technique                                                                                                                                                                                                                                       |
| <code>iterate(#)</code>                       | perform maximum of # iterations; default is <code>iterate(300)</code>                                                                                                                                                                                        |
| <code>[no]log</code>                          | display an iteration log of the log likelihood; typically, the default                                                                                                                                                                                       |
| <code>trace</code>                            | display current parameter vector in iteration log                                                                                                                                                                                                            |
| <code>gradient</code>                         | display current gradient vector in iteration log                                                                                                                                                                                                             |
| <code>showstep</code>                         | report steps within an iteration in iteration log                                                                                                                                                                                                            |
| <code>hessian</code>                          | display current negative Hessian matrix in iteration log                                                                                                                                                                                                     |
| <code>showtolerance</code>                    | report the calculated result that is compared to the effective convergence criterion                                                                                                                                                                         |
| <code>tolerance(#)</code>                     | tolerance for the coefficient vector; see <i>Options</i> for the defaults                                                                                                                                                                                    |
| <code>ltolerance(#)</code>                    | tolerance for the log likelihood; see <i>Options</i> for the defaults                                                                                                                                                                                        |
| <code>nrtolerance(#)</code>                   | tolerance for the scaled gradient; see <i>Options</i> for the defaults                                                                                                                                                                                       |
| <code>qtolerance(#)</code>                    | when specified with algorithms <code>bhhh</code> , <code>dfp</code> , or <code>bfgs</code> , the $\mathbf{q} - \mathbf{H}$ matrix is used as the final check for convergence rather than <code>nrtolerance()</code> and the $\mathbf{H}$ matrix; seldom used |
| <code>nonrtolerance</code>                    | ignore the <code>nrtolerance()</code> option                                                                                                                                                                                                                 |
| <code>from(<i>init_specs</i>)</code>          | initial values for the coefficients                                                                                                                                                                                                                          |

*algorithm\_spec* is

`algorithm [ # [ algorithm [ # ] ] ... ]`

*algorithm* is { `nr` | `bhhh` | `dfp` | `bfgs` }

*init\_specs* is one of

`matname [ , skip copy ]`

{ [ *eqname*: ] *name* = # | / *eqname* = # } [ ... ]

# [ # ... ] , copy

## Maximization options

`difficult` specifies that the likelihood function is likely to be difficult to maximize because of nonconcave regions. When the message “not concave” appears repeatedly, `m1`’s standard stepping algorithm may not be working well. `difficult` specifies that a different stepping algorithm be used in nonconcave regions. There is no guarantee that `difficult` will work better than the default; sometimes it is better and sometimes it is worse. You should use the `difficult` option only when the default stepper declares convergence and the last iteration is “not concave” or when the default stepper is repeatedly issuing “not concave” messages and producing only tiny improvements in the log likelihood.

`technique(algorithm_spec)` specifies how the likelihood function is to be maximized. The following algorithms are allowed. For details, see [Pitblado, Poi, and Gould \(2024\)](#).

`technique(nr)` specifies Stata’s modified Newton–Raphson (NR) algorithm.

`technique(bhhh)` specifies the Berndt–Hall–Hall–Hausman (BHHH) algorithm.

`technique(dfp)` specifies the Davidon–Fletcher–Powell (DFP) algorithm.

`technique(bfgs)` specifies the Broyden–Fletcher–Goldfarb–Shanno (BFGS) algorithm.

The default is `technique(nr)`.

You can switch between algorithms by specifying more than one in the `technique()` option. By default, an algorithm is used for five iterations before switching to the next algorithm. To specify a different number of iterations, include the number after the `technique` in the option. For example, specifying `technique(bhhh 10 nr 1000)` requests that `m1` perform 10 iterations with the BHHH algorithm followed by 1000 iterations with the NR algorithm, and then switch back to BHHH for 10 iterations, and so on. The process continues until convergence or until the maximum number of iterations is reached.

`iterate(#)` specifies the maximum number of iterations. When the number of iterations equals `iterate()`, the optimizer stops and presents the current results. If convergence is declared before this threshold is reached, it will stop when convergence is declared. Specifying `iterate(0)` is useful for viewing results evaluated at the initial value of the coefficient vector. Specifying `iterate(0)` and `from()` together allows you to view results evaluated at a specified coefficient vector; however, not all commands allow the `from()` option. The default value of `iterate(#)` for both estimators programmed internally and estimators programmed with `m1` is the number set using `set maxiter`, which is 300 by default.

`log` and `nolog` specify whether an iteration log showing the progress of the log likelihood is to be displayed. For most commands, the log is displayed by default, and `nolog` suppresses it; see `set iterlog` in [\[R\] set iter](#). For a few commands (such as the `svy` maximum likelihood estimators), you must specify `log` to see the log.

`trace` adds to the iteration log a display of the current parameter vector.

`gradient` adds to the iteration log a display of the current gradient vector.

`showstep` adds to the iteration log a report on the steps within an iteration. This option was added so that developers at StataCorp could view the stepping when they were improving the `m1` optimizer code. At this point, it mainly provides entertainment.

`hessian` adds to the iteration log a display of the current negative Hessian matrix.

`showtolerance` adds to the iteration log the calculated value that is compared with the effective convergence criterion at the end of each iteration. Until convergence is achieved, the smallest calculated value is reported.

`shownrtolerance` is a synonym of `showtolerance`.

Below, we describe the three convergence tolerances. Convergence is declared when the `nrtolerance()` criterion is met and either the `tolerance()` or the `ltolerance()` criterion is also met.

`tolerance(#)` specifies the tolerance for the coefficient vector. When the relative change in the coefficient vector from one iteration to the next is less than or equal to `tolerance()`, the `tolerance()` convergence criterion is satisfied.

`tolerance(1e-4)` is the default for estimators programmed with `ml`.

`tolerance(1e-6)` is the default.

`ltolerance(#)` specifies the tolerance for the log likelihood. When the relative change in the log likelihood from one iteration to the next is less than or equal to `ltolerance()`, the `ltolerance()` convergence is satisfied.

`ltolerance(0)` is the default for estimators programmed with `ml`.

`ltolerance(1e-7)` is the default.

`nrtolerance(#)` specifies the tolerance for the scaled gradient. Convergence is declared when  $\mathbf{g}\mathbf{H}^{-1}\mathbf{g}' < \text{nrtolerance}()$ . The default is `nrtolerance(1e-5)`.

`qtolerance(#)` when specified with algorithms `bhhh`, `dfp`, or `bfgs` uses the  $\mathbf{q} - \mathbf{H}$  matrix as the final check for convergence rather than `nrtolerance()` and the  $\mathbf{H}$  matrix.

Beginning with Stata 12, by default, Stata now computes the  $\mathbf{H}$  matrix when the  $\mathbf{q} - \mathbf{H}$  matrix passes the convergence tolerance, and Stata requires that  $\mathbf{H}$  be concave and pass the `nrtolerance()` criterion before concluding convergence has occurred.

`qtolerance()` provides a way for the user to obtain Stata's earlier behavior.

`nonrtolerance` specifies that the default `nrtolerance()` criterion be turned off.

`from()` specifies initial values for the coefficients. Not all estimators in Stata support this option. You can specify the initial values in one of three ways: by specifying the name of a vector containing the initial values (for example, `from(b0)`, where `b0` is a properly labeled vector); by specifying coefficient names with the values (for example, `from(age=2.1 /sigma=7.4)`); or by specifying a list of values (for example, `from(2.1 7.4, copy)`). `from()` is intended for use when doing bootstraps (see [R] [bootstrap](#)) and in other special situations (for example, with `iterate(0)`). Even when the values specified in `from()` are close to the values that maximize the likelihood, only a few iterations may be saved. Poor values in `from()` may lead to convergence problems.

`skip` specifies that any parameters found in the specified initialization vector that are not also found in the model be ignored. The default action is to issue an error message.

`copy` specifies that the list of values or the initialization vector be copied into the initial-value vector by position rather than by name.

## Remarks and examples

Only in rare circumstances would you ever need to specify any of these options, except `nolog`. The `nolog` option is useful for reducing the amount of output appearing in log files; also see `set iterlog` in [R] *set iter*.

The following is an example of an iteration log:

```
Iteration 0: Log likelihood = -3791.0251
Iteration 1: Log likelihood = -3761.738
Iteration 2: Log likelihood = -3758.0632 (not concave)
Iteration 3: Log likelihood = -3758.0447
Iteration 4: Log likelihood = -3757.5861
Iteration 5: Log likelihood = -3757.474
Iteration 6: Log likelihood = -3757.4613
Iteration 7: Log likelihood = -3757.4606
Iteration 8: Log likelihood = -3757.4606
(table of results omitted$ $)
```

At iteration 8, the model converged. The message “not concave” at the second iteration is notable. This example was produced using the `heckman` command; its likelihood is not globally concave, so it is not surprising that this message sometimes appears. The other message that is occasionally seen is “backed up”. Neither of these messages should be of any concern unless they appear at the final iteration.

If a “not concave” message appears at the last step, there are two possibilities. One is that the result is valid, but there is collinearity in the model that the command did not otherwise catch. Stata checks for obvious collinearity among the independent variables before performing the maximization, but strange collinearities or near collinearities can sometimes arise between coefficients and ancillary parameters. The second, more likely cause for a “not concave” message at the final step is that the optimizer entered a flat region of the likelihood and prematurely declared convergence.

If a “backed up” message appears at the last step, there are also two possibilities. One is that Stata found a perfect maximum and could not step to a better point; if this is the case, all is fine, but this is a highly unlikely occurrence. The second is that the optimizer worked itself into a bad concave spot where the computed gradient and Hessian gave a bad direction for stepping.

If either of these messages appears at the last step, perform the maximization again with the `gradient` option. If the gradient goes to zero, the optimizer has found a maximum that may not be unique but is a maximum. From the standpoint of maximum likelihood estimation, this is a valid result. If the gradient is not zero, it is not a valid result, and you should try tightening up the convergence criterion, or try `lto1(0) to1(1e-7)` to see if the optimizer can work its way out of the bad region.

If you get repeated “not concave” steps with little progress being made at each step, try specifying the `difficult` option. Sometimes `difficult` works wonderfully, reducing the number of iterations and producing convergence at a good (that is, concave) point. Other times, `difficult` works poorly, taking much longer to converge than the default stepper.

## Stored results

Maximum likelihood estimators store the following in `e()`:

### Scalars

|                            |                                           |                                                                                                                                |
|----------------------------|-------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------|
| <code>e(N)</code>          | number of observations                    | always stored                                                                                                                  |

| <code>e(Cns)</code>            | constraints matrix                           | sometimes stored                                                                               |
| <code>e(ilog)</code>           | iteration log (up to 20 iterations)          | usually stored                                                                                 |
| <code>e(gradient)</code>       | gradient vector                              | usually stored                                                                                 |
| <code>e(V)</code>              | variance–covariance matrix of the estimators | always stored                                                                                  |
| <code>e(V_modelbased)</code>   | model-based variance                         | only stored when <code>e(V)</code> is robust, cluster–robust, bootstrap, or jackknife variance |
| <code>e(deriv_minbound)</code> | minimum values for step sizes                | only stored when <code>e(deriv_useminbound)</code> is on                                       |

## Functions

|                        |                         |               |
|------------------------|-------------------------|---------------|
| <code>e(sample)</code> | marks estimation sample | always stored |
|------------------------|-------------------------|---------------|

---

1. Type `ereturn list, all` to view these results; see [P] [return](#).

See *Stored results* in the manual entry for any maximum likelihood estimator for a list of returned results.

## Methods and formulas

Optimization is currently performed by `moptimize()` and `optimize()`, with the former implemented in terms of the latter; see [M-5] [moptimize\(\)](#) and [M-5] [optimize\(\)](#). Some estimators use `moptimize()` and `optimize()` directly, and others use the `ml` ado-file interface to `moptimize()`.

Prior to Stata 11, Stata had three separate optimization engines: an internal one used by estimation commands implemented in C code; `ml` implemented in ado-code separately from `moptimize()` and used by most estimators; and `moptimize()` and `optimize()` used by a few recently written estimators. These days, the internal optimizer and the old version of `ml` are used only under version control. In addition, `arch` and `arima` (see [TS] [arch](#) and [TS] [arima](#)) are currently implemented using the old `ml`.

Let  $L_1$  be the log likelihood of the full model (that is, the log-likelihood value shown on the output), and let  $L_0$  be the log likelihood of the “constant-only” model. The likelihood-ratio  $\chi^2$  model test is defined as  $2(L_1 - L_0)$ . The pseudo- $R^2$  (McFadden 1974) is defined as  $1 - L_1/L_0$ . This is simply the log likelihood on a scale where 0 corresponds to the “constant-only” model and 1 corresponds to perfect prediction for a discrete model (in which case the overall log likelihood is 0).

Some maximum likelihood routines can report coefficients in an exponentiated form, for example, odds ratios in `logistic`. Let  $b$  be the unexponentiated coefficient,  $s$  its standard error, and  $b_0$  and  $b_1$  the reported confidence interval for  $b$ . In exponentiated form, the point estimate is  $e^b$ , the standard error  $e^b s$ , and the confidence interval  $e^{b_0}$  and  $e^{b_1}$ . The displayed  $Z$  (or  $t$ ) statistics and  $p$ -values are the same as those for the unexponentiated results. This is justified because  $e^b = 1$  and  $b = 0$  are equivalent hypotheses, and normality is more likely to hold in the  $b$  metric.

## Description

`mean` produces estimates of means, along with standard errors.

## Quick start

Mean, standard error, and 95% confidence interval for `v1`

```
mean v1
```

Also compute statistics for `v2`

```
mean v1 v2
```

Same as above, but for each level of categorical variable `catvar1`

```
mean v1 v2, over(catvar1)
```

Weighting by probability weight `wvar`

```
mean v1 v2 [pweight=wvar]
```

Population mean using `svyset` data

```
svy: mean v3
```

Subpopulation means for each level of categorical variable `catvar2` using `svyset` data

```
svy: mean v3, over(catvar2)
```

Test equality of two subpopulation means

```
svy: mean v3, over(catvar2)
test v3@1.catvar2 = v3@2.catvar2
```

## Menu

Statistics > Summaries, tables, and tests > Summary and descriptive statistics > Means

## Syntax

```
mean varlist [if] [in] [weight] [, options]
```

*varlist* may contain factor variables; see [U] 11.4.3 Factor variables.

bayesboot, bootstrap, collect, jackknife, mi estimate, rolling, statsby, and svy are allowed; see [U] 11.1.10 Prefix commands.

vce(bootstrap) and vce(jackknife) are not allowed with the mi estimate prefix; see [MI] mi estimate.

Weights are not allowed with the bootstrap prefix; see [R] bootstrap.

aweight are not allowed with the jackknife prefix; see [R] jackknife.

vce() and weights are not allowed with the svy prefix; see [SVY] svy.

fweights, aweights, iweights, and pweights are allowed; see [U] 11.1.6 weight.

coeflegend does not appear in the dialog box.

See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

## Options

### Model

`stdize(varname)` specifies that the point estimates be adjusted by direct standardization across the strata identified by *varname*. This option requires the `stdweight()` option.

`stdweight(varname)` specifies the weight variable associated with the standard strata identified in the `stdize()` option. The standardization weights must be constant within the standard strata.

`nostdrescale` prevents the standardization weights from being rescaled within the `over()` groups. This option requires `stdize()` but is ignored if the `over()` option is not specified.

### if/in/over

`over(varlisto)` specifies that estimates be computed for multiple subpopulations, which are identified by the different values of the variables in *varlist<sub>o</sub>*. Only numeric, nonnegative, integer-valued variables are allowed in `over(varlisto)`.

## SE/Cluster

`vce(vcetype)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory (`analytic`), that allow for intragroup correlation (`cluster clustvar`), and that use bootstrap or jackknife methods (`bootstrap`, `jackknife`); see [R] [vce\\_option](#).

`vce(analytic)`, the default, uses the analytically derived variance estimator associated with the sample mean.

## Reporting

`level(#)`; see [R] [Estimation options](#).

`noheader` prevents the table header from being displayed.

`display_options`: `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, and `nolstretch`; see [R] [Estimation options](#).

The following option is available with `mean` but is not shown in the dialog box:

`coeflegend`; see [R] [Estimation options](#).

## Remarks and examples

### ▷ Example 1

Using the fuel data from [example 3](#) of [R] [ttest](#), we estimate the average mileage of the cars without the fuel treatment (`mpg1`) and those with the fuel treatment (`mpg2`).

```
. use https://www.stata-press.com/data/r19/fuel
. mean mpg1 mpg2
```

| Mean estimation |       | Number of obs = 12 |                      |          |
|-----------------|-------|--------------------|----------------------|----------|
|                 | Mean  | Std. err.          | [95% conf. interval] |          |
| mpg1            | 21    | .7881701           | 19.26525             | 22.73475 |
| mpg2            | 22.75 | .9384465           | 20.68449             | 24.81551 |

Using these results, we can test the equality of the mileage between the two groups of cars.

```
. test mpg1 = mpg2
(1) mpg1 - mpg2 = 0
 F(1, 11) = 5.04
 Prob > F = 0.0463
```

## ▷ Example 2

In [example 1](#), the joint observations of `mpg1` and `mpg2` were used to estimate a covariance between their means.

```
. matrix list e(V)
symmetric e(V) [2,2]
 mpg1 mpg2
mpg1 .62121212
mpg2 .4469697 .88068182
```

If the data were organized this way out of convenience but the two variables represent independent samples of cars (coincidentally of the same sample size), we should reshape the data and use the `over()` option to ensure that the covariance between the means is zero.

```
. use https://www.stata-press.com/data/r19/fuel
. stack mpg1 mpg2, into(mpg) clear
. rename _stack trt
. label define trt_lab 1 "without" 2 "with"
. label values trt trt_lab
. label var trt "Fuel treatment"
. mean mpg, over(trt)
Mean estimation Number of obs = 24
```

|           | Mean  | Std. err. | [95% conf. interval] |          |
|-----------|-------|-----------|----------------------|----------|
| c.mpg@trt |       |           |                      |          |
| without   | 21    | .7881701  | 19.36955             | 22.63045 |
| with      | 22.75 | .9384465  | 20.80868             | 24.69132 |

```
. matrix list e(V)
symmetric e(V) [2,2]
 c.mpg@ c.mpg@
 1.trt 2.trt
c.mpg@1.trt .62121212
c.mpg@2.trt 0 .88068182
```

Now, we can test the equality of the mileage between the two independent groups of cars.

```
. test mpg@1.trt = mpg@2.trt
(1) c.mpg@1bn.trt - c.mpg@2.trt = 0
 F(1, 23) = 2.04
 Prob > F = 0.1667
```

### ► Example 3: standardized means

Suppose that we collected the blood pressure data from [example 2](#) of [R] [dstdize](#), and we wish to obtain standardized high blood pressure rates for each city in 1990 and 1992, using, as the standard, the age, sex, and race distribution of the four cities and two years combined. Our rate is really the mean of a variable that indicates whether a sampled individual has high blood pressure. First, we generate the strata and weight variables from our standard distribution, and then use `mean` to compute the rates.

```
. use https://www.stata-press.com/data/r19/hbp, clear
. egen strata = group(age race sex) if inlist(year, 1990, 1992)
(675 missing values generated)
. by strata, sort: gen stdw = _N
. mean hbp, over(city year) stdize(strata) stdweight(stdw)
Mean estimation
N. of std strata = 24 Number of obs = 455
```

|                 | Mean     | Std. err. | [95% conf. interval] |          |
|-----------------|----------|-----------|----------------------|----------|
| c.hbp@city#year |          |           |                      |          |
| 1 1990          | .058642  | .0296273  | .0004182             | .1168657 |
| 1 1992          | .0117647 | .0113187  | -.0104789            | .0340083 |
| 2 1990          | .0488722 | .0238958  | .0019121             | .0958322 |
| 2 1992          | .014574  | .007342   | .0001455             | .0290025 |
| 3 1990          | .1011211 | .0268566  | .0483425             | .1538998 |
| 3 1992          | .0810577 | .0227021  | .0364435             | .1256719 |
| 5 1990          | .0277778 | .0155121  | -.0027066            | .0582622 |
| 5 1992          | .0548926 | 0         | .                    | .        |

The standard error of the high blood pressure rate estimate is missing for city 5 in 1992 because there was only one individual with high blood pressure; that individual was the only person observed in the stratum of white males 30–35 years old.

By default, `mean` rescales the standard weights within the `over()` groups. In the following, we use the `nostdrescale` option to prevent this, thus reproducing the results in [R] [dstdize](#).

```
. mean hbp, over(city year) stdize(strata) stdweight(stdw) nostdrescale
Mean estimation
N. of std strata = 24 Number of obs = 455
```

|                 | Mean     | Std. err. | [95% conf. interval] |          |
|-----------------|----------|-----------|----------------------|----------|
| c.hbp@city#year |          |           |                      |          |
| 1 1990          | .0073302 | .0037034  | .0000523             | .0146082 |
| 1 1992          | .0015432 | .0014847  | -.0013745            | .004461  |
| 2 1990          | .0078814 | .0038536  | .0003084             | .0154544 |
| 2 1992          | .0025077 | .0012633  | .000025              | .0049904 |
| 3 1990          | .0155271 | .0041238  | .007423              | .0236312 |
| 3 1992          | .0081308 | .0022772  | .0036556             | .012606  |
| 5 1990          | .0039223 | .0021904  | -.0003822            | .0082268 |
| 5 1992          | .0088735 | 0         | .                    | .        |

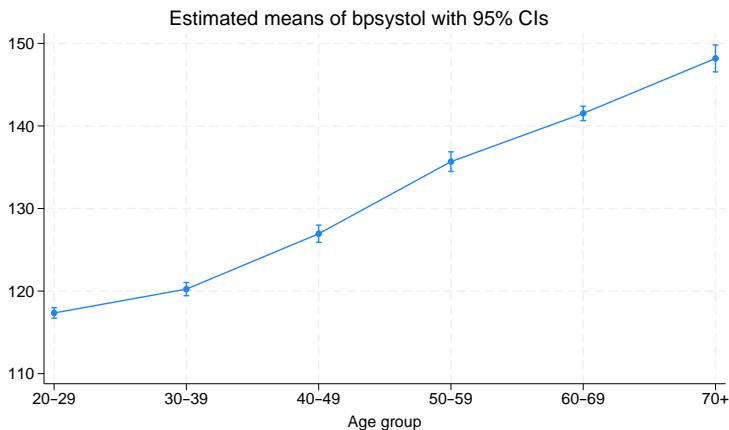

## ► Example 4: profile plots and contrasts

The [first example](#) in [\[R\] marginsplot](#) shows how to use margins and marginsplot to get profile plots from a linear regression. We can similarly explore the data using marginsplot after mean with the `over()` option. Here we use marginsplot to plot the means of systolic blood pressure for each age group.

```
. use https://www.stata-press.com/data/r19/nhanes2, clear
. mean bpsystol, over(agegrp)
Mean estimation Number of obs = 10,351
```

|                   | Mean     | Std. err. | [95% conf. interval] |          |
|-------------------|----------|-----------|----------------------|----------|
| c.bpsystol@agegrp |          |           |                      |          |
| 20-29             | 117.3466 | .3247329  | 116.71               | 117.9831 |
| 30-39             | 120.2374 | .4095845  | 119.4345             | 121.0402 |
| 40-49             | 126.9442 | .532033   | 125.9013             | 127.9871 |
| 50-59             | 135.6754 | .6061842  | 134.4872             | 136.8637 |
| 60-69             | 141.5227 | .4433527  | 140.6537             | 142.3918 |
| 70+               | 148.1765 | .8321116  | 146.5454             | 149.8076 |

```
. marginsplot
Variables that uniquely identify means: agegrp
```

We see that the mean systolic blood pressure increases with age. We can use `contrast` to formally test whether each mean is different from the mean in the previous age group using the `ar.` contrast operator; see [\[R\] contrast](#) for more information on this command.

```
. contrast ar.agegrp#c.bpsystol, effects nowald
```

Contrasts of means

|                                                                                                                                                       | Contrast | Std. err. | t     | P> t  | [95% conf. interval] |          |
|-------------------------------------------------------------------------------------------------------------------------------------------------------|----------|-----------|-------|-------|----------------------|----------|
| agegrp#<br>c.bpsystol<br>(30-39<br>vs<br>20-29)<br>(40-49<br>vs<br>30-39)<br>(50-59<br>vs<br>40-49)<br>(60-69<br>vs<br>50-59)<br>(70+<br>vs<br>60-69) | 2.89081  | .5226958  | 5.53  | 0.000 | 1.866225             | 3.915394 |
|                                                                                                                                                       | 6.706821 | .6714302  | 9.99  | 0.000 | 5.390688             | 8.022954 |
|                                                                                                                                                       | 8.731263 | .8065472  | 10.83 | 0.000 | 7.150275             | 10.31225 |
|                                                                                                                                                       | 5.847282 | .7510133  | 7.79  | 0.000 | 4.375151             | 7.319413 |
|                                                                                                                                                       | 6.653743 | .9428528  | 7.06  | 0.000 | 4.80557              | 8.501917 |

The first row of the output reports that the mean systolic blood pressure for the 30–39 age group is 2.89 higher than the mean for the 20–29 age group. The mean for the 40–49 age group is 6.71 higher than the mean for the 30–39 age group, and so on. Each of these differences is significantly different from zero.

We can include both agegrp and sex in the over() option to estimate means separately for men and women in each age group.

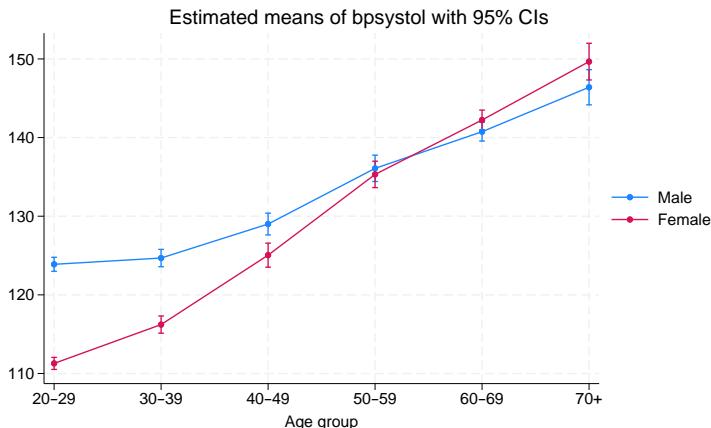

```
. mean bpsystol, over(agegrp sex)
```

Mean estimation

Number of obs = 10,351

|                       | Mean     | Std. err. | [95% conf. interval] |          |
|-----------------------|----------|-----------|----------------------|----------|
| c.bpsystol@agegrp#sex |          |           |                      |          |
| 20-29#Male            | 123.8862 | .4528516  | 122.9985             | 124.7739 |
| 20-29#Female          | 111.2849 | .3898972  | 110.5206             | 112.0492 |
| 30-39#Male            | 124.6818 | .5619855  | 123.5802             | 125.7834 |
| 30-39#Female          | 116.2207 | .5572103  | 115.1284             | 117.3129 |

```
. marginsplot
Variables that uniquely identify means: agegrp sex
```

Are the means different for men and women within each age group? We can again perform the tests using contrast. This time, we will use `r.sex` to obtain contrasts comparing men and women and use `@agegrp` to request that the tests are performed for each age group.

```
. contrast r.sex#c.bpsystol@agegrp, effects nowald
Contrasts of means
```

|                                                              | Contrast  | Std. err. | t      | P> t  | [95% conf. interval] |           |
|--------------------------------------------------------------|-----------|-----------|--------|-------|----------------------|-----------|
| sex@agegrp#<br>c.bpsystol<br>(Female<br>vs<br>Male)<br>20-29 | -12.60132 | .5975738  | -21.09 | 0.000 | -13.77268            | -11.42996 |
| (Female<br>vs<br>Male)<br>30-39                              | -8.461161 | .7913981  | -10.69 | 0.000 | -10.01245            | -6.909868 |
| (Female<br>vs<br>Male)<br>40-49                              | -3.956451 | 1.053648  | -3.76  | 0.000 | -6.021805            | -1.891097 |
| (Female<br>vs<br>Male)<br>50-59                              | -.7699782 | 1.209886  | -0.64  | 0.525 | -3.141588            | 1.601631  |
| (Female<br>vs<br>Male)<br>60-69                              | 1.491684  | .8834022  | 1.69   | 0.091 | -.2399545            | 3.223323  |
| (Female<br>vs<br>Male)<br>70+                                | 3.264762  | 1.648699  | 1.98   | 0.048 | .0329927             | 6.496531  |

Using a 0.05 significance level, we find that the mean systolic blood pressure is different for men and women in all age groups except the fifties and sixties.

| <code>e(V)</code>         | (co)variance estimates                                       |
| <code>e(sd)</code>        | vector of standard deviation estimates                       |
| <code>e(_N)</code>        | vector of numbers of nonmissing observations                 |
| <code>e(_N_stdsum)</code> | number of nonmissing observations within the standard strata |
| <code>e(_p_stdize)</code> | standardizing proportions                                    |
| <code>e(error)</code>     | error code corresponding to <code>e(b)</code>                |

### Functions

|                        |                         |
|------------------------|-------------------------|
| <code>e(sample)</code> | marks estimation sample |
|------------------------|-------------------------|

In addition to the above, the following is stored in `r()`:

### Matrices

|                       |                                                                                                                            |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------|
| <code>r(table)</code> | matrix containing the coefficients with their standard errors, test statistics, <i>p</i> -values, and confidence intervals |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------|

Note that results stored in `r()` are updated when the command is replayed and will be replaced when any `r-class` command is run after the estimation command.

## Methods and formulas

Methods and formulas are presented under the following headings:

*The mean estimator*  
*Survey data*  
*The survey mean estimator*  
*The standardized mean estimator*  
*The poststratified mean estimator*  
*The standardized poststratified mean estimator*  
*Subpopulation estimation*

### The mean estimator

Let  $y$  be the variable on which we want to calculate the mean and  $y_j$  an individual observation on  $y$ , where  $j = 1, \dots, n$  and  $n$  is the sample size. Let  $w_j$  be the weight, and if no weight is specified, define  $w_j = 1$  for all  $j$ . For  $n$  weights, the  $w_j$  are normalized to sum to  $n$ . See *The survey mean estimator* for **weighted data**.

Let  $W$  be the sum of the weights

$$W = \sum_{j=1}^n w_j$$

The mean is defined as

$$\bar{y} = \frac{1}{W} \sum_{j=1}^n w_j y_j$$

The default variance estimator for the mean is

$$\hat{V}(\bar{y}) = \frac{1}{W(W-1)} \sum_{j=1}^n w_j (y_j - \bar{y})^2$$

The standard error of the mean is the square root of the variance.

If  $x$ ,  $x_j$ , and  $\bar{x}$  are similarly defined for another variable (observed jointly with  $y$ ), the covariance estimator between  $\bar{x}$  and  $\bar{y}$  is

$$\widehat{\text{Cov}}(\bar{x}, \bar{y}) = \frac{1}{W(W-1)} \sum_{j=1}^n w_j (x_j - \bar{x})(y_j - \bar{y})$$

### Survey data

See **[SVY] Variance estimation**, **[SVY] Direct standardization**, and **[SVY] Poststratification** for discussions that provide background information for the following formulas. The following formulas are derived from the fact that the mean is a special case of the ratio estimator where the denominator variable is one,  $x_j = 1$ ; see **[R] ratio**.

## The survey mean estimator

Let  $Y_j$  be a survey item for the  $j$ th individual in the population, where  $j = 1, \dots, M$  and  $M$  is the size of the population. The associated population mean for the item of interest is  $\bar{Y} = Y/M$  where

$$Y = \sum_{j=1}^M Y_j$$

Let  $y_j$  be the survey item for the  $j$ th sampled individual from the population, where  $j = 1, \dots, m$  and  $m$  is the number of observations in the sample.

The estimator for the mean is  $\bar{y} = \hat{Y}/\widehat{M}$ , where

$$\hat{Y} = \sum_{j=1}^m w_j y_j \quad \text{and} \quad \widehat{M} = \sum_{j=1}^m w_j$$

and  $w_j$  is a sampling weight. The score variable for the mean estimator is

$$z_j(\bar{y}) = \frac{y_j - \bar{y}}{\widehat{M}} = \frac{\widehat{M}y_j - \hat{Y}}{\widehat{M}^2}$$

## The standardized mean estimator

Let  $D_g$  denote the set of sampled observations that belong to the  $g$ th standard stratum and define  $I_{D_g}(j)$  to indicate if the  $j$ th observation is a member of the  $g$ th standard stratum; where  $g = 1, \dots, L_D$  and  $L_D$  is the number of standard strata. Also, let  $\pi_g$  denote the fraction of the population that belongs to the  $g$ th standard stratum, thus  $\pi_1 + \dots + \pi_{L_D} = 1$ .  $\pi_g$  is derived from the `stdweight()` option.

The estimator for the standardized mean is

$$\bar{y}^D = \sum_{g=1}^{L_D} \pi_g \frac{\hat{Y}_g}{\widehat{M}_g}$$

where

$$\hat{Y}_g = \sum_{j=1}^m I_{D_g}(j) w_j y_j \quad \text{and} \quad \widehat{M}_g = \sum_{j=1}^m I_{D_g}(j) w_j$$

The score variable for the standardized mean is

$$z_j(\bar{y}^D) = \sum_{g=1}^{L_D} \pi_g I_{D_g}(j) \frac{\widehat{M}_g y_j - \hat{Y}_g}{\widehat{M}_g^2}$$

## The poststratified mean estimator

Let  $P_k$  denote the set of sampled observations that belong to poststratum  $k$  and define  $I_{P_k}(j)$  to indicate if the  $j$ th observation is a member of poststratum  $k$ ; where  $k = 1, \dots, L_P$  and  $L_P$  is the number of poststrata. Also let  $M_k$  denote the population size for poststratum  $k$ .  $P_k$  and  $M_k$  are identified by specifying the `poststrata()` and `postweight()` options on `svyset`; see [\[SVY\] svyset](#).

The estimator for the poststratified mean is

$$\bar{y}^P = \frac{\hat{Y}^P}{\widehat{M}^P} = \frac{\hat{Y}^P}{M}$$

where

$$\hat{Y}^P = \sum_{k=1}^{L_P} \frac{M_k}{\widehat{M}_k} \hat{Y}_k = \sum_{k=1}^{L_P} \frac{M_k}{\widehat{M}_k} \sum_{j=1}^m I_{P_k}(j) w_j y_j$$

and

$$\widehat{M}^P = \sum_{k=1}^{L_P} \frac{M_k}{\widehat{M}_k} \widehat{M}_k = \sum_{k=1}^{L_P} M_k = M$$

The score variable for the poststratified mean is

$$z_j(\bar{y}^P) = \frac{z_j(\hat{Y}^P)}{M} = \frac{1}{M} \sum_{k=1}^{L_P} I_{P_k}(j) \frac{M_k}{\widehat{M}_k} \left( y_j - \frac{\hat{Y}_k}{\widehat{M}_k} \right)$$

## The standardized poststratified mean estimator

The estimator for the standardized poststratified mean is

$$\bar{y}^{DP} = \sum_{g=1}^{L_D} \pi_g \frac{\hat{Y}_g^P}{\widehat{M}_g^P}$$

where

$$\hat{Y}_g^P = \sum_{k=1}^{L_p} \frac{M_k}{\widehat{M}_k} \hat{Y}_{g,k} = \sum_{k=1}^{L_p} \frac{M_k}{\widehat{M}_k} \sum_{j=1}^m I_{D_g}(j) I_{P_k}(j) w_j y_j$$

and

$$\widehat{M}_g^P = \sum_{k=1}^{L_p} \frac{M_k}{\widehat{M}_k} \widehat{M}_{g,k} = \sum_{k=1}^{L_p} \frac{M_k}{\widehat{M}_k} \sum_{j=1}^m I_{D_g}(j) I_{P_k}(j) w_j$$

The score variable for the standardized poststratified mean is

$$z_j(\bar{y}^{DP}) = \sum_{g=1}^{L_D} \pi_g \frac{\widehat{M}_g^P z_j(\hat{Y}_g^P) - \hat{Y}_g^P z_j(\widehat{M}_g^P)}{(\widehat{M}_g^P)^2}$$

where

$$z_j(\hat{Y}_g^P) = \sum_{k=1}^{L_P} I_{P_k}(j) \frac{M_k}{\widehat{M}_k} \left\{ I_{D_g}(j) y_j - \frac{\hat{Y}_{g,k}}{\widehat{M}_k} \right\}$$

and

$$z_j(\widehat{M}_g^P) = \sum_{k=1}^{L_P} I_{P_k}(j) \frac{M_k}{\widehat{M}_k} \left\{ I_{D_g}(j) - \frac{\widehat{M}_{g,k}}{\widehat{M}_k} \right\}$$

### Subpopulation estimation

Let  $S$  denote the set of sampled observations that belong to the subpopulation of interest, and define  $I_S(j)$  to indicate if the  $j$ th observation falls within the subpopulation.

The estimator for the subpopulation mean is  $\bar{y}^S = \hat{Y}^S / \widehat{M}^S$ , where

$$\hat{Y}^S = \sum_{j=1}^m I_S(j) w_j y_j \quad \text{and} \quad \widehat{M}^S = \sum_{j=1}^m I_S(j) w_j$$

Its score variable is

$$z_j(\bar{y}^S) = I_S(j) \frac{y_j - \bar{y}^S}{\widehat{M}^S} = I_S(j) \frac{\widehat{M}^S y_j - \hat{Y}^S}{(\widehat{M}^S)^2}$$

The estimator for the standardized subpopulation mean is

$$\bar{y}^{DS} = \sum_{g=1}^{L_D} \pi_g \frac{\hat{Y}_g^S}{\widehat{M}_g^S}$$

where

$$\hat{Y}_g^S = \sum_{j=1}^m I_{D_g}(j) I_S(j) w_j y_j \quad \text{and} \quad \widehat{M}_g^S = \sum_{j=1}^m I_{D_g}(j) I_S(j) w_j$$

Its score variable is

$$z_j(\bar{y}^{DS}) = \sum_{g=1}^{L_D} \pi_g I_{D_g}(j) I_S(j) \frac{\widehat{M}_g^S y_j - \hat{Y}_g^S}{(\widehat{M}_g^S)^2}$$

The estimator for the poststratified subpopulation mean is

$$\bar{y}^{PS} = \frac{\hat{Y}^{PS}}{\widehat{M}^{PS}}$$

where

$$\hat{Y}^{PS} = \sum_{k=1}^{L_P} \frac{M_k}{\widehat{M}_k} \hat{Y}_k^S = \sum_{k=1}^{L_P} \frac{M_k}{\widehat{M}_k} \sum_{j=1}^m I_{P_k}(j) I_S(j) w_j y_j$$

and

$$\widehat{M}^{PS} = \sum_{k=1}^{L_P} \frac{M_k}{\widehat{M}_k} \widehat{M}_k^S = \sum_{k=1}^{L_P} \frac{M_k}{\widehat{M}_k} \sum_{j=1}^m I_{P_k}(j) I_S(j) w_j$$

Its score variable is

$$z_j(\bar{y}^{PS}) = \frac{\widehat{M}^{PS} z_j(\hat{Y}^{PS}) - \hat{Y}^{PS} z_j(\widehat{M}^{PS})}{(\widehat{M}^{PS})^2}$$

where

$$z_j(\hat{Y}^{PS}) = \sum_{k=1}^{L_P} I_{P_k}(j) \frac{M_k}{\widehat{M}_k} \left\{ I_S(j) y_j - \frac{\hat{Y}_k^S}{\widehat{M}_k} \right\}$$

and

$$z_j(\widehat{M}^{PS}) = \sum_{k=1}^{L_P} I_{P_k}(j) \frac{M_k}{\widehat{M}_k} \left\{ I_S(j) - \frac{\widehat{M}_k^S}{\widehat{M}_k} \right\}$$

The estimator for the standardized poststratified subpopulation mean is

$$\bar{y}^{DPS} = \sum_{g=1}^{L_D} \pi_g \frac{\hat{Y}_g^{PS}}{\widehat{M}_g^{PS}}$$

where

$$\hat{Y}_g^{PS} = \sum_{k=1}^{L_p} \frac{M_k}{\widehat{M}_k} \hat{Y}_{g,k}^S = \sum_{k=1}^{L_p} \frac{M_k}{\widehat{M}_k} \sum_{j=1}^m I_{D_g}(j) I_{P_k}(j) I_S(j) w_j y_j$$

and

$$\widehat{M}_g^{PS} = \sum_{k=1}^{L_p} \frac{M_k}{\widehat{M}_k} \widehat{M}_{g,k}^S = \sum_{k=1}^{L_p} \frac{M_k}{\widehat{M}_k} \sum_{j=1}^m I_{D_g}(j) I_{P_k}(j) I_S(j) w_j$$

Its score variable is

$$z_j(\bar{y}^{DPS}) = \sum_{g=1}^{L_D} \pi_g \frac{\widehat{M}_g^{PS} z_j(\widehat{Y}_g^{PS}) - \widehat{Y}_g^{PS} z_j(\widehat{M}_g^{PS})}{(\widehat{M}_g^{PS})^2}$$

where

$$z_j(\widehat{Y}_g^{PS}) = \sum_{k=1}^{L_P} I_{P_k}(j) \frac{M_k}{\widehat{M}_k} \left\{ I_{D_g}(j) I_S(j) y_j - \frac{\widehat{Y}_{g,k}^S}{\widehat{M}_k} \right\}$$

and

$$z_j(\widehat{M}_g^{PS}) = \sum_{k=1}^{L_P} I_{P_k}(j) \frac{M_k}{\widehat{M}_k} \left\{ I_{D_g}(j) I_S(j) - \frac{\widehat{M}_{g,k}^S}{\widehat{M}_k} \right\}$$

## Postestimation commands

The following postestimation commands are of special interest after `mean`:

| Command               | Description                  |
|-----------------------|------------------------------|
| <code>estat sd</code> | standard deviation estimates |

The following standard postestimation commands are also available:

| Command                  | Description                                                                                       |
|--------------------------|---------------------------------------------------------------------------------------------------|
| <code>contrast</code>    | contrasts and ANOVA-style joint tests of parameters                                               |
| <code>estat vce</code>   | variance–covariance matrix of the estimators (VCE)                                                |
| <code>estat (svy)</code> | postestimation statistics for survey data                                                         |
| <code>estimates</code>   | cataloging estimation results                                                                     |
| <code>etable</code>      | table of estimation results                                                                       |
| <code>hausman</code>     | Hausman’s specification test                                                                      |
| <code>lincom</code>      | point estimates, standard errors, testing, and inference for linear combinations of parameters    |
| <code>marginsplot</code> | graph the results from <code>mean</code>                                                          |
| <code>nlcom</code>       | point estimates, standard errors, testing, and inference for nonlinear combinations of parameters |
| <code>pwcompare</code>   | pairwise comparisons of parameters                                                                |
| <code>test</code>        | Wald tests of simple and composite linear hypotheses                                              |
| <code>testnl</code>      | Wald tests of nonlinear hypotheses                                                                |

## estat sd

### Description for estat sd

`estat sd` reports standard deviations based on the estimation results from `mean`. `estat sd` is not appropriate with estimation results that used direct standardization.

`estat sd` can also report subpopulation standard deviations based on estimation results from `svy: mean`; see [\[SVY\] estat](#).

### Menu for estat sd

Statistics > Postestimation

### Syntax for estat sd

```
estat sd [, variance]
```

### Option for estat sd

`variance` requests that the variance be displayed instead of the standard deviation.

### Stored results for estat sd

`estat sd` stores the following in `r()`:

Matrices

|                          |                                        |
|--------------------------|----------------------------------------|
| <code>r(mean)</code>     | vector of mean estimates               |
| <code>r(sd)</code>       | vector of standard deviation estimates |
| <code>r(variance)</code> | vector of variance estimates           |

## Description

`mfp` selects the multivariable fractional polynomial (MFP) model that best predicts the outcome variable from the right-hand-side variables in *xvarlist*.

For univariate fractional polynomials, `fp` can be used to fit a wider range of models than `mfp`. See [R] `fp` for more details.

## Quick start

Find optimal MFP model for regression of *y* on fractional polynomials of *x1*, *x2*, and *x3*

```
mfp: regress y x1 x2 x3
```

Same as above, but search only powers of  $-1$ ,  $-0.5$ ,  $1$ , and  $2$

```
mfp, xpowers(-1 -.5 1 2): regress y x1 x2 x3
```

Allow a maximum of 2 degrees of freedom for all covariates

```
mfp, dfdefault(2): regress y x1 x2 x3
```

Allow 4 degrees of freedom for *x1* and 2 degrees of freedom for *x2* and *x3*

```
mfp, dfdefault(2) df(x1:4): regress y x1 x2 x3
```

Same as above

```
mfp, df(x1:4, x2 x3:2): regress y x1 x2 x3
```

Use a 10% significance level when testing between fractional polynomials of different degrees

```
mfp, alpha(0.1): regress y x1 x2 x3
```

Perform backward selection using a nominal *p*-value of 0.05 for all variables

```
mfp, select(0.05): regress y x1 x2 x3
```

Same as above, but force *x3* into the model by setting its nominal *p*-value to 1

```
mfp, select(0.05, x3:1): regress y x1 x2 x3
```

Note: In the above examples, `regress` could be replaced with any estimation command allowing the `mfp` prefix.

## Menu

Statistics > Linear models and related > Fractional polynomials > Multivariable fractional polynomial models

## Syntax

```
mfp [, options] : regression_cmd [yvar_1 [yvar_2]] xvarlist [if] [in] [weight]
[, regression_cmd_options]
```

*regression\_cmd* may be `clogit`, `glm`, `intreg`, `logistic`, `logit`, `mlogit`, `nbreg`, `ologit`, `oprobit`, `poisson`, `probit`, `qreg`, `regress`, `rreg`, `stcox`, `stcrreg`, `streg`, or `xtgee`.

*yvar\_1* is not allowed for `streg`, `stcrreg`, and `stcox`. For these commands, you must first `stset` your data.

*yvar\_1* and *yvar\_2* must both be specified when *regression\_cmd* is `intreg`.

*xvarlist* has elements of type *varlist* or (*varlist*) or both, for example, `x1 x2 (x3 x4 x5)`. Elements enclosed in parentheses are tested jointly for inclusion in the model and are not eligible for fractional polynomial transformation.

`collect` is allowed; see [U] 11.1.10 Prefix commands.

All weight types supported by *regression\_cmd* are allowed; see [U] 11.1.6 weight.

See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

`fp generate` may be used to create new variables containing fractional polynomial powers. See [R] fp.

## Options

Model 2

`sequential` chooses the sequential fractional polynomial (FP) selection algorithm (see *Methods of FP model selection*).

`cycles(#)` sets the maximum number of iteration cycles permitted. `cycles(5)` is the default.

`dfdefault(#)` determines the default maximum degrees of freedom (df) for a predictor. The default is `dfdefault(4)` (second-degree FP).

`center(cent_list)` defines the centering of the covariates  $xvar_1, xvar_2, \dots$  of *xvarlist*. The default is `center(mean)`, except for binary covariates, where it is `center(#)`, with # being the lower of the two distinct values of the covariate. A typical item in *cent\_list* is *varlist*:{mean|#|no}. Items are separated by commas. The first item is special in that *varlist* is optional, and if it is omitted, the default is reset to the specified value (mean, #, or no). For example, `center(no, age:mean)` sets the default to no (that is, no centering) and the centering of age to mean.

`alpha(alpha_list)` sets the significance levels for testing between FP models of different degrees. The rules for *alpha\_list* are the same as those for *df\_list* in the `df()` option (see below). The default nominal *p*-value (significance level, selection level) is 0.05 for all variables.

Example: `alpha(0.01)` specifies that all variables have an FP selection level of 1%.

Example: `alpha(0.05, weight:0.1)` specifies that all variables except `weight` have an FP selection level of 5%; `weight` has a level of 10%.

`df(df_list)` sets the df for each predictor. The df (not counting the regression constant, `_cons`) is twice the degree of the FP, so, for example, an *xvar* fit as a second-degree FP (FP2) has 4 df. The first item in *df\_list* may be either # or *varlist*:#. Subsequent items must be *varlist*:#. Items are separated by commas, and *varlist* is specified in the usual way for variables. With the first type of item, the df for all predictors is taken to be #. With the second type of item, all members of *varlist* (which must be a subset of *xvarlist*) have # df.

The default number of degrees of freedom for a predictor of type *varlist* specified in *xvarlist* but not in *df\_list* is assigned according to the number of distinct (unique) values of the predictor, as follows:

| # of distinct values | Default df                       |
|----------------------|----------------------------------|
| 1                    | (invalid predictor)              |
| 2–3                  | 1                                |
| 4–5                  | <code>min(2, dfdefault())</code> |
| ≥ 6                  | <code>dfdefault()</code>         |

Example: `df(4)`

All variables have 4 df.

Example: `df(2, weight displ:4)`

`weight` and `displ` have 4 df; all other variables have 2 df.

Example: `df(weight displ:4, mpg:2)`

`weight` and `displ` have 4 df, `mpg` has 2 df; all other variables have default df.

`powers(numlist)` is the set of FP powers to be used. The default set is `-2, -1, -0.5, 0, 0.5, 1, 2, 3` (0 means log).

## Adv. model

`xorder(+|-|n)` determines the order of entry of the covariates into the model-selection algorithm.

The default is `xorder(+)`, which enters them in decreasing order of significance in a multiple linear regression (most significant first). `xorder(-)` places them in reverse significance order, whereas `xorder(n)` respects the original order in *xvarlist*.

`select(select_list)` sets the nominal *p*-values (significance levels) for variable selection by backward elimination. A variable is dropped if its removal causes a nonsignificant increase in deviance. The rules for *select\_list* are the same as those for *df\_list* in the `df()` option (see above). Using the default selection level of 1 for all variables forces them all into the model. Setting the nominal *p*-value to be 1 for a given variable forces it into the model, leaving others to be selected or not. The nominal *p*-value for elements of *xvarlist* bound by parentheses is specified by including (*varlist*) in *select\_list*.

Example: `select(0.05)`

All variables have a nominal *p*-value of 5%.

Example: `select(0.05, weight:1)`

All variables except `weight` have a nominal *p*-value of 5%; `weight` is forced into the model.

Example: `select(a (b c):0.05)`

All variables except `a`, `b`, and `c` are forced into the model. `b` and `c` are tested jointly with 2 df at the 5% level, and `a` is tested singly at the 5% level.

`xpowers(xp_list)` sets the permitted FP powers for covariates individually. The rules for *xp\_list* are the same as for *df\_list* in the `df()` option. The default selection is the same as that for the `powers()` option.

Example: `xpowers(-1 0 1)`

All variables have powers  $-1, 0, 1$ .

Example: `xpowers(x5:-1 0 1)`

All variables except `x5` have default powers; `x5` has powers  $-1, 0, 1$ .

`zero(varlist)` treats negative and zero values of members of *varlist* as zero when FP transformations are applied. By default, such variables are subjected to a preliminary linear transformation to avoid negative and zero values, as described in the `scale` option of `[R] fp`. *varlist* must be part of *xvarlist*.

`catzero(varlist)` is a variation on `zero()`; see *Zeros and zero categories* below. *varlist* must be part of *xvarlist*.

*regression\_cmd\_options* may be any of the options appropriate to *regression\_cmd*.

`all` includes out-of-sample observations when generating the FP variables. By default, the generated FP variables contain missing values outside the estimation sample.

## Reporting

`level(#)` specifies the confidence level, as a percentage, for confidence intervals. The default is `level(95)` or as set by `set level`; see [\[U\] 20.8 Specifying the width of confidence intervals](#).

*display\_options*: `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `no1stretch`; see [\[R\] Estimation options](#).

## Remarks and examples

Remarks are presented under the following headings:

*Iteration report*  
*Estimation algorithm*  
*Methods of FP model selection*  
*Zeros and zero categories*

For elements in *xvarlist* not enclosed in parentheses, mfp leaves variables in the data named  $Ixvar\_1$ ,  $Ixvar\_2$ ,  $\dots$ , where *xvar* represents the first four letters of the name of  $xvar_1$ , and so on, for  $xvar_2$ ,  $xvar_3$ , etc. The new variables contain the best-fitting FP powers of  $xvar_1$ ,  $xvar_2$ ,  $\dots$ .

### Iteration report

By default, for each continuous predictor, *x*, mfp compares null, linear, and FP1 models for *x* with an FP2 model. The deviance for each of these nested submodels is given in the column labeled “Deviance”. The line labeled “Final” gives the deviance for the selected model and its powers. All the other predictors currently selected are included, with their transformations (if any). For models specified as having 1 df, the only choice is whether the variable enters the model.

### Estimation algorithm

The estimation algorithm in mfp processes the *xvars* in turn. Initially, mfp silently arranges *xvarlist* in order of increasing *p*-value (that is, of decreasing statistical significance) for omitting each predictor from the model comprising *xvarlist*, with each term linear. The aim is to model relatively important variables before unimportant ones. This approach may help to reduce potential model-fitting difficulties caused by collinearity or, more generally, “concurvity” among the predictors. See the `xorder()` option above for details on how to change the ordering.

At the initial cycle, the best-fitting FP function for  $xvar_1$  (the first of *xvarlist*) is determined, with all the other variables assumed to be linear. Either the default or the alternative procedure is used (see *Methods of FP model selection* below). The functional form (but not the estimated regression coefficients) for  $xvar_1$  is kept, and the process is repeated for  $xvar_2$ ,  $xvar_3$ , etc. The first iteration concludes when all the variables have been processed in this way. The next cycle is similar, except that the functional forms from the initial cycle are retained for all variables except the one currently being processed.

A variable whose functional form is prespecified to be linear (that is, to have 1 df) is tested for exclusion within the above procedure when its nominal *p*-value (selection level) according to `select()` is less than 1; otherwise, it is included.

Updating of FP functions and candidate variables continues until the functions and variables included in the overall model do not change (convergence). Convergence is usually achieved within 1–4 cycles.

## Methods of FP model selection

`mfp` includes two algorithms for FP model selection, both of which combine backward elimination with the selection of an FP function. For each continuous variable in turn, they start from a most-complex permitted FP model and attempt to simplify the model by reducing the degree. The default algorithm resembles a closed-test procedure, a sequence of tests maintaining the overall type I error rate at a pre-specified nominal level, such as 5%. All significance tests are approximate; therefore, the algorithm is not precisely a closed-test procedure (Royston and Sauerbrei 2008, chap. 6).

The closed-test algorithm for choosing an FP model with maximum permitted degree  $m = 2$  (that is, an FP2 model with 4 df) for one continuous predictor,  $x$ , is as follows:

1. Inclusion: Test FP2 against the null model for  $x$  on 4 df at the significance level determined by `select()`. If  $x$  is significant, continue; otherwise, drop  $x$  from the model.
2. Nonlinearity: Test FP2 against a straight line in  $x$  on 3 df at the significance level determined by `alpha()`. If significant, continue; otherwise, stop, with the chosen model for  $x$  being a straight line.
3. Simplification: Test FP2 against FP1 on 2 df at the significance level determined by `alpha()`. If significant, the final model is FP2; otherwise, it is FP1.

The first step is omitted if  $x$  is to be retained in the model, that is, if its nominal  $p$ -value, according to the `select()` option, is 1.

An alternative algorithm is available with the `sequential` option, as originally suggested by Royston and Altman (1994):

1. Test FP2 against FP1 on 2 df at the `alpha()` significance level. If significant, the final model is FP2; otherwise, continue.
2. Test FP1 against a straight line on 1 df at the `alpha()` level. If significant, the final model is FP1; otherwise, continue.
3. Test a straight line against omitting  $x$  on 1 df at the `select()` level. If significant, the final model is a straight line; otherwise, drop  $x$ .

The final step is omitted if  $x$  is to be retained in the model, that is, if its nominal  $p$ -value, according to the `select()` option, is 1.

If  $x$  is uninfluential, the overall type I error rate of this procedure is about double that of the closed-test procedure, for which the rate is close to the nominal value. This inflated type I error rate confers increased apparent power to detect nonlinear relationships.

## Zeros and zero categories

The `zero()` option permits fitting an FP model to the positive values of a covariate, taking nonpositive values as zero. An application is the assessment of the effect of cigarette smoking as a risk factor in an epidemiological study. Nonsmokers may be qualitatively different from smokers, so the effect of smoking (regarded as a continuous variable) may not be continuous between one and zero cigarettes. To allow for this, the risk may be modeled as constant for the nonsmokers and as an FP function of the number of cigarettes for the smokers:

```
. generate byte nonsmokr = cond(n_cigs==0, 1, 0) if n_cigs != .
. mfp, zero(n_cigs) df(4, nonsmokr:1): logit case n_cigs nonsmokr age
```

Omission of `zero(n_cigs)` would cause `n_cigs` to be transformed before analysis by the addition of a suitable constant, probably 1.

A closely related approach involves the `catzero()` option. The command

```
. mfp, catzero(n_cigs): logit case n_cigs age
```

would achieve a similar result to the previous command but with important differences. First, `mfp` would create the equivalent of the binary variable `nonsmokr` automatically and include it in the model. Second, the two smoking variables would be treated as one predictor in the model. With the `select()` option active, the two variables would be tested jointly for inclusion in the model. A modified version is described in [Royston and Sauerbrei \(2008, sec. 4.15\)](#).

### ▷ Example 1

We illustrate two of the analyses performed by [Sauerbrei and Royston \(1999\)](#). We use `brcancer.dta`, which contains prognostic factors data from the German Breast Cancer Study Group of patients with node-positive breast cancer. The response variable is recurrence-free survival time (`rectime`), and the censoring variable is `censrec`. There are 686 patients with 299 events. We use Cox regression to predict the log hazard of recurrence from prognostic factors of which five are continuous (`x1`, `x3`, `x5`, `x6`, `x7`) and three are binary (`x2`, `x4a`, `x4b`). Hormonal therapy (`hormon`) is known to reduce recurrence rates and is forced into the model. We use `mfp` to build a model from the initial set of eight predictors by using the backfitting model-selection algorithm. We set the nominal  $p$ -value for variable and FP selection to 0.05 for all variables except `hormon`, which it is set to 1:

```
. use https://www.stata-press.com/data/r19/brcancer
(German breast cancer data)
. stset rectime, fail(censrec)
(output omitted)
```

```
. mfp, alpha(.05) select(.05, hormon:1): stcox x1 x2 x3 x4a x4b x5 x6 x7 hormon,
> nohr
```

Deviance for model with all terms untransformed = 3471.637, 686 observations

| Variable                             | Model | (vs.) | Deviance | Dev diff. | P      | Powers | (vs.)  |

| hormon | -.4024169   | .1280843  | -3.14 | 0.002 | -.6534575            | -.1513763 |

Deviance = 3420.724.

Some explanation of the output from the model-selection algorithm is desirable. Consider the first few lines of output in the iteration log:

```
1. Deviance for model with all terms untransformed = 3471.637, 686 observations
```

| Variable | Model (vs.) | Deviance | Dev diff. | P      | Powers | (vs.) |
|----------|-------------|----------|-----------|--------|--------|-------|
| 2. x5    | null FP2    | 3503.610 | 61.366    | 0.000* | .      | .5 3  |
| 3.       | lin.        | 3471.637 | 29.393    | 0.000+ | 1      |       |
| 4.       | FP1         | 3449.203 | 6.959     | 0.031+ | 0      |       |
| 5.       | Final       | 3442.244 |           |        | .5 3   |       |

Line 1 gives the deviance ( $-2 \times \log$  partial likelihood) for the Cox model with all terms linear, the place where the algorithm starts. The model is modified variable by variable in subsequent steps. The most significant linear term turns out to be x5, which is therefore processed first. Line 2 compares the best-fitting FP2 for x5 with a model omitting x5. The FP has powers (0.5, 3), and the test for inclusion of x5 is highly significant. The reported deviance of 3,503.610 is of the null model, not for the FP2 model.

The deviance for the FP2 model may be calculated by subtracting the deviance difference (`Dev diff.`) from the reported deviance, giving  $3,503.610 - 61.366 = 3,442.244$ . Line 3 shows that the FP2 model is also a significantly better fit than a straight line (`lin.`) and line 4 that FP2 is also somewhat better than FP1 ( $p = 0.031$ ). Thus at this stage in the model-selection procedure, the final model for `x5` (line 5) is FP2 with powers (0.5, 3). The overall model with an FP2 for `x5` and all other terms linear has a deviance of 3,442.244.

After all the variables have been processed (cycle 1) and reprocessed (cycle 2) in this way, convergence is achieved because the functional forms (FP powers and variables included) after cycle 2 are the same as they were after cycle 1. The model finally chosen is Model II as given in tables 3 and 4 of [Sauerbrei and Royston \(1999\)](#). Because of scaling of variables, the regression coefficients reported there are different, but the model and its deviance are identical. The model includes `x1` with powers  $(-2, -0.5)$ , `x4a`, `x5` with powers  $(-2, -1)$ , and `x6` with power 0.5. There is strong evidence of nonlinearity for `x1` and for `x5`, the deviance differences for comparison with a straight-line model (FP2 vs `lin.`) being, respectively, 19.3 and 31.1 at convergence (cycle 2). Predictors `x2`, `x3`, `x4b`, and `x7` are dropped, as may be seen from their status out in the table `Final multivariable fractional polynomial model for _t` (the assumed `depvar` when using `stcox`).

All predictors except `x4a` and `hormon`, which are binary, have been centered on the mean of the original variable. For example, the mean of `x1` (`age`) is 53.05 years. The first FP-transformed variable for `x1` is  $x1^{-2}$  and is created by the expression `generate double Ix1__1 = X^-2-.0355 if e(sample)`. The value 0.0355 is obtained from  $(53.05/10)^{-2}$ . The division by 10 is applied automatically to improve the scaling of the regression coefficient for `Ix1__1`.

According to [Sauerbrei and Royston \(1999\)](#), medical knowledge dictates that the estimated risk function for `x5` (number of positive nodes), which was based on the above FP with powers  $(-2, -1)$ , should be monotonic, but it was not. They improved Model II by estimating a preliminary exponential transformation,  $x5e = \exp(-0.12 \cdot x5)$ , for `x5` and fitting a degree 1 FP for `x5e`, thus obtaining a monotonic risk function. The value of  $-0.12$  was estimated univariately using nonlinear Cox regression with the `ado-file` `boxtid` ([Royston and Ambler 1999b, 1999d](#)). To ensure a negative exponent, [Sauerbrei and Royston \(1999\)](#) restricted the powers for `x5e` to be positive. Their Model III may be fit by using the following command:

```
. mfp, alpha(.05) select(.05, hormon:1) df(x5e:2) xpowers(x5e:0.5 1 2 3):
> stcox x1 x2 x3 x4a x4b x5e x6 x7 hormon
```

## Stored results

In addition to what *regression\_cmd* stores, *mfp* stores the following in `e()`:

## Postestimation commands

The following postestimation commands are of special interest after `mfp`:

| Command               | Description                                                                        |
|-----------------------|------------------------------------------------------------------------------------|
| <code>fracplot</code> | plot data and fit from most recently fit fractional polynomial model               |
| <code>fracpred</code> | create variable containing prediction, deviance residuals, or SEs of fitted values |

The following standard postestimation commands are also available if available after `regression_cmd`:

| Command                      | Description                                                                                                                             |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <code>estat ic</code>        | Akaike's, consistent Akaike's, corrected Akaike's, and Schwarz's Bayesian information criteria (AIC, CAIC, AICc, and BIC, respectively) |
| <code>estat summarize</code> | summary statistics for the estimation sample                                                                                            |
| <code>estat vce</code>       | variance–covariance matrix of the estimators (VCE)                                                                                      |
| <code>estimates</code>       | cataloging estimation results                                                                                                           |
| <code>etable</code>          | table of estimation results                                                                                                             |
| <code>lincom</code>          | point estimates, standard errors, testing, and inference for linear combinations of parameters                                          |
| <code>linktest</code>        | link test for model specification                                                                                                       |
| <code>lrtest</code>          | likelihood-ratio test                                                                                                                   |
| <code>nlcom</code>           | point estimates, standard errors, testing, and inference for nonlinear combinations of parameters                                       |
| <code>test</code>            | Wald tests of simple and composite linear hypotheses                                                                                    |
| <code>testnl</code>          | Wald tests of nonlinear hypotheses                                                                                                      |

## fracplot and fracpred

### Description for fracplot and fracpred

`fracplot` plots the data and fit, with 95% confidence limits, from the most recently fit fractional polynomial (FP) model. The data and fit are plotted against *varname*, which may be *xvar*<sub>1</sub> or another of the covariates (*xvar*<sub>2</sub>, ..., or a variable from *xvarlist*). If *varname* is not specified, *xvar*<sub>1</sub> is assumed.

`fracpred` creates *newvar* containing the fitted index or deviance residuals for the whole model, or the fitted index or its standard error for *varname*, which may be *xvar*<sub>1</sub> or another covariate.

### Menu for fracplot and fracpred

#### fracplot

Statistics > Linear models and related > Fractional polynomials > Multivariable fractional polynomial plot

#### fracpred

Statistics > Linear models and related > Fractional polynomials > Multivariable fractional polynomial prediction

### Syntax for fracplot and fracpred

*Plot data and fit from most recently fit fractional polynomial model*

```
fracplot [varname] [if] [in] [, fracplot_options]
```

*Create variable containing the prediction, deviance residuals, or SEs of fitted values*

```
fracpred newvar [, fracpred_options]
```

| <i>fracplot_options</i>                  | Description                                                           |
|------------------------------------------|-----------------------------------------------------------------------|
| Plot                                     |                                                                       |
| <i>marker_options</i>                    | change look of markers (color, size, etc.)                            |
| <i>marker_label_options</i>              | add marker labels; change look or position                            |
| Fitted line                              |                                                                       |
| <i>lineopts</i> ( <i>cline_options</i> ) | affect rendition of the fitted line                                   |
| CI plot                                  |                                                                       |
| <i>ciopts</i> ( <i>area_options</i> )    | affect rendition of the confidence bands                              |
| Add plots                                |                                                                       |
| <i>addplot</i> ( <i>plot</i> )           | add other plots to the generated graph                                |
| Y axis, X axis, Titles, Legend, Overall  |                                                                       |
| <i>twoway_options</i>                    | any options other than by() documented in [G-3] <i>twoway_options</i> |

| <i>fracpred_options</i>       | Description                                                 |
|-------------------------------|-------------------------------------------------------------|
| <i>for</i> ( <i>varname</i> ) | compute prediction for <i>varname</i>                       |
| <i>dresid</i>                 | compute deviance residuals                                  |
| <i>stdp</i>                   | compute standard errors of the fitted values <i>varname</i> |

`fracplot` is not allowed after `mfp` with `clogit`, `mlogit`, or `stcrreg`. `fracpred`, `dresid` is not allowed after `mfp` with `clogit`, `mlogit`, or `stcrreg`.

## Options for fracplot

### Plot

`marker_options` affect the rendition of markers drawn at the plotted points, including their shape, size, color, and outline; see [G-3] [marker\\_options](#).

`marker_label_options` specify if and how the markers are to be labeled; see [G-3] [marker\\_label\\_options](#).

### Fitted line

`lineopts` (`cline_options`) affect the rendition of the fitted line; see [G-3] [cline\\_options](#).

### CI plot

`ciopts` (`area_options`) affect the rendition of the confidence bands; see [G-3] [area\\_options](#).

### Add plots

`addplot` (`plot`) provides a way to add other plots to the generated graph. See [G-3] [addplot\\_option](#).

### Y axis, X axis, Titles, Legend, Overall

`twoway_options` are any of the options documented in [G-3] [twoway\\_options](#), excluding `by()`. These include options for titling the graph (see [G-3] [title\\_options](#)) and for saving the graph to disk (see [G-3] [saving\\_option](#)).

## Options for fracpred

`for` (`varname`) specifies (partial) prediction for variable `varname`. The fitted values are adjusted to the value specified by the `center()` option in `mfp`.

`dresid` specifies that deviance residuals be calculated.

`stdp` specifies calculation of the standard errors of the fitted values `varname`, adjusted for all the other predictors at the values specified by `center()`.

## Remarks and examples

`fracplot` actually produces a component-plus-residual plot. For normal-error models with constant weights and one covariate, this amounts to a plot of the observations with the fitted line inscribed. For other normal-error models, weighted residuals are calculated and added to the fitted values.

For models with additional covariates, the line is the partial linear predictor for the variable in question (`xvar1` or a covariate) and includes the intercept  $\beta_0$ .

For generalized linear and Cox models, the fitted values are plotted on the scale of the “index” (linear predictor). Deviance residuals are added to the (partial) linear predictor to give component-plus-residual values. These values are plotted as small circles.

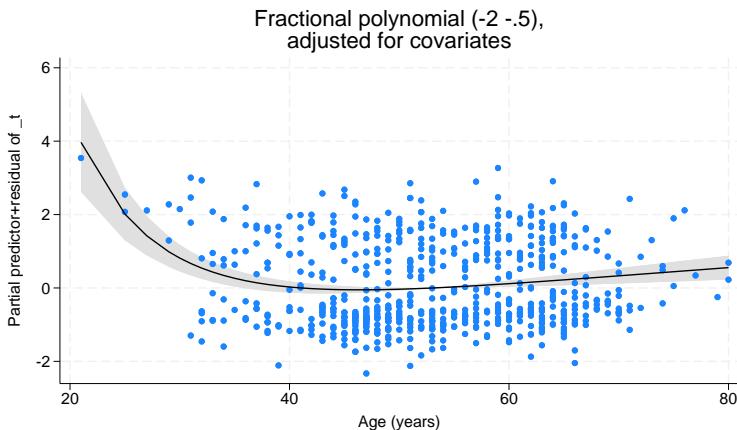

## ► Example 1

In [example 1](#) of [\[R\] mfp](#), we used Cox regression to predict the log hazard of breast cancer recurrence from prognostic factors of which five are continuous ( $x_1$ ,  $x_3$ ,  $x_5$ ,  $x_6$ ,  $x_7$ ) and three are binary ( $x_2$ ,  $x_{4a}$ ,  $x_{4b}$ ). We also controlled for hormonal therapy (`hormon`). We used `mfp` to build a model from the initial set of eight predictors by using the backfitting model-selection algorithm. The nominal  $p$ -value for variable and FP selection was set to 0.05 for all variables except `hormon`, which is set to 1.

```
. use https://www.stata-press.com/data/r19/brcancer
(German breast cancer data)
. stset rectime, fail(censrec)
(output omitted)
. mfp, alpha(.05) select(.05, hormon:1): stcox x1 x2 x3 x4a x4b x5 x6 x7 hormon,
> nohr
(output omitted)
```

We can use `fracplot` to produce component-plus-residual plots of the continuous variables. We produce the component-plus-residual plot for  $x_1$  with `fracplot` by specifying  $x_1$  after the command name.

```
. fracplot x1
```

We use `fracpred` with the `stdp` option to predict the standard error of the fractional polynomial prediction for  $x_1$ . The standard error prediction will be stored in variable `sepx1`. We specify that prediction is made for  $x_1$  with the `for()` option. After prediction, we use `summarize` to show how the standard error estimate varies over different values of  $x_1$ .

```
. fracpred sepx1, stdp for(x1)
```

```
. summarize sepx1
```

| Variable | Obs | Mean     | Std. dev. | Min      | Max      |
|----------|-----|----------|-----------|----------|----------|
| sepx1    | 686 | .0542654 | .0471993  | .0003304 | .6862065 |

◀

## Methods and formulas

The general definition of an FP, accommodating possible repeated powers, may be written for functions  $H_1(x), \dots, H_m(x)$  as

$$\beta_0 + \sum_{j=1}^m \beta_j H_j(x)$$

where  $H_1(x) = x^{(p_1)}$  and for  $j = 2, \dots, m$ ,

$$H_j(x) = \begin{cases} x^{(p_j)} & \text{if } p_j \neq p_{j-1} \\ H_{j-1}(x) \log x & \text{if } p_j = p_{j-1} \end{cases}$$

For example, an FP of degree 3 with powers (1, 3, 3) has  $H_1(x) = x$ ,  $H_2(x) = x^3$ , and  $H_3(x) = x^3 \log x$  and equals  $\beta_0 + \beta_1 x + \beta_2 x^3 + \beta_3 x^3 \log x$ .

The component-plus-residual values graphed by `fracplot` are calculated as follows: Let the data consist of triplets  $(y_i, x_i, \mathbf{z}_i)$ ,  $i = 1, \dots, n$ , where  $\mathbf{z}_i$  is the vector of covariates for the  $i$ th observation, after applying possible fractional polynomial transformation and adjustment as described earlier. Let  $\hat{\eta}_i = \hat{\beta}_0 + \{\mathbf{H}(x_i) - \mathbf{H}(x_0)\}' \hat{\beta} + \mathbf{z}_i' \hat{\gamma}$  be the linear predictor from the FP model, as given by the `fracpred` command or, equivalently, by the `predict` command with the `xb` option, following `mfp`. Here  $\mathbf{H}(x_i) = \{H_1(x_i), \dots, H_m(x_i)\}'$  is the vector of FP functions described above,  $\mathbf{H}(x_0) = \{H_1(x_0), \dots, H_m(x_0)\}'$  is the vector of adjustments to  $x_0$  (often,  $x_0$  is chosen to be the mean of the  $x_i$ ),  $\hat{\beta}$  is the estimated parameter vector, and  $\hat{\gamma}$  is the estimated parameter vector for the covariates. The values  $\hat{\eta}_i^* = \hat{\beta}_0 + \{\mathbf{H}(x_i) - \mathbf{H}(x_0)\}' \hat{\beta}$  represent the behavior of the FP model for  $x$  at fixed values  $\mathbf{z} = \mathbf{0}$  of the (adjusted) covariates. The  $i$ th component-plus-residual is defined as  $\hat{\eta}_i^* + d_i$ , where  $d_i$  is the deviance residual for the  $i$ th observation. For normal-errors models,  $d_i = \sqrt{w_i}(y_i - \hat{\eta}_i)$ , where  $w_i$  is the case weight (or 1, if *weight* is not specified). For logistic, Cox, and generalized linear regression models, see [R] [logistic](#), [R] [probit](#), [ST] [stcox](#), and [R] [glm](#) for the formula for  $d_i$ . The formula for poisson models is the same as that for `glm` with `family(poisson)`. For `stcox`,  $d_i$  is the partial martingale residual (see [ST] [stcox postestimation](#)).

`fracplot` plots the values of  $d_i$  and the curve represented by  $\hat{\eta}_i^*$  against  $x_i$ . The confidence interval for  $\hat{\eta}_i^*$  is obtained from the variance–covariance matrix of the entire model and takes into account the uncertainty in estimating  $\beta_0$ ,  $\beta$ , and  $\gamma$  (but not in estimating the FP powers for  $x$ ).

`fracpred` with the `for(varname)` option calculates the predicted index at  $x_i = x_0$  and  $\mathbf{z}_i = \mathbf{0}$ ; that is,  $\hat{\eta}_i = \hat{\beta}_0 + \{\mathbf{H}(x_i) - \mathbf{H}(x_0)\}' \hat{\beta}$ . The standard error is calculated from the variance–covariance matrix of  $(\hat{\beta}_0, \hat{\beta})$ , again ignoring estimation of the powers.

## Description

`misstable` makes tables that help you understand the pattern of missing values in your data.

## Quick start

*Tables with counts of missing values*

Missing observations in `v1`, `v2`, and `v3`

```
misstable summarize v1 v2 v3
```

Missing observations in `v1`–`v3` for cases where `v4 > 10`

```
misstable summarize v1 v2 v3 if v4>10
```

All variables with missing values

```
misstable summarize
```

Include variables with no missing values in the table

```
misstable summarize, all
```

Create 3 missing-data indicator variables with prefix `m` for `v1`, `v2`, and `v3`

```
misstable summarize v1 v2 v3, generate(m)
```

*Tables of missing-value patterns*

Missing-value patterns for `v1`, `v2`, and `v3`

```
misstable patterns v1 v2 v3
```

Same as above, but for all variables with missing values

```
misstable patterns
```

Show variables in the order listed in the command

```
misstable patterns v1 v3 v2, asis
```

Show frequencies, rather than percentages, in the output

```
misstable patterns v1 v2 v3, frequency
```

*Missing-value patterns displayed as trees*

A tree view of missing-value patterns for `v1`, `v2`, and `v3`

```
misstable tree v1 v2 v3
```

For all variables with missing values

```
misstable tree
```

*Nesting patterns of missing values*

Missing values for v1, v2, and v3

```
misstable nested v1 v2 v3
```

Same as above, but for all variables with missing values

```
misstable nested
```

Treat extended missing values (.a, .b, ..., .z) as nonmissing

```
misstable nested v1 v2 v3, exok
```

## Menu

Statistics > Summaries, tables, and tests > Other tables > Tabulate missing values

## Syntax

Report counts of missing values

```
misstable summarize [varlist] [if] [in] [, summarize_options]
```

Report pattern of missing values

```
misstable patterns [varlist] [if] [in] [, patterns_options]
```

Present a tree view of the pattern of missing values

```
misstable tree [varlist] [if] [in] [, tree_options]
```

List the nesting rules that describe the missing-value pattern

```
misstable nested [varlist] [if] [in] [, nested_options]
```

| <i>summarize_options</i>                 | Description                       |
|------------------------------------------|-----------------------------------|
| all                                      | show all variables                |
| showzeros                                | show zeros in table               |
| generate( <i>stub</i> [ , <i>exok</i> ]) | generate missing-value indicators |

| <i>patterns_options</i> | Description                                     |
|-------------------------|-------------------------------------------------|

| frequency               | report frequencies instead of percentages       |
| exok                    | treat .a, .b, ..., .z as nonmissing             |
| replace                 | replace data in memory with dataset of patterns |
| clear                   | okay to replace even if original unsaved        |
| bypatterns              | list by patterns rather than by frequency       |

| <i>tree_options</i> | Description                               |
|---------------------|-------------------------------------------|
| asis                | use variables in order given              |
| frequency           | report frequencies instead of percentages |
| exok                | treat .a, .b, ..., .z as nonmissing       |

| <i>nested_options</i> | Description                         |
|-----------------------|-------------------------------------|
| exok                  | treat .a, .b, ..., .z as nonmissing |

In addition, programmer's option `nopreserve` is allowed with all syntaxes; see [P] [nopreserve option](#).

`collect` is allowed; see [U] [11.1.10 Prefix commands](#).

## Options

Options are presented under the following headings:

*Options for misstable summarize*  
*Options for misstable patterns*  
*Options for misstable tree*  
*Option for misstable nested*  
*Common options*

### Options for misstable summarize

`all` specifies that the table should include all the variables specified or all the variables in the dataset. The default is to include only numeric variables that contain missing values.

`showzeros` specifies that zeros in the table should display as 0 rather than being omitted.

`generate(stub [ , exok ])` requests that a missing-value indicator *newvar*, a new binary variable containing 0 for complete observations and 1 for incomplete observations, be generated for every numeric variable in *varlist* containing missing values. If the `all` option is specified, missing-value indicators are created for all the numeric variables specified or for all the numeric variables in the dataset. If `exok` is specified within `generate()`, the extended missing values `.a`, `.b`, ..., `.z` are treated as if they do not designate missing.

For each variable in *varlist*, *newvar* is the corresponding variable name *varname* prefixed with *stub*. If the total length of *stub* and *varname* exceeds 32 characters, *newvar* is abbreviated so that its name does not exceed 32 characters.

### Options for misstable patterns

`asis`, `frequency`, and `exok` – see *Common options* below.

`replace` specifies that the data in memory be replaced with a dataset corresponding to the table just displayed; see *misstable patterns* under *Remarks and examples* below.

`clear` is for use with `replace`; it specifies that it is okay to change the data in memory even if they have not been saved to disk.

`bypatterns` specifies the table be ordered by pattern rather than by frequency. That is, `bypatterns` specifies that patterns containing one incomplete variable be listed first, followed by those for two incomplete variables, and so on. The default is to list the most frequent pattern first, followed by the next most frequent pattern, etc.

### Options for misstable tree

`asis`, `frequency`, and `exok` – see *Common options* below.

### Option for misstable nested

`exok` – see *Common options* below.

## Common options

`asis` specifies that the order of the variables in the table be the same as the order in which they are specified on the `misstable` command. The default is to order the variables by the number of missing values, and within that, by the amount of overlap of missing values.

`frequency` specifies that the table should report frequencies instead of percentages.

`exok` specifies that the extended missing values `.a`, `.b`, `. . .`, `.z` should be treated as if they do not designate missing. Some users use extended missing values to designate values that are missing for a known and valid reason.

`nopreserve` is a programmer's option allowed with all `misstable` commands; see [P] [nopreserve option](#).

## Remarks and examples

Remarks are presented under the following headings:

*misstable summarize*  
*misstable patterns*  
*misstable tree*  
*misstable nested*  
*Execution time of misstable nested*

In what follows, we will use data from a 125-observation, fictional, student-satisfaction survey:

```
. use https://www.stata-press.com/data/r19/studentsurvey
(Student survey)
. summarize
```

| Variable  | Obs | Mean     | Std. dev. | Min | Max |
|-----------|-----|----------|-----------|-----|-----|
| m1        | 125 | 2.456    | .8376619  | 1   | 4   |
| m2        | 125 | 2.472    | .8089818  | 1   | 4   |
| age       | 122 | 18.97541 | .8763477  | 17  | 21  |
| female    | 122 | .5245902 | .5014543  | 0   | 1   |
| dept      | 116 | 2.491379 | 1.226488  | 1   | 4   |
| offcampus | 125 | .36      | .4819316  | 0   | 1   |
| comment   | 0   |          |           |     |     |

The `m1` and `m2` variables record the student's satisfaction with teaching and with academics. `comment` is a string variable recording any comments the student might have had.

## misstable summarize

### ▷ Example 1

misstable summarize reports counts of missing values:

```
. misstable summarize
```

| Variable | Obs=. | Obs>. | Obs<. | Obs<.         |     |     |
|----------|-------|-------|-------|---------------|-----|-----|
|          |       |       |       | Unique values | Min | Max |
| age      | 3     |       | 122   | 5             | 17  | 21  |
| female   | 3     |       | 122   | 2             | 0   | 1   |
| dept     | 9     |       | 116   | 4             | 1   | 4   |

Stata provides 27 different missing values, namely, ., .a, .b, ..., .z. The first of those, ., is often called system missing. The remaining missing values are called extended missings. The nonmissing and missing values are ordered *nonmissing* < . < .a < .b < ... < .z. Thus, reported in the column “Obs=.” are counts of system missing values; in the column “Obs>.”, extended missing values; and in the column “Obs<.”, nonmissing values.

The rightmost portion of the table is included to remind you how the variables are encoded.

Our data contain seven variables and yet misstable reported only three of them. The omitted variables contain no missing values or are string variables. Even if we specified the varlist explicitly, those variables would not appear in the table unless we specified the all option.

We can also create missing-value indicators for each of the variables above using the generate() option:

```
. quietly misstable summarize, generate(miss_)
. describe miss_*
```

| Variable name | Storage type | Display format | Value label | Variable label |
|---------------|--------------|----------------|-------------|----------------|
| miss_age      | byte         | %8.0g          |             | (age>=.)       |
| miss_female   | byte         | %8.0g          |             | (female>=.)    |
| miss_dept     | byte         | %8.0g          |             | (dept>=.)      |

For each variable containing missing values, the generate() option creates a new binary variable containing 0 for complete observations and 1 for incomplete observations. In our example, three new missing-value indicators are generated, one for each of the incomplete variables age, female, and dept. The naming convention of generate() is to prefix the corresponding variable names with the specified stub, which is miss\_ in this example.

Missing-value indicators are useful, for example, for checking whether data are missing completely at random. They are also often used within the multiple-imputation context to identify the observed and imputed data; see [MI] [Intro substantive](#) for a general introduction to multiple imputation. Within Stata’s multiple-imputation commands, an incomplete value is identified by the system missing value, a dot. By default, misstable summarize, generate() marks the extended missing values as incomplete values, as well. You can use exok within generate() to treat extended missing values as complete when creating missing-value identifiers.

## misstable patterns

### ▷ Example 2

misstable patterns reports the pattern of missing values:

```
. misstable patterns
Missing-value patterns
(1 means complete)
```

| Percent | Pattern |   |   |
|---------|---------|---|---|
|         | 1       | 2 | 3 |
| 93%     | 1       | 1 | 1 |
| 5       | 1       | 1 | 0 |
| 2       | 0       | 0 | 0 |
| 100%    |         |   |   |

Variables are (1) age (2) female (3) dept

There are three patterns in these data: (1,1,1), (1,1,0), and (0,0,0). By default, the rows of the table are ordered by frequency. In larger tables that have more patterns, it is sometimes useful to order the rows by pattern. We could have obtained that by typing `mi misstable patterns, bypatterns`.

In a pattern, 1 indicates that all values of the variable are nonmissing and 0 indicates that all values are missing. Thus, pattern (1,1,1) means no missing values, and 93% of our data have that pattern. There are two patterns in which variables are missing, (1,1,0) and (0,0,0). Pattern (1,1,0) means that age is nonmissing, female is nonmissing, and dept is missing. The order of the variables in the patterns appears in the key at the bottom of the table. Five percent of the observations have pattern (1,1,0). The remaining 2% have pattern (0,0,0), meaning that all three variables contain missing.

As with `misstable summarize`, only numeric variables that contain missing are listed, so had we typed `misstable patterns comments age female offcampus dept`, we still would have obtained the same table. Variables that are automatically omitted contain no missing values or are string variables.

The variables in the table are ordered from lowest to highest frequency of missing values, although you cannot see that from the information presented in the table. The variables are ordered this way even if you explicitly specify the varlist with a different ordering. Typing `misstable patterns dept female age` would produce the same table as above. Specify the `asis` option if you want the variables in the order in which you specify them.

You can obtain a dataset of the patterns by specifying the `replace` option:

```
. misstable patterns, replace clear
Missing-value patterns
(1 means complete)
```

| Percent | Pattern |   |   |
|---------|---------|---|---|
|         | 1       | 2 | 3 |
| 93%     | 1       | 1 | 1 |
| 5       | 1       | 1 | 0 |
| 2       | 0       | 0 | 0 |
| 100%    |         |   |   |

Variables are (1) age (2) female (3) dept  
(summary data now in memory)

```
. list
```

|    | _freq | age | female | dept |
|----|-------|-----|--------|------|
| 1. | 3     | 0   | Male   | 0    |
| 2. | 6     | 1   | Female | 0    |
| 3. | 116   | 1   | Female | 1    |

The differences between the dataset and the printed table are that 1) the dataset always records frequency and 2) the rows are reversed.

## misstable tree

### ▷ Example 3

`misstable tree` presents a tree view of the pattern of missing values:

```
. use https://www.stata-press.com/data/r19/studentsurvey, clear
(Student survey)
```

```
. misstable tree, frequency
```

```
Nested pattern of missing values
```

| dept | age | female |
|------|-----|--------|
| 9    | 3   | 3      |
|      |     | 0      |
|      | 6   | 0      |
|      |     | 6      |
| 116  | 0   | 0      |
|      |     | 0      |
|      | 116 | 0      |
|      |     | 116    |

```
(number missing listed first)
```

In this example, we specified the `frequency` option to see the table in frequency rather than percentage terms. In the table, each column sums to the total number of observations in the data, 125. Variables are ordered from those with the most missing values to those with the least. Start with the first column. The `dept` variable is missing in 9 observations and, farther down, the table reports that it is not missing in 116 observations.

Go back to the first row and read across, but only to the second column. The `dept` variable is missing in 9 observations. Within those 9, `age` is missing in 3 of them and is not missing in the remaining 6. Reading down the second column, within the 116 observations that `dept` is not missing, `age` is missing in 0 and not missing in 116.

Reading straight across the first row again, `dept` is missing in 9 observations, and within the 9, `age` is missing in 3, and within the 3, `female` is also missing in 3. Skipping down just a little, within the 6 observations for which `dept` is missing and `age` is not missing, `female` is not missing, too.

## misstable nested

### ▷ Example 4

`misstable nested` lists the nesting rules that describe the missing-value pattern,

```
. misstable nested
 1. female(3) <-> age(3) -> dept(9)
```

This line says that in observations in which `female` is missing, so is `age` missing, and vice versa, and in observations in which `age` (or `female`) is missing, so is `dept`. The numbers in parentheses are counts of the missing values. The `female` variable happens to be missing in 3 observations, and the same is true for `age`; the `dept` variable is missing in 9 observations. Thus, `dept` is missing in the 3 observations for which `age` and `female` are missing, and in 6 more observations, too.

In these data, it turns out that the missing-value pattern can be summarized in one statement. In a larger dataset, you might see something like this:

```
. misstable nested
 1. female(50) <-> age(50) -> dept(120)
 2. female(50) -> m1(58)
 3. offcampus(11)
```

`misstable nested` accounts for every missing value. In the above, in addition to `female <-> age -> dept`, we have that `female -> m1`, and we have `offcampus`, the last all by itself. The last line says that the 11 missing values in `offcampus` are not themselves nested in the missing value of any other variable, nor do they imply the missing values in another variable. In some datasets, all the statements will be of this last form.

In our data, however, we have one statement:

```
. misstable nested
 1. female(3) <-> age(3) -> dept(9)
```

When the missing-value pattern can be summarized in one `misstable nested` statement, the pattern of missing values in the data is said to be monotone.

## Execution time of misstable nested

The execution time of `misstable nested` is affected little by the number of observations but can grow quickly with the number of variables, depending on the fraction of missing values within variable. The execution time of the example above, which has 3 variables containing missing, is instant. In worst-case scenarios, with 500 variables, the time might be 25 seconds; with 1,000 variables, the execution time might be closer to an hour.

In situations where `misstable nested` takes a long time to complete, it will produce thousands of rules that will defy interpretation. A 523-variable dataset we have seen ran in 20 seconds and produced 8,040 rules. Although we spotted a few rules in the output that did not surprise us, such as the year of the date being missing implied that the month and the day were also missing, mostly the output was not helpful.

If you have such a dataset, we recommend you run `misstable` on groups of variables that you have reason to believe the pattern of missing values might be related.

## Stored results

`misstable summarize` stores the following values of the last variable summarized in `r()`:

### Scalars

|                          |                                                   |
|--------------------------|---------------------------------------------------|
| <code>r(N_eq_dot)</code> | number of observations containing .               |
| <code>r(N_gt_dot)</code> | number of observations containing .a, .b, ..., .z |
| <code>r(N_lt_dot)</code> | number of observations containing nonmissing      |
| <code>r(K_uniq)</code>   | number of unique, nonmissing values               |
| <code>r(min)</code>      | variable's minimum value                          |
| <code>r(max)</code>      | variable's maximum value                          |

### Macros

|                         |                          |
|-------------------------|--------------------------|
| <code>r(vartype)</code> | numeric, string, or none |
|-------------------------|--------------------------|

`r(K_uniq)` contains . if the number of unique, nonmissing values is greater than 500. `r(vartype)` contains none if no variables are summarized, and in that case, the value of the scalars are all set to missing (.). Programmers intending to access results after `misstable summarize` should specify the all option.

`misstable patterns` stores the following in `r()`:

### Scalars

|                              |                                   |
|------------------------------|-----------------------------------|
| <code>r(N_complete)</code>   | number of complete observations   |
| <code>r(N_incomplete)</code> | number of incomplete observations |
| <code>r(K)</code>            | number of patterns                |

### Macros

|                      |                                   |
|----------------------|-----------------------------------|
| <code>r(vars)</code> | variables used in order presented |
|----------------------|-----------------------------------|

`r(N_complete)` and `r(N_incomplete)` are defined with respect to the variables specified if variables were specified and otherwise, defined with respect to all the numeric variables in the dataset. `r(N_complete)` is the number of observations that contain no missing values.

`misstable tree` stores the following in `r()`:

### Macros

|                      |                                   |
|----------------------|-----------------------------------|
| <code>r(vars)</code> | variables used in order presented |
|----------------------|-----------------------------------|

misstable nested stores the following in `r()`:

Scalars

`r(K)`                      number of statements

Macros

|                            |                                                 |
|----------------------------|-------------------------------------------------|
| <code>r(stmt1)</code>      | first statement                                 |
| <code>r(stmt2)</code>      | second statement                                |
| .                          | .                                               |
| .                          | .                                               |
| <code>r(stmt'r(K)')</code> | last statement                                  |
| <code>r(stmt1wc)</code>    | <code>r(stmt1)</code> with missing-value counts |
| <code>r(vars)</code>       | variables considered                            |

A statement is encoded “*varname*”, “*varname op varname*”, or “*varname op varname op varname*”, and so on; *op* is either “->” or “<->”.

## Description

`ml model` defines the current problem.

`ml clear` clears the current problem definition. This command is rarely used because when you type `ml model`, any previous problem is automatically cleared.

`ml query` displays a description of the current problem.

`ml check` verifies that the log-likelihood evaluator you have written works. We strongly recommend using this command.

`ml search` searches for (better) initial values. We recommend using this command.

`ml plot` provides a graphical way of searching for (better) initial values.

`ml init` provides a way to specify initial values.

`ml report` reports  $\ln L$ 's values, gradient, and Hessian at the initial values or current parameter estimates,  $\mathbf{b}_0$ .

`ml trace` traces the execution of the user-defined log-likelihood evaluation program.

`ml count` counts the number of times the user-defined log-likelihood evaluation program is called; this command is seldom used. `ml count clear` clears the counter. `ml count on` turns on the counter. `ml count` without arguments reports the current values of the counter. `ml count off` stops counting calls.

`ml maximize` maximizes the likelihood function and reports results. Once `ml maximize` has successfully completed, the previously mentioned `ml` commands may no longer be used unless `noclear` is specified. `ml graph` and `ml display` may be used whether or not `noclear` is specified.

`ml graph` graphs the log-likelihood values against the iteration number.

`ml display` redisplay results.

`ml footnote` displays a warning message when the model did not converge within the specified number of iterations.

`ml score` creates new variables containing the equation-level scores. The variables generated by `ml score` are equivalent to those generated by specifying the `score()` option of `ml maximize` (and `ml model ... , ... maximize`).

*progname* is the name of a Stata program you write to evaluate the log-likelihood function.

*funcname()* is the name of a Mata function you write to evaluate the log-likelihood function.

In this documentation, *progname* and *funcname()* are referred to as the user-written evaluator, the likelihood evaluator, or sometimes simply as the evaluator. The program you write is written in the style required by the method you choose. The methods are lf, d0, d1, d2, lf0, lf1, lf2, and gf0. Thus, if you choose to use method lf, your program is called a method-lf evaluator.

Method-lf evaluators are required to evaluate the observation-by-observation log likelihood  $\ln \ell_j, j = 1, \dots, N$ .

Method-d0 evaluators are required to evaluate the overall log likelihood  $\ln L$ . Method-d1 evaluators are required to evaluate the overall log likelihood and its gradient vector  $\mathbf{g} = \partial \ln L / \partial \mathbf{b}$ . Method-d2 evaluators are required to evaluate the overall log likelihood, its gradient, and its Hessian matrix  $H = \partial^2 \ln L / \partial \mathbf{b} \partial \mathbf{b}'$ .

Method-lf0 evaluators are required to evaluate the observation-by-observation log likelihood  $\ln \ell_j$ ,  $j = 1, \dots, N$ . Method-lf1 evaluators are required to evaluate the observation-by-observation log likelihood and its equation-level scores  $g_{ji} = \partial \ln \ell / \partial \mathbf{x}_{ji} \mathbf{b}_i$ . Method-lf2 evaluators are required to evaluate the observation-by-observation log likelihood, its equation-level scores, and its Hessian matrix  $H = \partial^2 \ln \ell / \partial \mathbf{b} \partial \mathbf{b}'$ .

Method-gf0 evaluators are required to evaluate the summable pieces of the log likelihood  $\ln \ell_k$ ,  $k = 1, \dots, K$ .

`mlevel` is a subroutine used by evaluators of methods d0, d1, d2, lf0, lf1, lf2, and gf0 to evaluate the coefficient vector,  $\mathbf{b}$ , that they are passed.

`mlsum` is a subroutine used by evaluators of methods d0, d1, and d2 to define the value,  $\ln L$ , that is to be returned.

`mlvecsum` is a subroutine used by evaluators of methods d1 and d2 to define the gradient vector,  $\mathbf{g}$ , that is to be returned. It is suitable for use only when the likelihood function meets the linear-form restrictions.

`mlmatsum` is a subroutine used by evaluators of methods d2 and lf2 to define the Hessian matrix,  $\mathbf{H}$ , that is to be returned. It is suitable for use only when the likelihood function meets the linear-form restrictions.

`mlmatbysum` is a subroutine used by evaluator of method d2 to help define the Hessian matrix,  $\mathbf{H}$ , that is to be returned. It is suitable for use when the likelihood function contains terms made up of grouped sums, such as in panel-data models. For such models, use `mlmatsum` to compute the observation-level outer products and `mlmatbysum` to compute the group-level outer products. `mlmatbysum` requires that the data be sorted by the variable identified in the `by()` option.

## Syntax

*ml model in interactive mode*

```
ml model method progname eq [eq ...] [if] [in] [weight]
 [, model_options svy diparm_options]
```

```
ml model method funcname() eq [eq ...] [if] [in] [weight]
 [, model_options svy diparm_options]
```

*ml model in noninteractive mode*

```
ml model method progname eq [eq ...] [if] [in] [weight], maximize
 [, model_options svy diparm_options noninteractive_options]
```

```
ml model method funcname() eq [eq ...] [if] [in] [weight], maximize
 [, model_options svy diparm_options noninteractive_options]
```

Noninteractive mode is invoked by specifying the `maximize` option. Use `maximize` when `ml` will be used as a subroutine of another ado-file or program and you want to carry forth the problem, from definition to posting of results, in one command.

```
ml clear

ml query

ml check

ml search [[/]eqname[:] #lb #ub] [...] [, search_options]

ml plot [eqname:]name [# [# [#]]] [, saving(filename[, replace])]

ml init { [eqname:]name=#|/eqname=# } [...]

ml init # [#...], copy

ml init matname [, copy skip]

ml report

ml trace { on|off }

ml count [clear|on|off]

ml maximize [, ml_maximize_options display_options eform_option]

ml graph [#] [, saving(filename[, replace])]

ml display [, display_options eform_option]

ml footnote

ml score newvar [if] [in] [, equation(eqname) missing]

ml score newvarlist [if] [in] [, missing]

ml score [type] stub* [if] [in] [, missing]
```

where *method* is one of

|    |         |          |     |
|----|---------|----------|-----|
| lf | d0      | lf0      | gf0 |
|    | d1      | lf1      |     |
|    | d1debug | lf1debug |     |
|    | d2      | lf2      |     |
|    | d2debug | lf2debug |     |

or *method* can be specified using one of the longer, more descriptive names

| <i>method</i> | Longer name      |
|---------------|------------------|

*eq* is the equation to be estimated, enclosed in parentheses, and optionally with a name to be given to the equation, preceded by a colon,

( [*eqname*: ] [ *varlist*<sub>y</sub> = ] [ *varlist*<sub>x</sub> ] [ , *eq\_options* ] )

or *eq* is the name of a parameter, such as sigma, with a slash in front

*/eqname* which is equivalent to (*eqname*:, freeparm)

and *diparm\_options* is one or more `diparm(diparm_args)` options where *diparm\_args* is either `__sep__` or anything accepted by the “undocumented” `_diparm` command; see help `_diparm`.

| <i>eq_options</i>                                 | Description                                                                    |
|---------------------------------------------------|--------------------------------------------------------------------------------|
| <code>noconstant</code>                           | do not include an intercept in the equation                                    |
| <code>offset(<i>varname</i><sub>o</sub>)</code>   | include <i>varname</i> <sub>o</sub> in model with coefficient constrained to 1 |
| <code>exposure(<i>varname</i><sub>e</sub>)</code> | include $\ln(\text{varname}_e)$ in model with coefficient constrained to 1     |
| <code>freeparm</code>                             | <i>eqname</i> is a free parameter                                              |

| <i>model_options</i>                                   | Description                                                                                                                   |
|--------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------|
| <code>group(<i>varname</i>)</code>                     | use <i>varname</i> to identify groups                                                                                         |
| <code>vce(<i>vcetype</i>)</code>                       | <i>vcetype</i> may be <code>robust</code> , <code>cluster</code> <i>clustvar</i> , <code>oim</code> , or <code>opg</code>     |
| <code>constraints(<i>numlist</i>)</code>               | constraints by number to be applied                                                                                           |
| <code>constraints(<i>matname</i>)</code>               | matrix that contains the constraints to be applied                                                                            |
| <code>nocnsnotes</code>                                | do not display notes when constraints are dropped                                                                             |
| <code>title(<i>string</i>)</code>                      | place a title on the estimation output                                                                                        |
| <code>nopreserve</code>                                | do not preserve the estimation subsample in memory                                                                            |
| <code>collinear</code>                                 | keep collinear variables within equations                                                                                     |
| <code>missing</code>                                   | keep observations containing variables with missing values                                                                    |
| <code>lfl0(<i>#<sub>k</sub> #<sub>ll</sub></i>)</code> | number of parameters and log-likelihood value of the constant-only model                                                      |
| <code>continue</code>                                  | specifies that a model has been fit and sets the initial values $\mathbf{b}_0$ for the model to be fit based on those results |
| <code>waldtest(<i>#</i>)</code>                        | perform a Wald test; see <i>Options for use with ml model in interactive or noninteractive mode</i> below                     |
| <code>obs(<i>#</i>)</code>                             | number of observations                                                                                                        |
| <code>crittype(<i>string</i>)</code>                   | describe the criterion optimized by ml                                                                                        |
| <code>subpop(<i>varname</i>)</code>                    | compute estimates for the single subpopulation                                                                                |
| <code>nosvyadjust</code>                               | carry out Wald test as $W/k \sim F(k, d)$                                                                                     |
| <code>technique(nr)</code>                             | Stata's modified Newton–Raphson (NR) algorithm                                                                                |
| <code>technique(bhhh)</code>                           | Berndt–Hall–Hall–Hausman (BHHH) algorithm                                                                                     |
| <code>technique(dfpr)</code>                           | Davidon–Fletcher–Powell (DFP) algorithm                                                                                       |
| <code>technique(bfgs)</code>                           | Broyden–Fletcher–Goldfarb–Shanno (BFGS) algorithm                                                                             |
| <code>deriv(<i>min_spec</i>)</code>                    | specify the minimum step size for computing numerical derivatives                                                             |

| <i>noninteractive_options</i>                | Description                                                            |
|----------------------------------------------|------------------------------------------------------------------------|
| <code>init(<i>ml_init_args</i>)</code>       | set the initial values $\mathbf{b}_0$                                  |
| <code>search(on)</code>                      | equivalent to <code>ml search, repeat(0)</code> ; the default          |
| <code>search(norescale)</code>               | equivalent to <code>ml search, repeat(0) norescale</code>              |
| <code>search(quietly)</code>                 | same as <code>search(on)</code> , except that output is suppressed     |
| <code>search(off)</code>                     | prevents calling <code>ml search</code>                                |
| <code>repeat(<i>#</i>)</code>                | <code>ml search</code> 's <code>repeat()</code> option; see below      |
| <code>bounds(<i>ml_search_bounds</i>)</code> | specify bounds for <code>ml search</code>                              |
| <code>nowarning</code>                       | suppress “convergence not achieved” message of <code>iterate(0)</code> |
| <code>novce</code>                           | substitute the zero matrix for the variance matrix                     |
| <code>negh</code>                            | indicates that the evaluator returns the negative Hessian matrix       |
| <code>score(<i>newvars</i>)</code>           | new variables containing the contribution to the score                 |
| <code>maximize_options</code>                | control the maximization process; seldom used                          |

| <i>search_options</i>               | Description                                                                                                                                                             |
|-------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>repeat(#)</code>              | number of random attempts to find better initial-value vector; default is <code>repeat(10)</code> in interactive mode and <code>repeat(0)</code> in noninteractive mode |
| <code>restart</code>                | use random actions to find starting values; not recommended                                                                                                             |
| <code>norescale</code>              | do not rescale to improve parameter vector; not recommended                                                                                                             |
| <i>maximize_options</i>             | control the maximization process; seldom used                                                                                                                           |
| <i>ml_maximize_options</i>          | Description                                                                                                                                                             |
| <code>nowarning</code>              | suppress “convergence not achieved” message of <code>iterate(0)</code>                                                                                                  |
| <code>novce</code>                  | substitute the zero matrix for the variance matrix                                                                                                                      |
| <code>negh</code>                   | indicates that the evaluator returns the negative Hessian matrix                                                                                                        |
| <code>score(newvars   stub*)</code> | new variables containing the contribution to the score                                                                                                                  |
| <code>nooutput</code>               | suppress display of final results                                                                                                                                       |
| <code>noskipline</code>             | suppress display of blank line before iteration log                                                                                                                     |
| <code>noclear</code>                | do not clear ml problem definition after model has converged                                                                                                            |
| <i>maximize_options</i>             | control the maximization process; seldom used                                                                                                                           |
| <i>display_options</i>              | Description                                                                                                                                                             |
| <code>noheader</code>               | suppress header display above the coefficient table                                                                                                                     |
| <code>nofootnote</code>             | suppress footnote display below the coefficient table                                                                                                                   |
| <code>level(#)</code>               | set confidence level; default is <code>level(95)</code>                                                                                                                 |
| <code>first</code>                  | display coefficient table reporting results for first equation only                                                                                                     |
| <code>neq(#)</code>                 | display coefficient table reporting first # equations                                                                                                                   |
| <code>showeqns</code>               | display equation names in the coefficient table                                                                                                                         |
| <code>plus</code>                   | display coefficient table ending in dashes–plus–sign–dashes                                                                                                             |
| <code>nocnsreport</code>            | suppress constraints display above the coefficient table                                                                                                                |
| <code>noomitted</code>              | suppress display of omitted variables                                                                                                                                   |
| <code>vsquish</code>                | suppress blank space separating factor-variable terms or time-series–operated variables from other variables                                                            |
| <code>noemptycells</code>           | suppress empty cells for interactions of factor variables                                                                                                               |
| <code>baselevels</code>             | report base levels of factor variables and interactions                                                                                                                 |
| <code>allbaselevels</code>          | display all base levels of factor variables and interactions                                                                                                            |
| <code>cformat(%fmt)</code>          | format the coefficients, standard errors, and confidence limits in the coefficient table                                                                                |
| <code>pformat(%fmt)</code>          | format the <i>p</i> -values in the coefficient table                                                                                                                    |
| <code>sformat(%fmt)</code>          | format the test statistics in the coefficient table                                                                                                                     |
| <code>no1stretch</code>             | do not automatically widen the coefficient table to accommodate longer variable names                                                                                   |
| <code>coeflegend</code>             | display legend instead of statistics                                                                                                                                    |

| <i>eform_option</i>        | Description                                                  |
|----------------------------|--------------------------------------------------------------|
| <code>eform(string)</code> | display exponentiated coefficients; column title is “string” |
| <code>eform</code>         | display exponentiated coefficients; column title is “exp(b)” |
| <code>hr</code>            | report hazard ratios                                         |
| <code>shr</code>           | report subhazard ratios                                      |
| <code>irr</code>           | report incidence-rate ratios                                 |
| <code>or</code>            | report odds ratios                                           |
| <code>rrr</code>           | report relative-risk ratios                                  |

`fweights`, `awweights`, `iweights`, and `pweights` are allowed; see [U] 11.1.6 **weight**. With all but method `lf`, you must write your likelihood-evaluation program carefully if `pweights` are to be specified, and `pweights` may not be specified with method `d0`, `d1`, `d1debug`, `d2`, or `d2debug`. See Pitblado, Poi, and Gould (2024, chap. 7) for details.

See [U] 20 **Estimation and postestimation commands** for more capabilities of estimation commands.

To redisplay results, type `ml display`.

## Syntax of subroutines for use by evaluator programs

```

mleval newvar = vecname [, eq(#)]
mleval scalarname = vecname , scalar [eq(#)]

mlsum scalarnamelnf = exp [if] [, noweight]
mlvecsum scalarnamelnf rowvecname = exp [if] [, eq(#)]
mlmatsum scalarnamelnf matrixname = exp [if] [, eq(#[, #])]
mlmatbysum scalarnamelnf matrixname varnamea varnameb [varnamec] [if] ,
 by(varname) [eq(#[, #])]

```

## Syntax of user-written evaluator

### Summary of notation

The log-likelihood function is  $\ln L(\theta_{1j}, \theta_{2j}, \dots, \theta_{Ej})$ , where  $\theta_{ij} = \mathbf{x}_{ij}\mathbf{b}_i$ ,  $j = 1, \dots, N$  indexes observations, and  $i = 1, \dots, E$  indexes the linear equations defined by `ml model1`. If the likelihood satisfies the linear-form restrictions, it can be decomposed as  $\ln L = \sum_{j=1}^N \ln \ell(\theta_{1j}, \theta_{2j}, \dots, \theta_{Ej})$ .

### Method-`lf` evaluators

```

program progname
 version 19.5 // (or version 19 if you do not have StataNow)
 args lnfj theta1 theta2 ...
 // if you need to create any intermediate results:
 tempvar tmp1 tmp2 ...
 quietly generate double `tmp1' = ...
 ...
 quietly replace `lnfj' = ...
end

```

where

- 'lnfj' variable to be filled in with observation-by-observation values of  $\ln \ell_j$
- 'theta1' variable containing evaluation of first equation  $\theta_{1j} = \mathbf{x}_{1j} \mathbf{b}_1$
- 'theta2' variable containing evaluation of second equation  $\theta_{2j} = \mathbf{x}_{2j} \mathbf{b}_2$
- ...

## Method-d0 evaluators

```

program progname
 version 19.5 // (or version 19 if you do not have StataNow)
 args todo b lnf
 tempvar theta1 theta2 ...
 mlevel 'theta1' = 'b', eq(1)
 mlevel 'theta2' = 'b', eq(2) // if there is a θ_2
 ...
 // if you need to create any intermediate results:
 tempvar tmp1 tmp2 ...
 generate double 'tmp1' = ...
 ...
 mlsum 'lnf' = ...
end

```

where

- 'todo' always contains 0 (may be ignored)
- 'b' full parameter row vector  $\mathbf{b} = (\mathbf{b}_1, \mathbf{b}_2, \dots, \mathbf{b}_E)$
- 'lnf' scalar to be filled in with overall  $\ln L$

## Method-d1 evaluators

```

program progname
 version 19.5 // (or version 19 if you do not have StataNow)
 args todo b lnf g
 tempvar theta1 theta2 ...
 mlevel 'theta1' = 'b', eq(1)
 mlevel 'theta2' = 'b', eq(2) // if there is a θ_2
 ...
 // if you need to create any intermediate results:
 tempvar tmp1 tmp2 ...
 generate double 'tmp1' = ...
 ...
 mlsum 'lnf' = ...
 if ('todo'==0 | 'lnf'>=.) exit
 tempname d1 d2 ...
 mlvecsum 'lnf' 'd1' = formula for $\partial \ln \ell_{-j} / \partial \theta_{-1j}$, eq(1)
 mlvecsum 'lnf' 'd2' = formula for $\partial \ln \ell_{-j} / \partial \theta_{-2j}$, eq(2)
 ...
 matrix 'g' = ('d1', 'd2', ...)
end

```

where

- 'todo' contains 0 or 1
  - 0  $\Rightarrow$  'lnf' to be filled in;
  - 1  $\Rightarrow$  'lnf' and 'g' to be filled in
- 'b' full parameter row vector  $\mathbf{b} = (\mathbf{b}_1, \mathbf{b}_2, \dots, \mathbf{b}_E)$
- 'lnf' scalar to be filled in with overall  $\ln L$
- 'g' row vector to be filled in with overall  $\mathbf{g} = \partial \ln L / \partial \mathbf{b}$

## Method-d2 evaluators

```

program programe
 version 19.5 // (or version 19 if you do not have StataNow)
 args todo b lnf g H
 tempvar theta1 theta2 ...
 mlevel 'theta1' = 'b', eq(1)
 mlevel 'theta2' = 'b', eq(2) // if there is a θ_2
 ...
 // if you need to create any intermediate results:
 tempvar tmp1 tmp2 ...
 generate double 'tmp1' = ...
 ...
 mlsum 'lnf' = ...
 if ('todo'==0 | 'lnf'>=.) exit
 tempname d1 d2 ...
 mlvecsum 'lnf' 'd1' = formula for $\partial \ln \ell_{-j} / \partial \theta_{-1j}$, eq(1)
 mlvecsum 'lnf' 'd2' = formula for $\partial \ln \ell_{-j} / \partial \theta_{-2j}$, eq(2)
 ...
 matrix 'g' = ('d1', 'd2', ...)
 if ('todo'==1 | 'lnf'>=.) exit
 tempname d11 d12 d22 ...
 mlmatsum 'lnf' 'd11' = formula for $\partial^2 \ln \ell_{-j} / \partial \theta_{-1j}^2$, eq(1)
 mlmatsum 'lnf' 'd12' = formula for $\partial^2 \ln \ell_{-j} / \partial \theta_{-1j} \partial \theta_{-2j}$, eq(1,2)
 mlmatsum 'lnf' 'd22' = formula for $\partial^2 \ln \ell_{-j} / \partial \theta_{-2j}^2$, eq(2)
 ...
 matrix 'H' = ('d11', 'd12', ... \ 'd12', 'd22', ...)
end

```

where

```

'todo' contains 0, 1, or 2
 0 ⇒ 'lnf' to be filled in;
 1 ⇒ 'lnf' and 'g' to be filled in;
 2 ⇒ 'lnf', 'g', and 'H' to be filled in
'b' full parameter row vector $\mathbf{b} = (\mathbf{b}_1, \mathbf{b}_2, \dots, \mathbf{b}_E)$
'lnf' scalar to be filled in with overall $\ln L$
'g' row vector to be filled in with overall $\mathbf{g} = \partial \ln L / \partial \mathbf{b}$
'H' matrix to be filled in with overall Hessian $\mathbf{H} = \partial^2 \ln L / \partial \mathbf{b} \partial \mathbf{b}'$

```

## Method-lf0 evaluators

```

program programe
 version 19.5 // (or version 19 if you do not have StataNow)

## Method-gf0 evaluators

```

program prognam
version 19.5 // (or version 19 if you do not have StataNow)
args todo b lnfj
tempvar theta1 theta2 ...
mlevel 'theta1' = 'b', eq(1)
mlevel 'theta2' = 'b', eq(2) // if there is a θ_{-2}
...
// if you need to create any intermediate results:
tempvar tmp1 tmp2 ...
generate double 'tmp1' = ...
...
quietly replace 'lnfj' = ...
end

```

where

```

'todo' always contains 0 (may be ignored)
'b' full parameter row vector $\mathbf{b} = (\mathbf{b}_1, \mathbf{b}_2, \dots, \mathbf{b}_E)$
'lnfj' variable to be filled in with the values of the log-likelihood $\ln \ell_j$

```

## Global macros for use by all evaluators

```

$ML_y1 name of first dependent variable
$ML_y2 name of second dependent variable, if any
...
$ML_samp variable containing 1 if observation to be used; 0 otherwise
$ML_w variable containing weight associated with observation or 1 if no weights specified

```

Method-lf evaluators can ignore \$ML\_samp, but restricting calculations to the \$ML\_samp==1 subsample will speed execution. Method-lf evaluators must ignore \$ML\_w; application of weights is handled by the method itself.

Methods `d0`, `d1`, `d2`, `lf0`, `lf1`, `lf2`, and `gf0` can ignore `$ML_samp` as long as `ml` model's `nopreserve` option is not specified. These methods will run more quickly if `nopreserve` is specified. These evaluators can ignore `$ML_w` only if they use `mlsum`, `mlvecsum`, `mlmatsum`, and `mlmatbysum` to produce all final results.

## Options

Options are presented under the following headings:

- Options for use with ml model in interactive or noninteractive mode*
- Options for use with ml model in noninteractive mode*
- Options for use when specifying equations*
- Options for use with ml search*
- Option for use with ml plot*
- Options for use with ml init*
- Options for use with ml maximize*
- Option for use with ml graph*
- Options for use with ml display*
- Options for use with mlevel*
- Option for use with mlsum*
- Option for use with mlvecsum*
- Option for use with mlmatsum*
- Options for use with mlmatbysum*
- Options for use with ml score*

### Options for use with ml model in interactive or noninteractive mode

`group(varname)` specifies the numeric variable that identifies groups. This option is typically used to identify panels for panel-data models.

`vce(vcetype)` specifies the type of standard error reported, which includes types that are robust to some kinds of misspecification (`robust`), that allow for intragroup correlation (`cluster clustvar`), and that are derived from asymptotic theory (`oim`, `opg`); see [R] [vce\\_option](#).

`vce(robust)`, `vce(cluster clustvar)`, `pweight`, and `svy` will work with evaluators of methods `lf`, `lf0`, `lf1`, `lf2`, and `gf0`; all you need to do is specify them.

These options will not work with evaluators of methods `d0`, `d1`, or `d2`, and specifying these options will produce an error message.

`constraints(numlist | matname)` specifies the linear constraints to be applied during estimation. `constraints(numlist)` specifies the constraints by number. Constraints are defined by using the `constraint` command; see [R] [constraint](#). `constraint(matname)` specifies a matrix that contains the constraints.

`nocnsnotes` prevents notes from being displayed when constraints are dropped. A constraint will be dropped if it is inconsistent, contradicts other constraints, or causes some other error when the constraint matrix is being built. Constraints are checked in the order in which they are specified.

`title(string)` specifies the title for the estimation output when results are complete.

`nopreserve` specifies that `ml` need not ensure that only the estimation subsample is in memory when the user-written likelihood evaluator is called. `nopreserve` is irrelevant when you use method `lf`.

For the other methods, if `nopreserve` is not specified, `ml` saves the data in a file (preserves the original dataset) and drops the irrelevant observations before calling the user-written evaluator. This way, even if the evaluator does not restrict its attentions to the `$ML_samp==1` subsample, results will still be correct. Later, `ml` automatically restores the original dataset.

ml need not go through these machinations for method lf because the user-written evaluator calculates observation-by-observation values, and ml itself sums the components.

ml goes through these machinations if and only if the estimation sample is a subsample of the data in memory. If the estimation sample includes every observation in memory, ml does not preserve the original dataset. Thus, programmers must not alter the original dataset unless they preserve the data themselves.

We recommend that interactive users of ml not specify nopreserve; the speed gain is not worth the possibility of getting incorrect results.

We recommend that programmers specify nopreserve, but only after verifying that their evaluator really does restrict its attentions solely to the \$ML\_samp==1 subsample.

collinear specifies that ml not remove the collinear variables within equations. There is no reason to leave collinear variables in place, but this option is of interest to programmers who, in their code, have already removed collinear variables and do not want ml to waste computer time checking again.

missing specifies that observations containing variables with missing values not be eliminated from the estimation sample. There are two reasons you might want to specify missing:

Programmers may wish to specify missing because, in other parts of their code, they have already eliminated observations with missing values and do not want ml to waste computer time looking again.

You may wish to specify missing if your model explicitly deals with missing values. Stata's heckman command is a good example of this. In such cases, there will be observations where missing values are allowed and other observations where they are not—where their presence should cause the observation to be eliminated. If you specify missing, it is your responsibility to specify an if exp that eliminates the irrelevant observations.

lf0( $\#_k$   $\#_{ll}$ ) is typically used by programmers. It specifies the number of parameters and log-likelihood value of the constant-only model so that ml can report a likelihood-ratio test rather than a Wald test. These values may have been analytically determined, or they may have been determined by a previous fitting of the constant-only model on the estimation sample.

Also see the continue option directly below.

If you specify lf0(), it must be safe for you to specify the missing option, too, else how did you calculate the log likelihood for the constant-only model on the same sample? You must have identified the estimation sample, and done so correctly, so there is no reason for ml to waste time rechecking your results. All of which is to say, do not specify lf0() unless you are certain your code identifies the estimation sample correctly.

lf0(), even if specified, is ignored if vce(robust), vce(cluster *clustvar*), pweight, or svy is specified because, in that case, a likelihood-ratio test would be inappropriate.

continue is typically specified by programmers and does two things:

First, it specifies that a model has just been fit by either ml or some other estimation command, such as logit, and that the likelihood value stored in e(l1) and the number of parameters stored in e(b) as of that instant are the relevant values of the constant-only model. The current value of the log likelihood is used to present a likelihood-ratio test unless vce(robust), vce(cluster *clustvar*), pweight, svy, or constraints() is specified. A likelihood-ratio test is inappropriate when vce(robust), vce(cluster *clustvar*), pweight, or svy is specified. We suggest using lrtest when constraints() is specified; see [R] lrtest.

Second, `continue` sets the initial values,  $\mathbf{b}_0$ , for the model about to be fit according to the `e(b)` currently stored.

The comments made about specifying missing with `lfl0()` apply equally well here.

`waldtest(#)` is typically specified by programmers. By default, `ml` presents a Wald test, but that is overridden if the `lfl0()` or `continue` option is specified. A Wald test is performed if `vce(robust)`, `vce(cluster clustvar)`, or `pweight` is specified.

`waldtest(0)` prevents even the Wald test from being reported.

`waldtest(-1)` is the default. It specifies that a Wald test be performed by constraining all coefficients except the intercept to 0 in the first equation. Remaining equations are to be unconstrained. A Wald test is performed if neither `lfl0()` nor `continue` was specified, and a Wald test is forced if `vce(robust)`, `vce(cluster clustvar)`, or `pweight` was specified.

`waldtest(k)` for  $k \leq -1$  specifies that a Wald test be performed by constraining all coefficients except intercepts to 0 in the first  $|k|$  equations; remaining equations are to be unconstrained. A Wald test is performed if neither `lfl0()` nor `continue` was specified, and a Wald test is forced if `vce(robust)`, `vce(cluster clustvar)`, or `pweight` was specified.

`waldtest(k)` for  $k \geq 1$  works like the options above, except that it forces a Wald test to be reported even if the information to perform the likelihood-ratio test is available and even if none of `vce(robust)`, `vce(cluster clustvar)`, or `pweight` was specified. `waldtest(k)`,  $k \geq 1$ , may not be specified with `lfl0()`.

`obs(#)` is used mostly by programmers. It specifies that the number of observations reported and ultimately stored in `e(N)` be `#`. Ordinarily, `ml` works that out for itself. Programmers may want to specify this option when, for the likelihood evaluator to work for  $N$  observations, they first had to modify the dataset so that it contained a different number of observations.

`crittype(string)` is used mostly by programmers. It allows programmers to supply a string (up to 32 characters long) that describes the criterion that is being optimized by `ml`. The default is "Log likelihood" for nonrobust and "Log pseudolikelihood" for robust estimation.

`svy` indicates that `ml` is to pick up the `svy` settings set by `svyset` and use the robust variance estimator. This option requires the data to be `svyset`; see [\[SVY\] svyset](#). `svy` may not be specified with `vce()` or `weights`.

`subpop(varname)` specifies that estimates be computed for the single subpopulation defined by the observations for which `varname`  $\neq$  0. Typically, `varname` = 1 defines the subpopulation, and `varname` = 0 indicates observations not belonging to the subpopulation. For observations whose subpopulation status is uncertain, `varname` should be set to missing (`.'`). This option requires the `svy` option.

`nosvyadjust` specifies that the model Wald test be carried out as  $W/k \sim F(k, d)$ , where  $W$  is the Wald test statistic,  $k$  is the number of terms in the model excluding the constant term,  $d$  is the total number of sampled PSUs minus the total number of strata, and  $F(k, d)$  is an  $F$  distribution with  $k$  numerator degrees of freedom and  $d$  denominator degrees of freedom. By default, an adjusted Wald test is conducted:  $(d - k + 1)W/(kd) \sim F(k, d - k + 1)$ . See [Korn and Graubard \(1990\)](#) for a discussion of the Wald test and the adjustments thereof. This option requires the `svy` option.

`technique(algorithm_spec)` specifies how the likelihood function is to be maximized. The following algorithms are currently implemented in `ml`. For details, see [Pitblado, Poi, and Gould \(2024\)](#).

`technique(nr)` specifies Stata's modified Newton–Raphson (NR) algorithm.

`technique(bhhh)` specifies the Berndt–Hall–Hall–Hausman (BHHH) algorithm.

`technique(dfpr)` specifies the Davidon–Fletcher–Powell (DFP) algorithm.

`technique(bfgs)` specifies the Broyden–Fletcher–Goldfarb–Shanno (BFGS) algorithm.

The default is `technique(nr)`.

You can switch between algorithms by specifying more than one in the `technique()` option. By default, `ml` will use an algorithm for five iterations before switching to the next algorithm. To specify a different number of iterations, include the number after the technique in the option. For example, `technique(bhhh 10 nr 1000)` requests that `ml` perform 10 iterations using the BHHH algorithm, followed by 1,000 iterations using the NR algorithm, and then switch back to BHHH for 10 iterations, and so on. The process continues until convergence or until reaching the maximum number of iterations.

`deriv(min_spec)` specifies whether to use minimum values of step sizes for computing numerical derivatives and optionally specifies the minimum values.

`deriv(nomin)`, the default, suppresses the use of minimum values.

`deriv(min)` sets the minimum step size to  $1e-6$  for computing first-order derivatives and  $1e-4$  for computing second-order derivatives.

`deriv(min(#1, #2))` sets the minimum step size to #<sub>1</sub> for computing the first-order derivatives and #<sub>2</sub> for computing the second-order derivatives. Specifying `deriv(min(1e-6, 1e-4))` is equivalent to specifying `deriv(min)`.

`deriv(min(matname))` sets the minimum step size to the values in the  $1 \times 2$  matrix *matname*. The value in the first column of the row vector will set the minimum step size for the first-order derivatives, and the value in the second column will set the minimum step size for the second-order derivatives.

## Options for use with `ml model` in noninteractive mode

The following extra options are for use with `ml model` in noninteractive mode. Noninteractive mode is for programmers who use `ml` as a subroutine and want to issue one command that will carry forth the estimation from start to finish.

`maximize` is required. It specifies noninteractive mode.

`init(ml_init_args)` sets the initial values,  $\mathbf{b}_0$ . *ml\_init\_args* are whatever you would type after the `ml init` command.

`search(on|norescale|quietly|off)` specifies whether `ml search` is to be used to improve the initial values. `search(on)` is the default and is equivalent to separately running `ml search, repeat(0)`. `search(norescale)` is equivalent to separately running `ml search, repeat(0) norescale`. `search(quietly)` is equivalent to `search(on)`, except that it suppresses `ml search`'s output. `search(off)` prevents calling `ml search`.

`repeat(#)` is `ml search`'s `repeat()` option. `repeat(0)` is the default.

`bounds(ml_search_bounds)` specifies the search bounds. *ml\_search\_bounds* is specified as

`[eqn_name] lower_bound upper_bound ... [eqn_name] lower_bound upper_bound`

for instance, `bounds(100 100 lnsigma 0 10)`. The `ml model` command issues `ml search ml_search_bounds, repeat(#)`. Specifying search bounds is optional.

`nowarning`, `novce`, `negh`, and `score()` are `ml maximize`'s equivalent options.

*maximize\_options*: `difficult`, `technique(algorithm_spec)`, `iterate(#)`, `[no]log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `ltolerance(#)`, `nrtolerance(#)`, `nonrtolerance`, and `from(init_specs)`; see [R] **Maximize**. These options are seldom used.

## Options for use when specifying equations

`noconstant` specifies that the equation not include an intercept.

`offset(varnameo)` specifies that the equation be  $\mathbf{xb} + \text{varname}_o$ —that it include `varnameo` with coefficient constrained to be 1.

`exposure(varnamee)` is an alternative to `offset(varnameo)`; it specifies that the equation be  $\mathbf{xb} + \ln(\text{varname}_e)$ . The equation is to include  $\ln(\text{varname}_e)$  with coefficient constrained to be 1.

`freeparm` specifies that the associated `eqname` is a free parameter. The corresponding full column name on `e(b)` will be `/eqname` instead of `eqname: _cons`. This option is not allowed with `varliste`.

## Options for use with ml search

`repeat(#)` specifies the number of random attempts that are to be made to find a better initial-value vector. The default is `repeat(10)`.

`repeat(0)` specifies that no random attempts be made. More precisely, `repeat(0)` specifies that no random attempts be made if the first initial-value vector is a feasible starting point. If it is not, `ml search` will make random attempts, even if you specify `repeat(0)`, because it has no alternative. The `repeat()` option refers to the number of random attempts to be made to improve the initial values. When the initial starting value vector is not feasible, `ml search` will make up to 1,000 random attempts to find starting values. It stops when it finds one set of values that works and then moves into its improve-initial-values logic.

`repeat(k)`,  $k > 0$ , specifies the number of random attempts to be made to improve the initial values.

`restart` specifies that random actions be taken to obtain starting values and that the resulting starting values not be a deterministic function of the current values. Generally, you should not specify this option because, with `restart`, `ml search` intentionally does not produce as good a set of starting values as it could. `restart` is included for use by the optimizer when it gets into serious trouble. The random actions ensure that the optimizer and `ml search`, working together, do not cause an endless loop.

`restart` implies `norescale`, which is why we recommend that you do not specify `restart`. In testing, sometimes `rescale` worked so well that, even after randomization, the rescaler would bring the starting values right back to where they had been the first time and thus defeat the intended randomization.

`norescale` specifies that `ml search` not engage in its rescaling actions to improve the parameter vector. We do not recommend specifying this option because rescaling tends to work so well.

*maximize\_options*: `[no]log` and `trace`; see [R] **Maximize**. These options are seldom used.

## Option for use with ml plot

`saving(filename[, replace])` specifies that the graph be saved in `filename.gph`.

See [G-3] *saving\_option*.

## Options for use with ml init

`copy` specifies that the list of numbers or the initialization vector be copied into the initial-value vector by position rather than by name.

`skip` specifies that any parameters found in the specified initialization vector that are not also found in the model be ignored. The default action is to issue an error message.

## Options for use with ml maximize

`nowarning` is allowed only with `iterate(0)`. `nowarning` suppresses the “convergence not achieved” message. Programmers might specify `iterate(0) nowarning` when they have a vector  $\mathbf{b}$  already containing the final estimates and want `ml` to calculate the variance matrix and postestimation results. Then, specify `init(b) search(off) iterate(0) nowarning nolog`.

`novce` is allowed only with `iterate(0)`. `novce` substitutes the zero matrix for the variance matrix, which in effect posts estimation results as fixed constants.

`negh` indicates that the evaluator returns the negative Hessian matrix. By default, `ml` assumes `d2` and `lf2` evaluators return the Hessian matrix.

`score(newvars | stub*)` creates new variables containing the contributions to the score for each equation and ancillary parameter in the model; see [U] 20.23 **Obtaining scores**.

If `score(newvars)` is specified, the `newvars` must contain  $k$  new variables. For evaluators of methods `lf`, `lf0`, `lf1`, and `lf2`,  $k$  is the number of equations. For evaluators of method `gf0`,  $k$  is the number of parameters. If `score(stub*)` is specified, variables named `stub1`, `stub2`, ..., `stubk` are created.

For evaluators of methods `lf`, `lf0`, `lf1`, and `lf2`, the first variable contains  $\partial \ln \ell_j / \partial (\mathbf{x}_{1j} \mathbf{b}_1)$ , the second variable contains  $\partial \ln \ell_j / \partial (\mathbf{x}_{2j} \mathbf{b}_2)$ , and so on.

For evaluators of method `gf0`, the first variable contains  $\partial \ln \ell_j / \partial \mathbf{b}_1$ , the second variable contains  $\partial \ln \ell_j / \partial \mathbf{b}_2$ , and so on.

`nooutput` suppresses display of results. This option is different from prefixing `ml maximize` with `quietly` in that the iteration log is still displayed (assuming that `nolog` is not specified).

`noskipline` suppresses display of a blank line before the iteration log. This is useful in programs when there is a header preceding the iteration log and a blank line is not wanted after the header.

`noclear` specifies that the `ml` problem definition not be cleared after the model has converged. Perhaps you are having convergence problems and intend to run the model to convergence. If so, use `ml search` to see if those values can be improved, and then restart the estimation.

`maximize_options`: `difficult`, `iterate(#)`, `[no]log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `ltolerance(#)`, `nrtolerance(#)`, and `nonrntolerance`; see [R] **Maximize**. These options are seldom used.

`display_options`; see *Options for use with ml display* below.

`eform_option`; see *Options for use with ml display* below.

## Option for use with ml graph

`saving(filename[, replace])` specifies that the graph be saved in `filename.gph`.

See [G-3] *saving\_option*.

## Options for use with ml display

- `noheader` suppresses the header display above the coefficient table that displays the final log-likelihood value, the number of observations, and the model significance test.
- `nofootnote` suppresses the footnote display below the coefficient table, which displays a warning if the model fit did not converge within the specified number of iterations. Use `ml footnote` to display the warning if 1) you add to the coefficient table using the `plus` option or 2) you have your own footnotes and want the warning to be last.
- `level(#)` is the standard confidence-level option. It specifies the confidence level, as a percentage, for confidence intervals of the coefficients. The default is `level(95)` or as set by `set level`; see [\[U\] 20.8 Specifying the width of confidence intervals](#).
- `first` displays a coefficient table reporting results for the first equation only, and the report makes it appear that the first equation is the only equation. This option is used by programmers who estimate ancillary parameters in the second and subsequent equations and who wish to report the values of such parameters themselves.
- `neq(#)` is an alternative to `first`. `neq(#)` displays a coefficient table reporting results for the first # equations. This option is used by programmers who estimate ancillary parameters in the # + 1 and subsequent equations and who wish to report the values of such parameters themselves.
- `showeqns` is a seldom-used option that displays the equation names in the coefficient table. `ml display` uses the numbers stored in `e(k_eq)` and `e(k_aux)` to determine how to display the coefficient table. `e(k_eq)` identifies the number of equations, and `e(k_aux)` identifies how many of these are for ancillary parameters. The `first` option is implied when `showeqns` is not specified and all but the first equation are for ancillary parameters.
- `plus` displays the coefficient table, but rather than ending the table in a line of dashes, ends it in dashes–plus–sign–dashes. This is so that programmers can write additional display code to add more results to the table and make it appear as if the combined result is one table. Programmers typically specify `plus` with the `first` or `neq()` options. This option implies `nofootnote`.
- `nocnsreport` suppresses the display of constraints above the coefficient table. This option is ignored if constraints were not used to fit the model.
- `noomitted` specifies that variables that were omitted because of collinearity not be displayed. The default is to include in the table any variables omitted because of collinearity and to label them as “(omitted)”.
- `vsquish` specifies that the blank space separating factor-variable terms or time-series–operated variables from other variables in the model be suppressed.
- `noemptycells` specifies that empty cells for interactions of factor variables not be displayed. The default is to include in the table interaction cells that do not occur in the estimation sample and to label them as “(empty)”.
- `baselevels` and `allbaselevels` control whether the base levels of factor variables and interactions are displayed. The default is to exclude from the table all base categories.
- `baselevels` specifies that base levels be reported for factor variables and for interactions whose bases cannot be inferred from their component factor variables.
- `allbaselevels` specifies that all base levels of factor variables and interactions be reported.
- `cformat(%fmt)` specifies how to format coefficients, standard errors, and confidence limits in the coefficient table.

`pformat(%fmt)` specifies how to format  $p$ -values in the coefficient table.

`sformat(%fmt)` specifies how to format test statistics in the coefficient table.

`no1stretch` specifies that the width of the coefficient table not be automatically widened to accommodate longer variable names. The default, `1stretch`, is to automatically widen the coefficient table up to the width of the Results window. Specifying `1stretch` or `no1stretch` overrides the setting given by `set 1stretch`. If `set 1stretch` has not been set, the default is `1stretch`.

`coeflegend` specifies that the legend of the coefficients and how to specify them in an expression be displayed rather than displaying the statistics for the coefficients.

*eform\_option*: `eform(string)`, `eform`, `hr`, `shr`, `irr`, `or`, and `rrr` display the coefficient table in exponentiated form: for each coefficient,  $\exp(b)$  rather than  $b$  is displayed, and standard errors and confidence intervals are transformed. *string* is the table header that will be displayed above the transformed coefficients and must be 11 characters or shorter in length—for example, `eform("Odds ratio")`. The options `eform`, `hr`, `shr`, `irr`, `or`, and `rrr` provide a default *string* equivalent to “exp(b)”, “Haz. ratio”, “SHR”, “IRR”, “Odds ratio”, and “RRR”, respectively. These options may not be combined.

`ml display` looks at `e(k_iform)` to determine how many equations are affected by an *eform\_option*; by default, only the first equation is affected. Type `ereturn list, all` to view `e(k_iform)`; see [P] [ereturn](#).

## Options for use with `mlevel`

`eq(#)` specifies the equation number,  $i$ , for which  $\theta_{ij} = \mathbf{x}_{ij}\mathbf{b}_i$  is to be evaluated. `eq(1)` is assumed if `eq()` is not specified.

`scalar` asserts that the  $i$ th equation is known to evaluate to a constant, meaning that the equation was specified as `()`, `(name:)`, or `/name` on the `ml model` statement. If you specify this option, the new variable created is created as a scalar. If the  $i$ th equation does not evaluate to a scalar, an error message is issued.

## Option for use with `mlsum`

`noweight` specifies that weights (`$ML_w`) be ignored when summing the likelihood function.

## Option for use with `mlvecsum`

`eq(#)` specifies the equation for which a gradient vector  $\partial \ln L / \partial \mathbf{b}_i$  is to be constructed. The default is `eq(1)`.

## Option for use with `mlmatsum`

`eq([#, #])` specifies the equations for which the Hessian matrix is to be constructed. The default is `eq(1)`, which is the same as `eq(1,1)`, which means  $\partial^2 \ln L / \partial \mathbf{b}_1 \partial \mathbf{b}'_1$ . Specifying `eq(i,j)` results in  $\partial^2 \ln L / \partial \mathbf{b}_i \partial \mathbf{b}'_j$ .

## Options for use with `mlmatbysum`

`by(varname)` is required and specifies the group variable.

`eq(#[, #])` specifies the equations for which the Hessian matrix is to be constructed. The default is `eq(1)`, which is the same as `eq(1, 1)`, which means  $\partial^2 \ln L / \partial \mathbf{b}_1 \partial \mathbf{b}'_1$ . Specifying `eq(i, j)` results in  $\partial^2 \ln L / \partial \mathbf{b}_i \partial \mathbf{b}'_j$ .

## Options for use with ml score

`equation(eqname)` identifies from which equation the observation scores are to come. This option may be used only when generating one variable.

`missing` specifies that observations containing variables with missing values not be eliminated from the estimation sample.

## Remarks and examples

For a thorough discussion of `ml`, see the fifth edition of *Maximum Likelihood Estimation with Stata* (Pitblado, Poi, and Gould 2024). The book provides a tutorial introduction to `ml`, notes on advanced programming issues, and a discourse on maximum likelihood estimation from both theoretical and practical standpoints. See *Survey options and ml* at the end of *Remarks and examples* for examples of the new `svy` options. For more information about survey estimation, see `[SVY] Survey`, `[SVY] svy estimation`, and `[SVY] Variance estimation`.

`ml` requires that you write a program that evaluates the log-likelihood function and, possibly, its first and second derivatives. The style of the program you write depends upon the method you choose. Methods `lf`, `lf0`, `d0`, and `gf0` require that your program evaluate the log likelihood only. Methods `d1` and `lf1` require that your program evaluate the log likelihood and its first derivatives. Methods `d2` and `lf2` requires that your program evaluate the log likelihood and its first and second derivatives. Methods `lf`, `lf0`, `d0`, and `gf0` differ from each other in that, with methods `lf` and `lf0`, your program is required to produce observation-by-observation log-likelihood values  $\ln \ell_j$  and it is assumed that  $\ln L = \sum_j \ln \ell_j$ ; with method `d0`, your program is required to produce only the overall value  $\ln L$ ; and with method `gf0`, your program is required to produce the summable pieces of the log likelihood, such as those in panel-data models.

Once you have written the program—called an evaluator—you define a model to be fit using `ml model` and obtain estimates using `ml maximize`. You might type

```
. ml model ...
. ml maximize
```

but we recommend that you type

```
. ml model ...
. ml check
. ml search
. ml maximize
```

`ml check` verifies your evaluator has no obvious errors, and `ml search` finds better initial values.

You fill in the `ml model` statement with 1) the method you are using, 2) the name of your program, and 3) the “equations”. You write your evaluator in terms of  $\theta_1, \theta_2, \dots$ , each of which has a linear equation associated with it. That linear equation might be as simple as  $\theta_i = b_0$ , it might be  $\theta_i = b_1 \text{mpg} + b_2 \text{weight} + b_3$ , or it might omit the intercept  $b_3$ . The equations are specified in parentheses on the `ml model` line.

Suppose that you are using method lf and the name of your evaluator program is myprog. The statement

```
. ml model lf myprog (mpg weight)
```

would specify one equation with  $\theta_i = b_1\text{mpg} + b_2\text{weight} + b_3$ . If you wanted to omit  $b_3$ , you would type

```
. ml model lf myprog (mpg weight, nocons)
```

and if all you wanted was  $\theta_i = b_0$ , you would type

```
. ml model lf myprog ()
```

With multiple equations, you list the equations one after the other; so, if you typed

```
. ml model lf myprog (mpg weight) ()
```

you would be specifying  $\theta_1 = b_1\text{mpg} + b_2\text{weight} + b_3$  and  $\theta_2 = b_4$ . You would write your likelihood in terms of  $\theta_1$  and  $\theta_2$ . If the model was linear regression,  $\theta_1$  might be the  $\mathbf{x}\mathbf{b}$  part and  $\theta_2$  the variance of the residuals.

When you specify the equations, you also specify any dependent variables. If you typed

```
. ml model lf myprog (price = mpg weight) ()
```

price would be the one and only dependent variable, and that would be passed to your program in  $\$ML\_y1$ . If your model had two dependent variables, you could type

```
. ml model lf myprog (price displ = mpg weight) ()
```

Then,  $\$ML\_y1$  would be price and  $\$ML\_y2$  would be displ. You can specify however many dependent variables are necessary and specify them on any equation. It does not matter on which equation you specify them; the first one specified is placed in  $\$ML\_y1$ , the second in  $\$ML\_y2$ , and so on.

### ▷ Example 1: Method lf

Using method lf, we want to produce observation-by-observation values of the log likelihood. The probit log-likelihood function is

$$\ln \ell_j = \begin{cases} \ln \Phi(\theta_{1j}) & \text{if } y_j = 1 \\ \ln \Phi(-\theta_{1j}) & \text{if } y_j = 0 \end{cases}$$

$$\theta_{1j} = \mathbf{x}_j \mathbf{b}_1$$

The following is the method-lf evaluator for this likelihood function:

```
program myprobit
 version 19.5 // (or version 19 if you do not have StataNow)
 args lnf theta1
 quietly replace `lnf' = ln(normal(`theta1')) if $ML_y1==1
 quietly replace `lnf' = ln(normal(-`theta1')) if $ML_y1==0
end
```

If we wanted to fit a model of foreign on mpg and weight, we would type the following commands. The 'foreign =' part specifies that  $y$  is foreign. The 'mpg weight' part specifies that  $\theta_{1j} = b_1\text{mpg}_j + b_2\text{weight}_j + b_3$ .

```
. use https://www.stata-press.com/data/r19/auto
(1978 automobile data)
. ml model lf myprobit (foreign = mpg weight)
. ml maximize
```

```
Initial: Log likelihood = -51.292891
Alternative: Log likelihood = -45.055272
Rescale: Log likelihood = -45.055272
Iteration 0: Log likelihood = -45.055272
Iteration 1: Log likelihood = -27.904125
Iteration 2: Log likelihood = -26.858643
Iteration 3: Log likelihood = -26.844199
Iteration 4: Log likelihood = -26.844189
Iteration 5: Log likelihood = -26.844189
```

```
Number of obs = 74
Wald chi2(2) = 20.75
Prob > chi2 = 0.0000
```

```
Log likelihood = -26.844189
```

| foreign | Coefficient | Std. err. | z     | P> z  | [95% conf. interval] |           |
|---------|-------------|-----------|-------|-------|----------------------|-----------|
| mpg     | -.1039503   | .0515689  | -2.02 | 0.044 | -.2050235            | -.0028772 |
| weight  | -.0023355   | .0005661  | -4.13 | 0.000 | -.003445             | -.0012261 |

◀

### ▷ Example 2: Method lf for two-equation, two-dependent-variable model

A two-equation, two-dependent-variable model is a little different. Rather than receiving one  $\theta$ , our program will receive two. Rather than there being one dependent variable in `$ML_y1`, there will be dependent variables in `$ML_y1` and `$ML_y2`. For instance, the Weibull regression log-likelihood function is

$$\ln \ell_j = -(t_j e^{-\theta_{1j}})^{\exp(\theta_{2j})} + d_j \{ \theta_{2j} - \theta_{1j} + (e^{\theta_{2j}} - 1)(\ln t_j - \theta_{1j}) \}$$

$$\theta_{1j} = \mathbf{x}_j \mathbf{b}_1$$

$$\theta_{2j} = s$$

where  $t_j$  is the time of failure or censoring and  $d_j = 1$  if failure and 0 if censored. We can make the log likelihood a little easier to program by introducing some extra variables:

$$p_j = \exp(\theta_{2j})$$

$$M_j = \{t_j \exp(-\theta_{1j})\}^{p_j}$$

$$R_j = \ln t_j - \theta_{1j}$$

$$\ln \ell_j = -M_j + d_j \{ \theta_{2j} - \theta_{1j} + (p_j - 1)R_j \}$$

The method-lf evaluator for this is

```

program myweib
 version 19.5 // (or version 19 if you do not have StataNow)
 args lnf theta1 theta2
 tempvar p M R
 quietly generate double `p' = exp(`theta2')
 quietly generate double `M' = ($ML_y1*exp(-`theta1'))^`p'
 quietly generate double `R' = ln($ML_y1)-`theta1'
 quietly replace `lnf' = -`M' + $ML_y2*(`theta2'-`theta1' + (`p'-1)*`R')
end

```

We can fit a model by typing

```

. ml model lf myweib (studytime died = i.drug age) ()
. ml maximize

```

Note that we specified `()` for the second equation. The second equation corresponds to the Weibull shape parameter  $s$ , and the linear combination we want for  $s$  contains just an intercept. Alternatively, we could type

```

. ml model lf myweib (studytime died = i.drug age) /s

```

Typing `/s` means the same thing as typing `(s : , freeparm)`. The `s`, either after a slash or in parentheses before a colon, labels the equation. The leading slash, `/`, is a shortcut for specifying that “ $s$ ” is a free parameter. Free parameters are labeled using this shortcut notation, `/s`, in the column names of `e(b)` and in the estimation results. If we instead specified `(s :)`, then `s` would be the equation label for a constant linear equation and would be labeled as `s : _cons` in the column names of `e(b)` and in the estimation results.

```

. use https://www.stata-press.com/data/r19/cancer, clear
(Patient survival in drug trial)
. ml model lf myweib (studytime died = i.drug age) /s
. ml maximize
Initial: Log likelihood = -744

◀

### ▷ Example 3: Method d0

Method-d0 evaluators receive  $\mathbf{b} = (\mathbf{b}_1, \mathbf{b}_2, \dots, \mathbf{b}_E)$ , the coefficient vector, rather than the already evaluated  $\theta_1, \theta_2, \dots, \theta_E$ , and they are required to evaluate the overall log-likelihood  $\ln L$  rather than  $\ln \ell_j, j = 1, \dots, N$ .

Use `mlevel` to produce the thetas from the coefficient vector.

Use `mlsum` to sum the components that enter into  $\ln L$ .

In the case of Weibull,  $\ln L = \sum \ln \ell_j$ , and our method-d0 evaluator is

```

program weib0
 version 19.5 // (or version 19 if you do not have StataNow)
 args todo b lnf
 tempvar theta1 theta2
 mlevel 'theta1' = 'b', eq(1)
 mlevel 'theta2' = 'b', eq(2)
 local t "$ML_y1" // this is just for readability
 local d "$ML_y2"
 tempvar p M R
 quietly generate double 'p' = exp('theta2')
 quietly generate double 'M' = ('t'*exp(-'theta1'))^'p'
 quietly generate double 'R' = ln('t')-'theta1'
 mlsum 'lnf' = -'M' + 'd'*('theta2'-'theta1' + ('p'-1)*'R')
end

```

To fit our model using this evaluator, we would type

```

. ml model d0 weib0 (studytime died = i.drug age) /s
. ml maximize

```

◀

## □ Technical note

Method d0 does not require  $\ln L = \sum_j \ln \ell_j$ ,  $j = 1, \dots, N$ , as method lf does. Your likelihood function might have independent components only for groups of observations. Panel-data estimators have a log-likelihood value  $\ln L = \sum_i \ln L_i$ , where  $i$  indexes the panels, each of which contains multiple observations. Conditional logistic regression has  $\ln L = \sum_k \ln L_k$ , where  $k$  indexes the risk pools. Cox regression has  $\ln L = \sum_{(t)} \ln L_{(t)}$ , where  $(t)$  denotes the ordered failure times.

To evaluate such likelihood functions, first calculate the within-group log-likelihood contributions. This usually involves `generate` and `replace` statements prefixed with `by`, as in

```

tempvar sumd
by group: generate double 'sumd' = sum($ML_y1)

```

Structure your code so that the log-likelihood contributions are recorded in the last observation of each group. Say that a variable is named `'cont'`. To sum the contributions, code

```

tempvar last
quietly by group: generate byte 'last' = (_n==_N)
mlsum 'lnf' = 'cont' if 'last'

```

You must inform `mlsum` which observations contain log-likelihood values to be summed. First, you do not want to include intermediate results in the sum. Second, `mlsum` does not skip missing values. Rather, if `mlsum` sees a missing value among the contributions, it sets the overall result, `'lnf'`, to missing. That is how `ml maximize` is informed that the likelihood function could not be evaluated at the particular value of `b`. `ml maximize` will then take action to escape from what it thinks is an infeasible area of the likelihood function.

When the likelihood function violates the linear-form restriction  $\ln L = \sum_j \ln \ell_j$ ,  $j = 1, \dots, N$ , with  $\ln \ell_j$  being a function solely of values within the  $j$ th observation, use method d0. In the following examples, we will demonstrate methods d1 and d2 with likelihood functions that meet this linear-form

restriction. The d1 and d2 methods themselves do not require the linear-form restriction, but the utility routines `mlvecsum` and `mlmatsum` do. Using method d1 or d2 when the restriction is violated is difficult; however, `mlmatbysum` may be of some help for method-d2 evaluators. □

#### ▷ Example 4: Method d1

Method-d1 evaluators are required to produce the gradient vector  $\mathbf{g} = \partial \ln L / \partial \mathbf{b}$ , as well as the overall log-likelihood value. Using `mlvecsum`, we can obtain  $\partial \ln L / \partial \mathbf{b}$  from  $\partial \ln L / \partial \theta_i$ ,  $i = 1, \dots, E$ . The derivatives of the Weibull log-likelihood function are

$$\frac{\partial \ln \ell_j}{\partial \theta_{1j}} = p_j (M_j - d_j)$$

$$\frac{\partial \ln \ell_j}{\partial \theta_{2j}} = d_j - R_j p_j (M_j - d_j)$$

The method-d1 evaluator for this is

```

program weib1
 version 19.5 // (or version 19 if you do not have StataNow)
 args todo b lnf g // g is new
 tempvar t1 t2
 mlevel 't1' = 'b', eq(1)
 mlevel 't2' = 'b', eq(2)
 local t "$ML_y1"
 local d "$ML_y2"
 tempvar p M R
 quietly generate double 'p' = exp('t2')
 quietly generate double 'M' = ('t'*exp(-'t1'))^'p'
 quietly generate double 'R' = ln('t')-'t1'
 mlsum 'lnf' = -'M' + 'd'*('t2'-'t1') + ('p'-1)*'R'
 if ('todo'==0 | 'lnf'>=.) exit /* <-- new */
 tempname d1 d2 /* <-- new */
 mlvecsum 'lnf' 'd1' = 'p'*('M'-'d'), eq(1) /* <-- new */
 mlvecsum 'lnf' 'd2' = 'd' - 'R'*'p'*('M'-'d'), eq(2) /* <-- new */
 matrix 'g' = ('d1','d2') /* <-- new */
end

```

We obtained this code by starting with our method-d0 evaluator and then adding the extra lines that method d1 requires. To fit our model using this evaluator, we could type

```

. ml model d1 weib1 (studytime died = drug2 drug3 age) /s
. ml maximize

```

but we recommend substituting `method d1debug` for `method d1` and typing

```

. ml model d1debug weib1 (studytime died = drug2 drug3 age) /s
. ml maximize

```

Method `d1debug` will compare the derivatives we calculate with numerical derivatives and thus verify that our program is correct. Once we are certain the program is correct, then we would switch from `method d1debug` to `method d1`. ◀

## ▶ Example 5: Method d2

Method-d2 evaluators are required to produce  $\mathbf{H} = \partial^2 \ln L / \partial \mathbf{b} \partial \mathbf{b}'$ , the Hessian matrix, as well as the gradient and log-likelihood value. `mlmatsum` will help calculate  $\partial^2 \ln L / \partial \mathbf{b} \partial \mathbf{b}'$  from the second derivatives with respect to  $\theta$ . For the Weibull model, these second derivatives are

$$\begin{aligned}\frac{\partial^2 \ln \ell_j}{\partial \theta_{1j}^2} &= -p_j^2 M_j \\ \frac{\partial^2 \ln \ell_j}{\partial \theta_{1j} \partial \theta_{2j}} &= p_j (M_j - d_j + R_j p_j M_j) \\ \frac{\partial^2 \ln \ell_j}{\partial \theta_{2j}^2} &= -p_j R_j (R_j p_j M_j + M_j - d_j)\end{aligned}$$

The method-d2 evaluator is

```

program weib2
 version 19.5 // (or version 19 if you do not have StataNow)
 args todo b lnf g H // H added

 tempvar t1 t2
 mlevel 't1' = 'b', eq(1)
 mlevel 't2' = 'b', eq(2)

 local t "$ML_y1"
 local d "$ML_y2"

 tempvar p M R
 quietly generate double 'p' = exp('t2')
 quietly generate double 'M' = ('t'*exp(-'t1'))^-'p'
 quietly generate double 'R' = ln('t')-'t1'

 mlsum 'lnf' = -'M' + 'd'*('t2'-'t1' + ('p'-1)*'R')
 if ('todo'==0 | 'lnf'>=.) exit

 tempname d1 d2
 mlvecsum 'lnf' 'd1' = 'p'*('M'-'d'), eq(1)
 mlvecsum 'lnf' 'd2' = 'd' - 'R'*'p'*('M'-'d'), eq(2)
 matrix 'g' = ('d1','d2')
 if ('todo'==1 | 'lnf'>=.) exit // new from here down

 tempname d11 d12 d22
 mlmatsum 'lnf' 'd11' = -'p'^2 * 'M', eq(1)
 mlmatsum 'lnf' 'd12' = 'p'*('M'-'d' + 'R'*'p'*'M'), eq(1,2)
 mlmatsum 'lnf' 'd22' = -'p'*'R'*('R'*'p'*'M' + 'M' - 'd'), eq(2)
 matrix 'H' = ('d11','d12' \ 'd12''','d22')
end

```

We started with our previous method-d1 evaluator and added the lines that method d2 requires. We could now fit a model by typing

```
. ml model d2 weib2 (studytime died = drug2 drug3 age) /s
. ml maximize
```

but we would recommend substituting method `d2debug` for method `d2` and typing

```
. ml model d2debug weib2 (studytime died = drug2 drug3 age) /s
. ml maximize
```

Method `d2debug` will compare the first and second derivatives we calculate with numerical derivatives and thus verify that our program is correct. Once we are certain the program is correct, then we would switch from method `d2debug` to method `d2`.

As we stated earlier, to produce the robust variance estimator with method `lf`, there is nothing to do except specify `vce(robust)`, `vce(cluster clustvar)`, or `pweight`. For methods `d0`, `d1`, and `d2`, these options do not work. If your likelihood function meets the linear-form restrictions, you can use methods `lf0`, `lf1`, and `lf2`, then these options will work. The equation scores are defined as

$$\frac{\partial \ln \ell_j}{\partial \theta_{1j}}, \frac{\partial \ln \ell_j}{\partial \theta_{2j}}, \dots$$

Your evaluator will be passed variables, one for each equation, which you fill in with the equation scores. For *both* method `lf1` and `lf2`, these variables are passed in the fourth and subsequent positions of the argument list. That is, you must process the arguments as

```
args todo b lnf g1 g2 ... H
```

Note that for method `lf1`, the ‘H’ argument is not used and can be ignored.

### ▷ Example 6: Robust variance estimates

If you have used `mlvecsum` in your evaluator of method `d1` or `d2`, it is easy to turn it into an evaluator of method `lf1` or `lf2` that allows the computation of the robust variance estimator. The expression that you specified on the right-hand side of `mlvecsum` is the equation score.

Here we turn the program that we gave earlier in the `method-d1` example into a `method-lf1` evaluator that allows `vce(robust)`, `vce(cluster clustvar)`, or `pweight`.

```
program weib1
 version 19.5 // (or version 19 if you do not have StataNow)
 args todo b lnfj g1 g2 // g1 and g2 are new
 tempvar t1 t2
 mlevel 't1' = 'b', eq(1)
 mlevel 't2' = 'b', eq(2)
 local t "$ML_y1"
 local d "$ML_y2"
 tempvar p M R
 quietly generate double 'p' = exp('t2')
 quietly generate double 'M' = ('t'*exp(-'t1'))^-'p'
 quietly generate double 'R' = ln('t')-'t1'
 quietly replace 'lnfj' = -'M' + 'd'*('t2'-'t1' + ('p'-1)*'R')
 if ('todo'==0) exit
 quietly replace 'g1' = 'p'*('M'-'d') /* <-- new */
 quietly replace 'g2' = 'd' - 'R'*'p'*('M'-'d') /* <-- new */
end
```

To fit our model and get the robust variance estimates, we type

```
. ml model lf1 weib1 (studytime died = drug2 drug3 age) /s, vce(robust)
. ml maximize
```

◀

## Survey options and ml

`ml` can handle stratification, poststratification, multiple stages of clustering, and finite population corrections. Specifying the `svy` option implies that the data come from a survey design and also implies that the survey linearized variance estimator is to be used; see [\[SVY\] Variance estimation](#).

## ▶ Example 7

Suppose that we are interested in a probit analysis of data from a survey in which  $q_1$  is the answer to a yes/no question and  $x_1, x_2, x_3$  are demographic responses. The following is a `lf2` evaluator for the probit model that meets the requirements for `vce(robust)` (linear form and computes the scores).

```

program mylf2probit
 version 19.5 // (or version 19 if you do not have StataNow)
 args todo b lnfj g1 H

 tempvar z Fz lnf
 mlevel 'z' = 'b'

 quietly generate double 'Fz' = normal('z') if $ML_y1 == 1
 quietly replace 'Fz' = normal(-'z') if $ML_y1 == 0
 quietly replace 'lnfj' = log('Fz')
 if ('todo'==0) exit

 quietly replace 'g1' = normalden('z')/'Fz' if $ML_y1 == 1
 quietly replace 'g1' = -normalden('z')/'Fz' if $ML_y1 == 0
 if ('todo'==1) exit

 mlmatsum 'lnf' 'H' = -'g1'*('g1'+ 'z'), eq(1,1)
end

```

To fit a model, we `svyset` the data, then use `svy` with `ml`.

```

. svyset psuid [pw=w], strata(strid)
. ml model lf2 mylf2probit (q1 = x1 x2 x3), svy
. ml maximize

```

We could also use the `subpop()` option to make inferences about the subpopulation identified by the variable `sub`:

```

. svyset psuid [pw=w], strata(strid)
. ml model lf2 mylf2probit (q1 = x1 x2 x3), svy subpop(sub)
. ml maximize

```

◀

## Stored results

For results stored by `ml` without the `svy` option, see [R] [Maximize](#).

For results stored by `ml` with the `svy` option, see [SVY] [svy](#).

## Methods and formulas

`ml` is implemented using `moptimize()`; see [M-5] [moptimize\(\)](#).

## Description

`mlexp` performs maximum likelihood estimation of models that satisfy the linear-form restrictions, that is, models for which you can write the log likelihood for an individual observation and for which the overall log likelihood is the sum of the individual observations' log likelihoods.

You express the observation-level log-likelihood function by using a substitutable expression. Unlike models fit using `ml`, you do not need to do any programming. However, `ml` can fit classes of models that cannot be fit by `mlexp`.

## Quick start

Linear regression of `y` on `x1` and `x2`

```
mlexp (ln(normalden(y, {xb: x1 x2 _cons}, {sigma})))
```

Same as above

```
mlexp (ln(normalden(y, {b0} + {b1}*x1 + {b2}*x2, {sigma})))
```

Same as above, and set initial values for `b2` and `sigma`

```
mlexp (ln(normalden(y, {b0} + {b1}*x1 + {b2=0.5}*x2, {sigma=3})))
```

Constrain `sigma` and the coefficient on `x1` to be positive

```
mlexp (ln(normalden(y, {b0} + exp({lnb1})*x1+{b2}*x2, exp({lnsigma}))))
nlcom (b1: exp(_b[lnb1:_cons])) (sigma: exp(_b[lnsigma:_cons]))
```

Omit observations with missing values for `y`, `x1`, or `x2`

```
mlexp (ln(normalden(y, {xb: x1 x2 _cons}, {sigma}))), variables(y x1 x2)
```

## Menu

Statistics > Other > Maximum likelihood estimation of expression

## Syntax

```
mlexp (lexp) [if] [in] [weight] [, options]
```

where *lexp* is a substitutable expression representing the log-likelihood function.

| <i>options</i>                                      | Description                                                                                                                                                                    |

| <code>collinear</code>                              | keep collinear variables                                                                                                                                                       |
| <code>coeflegend</code>                             | display legend instead of statistics                                                                                                                                           |

*lexp* and *dexp* may contain factor variables and time-series operators; see [U] 11.4.3 Factor variables and [U] 11.4.4 Time-series varlists.

`bayesboot`, `bootstrap`, `by`, `collect`, `jackknife`, `rolling`, `statsby`, and `svy` are allowed; see [U] 11.1.10 Prefix commands.

Weights are not allowed with the `bootstrap` prefix; see [R] `bootstrap`.

`aweights` are not allowed with the `jackknife` prefix; see [R] `jackknife`.

`vce()` and weights are not allowed with the `svy` prefix; see [SVY] `svy`.

`aweights`, `fweights`, `iweights`, and `pweights` are allowed; see [U] 11.1.6 `weight`.

`debug`, `collinear`, and `coeflegend` do not appear in the dialog box.

See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

*lexp* and *dexp* are substitutable expressions, Stata expressions that also contain parameters to be estimated. The parameters are enclosed in curly braces and must satisfy the naming requirements for variables; `{beta}` is an example of a parameter. The notation `{lc: varlist}` is allowed for linear combinations of multiple covariates and their parameters. For example, `{xb: mpg price turn _cons}` defines a linear combination of the variables `mpg`, `price`, `turn`, and `_cons` (the constant term). See *Substitutable expressions* under *Remarks and examples* below.

## Options

### Model

`variables(varlist)` specifies the variables in the model. `mlexp` excludes observations for which any of these variables has missing values. If you do not specify `variables()`, then `mlexp` assumes all observations are valid. `mlexp` will exit with an error message if the log likelihood cannot be calculated at the initial values for any observation.

`from(initial_values)` specifies the initial values to begin the estimation. You can specify parameter names and values, or you can specify a  $1 \times k$  matrix, where  $k$  is the number of parameters in the model. For example, to initialize `alpha` to 1.23 and `delta` to 4.57, you would type

```
mlexp ..., from(alpha=1.23 delta=4.57) ...
```

or equivalently

```
matrix define initval = (1.23, 4.57)
mlexp ..., from(initval) ...
```

Initial values declared in the `from()` option override any that are declared within substitutable expressions. If you specify a parameter that does not appear in your model, `mlexp` exits with an error. If you specify a matrix, the values must be in the same order in which the parameters are declared in your model.

`constraints(numlist)`; see [R] [Estimation options](#).

### Derivatives

`derivative(/name = dexp)` specifies the derivative of the observation-level log-likelihood function with respect to parameter *name*. If you wish to specify analytic derivatives, you must specify `derivative()` for each parameter in your model.

*dexp* uses the same substitutable expression syntax as is used to specify the log-likelihood function. If you declare a linear combination in the log-likelihood function, you provide the derivative for the linear combination; `mlexp` then applies the chain rule for you. See [Specifying derivatives](#) under *Remarks and examples* for examples.

If you do not specify the `derivative()` option, `mlexp` calculates derivatives numerically.

### SE/Robust

`vce(vcetype)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory (`oim`, `opg`), that are robust to some kinds of misspecification (`robust`), that allow for intragroup correlation (`cluster clustvar`), and that use bootstrap or jackknife methods (`bootstrap`, `jackknife`); see [R] [vce\\_option](#).

### Reporting

`level(#)`; see [R] [Estimation options](#).

`title(string)` specifies an optional title that will be displayed just above the table of parameter estimates.

`title2(string)` specifies an optional subtitle that will be displayed between the title specified in `title()` and the table of parameter estimates. If `title2()` is specified but `title()` is not, then `title2()` has the same effect as `title()`.

*display\_options*: `nocl`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `no1stretch`; see [R] [Estimation options](#).

#### Maximization

*maximize\_options*: `difficult`, `technique(algorithm_spec)`, `iterate(#)`, `[no]log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `ltolerance(#)`, `nrtolerance(#)`, and `nonrtolerance`; see [R] [Maximize](#). These options are seldom used.

The following options are available with `mlexp` but are not shown in the dialog box:

`debug` specifies that differences between the numerically computed gradient and the gradient computed from your derivative expression are reported at each iteration. This option is only allowed with the `derivative()` option.

`collinear`, `coeflegend`; see [R] [Estimation options](#).

## Remarks and examples

Remarks are presented under the following headings:

- [Introduction](#)
- [Substitutable expressions](#)
- [Parameter interpretation using margins](#)
- [Parameter constraints](#)
- [Specifying derivatives](#)

## Introduction

`mlexp` performs maximum likelihood estimation of models that satisfy the linear-form restrictions, that is, models for which you can write the log likelihood for a single observation and for which the overall log likelihood is the sum of the individual observations' log likelihoods. Models designed for use with cross-sectional data usually meet the linear-form restrictions, including linear regression, many discrete choice models, limited-dependent-variable models, and selection models. Examples of models that do not satisfy the linear-form restrictions are random-effects panel-data models (because the likelihood function is defined at the panel level) and Cox proportional hazards models (because the likelihood function is defined for risk sets).

Because of its straightforward syntax and accessibility from the menu system, `mlexp` is particularly suited to users who are new to Stata and to those using Stata for pedagogical purposes. You specify the log-likelihood function that `mlexp` is to maximize by using [substitutable expressions](#) that are similar to those used by `nl`, `nlSUR`, and `gmm`. `mlexp` allows you to avoid the programming requirements of `m1`. However, `m1` can fit classes of models that cannot be fit by `mlexp`, including those that do not meet the linear-form restrictions. See [Pitblado, Poi, and Gould \(2024, chap. 2\)](#) for examples using `mlexp` and for further discussion of the advantages of both `mlexp` and `m1`.

## Substitutable expressions

Substitutable expressions allow you to distinguish between variables and parameters. There are three rules to follow when defining substitutable expressions:

1. Parameters of the model are bound in curly braces: `{b0}`, `{param}`, etc. Parameter names must follow the same conventions as variable names; see [\[U\] 11.3 Naming conventions](#).
2. Initial values for parameters are given by including an equal sign and the initial value inside the curly braces: `{b0=1}`, `{param=3.571}`, etc.
3. Linear combinations of variables can be included using the notation `{lc:varlist}`: `{xb: mpg price weight _cons}`, `{score: w x z}`, etc. Parameters of linear combinations are initialized to zero.

Substitutable expressions can include any mathematical expression involving scalars and variables. See [\[U\] 13.2 Operators](#) and [\[U\] 13.3 Functions](#) for more information on expressions.

### ► Example 1: The gamma density function

In an extract of the March 2014 Current Population Survey downloaded from Integrated Public Use Microdata Series (IPUMS), `wage` contains the wage and salary income earned in tens of thousands of dollars per year for working individuals; see [King et al. \(2010\)](#). We want to model `wage` using the two-parameter gamma distribution with shape parameter  $\alpha$  and rate parameter  $\beta$ . The density function for  $y > 0$  is

$$f(y) = \frac{\beta^\alpha}{\Gamma(\alpha)} y^{\alpha-1} \exp(-\beta y) \quad \beta > 0, \alpha > 0$$

so that the log likelihood for the  $i$ th observation is

$$\ln(\ell_i) = \alpha \ln(\beta) - \ln\{\Gamma(\alpha)\} + (\alpha - 1) \ln(y_i) - \beta y_i$$

To fit `wage` to the two-parameter gamma distribution, we let `a` be the parameter name that conforms to Stata naming conventions for  $\alpha$  and `b` be the parameter name for  $\beta$ . We enclose both in `{}` in our substitutable expression for the log-likelihood function:

```
. use https://www.stata-press.com/data/r19/cpswage
. mlexp ({a}*ln({b}) - lngamma({a}) + ({a}-1)*ln(wage) - {b}*wage)
Initial: Log likelihood = -<inf> (could not be evaluated)
Feasible: Log likelihood = -239367.36
Rescale: Log likelihood = -228037.02
Rescale eq: Log likelihood = -163560.64
Iteration 0: Log likelihood = -163560.64
Iteration 1: Log likelihood = -162820.41
Iteration 2: Log likelihood = -162808.55
Iteration 3: Log likelihood = -162808.55

Maximum likelihood estimation
Log likelihood = -162808.55 Number of obs = 64,748
```

|    | Coefficient | Std. err. | z      | P> z  | [95% conf. interval] |          |
|----|-------------|-----------|--------|-------|----------------------|----------|
| /a | 1.097287    | .0054134  | 202.70 | 0.000 | 1.086677             | 1.107897 |
| /b | .2406718    | .0014917  | 161.34 | 0.000 | .2377482             | .2435954 |

Because we did not specify initial values, mlexp initialized  $\alpha$  and  $\beta$  to be 0. When both parameters are 0, the log-likelihood function cannot be evaluated, because  $\ln(0)$  is undefined. Therefore, in the iteration log above the coefficient table, we see that mlexp reported the initial log likelihood to be  $-\infty$  (could not be evaluated). When this occurs, mlexp uses a search routine to find alternative initial values that do allow the log-likelihood function to be calculated.

We now initialize a to 1 and b to 0.1 the first time that we type them within the substitutable expression:

```
. mlexp ({a=1}*ln({b=.1}) - lngamma({a}) + ({a}-1)*ln(wage) - {b}*wage)
Initial: Log likelihood = -178608.12
Rescale: Log likelihood = -178608.12
Rescale eq: Log likelihood = -173389.94
Iteration 0: Log likelihood = -173389.94
Iteration 1: Log likelihood = -163081.69
Iteration 2: Log likelihood = -162813.54
Iteration 3: Log likelihood = -162808.55
Iteration 4: Log likelihood = -162808.55

Maximum likelihood estimation
Log likelihood = -162808.55 Number of obs = 64,748
```

|    | Coefficient | Std. err. | z      | P> z  | [95% conf. interval] |          |
|----|-------------|-----------|--------|-------|----------------------|----------|
| /a | 1.097287    | .0054134  | 202.70 | 0.000 | 1.086677             | 1.107897 |
| /b | .2406719    | .0014917  | 161.34 | 0.000 | .2377483             | .2435955 |

Even when mlexp can find alternative initial values, specifying your own values facilitates optimization.

By default, initial values of parameters are set to zero, and mlexp performs an iterative search for optimum starting values before beginning maximization. If mlexp cannot find initial parameter values for which it can calculate the log-likelihood function, it will exit with an error message. Restricting the sample or specifying starting values solves this problem.

Use the `variables()` option, an *if* qualifier, or an *in* qualifier to restrict the sample. You can also specify initial values by using the `from()` option or within the substitutable expression by including an equal sign and the initial value after the parameter. If you specify initial values by using `from()`, they

override whatever initial values are given within the substitutable expression. Regardless of whether you specify initial values, mlexp performs a search procedure for better starting values before commencing the first iteration of the maximization routine.

▷ Example 2: Linear combinations of covariates

We frequently want to model the parameters as linear combinations of variables. Continuing [example 1](#), we see that the mean of the two-parameter gamma distribution is  $E(y) = \alpha/\beta$ . By letting  $\alpha = a_1 \text{age} + a_0$ , we model the mean of wage conditional on age as  $E(\text{wage}|\text{age}) = (a_1 \text{age} + a_0)/\beta$ . Below, we specify {a: age \_cons} to model a as a linear combination of age and a constant term.

```
. mlexp ({a:age _cons}*ln({b=.1})-lngamma({a:})+({a:}-1)*ln(wage)-{b}*wage)
Initial: Log likelihood = -<inf> (could not be evaluated)
Feasible: Log likelihood = -239367.36
Rescale: Log likelihood = -228037.02
Rescale eq: Log likelihood = -163560.64
Iteration 0: Log likelihood = -163560.64
Iteration 1: Log likelihood = -160123.65
Iteration 2: Log likelihood = -159838.42
Iteration 3: Log likelihood = -159838.38
Iteration 4: Log likelihood = -159838.38

Maximum likelihood estimation
Log likelihood = -159838.38 Number of obs = 64,748
```

|          | Coefficient | Std. err. | z      | P> z  | [95% conf. interval] |          |
|----------|-------------|-----------|--------|-------|----------------------|----------|
| <b>a</b> |             |           |        |       |                      |          |
| age      | .0194396    | .0002689  | 72.31  | 0.000 | .0189126             | .0199665 |
| _cons    | .4108355    | .0096791  | 42.45  | 0.000 | .3918647             | .4298062 |
| /b       | .2667954    | .0016423  | 162.45 | 0.000 | .2635765             | .2700142 |

The notation {a: age \_cons} indicates to mlexp that you want a linear combination of the variable age and a constant term. We named the linear combination a, so mlexp names the parameters a:age and a:\_cons, respectively.

Once you have declared a linear combination, you can subsequently refer to the linear combination by specifying its name and a colon inside curly braces, as we did in this example. You cannot use the same name for both an individual parameter and a linear combination. However, after a linear combination has been declared, you can refer to the parameter of an individual variable within that linear combination by using the notation {lc: z}, where lc is the name of the linear combination, and z is the variable whose parameter you want to reference.

▷ Example 3: Linear combinations of factor variables

Factor variables and time-series operated variables can be included in a varlist defining a linear combination. Continuing [example 2](#), we want to allow different intercepts for males and females in  $\alpha$ , and we want different  $\beta$  parameters for males and females. We implement this model below by including `ibn.female` in each linear combination using [factor-variable](#) notation.

```
. mlexp ({a:age ibn.female}*ln({b:ibn.female}) - lngamma({a:}) +
> ({a:}-1)*ln(wage) - {b:}*wage)
Initial: Log likelihood = -<inf> (could not be evaluated)
Feasible: Log likelihood = -239367.36
Rescale: Log likelihood = -228037.02
Rescale eq: Log likelihood = -163560.64
Iteration 0: Log likelihood = -163560.64
Iteration 1: Log likelihood = -158999.51
Iteration 2: Log likelihood = -158135.16
Iteration 3: Log likelihood = -158130.94
Iteration 4: Log likelihood = -158130.93
Maximum likelihood estimation
Log likelihood = -158130.93 Number of obs = 64,748
```

|          | Coefficient | Std. err. | z      | P> z  | [95% conf. interval] |          |
|----------|-------------|-----------|--------|-------|----------------------|----------|
| <b>a</b> |             |           |        |       |                      |          |
| age      | .020543     | .0002781  | 73.88  | 0.000 | .019998              | .0210881 |
| female   |             |           |        |       |                      |          |
| Male     | .3917619    | .0111697  | 35.07  | 0.000 | .3698696             | .4136542 |
| Female   | .4475977    | .0116285  | 38.49  | 0.000 | .4248063             | .4703892 |
| <b>b</b> |             |           |        |       |                      |          |
| female   |             |           |        |       |                      |          |
| Male     | .2279862    | .0018677  | 122.07 | 0.000 | .2243256             | .2316468 |
| Female   | .3600628    | .0030156  | 119.40 | 0.000 | .3541523             | .3659733 |

## Parameter interpretation using margins

The `margins` command can be used after `mlexp` to estimate the effect of a covariate from a set of parameter estimates. The estimated covariate effects can be conditional on the other covariates or population-averaged effects that average out the other covariates.

### ▶ Example 4

Continuing [example 3](#), we use `margins` to estimate the average wage if everyone in the sample were male and if everyone in the sample were female. The `expression()` option is used to specify the formula for the mean. Wages, measured in tens of thousands of dollars, have a gamma distribution, so the mean is a ratio of the  $\alpha$  and  $\beta$  parameters. The linear prediction is specified in the expression with `xb()`.

```
. margins i.female, expression(xb(a)/xb(b))
Predictive margins Number of obs = 64,748
Model VCE: OIM
Expression: xb(a)/xb(b)
```

|        | Delta-method |           |        |       | [95% conf. interval] |          |
|--------|--------------|-----------|--------|-------|----------------------|----------|
|        | Margin       | std. err. | z      | P> z  |                      |          |
| female |              |           |        |       |                      |          |
| Male   | 5.452281     | .0267573  | 203.77 | 0.000 | 5.399838             | 5.504724 |
| Female | 3.607372     | .0178778  | 201.78 | 0.000 | 3.572332             | 3.642412 |

When everyone is male, the estimated average wage is 5.45; when everyone is female, the estimated average wage is 3.61.

## Parameter constraints

### ▷ Example 5

In examples 1, 2, and 3, we were lucky. The two-parameter gamma density function is defined only when both  $\alpha$  and  $\beta$  are positive. However, mlexp does not know this; when maximizing the log-likelihood function, it will consider all real values for the parameters. Also recall from above, mlexp will exit with an error message if it cannot find parameter values that produce nonmissing values for the likelihood for each sample observation.

We could reparameterize our model so that we avoid having to directly estimate parameters that are restricted. For example, consider the parameter  $\alpha > 0$ , and suppose we define the new parameter  $\theta = \ln(\alpha)$  so that  $\alpha = \exp(\theta)$ . With this parameterization, for any real value of  $\theta$  that mlexp might try to use when evaluating the log-likelihood function,  $\alpha$  is guaranteed to be positive. Below we apply this parameterization to the model in example 1.

```
. mlexp (exp({lna})*{lnb} - lngamma(exp({lna}))
> + (exp({lna})-1)*ln(wage) - exp({lnb})*wage)
Initial: Log likelihood = -295203.41
Alternative: Log likelihood = -249215.67
Rescale: Log likelihood = -230376.58
Rescale eq: Log likelihood = -166588.81
Iteration 0: Log likelihood = -166588.81
Iteration 1: Log likelihood = -162845.95
Iteration 2: Log likelihood = -162808.56
Iteration 3: Log likelihood = -162808.55
Iteration 4: Log likelihood = -162808.55
Maximum likelihood estimation
Log likelihood = -162808.55 Number of obs = 64,748
```

|      | Coefficient | Std. err. | z       | P> z  | [95% conf. interval] |           |
|------|-------------|-----------|---------|-------|----------------------|-----------|
| /lna | .0928409    | .0049334  | 18.82   | 0.000 | .0831716             | .1025103  |
| /lnb | -1.424321   | .0061979  | -229.81 | 0.000 | -1.436469            | -1.412173 |

We can use `nlcom` to obtain the back-transformed parameter estimates, but first we need to know how to refer to the parameters estimated by `mlexp`. We can replay the results and request the coefficient legend.

```
. mlexp, coeflegend
Maximum likelihood estimation
Log likelihood = -162808.55 Number of obs = 64,748
```

|      | Coefficient | Legend        |
|------|-------------|---------------|
| /lna | .0928409    | _b[lna:_cons] |
| /lnb | -1.424321   | _b[lnb:_cons] |

Now, we see that we can refer to `_b[lna:_cons]` and `_b[lnb:_cons]` in `nlcom`.

```
. nlcom (a: exp(_b[lna:_cons])) (b: exp(_b[lnb:_cons]))
 a: exp(_b[lna:_cons])
 b: exp(_b[lnb:_cons])
```

|   | Coefficient | Std. err. | z      | P> z  | [95% conf. interval] |          |
|---|-------------|-----------|--------|-------|----------------------|----------|
| a | 1.097287    | .0054134  | 202.70 | 0.000 | 1.086677             | 1.107897 |
| b | .2406718    | .0014917  | 161.34 | 0.000 | .2377482             | .2435954 |

The optimal value of the log-likelihood function and the back-transformed parameter estimates match those reported in [example 1](#).

However, when you impose nonlinear constraints on linear combinations of covariates, you change the model. These nonlinear constraints change the model because they are not invertible functions of the original parameters. For example, we can use the exponential function to ensure  $\alpha > 0$  and  $\beta > 0$  in the model from [example 3](#).

```
. mlexp (exp({a:age ibn.female})*{b:ibn.female} - lngamma(exp({a:}))
> + (exp({a:})-1)*ln(wage) - exp({b:})*wage)
Initial: Log likelihood = -295203.41
Alternative: Log likelihood = -249215.67
Rescale: Log likelihood = -230376.58
Rescale eq: Log likelihood = -166588.81
Iteration 0: Log likelihood = -166588.81
Iteration 1: Log likelihood = -160273.12
Iteration 2: Log likelihood = -158868.39
Iteration 3: Log likelihood = -158864.02
Iteration 4: Log likelihood = -158864.02
Maximum likelihood estimation
Log likelihood = -158864.02 Number of obs = 64,748
```

|          | Coefficient | Std. err. | z       | P> z  | [95% conf. interval] |           |
|----------|-------------|-----------|---------|-------|----------------------|-----------|
| <b>a</b> |             |           |         |       |                      |           |
| age      | .0126713    | .0001785  | 70.98   | 0.000 | .0123214             | .0130212  |
| female   |             |           |         |       |                      |           |
| Male     | -.3470203   | .009978   | -34.78  | 0.000 | -.3665769            | -.3274638 |
| Female   | -.3177398   | .0103376  | -30.74  | 0.000 | -.338001             | -.2974786 |
| <b>b</b> |             |           |         |       |                      |           |
| female   |             |           |         |       |                      |           |
| Male     | -1.502222   | .0085431  | -175.84 | 0.000 | -1.518966            | -1.485478 |
| Female   | -1.059358   | .0087602  | -120.93 | 0.000 | -1.076528            | -1.042189 |

The value of the log-likelihood function is now  $-158,864.02$ , which is less than the value  $-158,130.93$ , which was reported in [example 3](#). The constrained parameterization that keeps  $\alpha > 0$  and  $\beta > 0$  has changed the model, and the optimal value of the log-likelihood function in the constrained model is less than the optimal value in the unconstrained model.

Because neither the unconstrained nor the constrained parameterization generates missing predicted values for  $\alpha$  or  $\beta$ , we can choose between them. However, if any of the predicted values for  $\alpha$  or  $\beta$  produce missing values for the log-likelihood function using the unconstrained parameterization, we could not compute the log-likelihood function for the unconstrained parameterization, and we would have to use a constrained parameterization.

## Specifying derivatives

By default, `mlexp` calculates derivatives of the log-likelihood function numerically using an algorithm that produces accurate results. However, `mlexp` will fit your model more quickly (and even more accurately) if you specify analytic derivatives.

You specify derivatives by using substitutable expressions in much the same way as you specify the log-likelihood function. If you specify a linear combination in your log-likelihood function, then you supply a derivative with respect to that linear combination; `mlexp` then uses the chain rule to obtain the derivatives with respect to the individual parameters.

We will illustrate how to specify derivatives using the probit model for dichotomous outcomes. The log-likelihood function for the probit model is often written as

$$\ln \ell_i = \begin{cases} \ln \Phi(\mathbf{x}'_i \boldsymbol{\beta}) & y_i = 1 \\ \ln \Phi(-\mathbf{x}'_i \boldsymbol{\beta}) & y_i = 0 \end{cases}$$

using the fact that  $1 - \Phi(\mathbf{x}'_i \boldsymbol{\beta}) = \Phi(-\mathbf{x}'_i \boldsymbol{\beta})$ , where  $\Phi(\cdot)$  is the cumulative standard normal distribution function. If we use the trick suggested by [Greene \(2018, 742, fn. 16\)](#), we can simplify the log-likelihood function, making the derivative calculation easier. Let  $q_i = 2y_i - 1$ . Then, we can write the log-likelihood function as

$$\ln \ell_i = \ln \Phi(q_i \mathbf{x}'_i \boldsymbol{\beta})$$

and the first derivative as

$$\frac{\partial \ln \ell_i}{\partial \boldsymbol{\beta}} = \frac{q_i \phi(q_i \mathbf{x}'_i \boldsymbol{\beta})}{\Phi(q_i \mathbf{x}'_i \boldsymbol{\beta})} \mathbf{x}_i$$

### ► Example 6: Probit with a linear combination

Now, let's fit a probit model of the indicator for whether an individual is below the official poverty level of `fpov` on `age`, `female`, and a constant. We could specify the parameters and independent variables individually, but we will use a linear combination instead. First, note that

$$\frac{\partial \ln \ell_i}{\partial \mathbf{x}'_i \boldsymbol{\beta}} = \frac{q_i \phi(q_i \mathbf{x}'_i \boldsymbol{\beta})}{\Phi(q_i \mathbf{x}'_i \boldsymbol{\beta})}$$

When you specify a linear combination of variables, you specify the derivative with respect to the linear combination. That way, if you change the variables in the linear combination, you do not need to change the derivative. To see why this is the case, consider the function  $f(\mathbf{x}'_i \boldsymbol{\beta})$ , where  $\mathbf{x}'_i \boldsymbol{\beta}$  is a linear combination. Then, using the chain rule, we see that

$$\frac{\partial f(\mathbf{x}'_i \boldsymbol{\beta})}{\partial \beta_j} = \frac{\partial f(\mathbf{x}'_i \boldsymbol{\beta})}{\partial \mathbf{x}'_i \boldsymbol{\beta}} \times \frac{\partial \mathbf{x}'_i \boldsymbol{\beta}}{\partial \beta_j} = \frac{\partial f(\mathbf{x}'_i \boldsymbol{\beta})}{\partial \mathbf{x}'_i \boldsymbol{\beta}} \times x_{ij}$$

Once the derivative with respect to the linear combination is known, `mlexp` can then multiply it by each of the variables in the linear combination to get the full set of derivatives with respect to the parameters needed to maximize the likelihood function. Moreover, the derivative with respect to the linear combination does not depend on the variables within the linear combination, so even if you change the variables in it, you will not need to modify the specification of the corresponding `derivative()` option.

We type

```
. generate int q = 2*offpov - 1
. mlexp (ln(normal(q*({xb:age i.female _cons}))))
> deriv(/xb = q*normalden(q*{xb:})/normal(q*{xb:}))
Initial: Log likelihood = -44879.894
Alternative: Log likelihood = -27407.718
Rescale: Log likelihood = -17888.147
Iteration 0: Log likelihood = -17888.147
Iteration 1: Log likelihood = -15805.22
Iteration 2: Log likelihood = -15427.598
Iteration 3: Log likelihood = -15427.04
Iteration 4: Log likelihood = -15427.04

Maximum likelihood estimation
Log likelihood = -15427.04 Number of obs = 64,748
```

|        | Coefficient | Std. err. | z      | P> z  | [95% conf. interval] |           |
|--------|-------------|-----------|--------|-------|----------------------|-----------|
| xb     |             |           |        |       |                      |           |
| age    | -.0179139   | .0005852  | -30.61 | 0.000 | -.0190608            | -.016767  |
| female |             |           |        |       |                      |           |
| Female | .1514014    | .0154565  | 9.80   | 0.000 | .1211072             | .1816955  |
| _cons  | -.8773462   | .0244956  | -35.82 | 0.000 | -.9253567            | -.8293357 |

After defining *q*, we specified the log-likelihood function using *q* and the linear combination *xb*. We also use *xb* in specifying the derivative.

## Stored results

mlexp stores the following in *e()*:

### Scalars

- e(N)*                    number of observations
- e(k)*                    number of parameters
- e(k\_aux)*                number of ancillary parameters
- e(k\_eq)*                 number of equations in *e(b)*
- e(k\_eq\_model)*         number of equations in overall model test
- e(df\_m)*                 model degrees of freedom
- e(ll)*                    log likelihood
- e(N\_clust)*              number of clusters
- e(rank)*                 rank of *e(V)*
- e(ic)*                    number of iterations
- e(rc)*                    return code
- e(converged)*          1 if converged, 0 otherwise

### Macros

- e(cmd)*                    mlexp
- e(cmdline)*              command as typed
- e(lexp)*                  likelihood expression
- e(wtype)*                 weight type
- e(wexp)*                 weight expression
- e(usrtitle)*              user-specified title
- e(usrtitle2)*            user-specified secondary title
- e(clustvar)*              name of cluster variable
- e(vce)*                    *vcetype* specified in *vce()*
- e(vcetype)*              title used to label Std. err.

| e(asobserved)      | factor variables <code>fvset</code> as <code>asobserved</code>           |
| Matrices           |                                                                          |
| e(b)               | coefficient vector                                                       |
| e(Cns)             | constraints matrix                                                       |
| e(ilog)            | iteration log (up to 20 iterations)                                      |
| e(init)            | initial values                                                           |
| e(gradient)        | gradient vector                                                          |
| e(V)               | variance–covariance matrix of the estimators                             |
| e(V_modelbased)    | model-based variance                                                     |
| Functions          |                                                                          |
| e(sample)          | marks estimation sample                                                  |

1. Type `ereturn list, all` to view these results; see [P] [return](#).

In addition to the above, the following is stored in `r()`:

|          |                                                                                                                            |
|----------|----------------------------------------------------------------------------------------------------------------------------|
| Matrices |                                                                                                                            |
| r(table) | matrix containing the coefficients with their standard errors, test statistics, <i>p</i> -values, and confidence intervals |

Note that results stored in `r()` are updated when the command is replayed and will be replaced when any *r*-class command is run after the estimation command.

## Methods and formulas

Optimization is carried out using `moptimize()`; see [M-5] [moptimize\(\)](#).

## Postestimation commands

The following postestimation commands are available after `mlexp`:

| Command                      | Description                                                                                                                             |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <code>contrast</code>        | contrasts and ANOVA-style joint tests of parameters                                                                                     |
| <code>estat ic</code>        | Akaike's, consistent Akaike's, corrected Akaike's, and Schwarz's Bayesian information criteria (AIC, CAIC, AICc, and BIC, respectively) |
| <code>estat summarize</code> | summary statistics for the estimation sample                                                                                            |
| <code>estat vce</code>       | variance–covariance matrix of the estimators (VCE)                                                                                      |
| <code>estimates</code>       | cataloging estimation results                                                                                                           |
| <code>etable</code>          | table of estimation results                                                                                                             |
| <code>lincom</code>          | point estimates, standard errors, testing, and inference for linear combinations of parameters                                          |
| * <code>lrtest</code>        | likelihood-ratio test                                                                                                                   |
| <code>margins</code>         | marginal means, predictive margins, marginal effects, and average marginal effects                                                      |
| <code>marginsplot</code>     | graph the results from margins (profile plots, interaction plots, etc.)                                                                 |
| <code>nlcom</code>           | point estimates, standard errors, testing, and inference for nonlinear combinations of parameters                                       |
| <code>predict</code>         | linear predictions and scores                                                                                                           |
| <code>predictnl</code>       | point estimates, standard errors, testing, and inference for generalized predictions                                                    |
| <code>pwcompare</code>       | pairwise comparisons of parameters                                                                                                      |
| <code>suest</code>           | seemingly unrelated estimation                                                                                                          |
| <code>test</code>            | Wald tests of simple and composite linear hypotheses                                                                                    |
| <code>testnl</code>          | Wald tests of nonlinear hypotheses                                                                                                      |

\*`lrtest` is not appropriate with `svy` estimation results.

# predict

## Description for predict

`predict` creates a new variable containing predictions such as linear predictions and equation-level scores.

## Menu for predict

Statistics > Postestimation

## Syntax for predict

```
predict [type] newvar [if] [in] [, xb equation(eqno | eqname)]
```

```
predict [type] stub* [if] [in] , scores
```

Scores are only available for observations within the estimation sample.

## Options for predict

`xb` calculates the linear prediction.

`equation(eqno | eqname)` specifies the equation for which the linear prediction is desired. Specifying `equation(#1)` indicates that the calculation be made for the first equation. Specifying `equation(demand)` indicates that the calculation be made for the equation named `demand`, assuming there is an equation named `demand` in the model.

If you specify one new variable name and omit `equation()`, results are the same as if you had specified `equation(#1)`.

For more information on using `predict` after multiple-equation estimation commands, see [\[R\] predict](#).

`scores` calculates the equation-level score variables. The *j*th new variable will contain the scores for the *j*th equation of the model.

# margins

## Description for margins

`margins` estimates margins of response for linear predictions.

## Menu for margins

Statistics > Postestimation

## Syntax for margins

```
margins [marginlist] [, options]
```

```
margins [marginlist] , predict(statistic ...) [predict(statistic ...) ...] [options]
```

| <i>statistic</i> | Description |
|------------------|-------------|
|------------------|-------------|

---

## Description

`mlogit` fits a multinomial logit (MNL) model for a categorical dependent variable with outcomes that have no natural ordering. The actual values taken by the dependent variable are irrelevant. The MNL model is also known as the polytomous logistic regression model. Some people refer to conditional logistic regression as multinomial logistic regression. If you are one of them, see [\[R\] clogit](#).

## Quick start

MNL model of `y` on `x1`, `x2`, and categorical variable `a`

```
mlogit y x1 x2 i.a
```

Same as above, but use `y = 1` as the base outcome even if 1 is not the most frequent

```
mlogit y x1 x2 i.a, baseoutcome(1)
```

Report results as relative-risk ratios

```
mlogit y x1 x2 i.a, rrr
```

Constrain coefficient of `x1` to be equal for second and third outcomes

```
constraint 1 [#2=#3]:x1
mlogit y x1 x2 i.a, constraints(1)
```

## Menu

Statistics > Categorical outcomes > Multinomial logistic regression

## Syntax

```
mlogit depvar [indepvars] [if] [in] [weight] [, options]
```

| <i>options</i>                               | Description                                                                                                                                                                 |

| <code>coeflegend</code>                      | display legend instead of statistics                                                                                                                                        |

*indepvars* may contain factor variables; see [U] 11.4.3 **Factor variables**.

*indepvars* may contain time-series operators; see [U] 11.4.4 **Time-series varlists**.

`bayes`, `bayesboot`, `bootstrap`, `by`, `collect`, `fmm`, `fp`, `jackknife`, `mfp`, `mi estimate`, `rolling`, `statsby`, and `svy` are allowed; see [U] 11.1.10 **Prefix commands**. For more details, see [BAYES] **bayes: mlogit** and [FMM] **fmm: mlogit**.

`vce(bootstrap)` and `vce(jackknife)` are not allowed with the `mi estimate` prefix; see [MI] **mi estimate**.

Weights are not allowed with the `bootstrap` prefix; see [R] **bootstrap**.

`vce()` and weights are not allowed with the `svy` prefix; see [SVY] **svy**.

`fweights`, `iweights`, and `pweights` are allowed; see [U] 11.1.6 **weight**.

`collinear` and `coeflegend` do not appear in the dialog box.

See [U] 20 **Estimation and postestimation commands** for more capabilities of estimation commands.

## Options

Model

`noconstant`; see [R] **Estimation options**.

`baseoutcome(#)` specifies the value of *depvar* to be treated as the base outcome. The default is to choose the most frequent outcome.

`constraints(constraints)`; see [R] **Estimation options**.

## SE/Robust

`vce(vcetype)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory (`oim`, `opg`), that are robust to some kinds of misspecification (`robust`), that allow for intragroup correlation (`cluster clustvar`), and that use bootstrap or jackknife methods (`bootstrap`, `jackknife`); see [R] [vce\\_option](#).

If specifying `vce(bootstrap)` or `vce(jackknife)`, you must also specify `baseoutcome()`.

## Reporting

`level(#)`; see [R] [Estimation options](#).

`rrr` reports the estimated coefficients transformed to relative-risk ratios, that is,  $e^b$  rather than  $b$ ; see [Description of the model](#) below for an explanation of this concept. Standard errors and confidence intervals are similarly transformed. This option affects how results are displayed, not how they are estimated. `rrr` may be specified at estimation or when replaying previously estimated results.

`nocnsreport`; see [R] [Estimation options](#).

`display_options`: `nocl`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `no1stretch`; see [R] [Estimation options](#).

## Maximization

`maximize_options`: `difficult`, `technique(algorithm_spec)`, `iterate(#)`, `[no]log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `ltolerance(#)`, `nrtolerance(#)`, `nonrtolerance`, and `from(init_specs)`; see [R] [Maximize](#). These options are seldom used.

The following options are available with `mlogit` but are not shown in the dialog box:

`collinear`, `coeflegend`; see [R] [Estimation options](#).

## Remarks and examples

Remarks are presented under the following headings:

*Description of the model*  
*Fitting unconstrained models*  
*Fitting constrained models*

`mlogit` fits maximum likelihood models with discrete dependent (left-hand-side) variables when the dependent variable takes on more than two outcomes and the outcomes have no natural ordering. If the dependent variable takes on only two outcomes, estimates are identical to those produced by `logistic` or `logit`; see [R] [logistic](#) or [R] [logit](#). If the outcomes are ordered, see [R] [ologit](#). See [R] [logistic](#) for a list of related estimation commands.

## Description of the model

For an introduction to MNL models, see [Greene \(2018, 829–833\)](#), [Hosmer, Lemeshow, and Sturdivant \(2013, 269–289\)](#), [Long \(1997, chap. 6\)](#), [Long and Freese \(2014, chap. 8\)](#), and [Treiman \(2009, 336–341\)](#). For a description emphasizing the difference in assumptions and data requirements for conditional and multinomial logit, see [Davidson and MacKinnon \(1993\)](#).

Consider the outcomes  $1, 2, 3, \dots, m$  recorded in  $y$ , and the explanatory variables  $X$ . Assume that there are  $m = 3$  outcomes: “buy an American car”, “buy a Japanese car”, and “buy a European car”. The values of  $y$  are then said to be “unordered”. Even though the outcomes are coded 1, 2, and 3, the numerical values are arbitrary because  $1 < 2 < 3$  does not imply that outcome 1 (buy American) is less than outcome 2 (buy Japanese) is less than outcome 3 (buy European). This unordered categorical property of  $y$  distinguishes the use of `mlogit` from `regress` (which is appropriate for a continuous dependent variable), from `ologit` (which is appropriate for ordered categorical data), and from `logit` (which is appropriate for two outcomes, which can be thought of as ordered).

In the MNL model, you estimate a set of coefficients,  $\beta^{(1)}$ ,  $\beta^{(2)}$ , and  $\beta^{(3)}$ , corresponding to each outcome:

$$\Pr(y = 1) = \frac{e^{X\beta^{(1)}}}{e^{X\beta^{(1)}} + e^{X\beta^{(2)}} + e^{X\beta^{(3)}}}$$

$$\Pr(y = 2) = \frac{e^{X\beta^{(2)}}}{e^{X\beta^{(1)}} + e^{X\beta^{(2)}} + e^{X\beta^{(3)}}}$$

$$\Pr(y = 3) = \frac{e^{X\beta^{(3)}}}{e^{X\beta^{(1)}} + e^{X\beta^{(2)}} + e^{X\beta^{(3)}}}$$

The model, however, is unidentified in the sense that there is more than one solution to  $\beta^{(1)}$ ,  $\beta^{(2)}$ , and  $\beta^{(3)}$  that leads to the same probabilities for  $y = 1$ ,  $y = 2$ , and  $y = 3$ . To identify the model, you arbitrarily set one of  $\beta^{(1)}$ ,  $\beta^{(2)}$ , or  $\beta^{(3)}$  to 0—it does not matter which. That is, if you arbitrarily set  $\beta^{(1)} = 0$ , the remaining coefficients  $\beta^{(2)}$  and  $\beta^{(3)}$  will measure the change relative to the  $y = 1$  group. If you instead set  $\beta^{(2)} = 0$ , the remaining coefficients  $\beta^{(1)}$  and  $\beta^{(3)}$  will measure the change relative to the  $y = 2$  group. The coefficients will differ because they have different interpretations, but the predicted probabilities for  $y = 1, 2$ , and  $3$  will still be the same. Thus, either parameterization will be a solution to the same underlying model.

Setting  $\beta^{(1)} = 0$ , the equations become

$$\Pr(y = 1) = \frac{1}{1 + e^{X\beta^{(2)}} + e^{X\beta^{(3)}}}$$

$$\Pr(y = 2) = \frac{e^{X\beta^{(2)}}}{1 + e^{X\beta^{(2)}} + e^{X\beta^{(3)}}}$$

$$\Pr(y = 3) = \frac{e^{X\beta^{(3)}}}{1 + e^{X\beta^{(2)}} + e^{X\beta^{(3)}}}$$

The relative probability of  $y = 2$  to the base outcome is

$$\frac{\Pr(y = 2)}{\Pr(y = 1)} = e^{X\beta^{(2)}}$$

Let's call this ratio the relative risk, and let's further assume that  $X$  and  $\beta_k^{(2)}$  are vectors equal to  $(x_1, x_2, \dots, x_k)$  and  $(\beta_1^{(2)}, \beta_2^{(2)}, \dots, \beta_k^{(2)})'$ , respectively. The ratio of the relative risk for a one-unit change in  $x_i$  is then

$$\frac{e^{\beta_1^{(2)}x_1 + \dots + \beta_i^{(2)}(x_i+1) + \dots + \beta_k^{(2)}x_k}}{e^{\beta_1^{(2)}x_1 + \dots + \beta_i^{(2)}x_i + \dots + \beta_k^{(2)}x_k}} = e^{\beta_i^{(2)}}$$

Thus, the exponentiated value of a coefficient is the relative-risk ratio for a one-unit change in the corresponding variable (risk is measured as the risk of the outcome relative to the base outcome).

## Fitting unconstrained models

### ▷ Example 1: A first example

We have data on the type of health insurance available to 616 psychologically depressed subjects in the United States (Tarlov et al. 1989; Wells et al. 1989). The insurance is categorized as either an indemnity plan (that is, regular fee-for-service insurance, which may have a deductible or coinsurance rate) or a prepaid plan (a fixed up-front payment allowing subsequent unlimited use as provided, for instance, by an HMO). The third possibility is that the subject has no insurance whatsoever. We wish to explore the demographic factors associated with each subject's insurance choice. One of the demographic factors in our data is the race of the participant, coded as white or nonwhite:

```
. use https://www.stata-press.com/data/r19/sysdsn1
(Health insurance data)
. tabulate insure nonwhite, chi2 col
```

|                          |
|--------------------------|
| Key                      |
| <i>frequency</i>         |
| <i>column percentage</i> |

| Type of insurance | Nonwhite      |               | Total         |
|-------------------|---------------|---------------|---------------|
|                   | 0             | 1             |               |
| Indemnity         | 251<br>50.71  | 43<br>35.54   | 294<br>47.73  |
| Prepaid           | 208<br>42.02  | 69<br>57.02   | 277<br>44.97  |
| Uninsure          | 36<br>7.27    | 9<br>7.44     | 45<br>7.31    |
| Total             | 495<br>100.00 | 121<br>100.00 | 616<br>100.00 |

Pearson chi2(2) = 9.5599 Pr = 0.008

Although insure appears to take on the values Indemnity, Prepaid, and Uninsure, it actually takes on the values 1, 2, and 3. The words appear because we have associated a value label with the numeric variable insure; see [U] 12.6.3 Value labels.

When we fit an MNL model, we can tell mlogit which outcome to use as the base outcome, or we can let mlogit choose. To fit a model of insure on nonwhite, letting mlogit choose the base outcome, we type

```
. mlogit insure nonwhite
Iteration 0: Log likelihood = -556.59502
Iteration 1: Log likelihood = -551.78935
Iteration 2: Log likelihood = -551.78348
Iteration 3: Log likelihood = -551.78348

Multinomial logistic regression
Log likelihood = -551.78348
Number of obs = 616
LR chi2(2) = 9.62
Prob > chi2 = 0.0081
Pseudo R2 = 0.0086
```

| insure    | Coefficient    | Std. err. | z      | P> z  | [95% conf. interval] |           |
|-----------|----------------|-----------|--------|-------|----------------------|-----------|
| Indemnity | (base outcome) |           |        |       |                      |           |
| Prepaid   |                |           |        |       |                      |           |
| nonwhite  | .6608212       | .2157321  | 3.06   | 0.002 | .2379942             | 1.083648  |
| _cons     | -.1879149      | .0937644  | -2.00  | 0.045 | -.3716896            | -.0041401 |
| Uninsure  |                |           |        |       |                      |           |
| nonwhite  | .3779586       | .407589   | 0.93   | 0.354 | -.4209011            | 1.176818  |
| _cons     | -1.941934      | .1782185  | -10.90 | 0.000 | -2.291236            | -1.592632 |

mlogit chose the indemnity outcome as the base outcome and presented coefficients for the outcomes prepaid and uninsured. According to the model, the probability of prepaid for whites (nonwhite = 0) is

$$\Pr(\text{insure} = \text{Prepaid}) = \frac{e^{-.188}}{1 + e^{-.188} + e^{-1.942}} = 0.420$$

Similarly, for nonwhites, the probability of prepaid is

$$\Pr(\text{insure} = \text{Prepaid}) = \frac{e^{-.188+.661}}{1 + e^{-.188+.661} + e^{-1.942+.378}} = 0.570$$

These results agree with the column percentages presented by tabulate because the mlogit model is fully saturated. That is, there are enough terms in the model to fully explain the column percentage in each cell. The model  $\chi^2$  and the tabulate  $\chi^2$  are in almost perfect agreement; both test that the column percentages of insure are the same for both values of nonwhite.

▷ Example 2: Specifying the base outcome

By specifying the `baseoutcome()` option, we can control which outcome of the dependent variable is treated as the base. Left to its own, `mlogit` chose to make outcome 1, indemnity, the base outcome. To make outcome 2, prepaid, the base, we would type

```
. mlogit insure nonwhite, base(2)
Iteration 0: Log likelihood = -556.59502
Iteration 1: Log likelihood = -551.78935
Iteration 2: Log likelihood = -551.78348
Iteration 3: Log likelihood = -551.78348

Multinomial logistic regression Number of obs = 616
LR chi2(2) = 9.62
Prob > chi2 = 0.0081
Pseudo R2 = 0.0086

Log likelihood = -551.78348
```

| insure    | Coefficient    | Std. err. | z     | P> z  | [95% conf. interval] |           |
|-----------|----------------|-----------|-------|-------|----------------------|-----------|
| Indemnity |                |           |       |       |                      |           |
| nonwhite  | -.6608212      | .2157321  | -3.06 | 0.002 | -1.083648            | -.2379942 |
| _cons     | .1879149       | .0937644  | 2.00  | 0.045 | .0041401             | .3716896  |
| Prepaid   | (base outcome) |           |       |       |                      |           |
| Uninsure  |                |           |       |       |                      |           |
| nonwhite  | -.2828627      | .3977302  | -0.71 | 0.477 | -1.0624              | .4966742  |
| _cons     | -1.754019      | .1805145  | -9.72 | 0.000 | -2.107821            | -1.400217 |

The `baseoutcome()` option requires that we specify the numeric value of the outcome, so we could not type `base(Prepaid)`.

Although the coefficients now appear to be different, the summary statistics reported at the top are identical. With this parameterization, the probability of prepaid insurance for whites is

$$\Pr(\text{insure} = \text{Prepaid}) = \frac{1}{1 + e^{.188} + e^{-1.754}} = 0.420$$

This is the same answer we obtained previously.

▷ Example 3: Displaying relative-risk ratios

By specifying `rrr`, which we can do at estimation time or when we redisplay results, we see the model in terms of relative-risk ratios:

```
. mlogit, rrr
Multinomial logistic regression Number of obs = 616
 LR chi2(2) = 9.62
 Prob > chi2 = 0.0081
Log likelihood = -551.78348 Pseudo R2 = 0.0086
```

| insure    | RRR            | Std. err. | z     | P> z  | [95% conf. interval] |          |
|-----------|----------------|-----------|-------|-------|----------------------|----------|
| Indemnity |                |           |       |       |                      |          |
| nonwhite  | .516427        | .1114099  | -3.06 | 0.002 | .3383588             | .7882073 |
| _cons     | 1.206731       | .1131483  | 2.00  | 0.045 | 1.004149             | 1.450183 |
| Prepaid   | (base outcome) |           |       |       |                      |          |
| Uninsure  |                |           |       |       |                      |          |
| nonwhite  | .7536233       | .2997387  | -0.71 | 0.477 | .3456255             | 1.643247 |
| _cons     | .1730769       | .0312429  | -9.72 | 0.000 | .1215024             | .2465434 |

Note: `_cons` estimates baseline relative risk for each outcome.

Looked at this way, the relative risk of choosing an indemnity over a prepaid plan is 0.516 for nonwhites relative to whites.

To illustrate, from the output and discussions of examples 1 and 2 we find that

$$\Pr(\text{insure} = \text{Indemnity} \mid \text{white}) = \frac{1}{1 + e^{-.188} + e^{-1.942}} = 0.507$$

and thus the relative risk of choosing indemnity over prepaid (for whites) is

$$\frac{\Pr(\text{insure} = \text{Indemnity} \mid \text{white})}{\Pr(\text{insure} = \text{Prepaid} \mid \text{white})} = \frac{0.507}{0.420} = 1.207$$

For nonwhites,

$$\Pr(\text{insure} = \text{Indemnity} \mid \text{not white}) = \frac{1}{1 + e^{-.188+.661} + e^{-1.942+.378}} = 0.355$$

and thus the relative risk of choosing indemnity over prepaid (for nonwhites) is

$$\frac{\Pr(\text{insure} = \text{Indemnity} \mid \text{not white})}{\Pr(\text{insure} = \text{Prepaid} \mid \text{not white})} = \frac{0.355}{0.570} = 0.623$$

The ratio of these two relative risks, hence the name “relative-risk ratio”, is  $0.623/1.207 = 0.516$ , as given in the output under the heading “RRR”.

□ Technical note

In models where only two categories are considered, the mlogit model reduces to standard logit. Consequently, the exponentiated regression coefficients, labeled as RRR within mlogit, are equal to the odds ratios as given when the or option is specified under logit; see [R] logit.

As such, always referring to mlogit’s exponentiated coefficients as odds ratios may be tempting. However, the discussion in example 3 demonstrates that doing so would be incorrect. In general mlogit models, the exponentiated coefficients are ratios of relative risks, not ratios of odds.

▷ Example 4: Model with continuous and multiple categorical variables

One of the advantages of mlogit over tabulate is that we can include continuous variables and multiple categorical variables in the model. In examining the data on insurance choice, we decide that we want to control for age, gender, and site of study (the study was conducted in three sites):

```
. mlogit insure age male nonwhite i.site
Iteration 0: Log likelihood = -555.85446
Iteration 1: Log likelihood = -534.67443
Iteration 2: Log likelihood = -534.36284
Iteration 3: Log likelihood = -534.36165
Iteration 4: Log likelihood = -534.36165

Multinomial logistic regression
Log likelihood = -534.36165
Number of obs = 615
LR chi2(10) = 42.99
Prob > chi2 = 0.000
Pseudo R2 = 0.0387
```

| insure                   | Coefficient | Std. err. | z     | P> z  | [95% conf. interval] |           |
|--------------------------|-------------|-----------|-------|-------|----------------------|-----------|
| Indemnity (base outcome) |             |           |       |       |                      |           |
| Prepaid                  |             |           |       |       |                      |           |
| age                      | -.011745    | .0061946  | -1.90 | 0.058 | -.0238862            | .0003962  |
| male                     | .5616934    | .2027465  | 2.77  | 0.006 | .1643175             | .9590693  |
| nonwhite                 | .9747768    | .2363213  | 4.12  | 0.000 | .5115955             | 1.437958  |
| site                     |             |           |       |       |                      |           |
| 2                        | .1130359    | .2101903  | 0.54  | 0.591 | -.2989296            | .5250013  |
| 3                        | -.5879879   | .2279351  | -2.58 | 0.010 | -1.034733            | -.1412433 |
| _cons                    | .2697127    | .3284422  | 0.82  | 0.412 | -.3740222            | .9134476  |
| Uninsure                 |             |           |       |       |                      |           |
| age                      | -.0077961   | .0114418  | -0.68 | 0.496 | -.0302217            | .0146294  |
| male                     | .4518496    | .3674867  | 1.23  | 0.219 | -.268411             | 1.17211   |
| nonwhite                 | .2170589    | .4256361  | 0.51  | 0.610 | -.6171725            | 1.05129   |
| site                     |             |           |       |       |                      |           |
| 2                        | -1.211563   | .4705127  | -2.57 | 0.010 | -2.133751            | -.2893747 |
| 3                        | -.2078123   | .3662926  | -0.57 | 0.570 | -.9257327            | .510108   |
| _cons                    | -1.286943   | .5923219  | -2.17 | 0.030 | -2.447872            | -.1260134 |

These results suggest that the inclination of nonwhites to choose prepaid care is even stronger than it was without controlling. We also see that subjects in site 2 are less likely to be uninsured.

## Fitting constrained models

mlogit can fit models with subsets of coefficients constrained to be zero, with subsets of coefficients constrained to be equal both within and across equations, and with subsets of coefficients arbitrarily constrained to equal linear combinations of other estimated coefficients.

Before fitting a constrained model, you define the constraints with the `constraint` command; see [R] [constraint](#). Once the constraints are defined, you estimate using `mlogit`, specifying the `constraint()` option. Typing `constraint(4)` would use the constraint you previously saved as 4. Typing `constraint(1,4,6)` would use the previously stored constraints 1, 4, and 6. Typing `constraint(1-4,6)` would use the previously stored constraints 1, 2, 3, 4, and 6.

Sometimes, you will not be able to specify the constraints without knowing the omitted outcome. In such cases, assume that the omitted outcome is whatever outcome is convenient for you, and include the `baseoutcome()` option when you specify the `mlogit` command.

### ▷ Example 5: Specifying constraints to test hypotheses

We can use constraints to test hypotheses, among other things. In our insurance-choice model, let's test the hypothesis that there is no distinction between having indemnity insurance and being uninsured. Indemnity-style insurance was the omitted outcome, so we type

```
. test [Uninsure]
(1) [Uninsure]age = 0
(2) [Uninsure]male = 0
(3) [Uninsure]nonwhite = 0
(4) [Uninsure]1b.site = 0
(5) [Uninsure]2.site = 0
(6) [Uninsure]3.site = 0
Constraint 4 dropped
 chi2(5) = 9.31
 Prob > chi2 = 0.0973
```

If indemnity had not been the omitted outcome, we would have typed `test [Uninsure=Indemnity]`.

The results produced by `test` are an approximation based on the estimated covariance matrix of the coefficients. Because the probability of being uninsured is low, the log likelihood may be nonlinear for the uninsured. Conventional statistical wisdom is not to trust the asymptotic answer under these circumstances but to perform a likelihood-ratio test instead.

To use Stata's `lrtest` (likelihood-ratio test) command, we must fit both the unconstrained and constrained models. The unconstrained model is the one we have previously fit. Following the instruction in [R] [lrtest](#), we first store the unconstrained model results:

```
. estimates store unconstrained
```

To fit the constrained model, we must refit our model with all the coefficients except the constant set to 0 in the Uninsure equation. We define the constraint and then refit:

```
. constraint 1 [Uninsure]
. mlogit insure age male nonwhite i.site, constraints(1)
Iteration 0: Log likelihood = -555.85446
Iteration 1: Log likelihood = -539.80523
Iteration 2: Log likelihood = -539.75644
Iteration 3: Log likelihood = -539.75643

Multinomial logistic regression
Log likelihood = -539.75643
Number of obs = 615
Wald chi2(5) = 29.70
Prob > chi2 = 0.0000

(1) [Uninsure]o.age = 0
(2) [Uninsure]o.male = 0
(3) [Uninsure]o.nonwhite = 0
(4) [Uninsure]2o.site = 0
(5) [Uninsure]3o.site = 0
```

| insure         | Coefficient | Std. err. | z      | P> z  | [95% conf. interval] |           |
|----------------|-------------|-----------|--------|-------|----------------------|-----------|
| Indemnity      |             |           |        |       |                      |           |
| (base outcome) |             |           |        |       |                      |           |
| Prepaid        |             |           |        |       |                      |           |
| age            | -.0107025   | .0060039  | -1.78  | 0.075 | -.0224699            | .0010649  |
| male           | .4963616    | .1939683  | 2.56   | 0.010 | .1161907             | .8765324  |
| nonwhite       | .9421369    | .2252094  | 4.18   | 0.000 | .5007346             | 1.383539  |
| site           |             |           |        |       |                      |           |
| 2              | .2530912    | .2029465  | 1.25   | 0.212 | -.1446767            | .6508591  |
| 3              | -.5521773   | .2187237  | -2.52  | 0.012 | -.9808678            | -.1234869 |
| _cons          | .1792752    | .3171372  | 0.57   | 0.572 | -.4423023            | .8008527  |
| Uninsure       |             |           |        |       |                      |           |
| age            | 0 (omitted) |           |        |       |                      |           |
| male           | 0 (omitted) |           |        |       |                      |           |
| nonwhite       | 0 (omitted) |           |        |       |                      |           |
| site           |             |           |        |       |                      |           |
| 2              | 0 (omitted) |           |        |       |                      |           |
| 3              | 0 (omitted) |           |        |       |                      |           |
| _cons          | -1.87351    | .1601099  | -11.70 | 0.000 | -2.18732             | -1.5597   |

We can now perform the likelihood-ratio test:

```
. lrtest unconstrained .
Likelihood-ratio test
Assumption: . nested within unconstrained
LR chi2(5) = 10.79
Prob > chi2 = 0.0557
```

The likelihood-ratio  $\chi^2$  is 10.79 with 5 degrees of freedom—just slightly greater than the magic  $p = 0.05$  level—so we should not call this difference significant.

## □ Technical note

In certain circumstances, you should fit an MNL model with conditional logit; see [R] [clogit](#). With substantial data manipulation, `clogit` can handle the same class of models with some interesting additions. For example, if we had available the price and deductible of the most competitive insurance plan of each type, `mlogit` could not use this information, but `clogit` could.

□

## Stored results

`mlogit` stores the following in `e()`:

### Scalars

|                            |                                                                    |
|----------------------------|--------------------------------------------------------------------|
| <code>e(N)</code>          | number of observations                                             |
| <code>e(N_cd)</code>       | number of completely determined observations                       |
| <code>e(k_out)</code>      | number of outcomes                                                 |

| <code>e(k_eq_base)</code>  | equation number of the base outcome                                |
| <code>e(baseout)</code>    | the value of <code>depvar</code> to be treated as the base outcome |
| <code>e(ibaseout)</code>   | index of the base outcome                                          |
| <code>e(rank)</code>       | rank of <code>e(V)</code>                                          |
| <code>e(ic)</code>         | number of iterations                                               |
| <code>e(rc)</code>         | return code                                                        |
| <code>e(converged)</code>  | 1 if converged, 0 otherwise                                        |

### Macros

|                                |                                                                          |
|--------------------------------|--------------------------------------------------------------------------|
| <code>e(cmd)</code>            | <code>mlogit</code>                                                      |
| <code>e(cmdline)</code>        | command as typed                                                         |
| <code>e(depvar)</code>         | name of dependent variable                                               |
| <code>e(wtype)</code>          | weight type                                                              |
| <code>e(wexp)</code>           | weight expression                                                        |
| <code>e(title)</code>          | title in estimation output                                               |
| <code>e(clustvar)</code>       | name of cluster variable                                                 |
| <code>e(chi2type)</code>       | Wald or LR; type of model $\chi^2$ test                                  |
| <code>e(vce)</code>            | <code>vcetype</code> specified in <code>vce()</code>                     |
| <code>e(vcetype)</code>        | title used to label Std. err.                                            |
| <code>e(eqnames)</code>        | names of equations                                                       |
| <code>e(baselab)</code>        | value label corresponding to base outcome                                |
| <code>e(opt)</code>            | type of optimization                                                     |
| <code>e(which)</code>          | max or min; whether optimizer is to perform maximization or minimization |
| <code>e(ml_method)</code>      | type of ml method                                                        |
| <code>e(user)</code>           | name of likelihood-evaluator program                                     |
| <code>e(technique)</code>      | maximization technique                                                   |
| <code>e(properties)</code>     | <code>b V</code>                                                         |
| <code>e(predict)</code>        | program used to implement <code>predict</code>                           |
| <code>e(marginsnotok)</code>   | predictions disallowed by <code>margins</code>                           |
| <code>e(marginsdefault)</code> | default <code>predict()</code> specification for <code>margins</code>    |
| <code>e(asbalanced)</code>     | factor variables <code>fvset</code> as <code>asbalanced</code>           |
| <code>e(asobserved)</code>     | factor variables <code>fvset</code> as <code>asobserved</code>           |

|                 |                                              |
|-----------------|----------------------------------------------|
| Matrices        |                                              |
| e(b)            | coefficient vector                           |
| e(out)          | outcome values                               |
| e(Cns)          | constraints matrix                           |
| e(iilog)        | iteration log (up to 20 iterations)          |
| e(gradient)     | gradient vector                              |
| e(V)            | variance–covariance matrix of the estimators |
| e(V_modelbased) | model-based variance                         |
| Functions       |                                              |
| e(sample)       | marks estimation sample                      |

In addition to the above, the following is stored in `r()`:

|          |                                                                                                                            |
|----------|----------------------------------------------------------------------------------------------------------------------------|
| Matrices |                                                                                                                            |
| r(table) | matrix containing the coefficients with their standard errors, test statistics, <i>p</i> -values, and confidence intervals |

Note that results stored in `r()` are updated when the command is replayed and will be replaced when any *r*-class command is run after the estimation command.

## Methods and formulas

The MNL model is described in [Greene \(2018, 829–833\)](#).

Suppose that there are *k* categorical outcomes and—without loss of generality—let the base outcome be 1. The probability that the response for the *j*th observation is equal to the *i*th outcome is

$$p_{ij} = \Pr(y_j = i) = \begin{cases} \frac{1}{1 + \sum_{m=2}^k \exp(\mathbf{x}_j \boldsymbol{\beta}_m)}, & \text{if } i = 1 \\ \frac{\exp(\mathbf{x}_j \boldsymbol{\beta}_i)}{1 + \sum_{m=2}^k \exp(\mathbf{x}_j \boldsymbol{\beta}_m)}, & \text{if } i > 1 \end{cases}$$

where  $\mathbf{x}_j$  is the row vector of observed values of the independent variables for the *j*th observation and  $\boldsymbol{\beta}_m$  is the coefficient vector for outcome *m*. The log pseudolikelihood is

$$\ln L = \sum_j w_j \sum_{i=1}^k I_i(y_j) \ln p_{ik}$$

where  $w_j$  is an optional weight and

$$I_i(y_j) = \begin{cases} 1, & \text{if } y_j = i \\ 0, & \text{otherwise} \end{cases}$$

Newton–Raphson maximum likelihood is used; see [\[R\] Maximize](#).

For constrained equations, the set of constraints is orthogonalized, and a subset of maximizable parameters is selected. For example, a parameter that is constrained to zero is not a maximizable parameter. If two parameters are constrained to be equal to each other, only one is a maximizable parameter.

Let  $\mathbf{r}$  be the vector of maximizable parameters.  $\mathbf{r}$  is physically a subset of the solution parameters,  $\mathbf{b}$ . A matrix,  $\mathbf{T}$ , and a vector,  $\mathbf{m}$ , are defined as

$$\mathbf{b} = \mathbf{T}\mathbf{r} + \mathbf{m}$$

so that

$$\frac{\partial f}{\partial \mathbf{b}} = \frac{\partial f}{\partial \mathbf{r}} \mathbf{T}'$$

$$\frac{\partial^2 f}{\partial \mathbf{b}^2} = \mathbf{T} \frac{\partial^2 f}{\partial \mathbf{r}^2} \mathbf{T}'$$

$\mathbf{T}$  consists of a block form in which one part is a permutation of the identity matrix and the other part describes how to calculate the constrained parameters from the maximizable parameters.

This command supports the Huber/White/sandwich estimator of the variance and its clustered version using `vce(robust)` and `vce(cluster clustvar)`, respectively. See [P] [\\_robust](#), particularly *Maximum likelihood estimators* and *Methods and formulas*.

`mlogit` also supports estimation with survey data. For details on VCEs with survey data, see [SVY] [Variance estimation](#).

## Postestimation commands

The following postestimation commands are available after `mlogit`:

| Command                      | Description                                                                                                                             |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <code>contrast</code>        | contrasts and ANOVA-style joint tests of parameters                                                                                     |
| <code>estat ic</code>        | Akaike's, consistent Akaike's, corrected Akaike's, and Schwarz's Bayesian information criteria (AIC, CAIC, AICc, and BIC, respectively) |
| <code>estat summarize</code> | summary statistics for the estimation sample                                                                                            |
| <code>estat vce</code>       | variance–covariance matrix of the estimators (VCE)                                                                                      |
| <code>estat (svy)</code>     | postestimation statistics for survey data                                                                                               |
| <code>estimates</code>       | cataloging estimation results                                                                                                           |
| <code>etable</code>          | table of estimation results                                                                                                             |
| * <code>forecast</code>      | dynamic forecasts and simulations                                                                                                       |
| * <code>hausman</code>       | Hausman's specification test                                                                                                            |
| <code>lincom</code>          | point estimates, standard errors, testing, and inference for linear combinations of parameters                                          |
| * <code>lrtest</code>        | likelihood-ratio test                                                                                                                   |
| <code>margins</code>         | marginal means, predictive margins, marginal effects, and average marginal effects                                                      |
| <code>marginsplot</code>     | graph the results from margins (profile plots, interaction plots, etc.)                                                                 |
| <code>nlcom</code>           | point estimates, standard errors, testing, and inference for nonlinear combinations of parameters                                       |
| <code>predict</code>         | probabilities, linear predictions and their SEs, etc.                                                                                   |
| <code>predictnl</code>       | point estimates, standard errors, testing, and inference for generalized predictions                                                    |
| <code>pwcompare</code>       | pairwise comparisons of parameters                                                                                                      |
| <code>suest</code>           | seemingly unrelated estimation                                                                                                          |
| <code>test</code>            | Wald tests of simple and composite linear hypotheses                                                                                    |
| <code>testnl</code>          | Wald tests of nonlinear hypotheses                                                                                                      |

\* `forecast`, `hausman`, and `lrtest` are not appropriate with `svy` estimation results. `forecast` is also not appropriate with `mi` estimation results.

# predict

## Description for predict

`predict` creates a new variable containing predictions such as probabilities, linear predictions, and standard errors.

## Menu for predict

Statistics > Postestimation

## Syntax for predict

```
predict [type] { stub* | newvar | newvarlist } [if] [in] [, statistic outcome(outcome)]
```

```
predict [type] stub* [if] [in], scores
```

| <i>statistic</i>   | Description                                                |
|--------------------|------------------------------------------------------------|
| Main               |                                                            |
| <code>pr</code>    | predicted probabilities; the default                       |
| <code>xb</code>    | linear prediction                                          |
| <code>stdp</code>  | standard error of the linear prediction                    |
| <code>stddp</code> | standard error of the difference in two linear predictions |

You specify one or  $k$  new variables with `pr`, where  $k$  is the number of outcomes. If you specify one new variable and you do not specify `outcome()`, then `outcome(#1)` is assumed.

You specify one new variable with `xb`, `stdp`, and `stddp`. If you do not specify `outcome()`, then `outcome(#1)` is assumed. You must specify `outcome()` with the `stddp` option.

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

## Options for predict

Main

`pr`, the default, computes the predicted probabilities for all outcomes or for a specific outcome. To compute probabilities for all outcomes, you specify  $k$  new variables, where  $k$  is the number of categories of the dependent variable. Alternatively, you can specify `stub*`; in which case, `pr` will store predicted probabilities in variables `stub1`, `stub2`, ..., `stubk`. To compute the probability for a specific outcome, you specify one new variable and, optionally, the outcome value in option `outcome()`; if you omit `outcome()`, the first outcome value, `outcome(#1)`, is assumed.

Say that you fit a model by typing `estimation_cmd y x1 x2`, and `y` takes on four values. Then, you could type `predict p1 p2 p3 p4` to obtain all four predicted probabilities; alternatively, you could type `predict p*` to generate the four predicted probabilities. To compute specific probabilities one at a time, you can type `predict p1, outcome(#1)` (or simply `predict p1`), `predict p2, outcome(#2)`, and so on. See option `outcome()` for other ways to refer to outcome values.

`xb` calculates the linear prediction. You must also specify the `outcome(outcome)` option.

`stdp` calculates the standard error of the linear prediction. You must also specify the outcome (*outcome*) option.

`stddp` calculates the standard error of the difference in two linear predictions. You must specify the outcome (*outcome*) option, and here you specify the two particular outcomes of interest inside the parentheses, for example, `predict sed, stddp outcome(1,3)`.

`outcome(outcome)` specifies for which outcome the predicted probabilities are to be calculated. `outcome()` should contain either one value of the dependent variable or one of #1, #2, ..., with #1 meaning the first category of the dependent variable, #2 meaning the second category, etc. `outcome()` is not allowed with `scores`.

`scores` calculates equation-level score variables. The number of score variables created will be one less than the number of outcomes in the model. If the number of outcomes in the model were  $k$ , then

the first new variable will contain  $\partial \ln L / \partial (\mathbf{x}_j \beta_1)$ ;

the second new variable will contain  $\partial \ln L / \partial (\mathbf{x}_j \beta_2)$ ;

...

the  $(k - 1)$ th new variable will contain  $\partial \ln L / \partial (\mathbf{x}_j \beta_{k-1})$ .

## margins

### Description for margins

`margins` estimates margins of response for probabilities and linear predictions.

### Menu for margins

Statistics > Postestimation

### Syntax for margins

`margins` [*marginlist*] [, *options*]

`margins` [*marginlist*] , predict(*statistic* ...) [predict(*statistic* ...) ...] [*options*]

| <i>statistic</i> | Description                               |
|------------------|-------------------------------------------|
| default          | probabilities for each outcome            |
| pr               | probability for a specified outcome       |
| xb               | linear prediction for a specified outcome |
| stdp             | not allowed with margins                  |
| stddp            | not allowed with margins                  |

`pr` and `xb` default to the first outcome.

Statistics not allowed with `margins` are functions of stochastic quantities other than  $e(b)$ .

For the full syntax, see [R] [margins](#).

## Remarks and examples

Remarks are presented under the following headings:

*Obtaining predicted values*  
*Calculating marginal effects*  
*Testing hypotheses about coefficients*

### Obtaining predicted values

#### ▷ Example 1: Obtaining predicted probabilities

After estimation, we can use `predict` to obtain predicted probabilities, index values, and standard errors of the index, or differences in the index. For instance, in [example 4 of \[R\] mlogit](#), we fit a model of insurance choice on various characteristics. We can obtain the predicted probabilities for outcome 1 by typing

```
. use https://www.stata-press.com/data/r19/sysdsn1
(Health insurance data)
. mlogit insure age i.male i.nonwhite i.site
(output omitted)
. predict p1 if e(sample), outcome(1)
(option pr assumed; predicted probability)
(29 missing values generated)
. summarize p1
```

| Variable | Obs | Mean     | Std. dev. | Min      | Max    |
|----------|-----|----------|-----------|----------|--------|
| p1       | 615 | .4764228 | .1032279  | .1698142 | .71939 |

We added the `i.` prefix to the `male`, `nonwhite`, and `site` variables to explicitly identify them as factor variables. That makes no difference in the estimated results, but we will take advantage of it in later examples. We also included `if e(sample)` to restrict the calculation to the estimation sample. In [example 4 of \[R\] mlogit](#), the multinomial logit model was fit on 615 observations, so there must be missing values in our dataset.

Although we typed `outcome(1)`, specifying 1 for the indemnity outcome, we could have typed `outcome(Indemnity)`. For instance, to obtain the probabilities for prepaid, we could type

```
. predict p2 if e(sample), outcome(Prepaid)
(option pr assumed; predicted probability)
(29 missing values generated)
. summarize p2
```

| Variable | Obs | Mean     | Std. dev. | Min      | Max      |
|----------|-----|----------|-----------|----------|----------|
| p2       | 615 | .4504065 | .1125962  | .1964103 | .7885724 |

We must specify the label exactly as it appears in the underlying value label (or how it appears in the `mlogit` output), including capitalization.

Here we have used `predict` to obtain probabilities for the same sample on which we estimated. That is not necessary. We could use another dataset that had the independent variables defined (in our example, `age`, `male`, `nonwhite`, and `site`) and use `predict` to obtain predicted probabilities; here, we would not specify `if e(sample)`.

► Example 2: Obtaining index values

predict can also be used to obtain the index values—the  $\sum x_i \hat{\beta}_i^{(k)}$ —as well as the probabilities:

```
. predict idx1, outcome(Indemnity) xb
(1 missing value generated)
. summarize idx1
```

| Variable | Obs | Mean | Std. dev. | Min | Max |
|----------|-----|------|-----------|-----|-----|
| idx1     | 643 | 0    | 0         | 0   | 0   |

The indemnity outcome was our base outcome—the outcome for which all the coefficients were set to 0—so the index is always 0. For the prepaid and uninsured outcomes, we type

```
. predict idx2, outcome(Prepaid) xb
(1 missing value generated)
. predict idx3, outcome(Uninsure) xb
(1 missing value generated)
. summarize idx2 idx3
```

| Variable | Obs | Mean      | Std. dev. | Min       | Max       |
|----------|-----|-----------|-----------|-----------|-----------|
| idx2     | 643 | -.0566113 | .4962973  | -1.298198 | 1.700719  |
| idx3     | 643 | -1.980747 | .6018139  | -3.112741 | -.8258458 |

We can obtain the standard error of the index by specifying the stdp option:

```
. predict se2, outcome(Prepaid) stdp
(1 missing value generated)
. list p2 idx2 se2 in 1/5
```

|    | p2       | idx2      | se2      |
|----|----------|-----------|----------|
| 1. | .3709022 | -.4831167 | .2437772 |
| 2. | .4977667 | .055111   | .1694686 |
| 3. | .4113073 | -.1712106 | .1793498 |
| 4. | .5424927 | .3788345  | .2513701 |
| 5. | .        | -.0925817 | .1452616 |

We obtained the probability, p2, in the [previous example](#).

Finally, `predict` can calculate the standard error of the difference in the index values between two outcomes with the `stdp` option:

```
. predict se_2_3, outcome(Prepaid,Uninsure) stdp
(1 missing value generated)
. list idx2 idx3 se_2_3 in 1/5
```

|    | idx2      | idx3      | se_2_3   |
|----|-----------|-----------|----------|
| 1. | -.4831167 | -3.073253 | .5469354 |
| 2. | .055111   | -2.715986 | .4331918 |
| 3. | -.1712106 | -1.579621 | .3053815 |
| 4. | .3788345  | -1.462007 | .4492552 |
| 5. | -.0925817 | -2.814022 | .4024784 |

In the first observation, the difference in the indexes is  $-0.483 - (-3.073) = 2.59$ . The standard error of that difference is 0.547.

### ▷ Example 3: Interpreting results using predictive margins

It is more difficult to interpret the results from `mlogit` than those from `clogit` or `logit` because there are multiple equations. For example, suppose that one of the independent variables in our model takes on the values 0 and 1, and we are attempting to understand the effect of this variable. Assume that the coefficient on this variable for the second outcome,  $\beta^{(2)}$ , is positive. We might then be tempted to reason that the probability of the second outcome is higher if the variable is 1 rather than 0. Most of the time, that will be true, but occasionally we will be surprised. The probability of some other outcome could increase even more (say,  $\beta^{(3)} > \beta^{(2)}$ ), and thus the probability of outcome 2 would actually fall relative to that outcome. We can use `predict` to help interpret such results.

Continuing with our previously fit insurance-choice model, we wish to describe the model's predictions by race. For this purpose, we can use the method of predictive margins (also known as recycled predictions), in which we vary characteristics of interest across the whole dataset and average the predictions. That is, we have data on both whites and nonwhites, and our individuals have other characteristics as well. We will first pretend that all the people in our data are white but hold their other characteristics constant. We then calculate the probabilities of each outcome. Next we will pretend that all the people in our data are nonwhite, still holding their other characteristics constant. Again, we calculate the probabilities of each outcome. The difference in those two sets of calculated probabilities, then, is the difference due to race, holding other characteristics constant.

```
. gen byte nonwhold=nonwhite // save real race
. replace nonwhite=0 // make everyone white
(126 real changes made)
. predict wpiid, outcome(Indemnity) // predict probabilities
(option pr assumed; predicted probability)
(1 missing value generated)
. predict wpp, outcome(Prepaid)
(option pr assumed; predicted probability)
(1 missing value generated)
. predict wpoi, outcome(Uninsure)
(option pr assumed; predicted probability)
(1 missing value generated)
. replace nonwhite=1 // make everyone nonwhite
(644 real changes made)
```

```
. predict nwpind, outcome(Indemnity)
(option pr assumed; predicted probability)
(1 missing value generated)
. predict nwpp, outcome(Prepaid)
(option pr assumed; predicted probability)
(1 missing value generated)
. predict nwpnoi, outcome(Uninsure)
(option pr assumed; predicted probability)
(1 missing value generated)
. replace nonwhite=nonwhold // restore real race
(518 real changes made)
. summarize wp* nwp*, sep(3)
```

| Variable | Obs | Mean     | Std. dev. | Min      | Max      |
|----------|-----|----------|-----------|----------|----------|
| wpind    | 643 | .5141673 | .0872679  | .3092903 | .71939   |
| wpp      | 643 | .4082052 | .0993286  | .1964103 | .6502247 |
| wpnoi    | 643 | .0776275 | .0360283  | .0273596 | .1302816 |
| nwpind   | 643 | .3112809 | .0817693  | .1511329 | .535021  |
| nwpp     | 643 | .630078  | .0979976  | .3871782 | .8278881 |
| nwpnoi   | 643 | .0586411 | .0287185  | .0209648 | .0933874 |

In example 1 of [R] [mlogit](#), we presented a cross-tabulation of insurance type and race. Those values were unadjusted. The means reported above are the values adjusted for age, sex, and site. Combining the results gives

|           | Unadjusted |          | Adjusted |          |
|-----------|------------|----------|----------|----------|
|           | white      | nonwhite | white    | nonwhite |
| Indemnity | 0.51       | 0.36     | 0.51     | 0.31     |
| Prepaid   | 0.42       | 0.57     | 0.41     | 0.63     |
| Uninsured | 0.07       | 0.07     | 0.08     | 0.06     |

We find, for instance, after adjusting for age, sex, and site, that although 57% of nonwhites in our data had prepaid plans, 63% of nonwhites chose prepaid plans.

Computing predictive margins by hand was instructive, but we can compute these values more easily using the margins command (see [R] [margins](#)). The two margins for the indemnity outcome can be estimated by typing

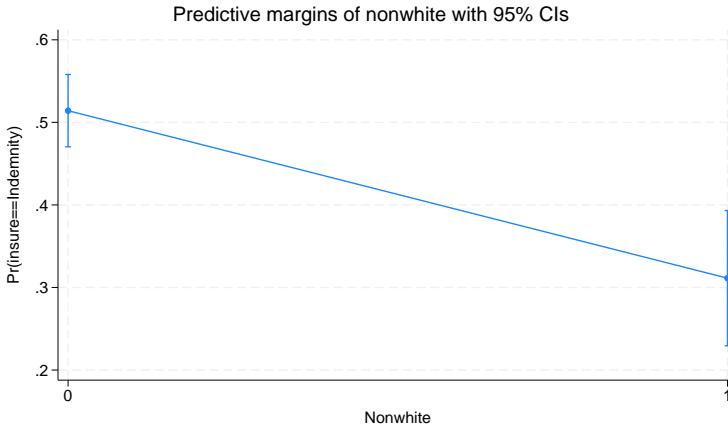

```
. margins nonwhite, predict(outcome(Indemnity)) noesample
Predictive margins Number of obs = 643
Model VCE: OIM
Expression: Pr(insure==Indemnity), predict(outcome(Indemnity))
```

|          | Delta-method |           |       |       | [95% conf. interval] |
|----------|--------------|-----------|-------|-------|----------------------|
|          | Margin       | std. err. | z     | P> z  |                      |
| nonwhite |              |           |       |       |                      |
| 0        | .5141673     | .0223485  | 23.01 | 0.000 | .470365 .5579695     |
| 1        | .3112809     | .0418049  | 7.45  | 0.000 | .2293448 .393217     |

margins also estimates the standard errors and confidence intervals of the margins. By default, margins uses only the estimation sample. We added the noesample option so that margins would use the entire sample and produce results comparable with our earlier analysis.

We can use `marginsplot` to graph the results from `margins`:

```
. marginsplot
Variables that uniquely identify margins: nonwhite
```

The margins for the other two outcomes can be computed by typing

```
. margins nonwhite, predict(outcome(Prepaid)) noesample
(output omitted)
. margins nonwhite, predict(outcome(Uninsure)) noesample
(output omitted)
```

The margins for each outcome is computed when no outcome is specified. For example,

```
. margins nonwhite, noesample
(output omitted)
```

◀

## □ Technical note

You can use `predict` to classify predicted values and compare them with the observed outcomes to interpret a multinomial logit model. This is a variation on the notions of sensitivity and specificity for logistic regression. Here we will classify indemnity and prepaid as definitely predicting indemnity, definitely predicting prepaid, and ambiguous.

```
. predict indem, outcome(Indemnity) index // obtain indexes
(1 missing value generated)
. predict prepaid, outcome(Prepaid) index
(1 missing value generated)
. gen diff = prepaid-indem // obtain difference
(1 missing value generated)
. predict sediff, outcome(Indemnity,Prepaid) stddp // & its standard error
(1 missing value generated)
. gen type = 1 if diff/sediff < -1.96 // definitely indemnity
(504 missing values generated)
. replace type = 3 if diff/sediff > 1.96 // definitely prepaid
(100 real changes made)
```

```
. replace type = 2 if type>=. & diff/sediff < . // ambiguous
(404 real changes made)
. label def type 1 "Def Ind" 2 "Ambiguous" 3 "Def Prep"
. label values type type // label results
. tabulate insure type
```

| Type of insurance | type    |           |          | Total |
|-------------------|---------|-----------|----------|-------|
|                   | Def Ind | Ambiguous | Def Prep |       |
| Indemnity         | 78      | 183       | 33       | 294   |
| Prepaid           | 44      | 177       | 56       | 277   |
| Uninsure          | 12      | 28        | 5        | 45    |
| Total             | 134     | 388       | 94       | 616   |

We can see that the predictive power of this model is modest. There are many misclassifications in both directions, though there are more correctly classified observations than misclassified observations.

Also, the uninsured look overwhelmingly as though they might have come from the indemnity system rather than from the prepaid system.

## Calculating marginal effects

### ▷ Example 4

We have already noted that the coefficients from multinomial logit can be difficult to interpret because they are relative to the base outcome. Another way to evaluate the effect of covariates is to examine the marginal effect of changing their values on the probability of observing an outcome.

The margins command can be used for this too. We can estimate the marginal effect of each covariate on the probability of observing the first outcome—indemnity insurance—by typing

```
. margins, dydx(*) predict(outcome(Indemnity))
Average marginal effects Number of obs = 615
Model VCE: OIM
Expression: Pr(insure==Indemnity), predict(outcome(Indemnity))
dy/dx wrt: age 1.male 1.nonwhite 2.site 3.site
```

|            | Delta-method |           |       |       | [95% conf. interval] |           |
|------------|--------------|-----------|-------|-------|----------------------|-----------|
|            | dy/dx        | std. err. | z     | P> z  |                      |           |
| age        | .0026655     | .001399   | 1.91  | 0.057 | -.0000765            | .0054074  |
| 1.male     | -.1295734    | .0450945  | -2.87 | 0.004 | -.2179571            | -.0411898 |
| 1.nonwhite | -.2032404    | .0482554  | -4.21 | 0.000 | -.2978192            | -.1086616 |
| site       |              |           |       |       |                      |           |
| 2          | .0070995     | .0479993  | 0.15  | 0.882 | -.0869775            | .1011765  |
| 3          | .1216165     | .0505833  | 2.40  | 0.016 | .022475              | .220758   |

Note: dy/dx for factor levels is the discrete change from the base level.

By default, `margins` estimates the average marginal effect over the estimation sample, and that is what we see above. Being male decreases the average probability of having indemnity insurance by 0.130. We also see, from the note at the bottom of the table, that the marginal effect was computed as a discrete change in the probability of being male rather than female. That is why we made `male` a factor variable when fitting the model.

The `dydx(*)` option requested that `margins` estimate the marginal effect for each regressor, `dydx(age)` would have produced estimates only for the effect of `age`. `margins` has many options for controlling how the marginal effect is computed, including the ability to average over subgroups or to compute estimates for specified values of the regressors; see [\[R\] margins](#).

`margins` will compute the marginal effects on each outcome when no outcome is specified.

```
. margins, dydx(*)
 (output omitted)
```

◀

## Testing hypotheses about coefficients

### ▷ Example 5

`test` tests hypotheses about the coefficients just as after any estimation command; see [\[R\] test](#). Note, however, `test`'s syntax for dealing with multiple-equation models. Because `test` bases its results on the estimated covariance matrix, we might prefer a likelihood-ratio test; see [example 5](#) in [\[R\] mlogit](#) for an example of `lrtest`.

If we simply list variables after the `test` command, we are testing that the corresponding coefficients are zero across all equations:

```
. test 2.site 3.site
(1) [Indemnity]2o.site = 0
(2) [Prepaid]2.site = 0
(3) [Uninsure]2.site = 0
(4) [Indemnity]3o.site = 0
(5) [Prepaid]3.site = 0
(6) [Uninsure]3.site = 0
 Constraint 1 dropped
 Constraint 4 dropped
 chi2(4) = 19.74
 Prob > chi2 = 0.0006
```

We can test that all the coefficients (except the constant) in an equation are zero by simply typing the outcome in square brackets:

```
. test [Uninsure]
(1) [Uninsure]age = 0
(2) [Uninsure]0b.male = 0
(3) [Uninsure]1.male = 0
(4) [Uninsure]0b.nonwhite = 0
(5) [Uninsure]1.nonwhite = 0
(6) [Uninsure]1b.site = 0
(7) [Uninsure]2.site = 0
(8) [Uninsure]3.site = 0
Constraint 2 dropped
Constraint 4 dropped
Constraint 6 dropped
 chi2(5) = 9.31
Prob > chi2 = 0.0973
```

We specify the outcome just as we do with `predict`; we can specify the label if the outcome variable is labeled, or we can specify the numeric value of the outcome. We would have obtained the same test as above if we had typed `test [3]` because 3 is the value of `insure` for the outcome `uninsured`.

We can combine the two syntaxes. To test that the coefficients on the site variables are 0 in the equation corresponding to the outcome `prepaid`, we can type

```
. test [Prepaid]: 2.site 3.site
(1) [Prepaid]2.site = 0
(2) [Prepaid]3.site = 0
 chi2(2) = 10.78
Prob > chi2 = 0.0046
```

We specified the outcome and then followed that with a colon and the variables we wanted to test.

We can also test that coefficients are equal across equations. To test that all coefficients except the constant are equal for the `prepaid` and `uninsured` outcomes, we can type

```
. test [Prepaid=Uninsure]
(1) [Prepaid]age - [Uninsure]age = 0
(2) [Prepaid]0b.male - [Uninsure]0b.male = 0
(3) [Prepaid]1.male - [Uninsure]1.male = 0
(4) [Prepaid]0b.nonwhite - [Uninsure]0b.nonwhite = 0
(5) [Prepaid]1.nonwhite - [Uninsure]1.nonwhite = 0
(6) [Prepaid]1b.site - [Uninsure]1b.site = 0
(7) [Prepaid]2.site - [Uninsure]2.site = 0
(8) [Prepaid]3.site - [Uninsure]3.site = 0
Constraint 2 dropped
Constraint 4 dropped
Constraint 6 dropped
 chi2(5) = 13.80
Prob > chi2 = 0.0169
```

To test that only the site variables are equal, we can type

```
. test [Prepaid=Uninsure]: 2.site 3.site
(1) [Prepaid]2.site - [Uninsure]2.site = 0
(2) [Prepaid]3.site - [Uninsure]3.site = 0
 chi2(2) = 12.68
Prob > chi2 = 0.0018
```

Finally, we can test any arbitrary constraint by simply entering the equation and specifying the coefficients as described in [U] [13.5 Accessing coefficients and standard errors](#). The following hypothesis is senseless but illustrates the point:

```
. test ([Prepaid]age+[Uninsure]2.site)/2 = 2-[Uninsure]1.nonwhite
(1) .5*[Prepaid]age + [Uninsure]1.nonwhite + .5*[Uninsure]2.site = 2
 chi2(1) = 22.45
 Prob > chi2 = 0.0000
```

See [R] [test](#) for more information about test. The [information](#) there about combining hypotheses across test commands (the `accumulate` option) also applies after `mlogit`.

## Reference

Fagerland, M. W., and D. W. Hosmer, Jr. 2012. [A generalized Hosmer–Lemeshow goodness-of-fit test for multinomial logistic regression models](#). *Stata Journal* 12: 447–453.

## Also see

[R] [mlogit](#) — Multinomial (polytomous) logistic regression

[U] [20 Estimation and postestimation commands](#)

## Description

`set more off`, which is the default, tells Stata not to pause or display a —more— message. `set more on` tells Stata to wait until you press a key before continuing when a —more— message is displayed.

`set pagesize #` sets the number of lines between —more— messages.

## Syntax

*Tell Stata to pause or not pause for —more— messages*

```
set more { on | off } [, permanently]
```

*Set number of lines between —more— messages*

```
set pagesize #
```

## Option

`permanently` specifies that, in addition to making the change right now, the `more` setting be remembered and become the default setting when you invoke Stata.

## Remarks and examples

—more— is Stata’s way of telling you that it has something more to show you but that showing it to you will cause the information on the screen to scroll off. If you type `set more off`, the —more— conditions will never arise, and Stata’s output will scroll by at full speed. If you type `set more on`, the —more— conditions will be restored at the appropriate places.

When you see —more— at the bottom of the screen, you can do the following:

| <u>Press ...</u>                | <u>and Stata ...</u>                |
|---------------------------------|-------------------------------------|
| letter <i>l</i> or <i>Enter</i> | displays the next line              |
| letter <i>q</i>                 | acts as if you pressed <i>Break</i> |
| Spacebar or any other key       | displays the next screen            |

You can also click on the **More** button or click on —more— to display the next screen.

If `set more` is used within a do-file or program, Stata automatically restores the previous `set more` setting when the do-file or program concludes.

Programmers should see [P] [more](#) for information on the `more` programming command.

## Description

`mprobit` fits a multinomial probit (MNP) model for a categorical dependent variable with outcomes that have no natural ordering. The actual values taken by the dependent variable are irrelevant. The error terms are assumed to be independent, standard normal, random variables. `cmmprobit` relaxes the independence of irrelevant alternatives assumption by specifying correlated latent-variable errors. `cmmprobit` also allows heteroskedastic latent-variable errors and alternative-specific independent variables.

## Quick start

Multinomial probit model of  $y$  on  $x_1$ ,  $x_2$ , and categorical  $a$

```
mprobit y x1 x2 i.a
```

Same as above, but use  $a$  as the base outcome  $y = 3$

```
mprobit y x1 x2 i.a, baseoutcome(3)
```

Probit variance parameterization of differenced latent errors

```
mprobit y x1 x2 i.a, probitparam
```

Multiple-imputation estimates with Monte Carlo errors from `mi` set data

```
mi estimate, merror: mprobit y x1 x2 i.a
```

## Menu

Statistics > Categorical outcomes > Multinomial probit regression

## Syntax

```
mprobit depvar [indepvars] [if] [in] [weight] [, options]
```

| <i>options</i>                               | Description                                                                                                                                                                 |

| <code>coeflegend</code>                      | display legend instead of statistics                                                                                                                                        |

*indepvars* may contain factor variables; see [U] 11.4.3 Factor variables.

`bayes`, `bayesboot`, `bootstrap`, `by`, `collect`, `fp`, `jackknife`, `mi estimate`, `rolling`, `statsby`, and `svy` are allowed; see [U] 11.1.10 Prefix commands. For more details, see [BAYES] bayes: mprobit.

`vce(bootstrap)` and `vce(jackknife)` are not allowed with the `mi estimate` prefix; see [MI] mi estimate.

Weights are not allowed with the `bootstrap` prefix; see [R] bootstrap.

`vce()` and weights are not allowed with the `svy` prefix; see [SVY] svy.

`fweights`, `iweights`, and `pweights` are allowed; see [U] 11.1.6 weight.

`collinear` and `coeflegend` do not appear in the dialog box.

See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

## Options

### Model

`noconstant` suppresses the  $J - 1$  constant terms.

`baseoutcome(# | lbl)` specifies the outcome used to normalize the location of the latent variable. The base outcome may be specified as a number or a label. The default is to use the most frequent outcome. The coefficients associated with the base outcome are zero.

`probitparam` specifies to use the probit variance parameterization by fixing the variance of the differenced latent errors between the scale and the base alternatives to be one. The default is to make the variance of the base and scale latent errors one, thereby making the variance of the difference to be two.

`constraints` (*constraints*); see [R] [Estimation options](#).

#### SE/Robust

`vce` (*vcetype*) specifies the type of standard error reported, which includes types that are derived from asymptotic theory (`oim`, `opg`), that are robust to some kinds of misspecification (`robust`), that allow for intragroup correlation (`cluster` *clustvar*), and that use bootstrap or jackknife methods (`bootstrap`, `jackknife`); see [R] [vce\\_option](#).

If specifying `vce(bootstrap)` or `vce(jackknife)`, you must also specify `baseoutcome()`.

#### Reporting

`level(#)`, `nocnsreport`; see [R] [Estimation options](#).

*display\_options*: `nocl`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `no1stretch`; see [R] [Estimation options](#).

#### Integration

`intpoints(#)` specifies the number of Gaussian quadrature points to use in approximating the likelihood. The default is `intpoints(15)`.

#### Maximization

*maximize\_options*: `difficult`, `technique` (*algorithm\_spec*), `iterate(#)`, `[no]log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `ltolerance(#)`, `nrtolerance(#)`, `nonrtolerance`, and `from` (*init\_specs*); see [R] [Maximize](#). These options are seldom used.

Setting the optimization type to `technique(bhhh)` resets the default *vcetype* to `vce(opg)`.

The following options are available with `mprobit` but are not shown in the dialog box:

`collinear`, `coeflegend`; see [R] [Estimation options](#).

## Remarks and examples

The MNP model is used with discrete dependent variables that take on more than two outcomes that do not have a natural ordering. The stochastic error terms for this implementation of the model are assumed to have independent, standard normal distributions. To use `mprobit`, you must have one observation for each decision maker in the sample. See [CM] [cmmprobit](#) for another implementation of the MNP model that permits correlated and heteroskedastic errors and is suitable when you have data for each alternative that a decision maker faced.

The MNP model is frequently motivated using a latent-variable framework. The latent variable for the  $j$ th alternative,  $j = 1, \dots, J$ , is

$$\eta_{ij} = \mathbf{z}_i \boldsymbol{\alpha}_j + \xi_{ij}$$

where the  $1 \times q$  row vector  $\mathbf{z}_i$  contains the observed independent variables for the  $i$ th decision maker. Associated with  $\mathbf{z}_i$  are the  $J$  vectors of regression coefficients  $\boldsymbol{\alpha}_j$ . The  $\xi_{i,1}, \dots, \xi_{i,J}$  are distributed independently and identically standard normal. The decision maker chooses the alternative  $k$  such that  $\eta_{ik} \geq \eta_{im}$  for  $m \neq k$ .

Suppose that case  $i$  chooses alternative  $k$ , and take the difference between latent variable  $\eta_{ik}$  and the  $J - 1$  others:

$$\begin{aligned} v_{ijk} &= \eta_{ij} - \eta_{ik} \\ &= \mathbf{z}_i (\boldsymbol{\alpha}_j - \boldsymbol{\alpha}_k) + \xi_{ij} - \xi_{ik} \\ &= \mathbf{z}_i \boldsymbol{\gamma}_{j'} + \epsilon_{ij'} \end{aligned} \tag{1}$$

where  $j' = j$  if  $j < k$  and  $j' = j - 1$  if  $j > k$  so that  $j' = 1, \dots, J - 1$ .  $\text{Var}(\epsilon_{ij'}) = \text{Var}(\xi_{ij} - \xi_{ik}) = 2$  and  $\text{Cov}(\epsilon_{ij'}, \epsilon_{il'}) = 1$  for  $j' \neq l'$ . The probability that alternative  $k$  is chosen is

$$\begin{aligned} \Pr(i \text{ chooses } k) &= \Pr(v_{i1k} \leq 0, \dots, v_{i,J-1,k} \leq 0) \\ &= \Pr(\epsilon_{i1} \leq -\mathbf{z}_i \boldsymbol{\gamma}_1, \dots, \epsilon_{i,J-1} \leq -\mathbf{z}_i \boldsymbol{\gamma}_{J-1}) \end{aligned}$$

Hence, evaluating the likelihood function involves computing probabilities from the multivariate normal distribution. That all the covariances are equal simplifies the problem somewhat; see [Methods and formulas](#) for details.

In (1), not all  $J$  of the  $\boldsymbol{\alpha}_j$  are identifiable. To remove the indeterminacy,  $\boldsymbol{\alpha}_l$  is set to the zero vector, where  $l$  is the base outcome as specified in the `baseoutcome()` option. That fixes the  $l$ th latent variable to zero so that the remaining variables measure the attractiveness of the other alternatives relative to the base.

### ► Example 1

As discussed in [example 1](#) of [\[R\] mlogit](#), we have data on the type of health insurance available to 616 psychologically depressed subjects in the United States (Tarlov et al. 1989; Wells et al. 1989). Patients may have either an indemnity (fee-for-service) plan or a prepaid plan such as an HMO, or the patient may be uninsured. Demographic variables include age, gender, race, and site. Indemnity insurance is the most popular alternative, so `mprobit` will choose it as the base outcome by default.

```
. use https://www.stata-press.com/data/r19/sysdsn1
(Health insurance data)
```

```
. mprobit insure age male nonwhite i.site
```

```
Iteration 0: Log likelihood = -535.89424
Iteration 1: Log likelihood = -534.56173
Iteration 2: Log likelihood = -534.52835
Iteration 3: Log likelihood = -534.52833
```

Multinomial probit regression

Number of obs = 615  
Wald chi2(10) = 40.18  
Prob > chi2 = 0.0000

Log likelihood = -534.52833

The likelihood function for `mprobit` is derived under the assumption that all decision-making units face the same choice set, which is the union of all outcomes observed in the dataset. If that is not true for your model, then an alternative is to use the `cmmprobit` command, which does not require this assumption. To do that, you will need to expand the dataset so that each decision maker has  $k_i$  observations, where  $k_i$  is the number of alternatives in the choice set faced by decision maker  $i$ . You will also need to create a binary variable to indicate the choice made by each decision maker. Moreover, you will need to use the `correlation(independent)` and `stddev(homoskedastic)` options with `cmmprobit` unless you have alternative-specific variables.

## Stored results

mprobit stores the following in `e()`:

### Scalars

|                             |                                                              |

| <code>e(vcetype)</code>        | title used to label Std. err.                                            |
| <code>e(outeqs)</code>         | outcome equations                                                        |
| <code>e(out#)</code>           | outcome labels, $\# = 1, \dots, e(k\_out)$                               |
| <code>e(opt)</code>            | type of optimization                                                     |
| <code>e(which)</code>          | max or min; whether optimizer is to perform maximization or minimization |
| <code>e(ml_method)</code>      | type of ml method                                                        |
| <code>e(user)</code>           | name of likelihood-evaluator program                                     |
| <code>e(technique)</code>      | maximization technique                                                   |
| <code>e(properties)</code>     | b V                                                                      |
| <code>e(predict)</code>        | program used to implement <code>predict</code>                           |
| <code>e(marginsnotok)</code>   | predictions disallowed by <code>margins</code>                           |
| <code>e(marginsdefault)</code> | default <code>predict()</code> specification for <code>margins</code>    |
| <code>e(asbalanced)</code>     | factor variables <code>fvset</code> as <code>asbalanced</code>           |
| <code>e(asobserved)</code>     | factor variables <code>fvset</code> as <code>asobserved</code>           |

|                 |                                              |
|-----------------|----------------------------------------------|
| Matrices        |                                              |
| e(b)            | coefficient vector                           |
| e(outcomes)     | outcome values                               |
| e(Cns)          | constraints matrix                           |
| e(iilog)        | iteration log (up to 20 iterations)          |
| e(gradient)     | gradient vector                              |
| e(V)            | variance–covariance matrix of the estimators |
| e(V_modelbased) | model-based variance                         |
| Functions       |                                              |
| e(sample)       | marks estimation sample                      |

In addition to the above, the following is stored in `r()`:

|          |                                                                                                                       |
|----------|-----------------------------------------------------------------------------------------------------------------------|
| Matrices |                                                                                                                       |
| r(table) | matrix containing the coefficients with their standard errors, test statistics, $p$ -values, and confidence intervals |

Note that results stored in `r()` are updated when the command is replayed and will be replaced when any  $r$ -class command is run after the estimation command.

## Methods and formulas

See [Cameron and Trivedi \(2005, chap. 15\)](#) for a discussion of multinomial models, including multinomial probit. [Long and Freese \(2014, chap. 8\)](#) discuss the multinomial logistic, multinomial probit, and stereotype logistic regression models, with examples using Stata.

As discussed in [Remarks and examples](#), the latent variables for a  $J$ -alternative model are  $\eta_{ij} = \mathbf{z}_i \boldsymbol{\alpha}_j + \xi_{ij}$ , for  $j = 1, \dots, J$ ,  $i = 1, \dots, n$ , and  $\{\xi_{i,1}, \dots, \xi_{i,J}\} \sim i.i.d.N(0, 1)$ . The experimenter observes alternative  $k$  for the  $i$ th observation if  $\eta_{ik} > \eta_{il}$  for  $l \neq k$ . For  $j \neq k$ , let

$$\begin{aligned} v_{ij'} &= \eta_{ij} - \eta_{ik} \\ &= \mathbf{z}_i (\boldsymbol{\alpha}_j - \boldsymbol{\alpha}_k) + \xi_{ij} - \xi_{ik} \\ &= \mathbf{z}_i \boldsymbol{\gamma}_{j'} + \epsilon_{ij'} \end{aligned}$$

where  $j' = j$  if  $j < k$  and  $j' = j - 1$  if  $j > k$  so that  $j' = 1, \dots, J - 1$ .  $\boldsymbol{\epsilon}_i = (\epsilon_{i1}, \dots, \epsilon_{i,J-1}) \sim MVN(\mathbf{0}, \boldsymbol{\Sigma})$ , where

$$\boldsymbol{\Sigma} = \begin{pmatrix} 2 & 1 & 1 & \dots & 1 \\ 1 & 2 & 1 & \dots & 1 \\ 1 & 1 & 2 & \dots & 1 \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 1 & 1 & 1 & \dots & 2 \end{pmatrix}$$

Denote the deterministic part of the model as  $\lambda_{ij'} = \mathbf{z}_i \boldsymbol{\gamma}_{j'}$ ; the probability that subject  $i$  chooses outcome  $k$  is

$$\begin{aligned} \Pr(y_i = k) &= \Pr(v_{i1} \leq 0, \dots, v_{i,J-1} \leq 0) \\ &= \Pr(\epsilon_{i1} \leq -\lambda_{i1}, \dots, \epsilon_{i,J-1} \leq -\lambda_{i,J-1}) \\ &= \frac{1}{(2\pi)^{(J-1)/2} |\boldsymbol{\Sigma}|^{1/2}} \int_{-\infty}^{-\lambda_{i1}} \dots \int_{-\infty}^{-\lambda_{i,J-1}} \exp\left(-\frac{1}{2} \mathbf{z}' \boldsymbol{\Sigma}^{-1} \mathbf{z}\right) d\mathbf{z} \end{aligned}$$

Because of the exchangeable correlation structure of  $\Sigma$  ( $\rho_{ij} = 1/2$  for all  $i \neq j$ ), we can use Dunnett's (1989) result to reduce the multidimensional integral to one dimension:

$$\Pr(y_i = k) = \frac{1}{\sqrt{\pi}} \int_0^\infty \left\{ \prod_{j=1}^{J-1} \Phi(-z\sqrt{2} - \lambda_{ij}) + \prod_{j=1}^{J-1} \Phi(z\sqrt{2} - \lambda_{ij}) \right\} e^{-z^2} dz$$

Gaussian quadrature is used to approximate this integral, resulting in the  $K$ -point quadrature formula

$$\Pr(y_i = k) \approx \frac{1}{2} \sum_{k=1}^K w_k \left\{ \prod_{j=1}^{J-1} \Phi(-\sqrt{2x_k} - \lambda_{ij}) + \prod_{j=1}^{J-1} \Phi(\sqrt{2x_k} - \lambda_{ij}) \right\}$$

where  $w_k$  and  $x_k$  are the weights and roots of the Laguerre polynomial of order  $K$ . In `mprobit`,  $K$  is specified by the `intpoints()` option.

This command supports the Huber/White/sandwich estimator of the variance and its clustered version using `vce(robust)` and `vce(cluster clustvar)`, respectively. See [P] `_robust`, particularly *Maximum likelihood estimators* and *Methods and formulas*.

`mprobit` also supports estimation with survey data. For details on VCEs with survey data, see [SVY] **Variance estimation**.

## Postestimation commands

The following postestimation commands are available after `mprobit`:

| Command                      | Description                                                                                                                             |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <code>contrast</code>        | contrasts and ANOVA-style joint tests of parameters                                                                                     |
| <code>estat ic</code>        | Akaike's, consistent Akaike's, corrected Akaike's, and Schwarz's Bayesian information criteria (AIC, CAIC, AICc, and BIC, respectively) |
| <code>estat summarize</code> | summary statistics for the estimation sample                                                                                            |
| <code>estat vce</code>       | variance–covariance matrix of the estimators (VCE)                                                                                      |
| <code>estat (svy)</code>     | postestimation statistics for survey data                                                                                               |
| <code>estimates</code>       | cataloging estimation results                                                                                                           |
| <code>etable</code>          | table of estimation results                                                                                                             |
| * <code>forecast</code>      | dynamic forecasts and simulations                                                                                                       |
| * <code>hausman</code>       | Hausman's specification test                                                                                                            |
| <code>lincom</code>          | point estimates, standard errors, testing, and inference for linear combinations of parameters                                          |
| * <code>lrtest</code>        | likelihood-ratio test                                                                                                                   |
| <code>margins</code>         | marginal means, predictive margins, marginal effects, and average marginal effects                                                      |
| <code>marginsplot</code>     | graph the results from <code>margins</code> (profile plots, interaction plots, etc.)                                                    |
| <code>nlcom</code>           | point estimates, standard errors, testing, and inference for nonlinear combinations of parameters                                       |
| <code>predict</code>         | probabilities, linear predictions and their SEs, etc.                                                                                   |
| <code>predictnl</code>       | point estimates, standard errors, testing, and inference for generalized predictions                                                    |
| <code>pwcompare</code>       | pairwise comparisons of parameters                                                                                                      |
| <code>suest</code>           | seemingly unrelated estimation                                                                                                          |
| <code>test</code>            | Wald tests of simple and composite linear hypotheses                                                                                    |
| <code>testnl</code>          | Wald tests of nonlinear hypotheses                                                                                                      |

\* `forecast`, `hausman`, and `lrtest` are not appropriate with `svy` estimation results. `forecast` is also not appropriate with `mi` estimation results.

# predict

## Description for predict

`predict` creates a new variable containing predictions such as probabilities, linear predictions, and standard errors.

## Menu for predict

Statistics > Postestimation

## Syntax for predict

```
predict [type] { stub* | newvar | newvarlist } [if] [in] [, statistic outcome(outcome)]
```

```
predict [type] stub* [if] [in] , scores
```

| <i>statistic</i> | Description |
|------------------|-------------|
|------------------|-------------|

Main

|                   |                                         |
|-------------------|-----------------------------------------|
| <code>pr</code>   | predicted probabilities; the default    |
| <code>xb</code>   | linear prediction                       |
| <code>stdp</code> | standard error of the linear prediction |

You specify one or  $k$  new variables with `pr`, where  $k$  is the number of outcomes. If you specify one new variable and you do not specify `outcome()`, then `outcome(#1)` is assumed.

You specify one new variable with `xb` and `stdp`. If you do not specify `outcome()`, then `outcome(#1)` is assumed.

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

## Options for predict

Main

`pr`, the default, computes the predicted probabilities for all outcomes or for a specific outcome. To compute probabilities for all outcomes, you specify  $k$  new variables, where  $k$  is the number of categories of the dependent variable. Alternatively, you can specify `stub*`; in which case, `pr` will store predicted probabilities in variables `stub1`, `stub2`, ..., `stubk`. To compute the probability for a specific outcome, you specify one new variable and, optionally, the outcome value in option `outcome()`; if you omit `outcome()`, the first outcome value, `outcome(#1)`, is assumed.

Say that you fit a model by typing `estimation_cmd y x1 x2`, and `y` takes on four values. Then, you could type `predict p1 p2 p3 p4` to obtain all four predicted probabilities; alternatively, you could type `predict p*` to generate the four predicted probabilities. To compute specific probabilities one at a time, you can type `predict p1, outcome(#1)` (or simply `predict p1`), `predict p2, outcome(#2)`, and so on. See option `outcome()` for other ways to refer to outcome values.

`xb` calculates the linear prediction,  $\mathbf{x}_i \boldsymbol{\alpha}_j$ , for alternative  $j$  and individual  $i$ . The index,  $j$ , corresponds to the outcome specified in `outcome()`.

`stdp` calculates the standard error of the linear prediction.

`outcome(outcome)` specifies for which outcome the predicted probabilities are to be calculated. `outcome()` should contain either one value of the dependent variable or one of #1, #2, ..., with #1 meaning the first category of the dependent variable, #2 meaning the second category, etc. `outcome()` is not allowed with `scores`.

`scores` calculates equation-level score variables. The  $j$ th new variable will contain the scores for the  $j$ th fitted equation.

## margins

### Description for margins

`margins` estimates margins of response for probabilities and linear predictions.

### Menu for margins

Statistics > Postestimation

### Syntax for margins

```
margins [marginlist] [, options]
margins [marginlist] , predict(statistic ...) [predict(statistic ...) ...] [options]
```

| <i>statistic</i> | Description                               |
|------------------|-------------------------------------------|
| default          | probabilities for each outcome            |
| pr               | probability for a specified outcome       |
| xb               | linear prediction for a specified outcome |
| stdp             | not allowed with <code>margins</code>     |

`pr` and `xb` default to the first outcome.

Statistics not allowed with `margins` are functions of stochastic quantities other than  $e(b)$ .

For the full syntax, see [\[R\] margins](#).

### Remarks and examples

Once you have fit a multinomial probit model, you can use `predict` to obtain probabilities that an individual will choose each of the alternatives for the estimation sample, as well as other samples; see [\[U\] 20 Estimation and postestimation commands](#) and [\[R\] predict](#).

## ▷ Example 1

In [example 1](#) of [\[R\] mprobit](#), we fit the multinomial probit model to a dataset containing the type of health insurance available to 616 psychologically depressed subjects in the United States (Tarlov et al. 1989; Wells et al. 1989). We can obtain the predicted probabilities by typing

```
. use https://www.stata-press.com/data/r19/sysdsn1
(Health insurance data)
. mprobit insure age male nonwhite i.site
(output omitted)
. predict p1-p3
(option pr assumed; predicted probabilities)
. list p1-p3 insure in 1/10
```

|     | p1       | p2       | p3       | insure    |
|-----|----------|----------|----------|-----------|
| 1.  | .5961306 | .3741824 | .029687  | Indemnity |
| 2.  | .4719296 | .4972289 | .0308415 | Prepaid   |
| 3.  | .4896086 | .4121961 | .0981953 | Indemnity |
| 4.  | .3730529 | .5416623 | .0852848 | Prepaid   |
| 5.  | .5063069 | .4629773 | .0307158 | .         |
| 6.  | .4768125 | .4923548 | .0308327 | Prepaid   |
| 7.  | .5035672 | .4657016 | .0307312 | Prepaid   |
| 8.  | .3326361 | .5580404 | .1093235 | .         |
| 9.  | .4758165 | .4384811 | .0857024 | Uninsure  |
| 10. | .5734057 | .3316601 | .0949342 | Prepaid   |

insure contains a missing value for observations 5 and 8. Because of that, those two observations were not used in the estimation. However, because none of the independent variables is missing, predict can still calculate the probabilities. Had we typed

```
. predict p1-p3 if e(sample)
```

predict would have filled in missing values for p1, p2, and p3 for those observations because they were not used in the estimation.

## Description

`nbreg` fits a negative binomial regression model for a nonnegative count dependent variable. In this model, the count variable is believed to be generated by a Poisson-like process, except that the variation is allowed to be greater than that of a true Poisson. This extra variation is referred to as overdispersion.

`gnbreg` fits a generalization of the negative binomial mean-dispersion model; the shape parameter  $\alpha$  may also be parameterized.

## Quick start

Negative binomial model of  $y$  on  $x_1$  and categorical variable  $a$

```
nbreg y x1 i.a
```

Same as above, but report results as incidence-rate ratios

```
nbreg y x1 i.a, irr
```

Same as above, and specify exposure variable  $evar$

```
nbreg y x1 i.a, irr exposure(evar)
```

Generalized negative binomial model with shape parameter  $\alpha$  a function of  $x_2$  and  $x_3$

```
gnbreg y x1 i.a, lnalpha(x2 x3)
```

Add log of exposure,  $lnevar$ , as an offset

```
gnbreg y x1 i.a, lnalpha(x2 x3) offset(lnevar)
```

*indepvars* and *varlist* may contain factor variables; see [U] 11.4.3 Factor variables.

*devar*, *indepvars*, *varname<sub>e</sub>*, and *varname<sub>o</sub>* may contain time-series operators (nbreg only); see [U] 11.4.4 Time-series varlists.

`bayes`, `bayesboot` (nbreg only), `bootstrap`, `by` (nbreg only), `collect`, `fmm` (nbreg only), `fp` (nbreg only), `jackknife`, `mfp` (nbreg only), `mi` estimate, `nestreg` (nbreg only), `rolling`, `statsby`, `stepwise`, and `svy` are allowed; see [U] 11.1.10 Prefix commands. For more details, see [BAYES] `bayes: nbreg`, [BAYES] `bayes: nbreg`, and [FMM] `fmm: nbreg`.

`vce(bootstrap)` and `vce(jackknife)` are not allowed with the `mi` estimate prefix; see [MI] `mi estimate`.

Weights are not allowed with the `bootstrap` prefix; see [R] `bootstrap`.

`vce()` and weights are not allowed with the `svy` prefix; see [SVY] `svy`.

`fweights`, `iwweights`, and `pweights` are allowed; see [U] 11.1.6 `weight`.

`collinear` and `coeflegend` do not appear in the dialog box.

See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

## Options for nbreg

Model

`noconstant`; see [R] Estimation options.

`dispersion(mean | constant)` specifies the parameterization of the model. `dispersion(mean)`, the default, yields a model with dispersion equal to  $1 + \alpha \exp(\mathbf{x}_j\beta + \text{offset}_j)$ ; that is, the dispersion is a function of the expected mean:  $\exp(\mathbf{x}_j\beta + \text{offset}_j)$ . `dispersion(constant)` has dispersion equal to  $1 + \delta$ ; that is, it is a constant for all observations.

`exposure(varnamee)`, `offset(varnameo)`, `constraints(constraints)`; see [R] Estimation options.

## SE/Robust

`vce(vctype)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory (`oim`, `opg`), that are robust to some kinds of misspecification (`robust`), that allow for intragroup correlation (`cluster clustvar`), and that use bootstrap or jackknife methods (`bootstrap`, `jackknife`); see [R] [vce\\_option](#).

## Reporting

`level(#)`; see [R] [Estimation options](#).

`no1rtest` suppresses fitting the Poisson model. Without this option, a comparison Poisson model is fit, and the likelihood is used in a likelihood-ratio test of the null hypothesis that the dispersion parameter is zero.

`irr` reports estimated coefficients transformed to incidence-rate ratios, that is,  $e^{\beta_i}$  rather than  $\beta_i$ . Standard errors and confidence intervals are similarly transformed. This option affects how results are displayed, not how they are estimated or stored. `irr` may be specified at estimation or when replaying previously estimated results.

`nocnsreport`; see [R] [Estimation options](#).

`display_options`: `nocl`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `no1stretch`; see [R] [Estimation options](#).

## Maximization

`maximize_options`: `difficult`, `technique(algorithm_spec)`, `iterate(#)`, `[no]log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `1tolerance(#)`, `nr1tolerance(#)`, `nonr1tolerance`, and `from(init_specs)`; see [R] [Maximize](#). These options are seldom used.

Setting the optimization type to `technique(bhhh)` resets the default `vctype` to `vce(opg)`.

The following options are available with `nbreg` but are not shown in the dialog box:

`collinear`, `coeflegend`; see [R] [Estimation options](#).

## Options for `gnbreg`

## Model

`noconstant`; see [R] [Estimation options](#).

`lnalpha(varlist)` allows you to specify a linear equation for  $\ln\alpha$ . Specifying `lnalpha(male old)` means that  $\ln\alpha = \gamma_0 + \gamma_1\text{male} + \gamma_2\text{old}$ , where  $\gamma_0$ ,  $\gamma_1$ , and  $\gamma_2$  are parameters to be estimated along with the other model coefficients. If this option is not specified, `gnbreg` and `nbreg` will produce the same results because the shape parameter will be parameterized as a constant.

`exposure(varnamee)`, `offset(varnameo)`, `constraints(constraints)`; see [R] [Estimation options](#).

## SE/Robust

`vce(vcetype)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory (`oim`, `opg`), that are robust to some kinds of misspecification (`robust`), that allow for intragroup correlation (`cluster clustvar`), and that use bootstrap or jackknife methods (`bootstrap`, `jackknife`); see [R] [vce\\_option](#).

## Reporting

`level(#)`; see [R] [Estimation options](#).

`irr` reports estimated coefficients transformed to incidence-rate ratios, that is,  $e^{\beta_i}$  rather than  $\beta_i$ . Standard errors and confidence intervals are similarly transformed. This option affects how results are displayed, not how they are estimated or stored. `irr` may be specified at estimation or when replaying previously estimated results.

`nocnsreport`; see [R] [Estimation options](#).

*display\_options*: `nocl`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `nolstretch`; see [R] [Estimation options](#).

## Maximization

*maximize\_options*: `difficult`, `technique(algorithm_spec)`, `iterate(#)`, `[no]log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `ltolerance(#)`, `nrtolerance(#)`, `nonrtolerance`, and `from(init_specs)`; see [R] [Maximize](#). These options are seldom used.

Setting the optimization type to `technique(bhhh)` resets the default `vcetype` to `vce(opg)`.

The following options are available with `gnbreg` but are not shown in the dialog box:

`collinear`, `coeflegend`; see [R] [Estimation options](#).

## Remarks and examples

Remarks are presented under the following headings:

[Introduction to negative binomial regression](#)  
[nbgreg](#)  
[gnbreg](#)

## Introduction to negative binomial regression

Negative binomial regression models the number of occurrences (counts) of an event when the event has extra-Poisson variation, that is, when it has overdispersion. The Poisson regression model is

$$y_j \sim \text{Poisson}(\mu_j)$$

where

$$\mu_j = \exp(\mathbf{x}_j\boldsymbol{\beta} + \text{offset}_j)$$

for observed counts  $y_j$  with covariates  $\mathbf{x}_j$  for the  $j$ th observation. One derivation of the negative binomial mean-dispersion model is that individual units follow a Poisson regression model, but there is an omitted variable  $\zeta_j$ , such that  $e^{\zeta_j}$  follows a gamma distribution with mean 1 and variance  $\alpha$ :

$$y_j \sim \text{Poisson}(\mu_j^*)$$

where

$$\mu_j^* = \exp(\mathbf{x}_j\boldsymbol{\beta} + \text{offset}_j + \zeta_j)$$

and

$$e^{\zeta_j} \sim \text{Gamma}(1/\alpha, \alpha)$$

With this parameterization, a  $\text{Gamma}(a, b)$  distribution will have expectation  $ab$  and variance  $ab^2$ .

We refer to  $\alpha$  as the overdispersion parameter. The larger  $\alpha$  is, the greater the overdispersion. The Poisson model corresponds to  $\alpha = 0$ . `nbreg` parameterizes  $\alpha$  as  $\ln\alpha$ . `gnbreg` allows  $\ln\alpha$  to be modeled as  $\ln\alpha_j = \mathbf{z}_j\boldsymbol{\gamma}$ , a linear combination of covariates  $\mathbf{z}_j$ .

`nbreg` will fit two different parameterizations of the negative binomial model. The default, described above and also given by the `dispersion(mean)` option, has dispersion for the  $j$ th observation equal to  $1 + \alpha \exp(\mathbf{x}_j\boldsymbol{\beta} + \text{offset}_j)$ . This is seen by noting that the above implies that

$$\mu_j^* \sim \text{Gamma}(1/\alpha, \alpha\mu_j)$$

and thus

$$\begin{aligned} \text{Var}(y_j) &= E\{\text{Var}(y_j|\mu_j^*)\} + \text{Var}\{E(y_j|\mu_j^*)\} \\ &= E(\mu_j^*) + \text{Var}(\mu_j^*) \\ &= \mu_j(1 + \alpha\mu_j) \end{aligned}$$

The alternative parameterization, given by the `dispersion(constant)` option, has dispersion equal to  $1 + \delta$ ; that is, it is constant for all observations. This is so because the constant-dispersion model assumes instead that

$$\mu_j^* \sim \text{Gamma}(\mu_j/\delta, \delta)$$

and thus  $\text{Var}(y_j) = \mu_j(1 + \delta)$ . The Poisson model corresponds to  $\delta = 0$ .

For detailed derivations of both models, see [Cameron and Trivedi \(2013, 80–89\)](#). In particular, note that the mean-dispersion model is known as the NB2 model in their terminology, whereas the constant-dispersion model is referred to as the NB1 model.

See [Long and Freese \(2014\)](#) and [Cameron and Trivedi \(2022, chap. 20\)](#) for a discussion of the negative binomial regression model with Stata examples and for a discussion of other regression models for count data.

[Hilbe \(2011\)](#) provides an extensive review of the negative binomial model and its variations, using Stata examples.

## nbreg

It is not uncommon to posit a Poisson regression model and observe a lack of model fit. The following data appeared in [Rodríguez \(1993\)](#):

```
. use https://www.stata-press.com/data/r19/rod93
. list, sepby(cohort)
```

|     | cohort    | age_mos | deaths | exposure |

| alpha     | 1.811212    | .4679475  |       |       | 1.09157              | 3.005295  |

```
LR test of alpha=0: chibar2(01) = 4056.27 Prob >= chibar2 = 0.000
```

Our original Poisson model is a special case of the negative binomial—it corresponds to  $\alpha = 0$ . nbreg, however, estimates  $\alpha$  indirectly, estimating instead  $\ln\alpha$ . In our model,  $\ln\alpha = 0.594$ , meaning that  $\alpha = 1.81$  (nbreg undoes the transformation for us at the bottom of the output).

To test  $\alpha = 0$  (equivalent to  $\ln\alpha = -\infty$ ), nbreg performs a likelihood-ratio test. The staggering  $\chi^2$  value of 4,056 asserts that the probability that we would observe these data conditional on  $\alpha = 0$  is virtually zero, that is, conditional on the process being Poisson. The data are not Poisson. It is not accidental that this  $\chi^2$  value is close to the goodness-of-fit statistic from the Poisson regression itself.

### □ Technical note

The usual Gaussian test of  $\alpha = 0$  is omitted because this test occurs on the boundary, invalidating the usual theory associated with such tests. However, the likelihood-ratio test of  $\alpha = 0$  has been modified to be valid on the boundary. In particular, the null distribution of the likelihood-ratio test statistic is not the usual  $\chi_1^2$ , but rather a 50 : 50 mixture of a  $\chi_0^2$  (point mass at zero) and a  $\chi_1^2$ , denoted as  $\bar{\chi}_{01}^2$ . See [Gutierrez, Carter, and Drukker \(2001\)](#) for more details.

□

### □ Technical note

The negative binomial model deals with cases in which there is more variation than would be expected if the process were Poisson. The negative binomial model is not helpful if there is less than Poisson variation—if the variance of the count variable is less than its mean. However, underdispersion is uncommon. Poisson models arise because of independently generated events. Overdispersion comes about if some of the parameters (causes) of the Poisson processes are unknown. To obtain underdispersion, the sequence of events somehow would have to be regulated; that is, events would not be independent but controlled based on past occurrences.

□

## gnbreg

`gnbreg` is a generalization of `nbreg`, `dispersion(mean)`. Whereas in `nbreg`, one  $\ln\alpha$  is estimated, `gnbreg` allows  $\ln\alpha$  to vary, observation by observation, as a linear combination of another set of covariates:  $\ln\alpha_j = \mathbf{z}_j\boldsymbol{\gamma}$ .

We will assume that the number of deaths is a function of age, whereas the  $\ln\alpha$  parameter is a function of cohort. To fit the model, we type

```
. nbreg deaths age_mos, lnalpha(i.cohort) offset(logexp)
Fitting constant-only model:
Iteration 0: Log likelihood = -187.067 (not concave)
Iteration 1: Log likelihood = -138.13047
Iteration 2: Log likelihood = -133.83164
Iteration 3: Log likelihood = -131.59551
Iteration 4: Log likelihood = -131.5795
Iteration 5: Log likelihood = -131.57948
Iteration 6: Log likelihood = -131.57948
Fitting full model:
Iteration 0: Log likelihood = -124.34327
Iteration 1: Log likelihood = -117.76701
Iteration 2: Log likelihood = -117.56403
Iteration 3: Log likelihood = -117.56164
Iteration 4: Log likelihood = -117.56164
Generalized negative binomial regression
Log likelihood = -117.56164
Number of obs = 21
LR chi2(1) = 28.04
Prob > chi2 = 0.0000
Pseudo R2 = 0.1065
```

|                | Coefficient | Std. err. | z     | P> z  | [95% conf. interval] |           |
|----------------|-------------|-----------|-------|-------|----------------------|-----------|
| <b>deaths</b>  |             |           |       |       |                      |           |
| age_mos        | -.0516657   | .0051747  | -9.98 | 0.000 | -.061808             | -.0415233 |
| _cons          | -1.867225   | .2227944  | -8.38 | 0.000 | -2.303894            | -1.430556 |
| logexp         | 1           | (offset)  |       |       |                      |           |
| <b>lnalpha</b> |             |           |       |       |                      |           |
| cohort         |             |           |       |       |                      |           |
| 1960-1967      | .0939546    | .7187747  | 0.13  | 0.896 | -1.314818            | 1.502727  |
| 1968-1976      | .0815279    | .7365476  | 0.11  | 0.912 | -1.362079            | 1.525135  |
| _cons          | -.4759581   | .5156502  | -0.92 | 0.356 | -1.486614            | .5346978  |

We find that age is a significant determinant of the number of deaths. The standard errors for the variables in the  $\ln\alpha$  equation suggest that the overdispersion parameter does not vary across cohorts. We can test this assertion by typing

```
. test 2.cohort 3.cohort
(1) [lnalpha]2.cohort = 0
(2) [lnalpha]3.cohort = 0
 chi2(2) = 0.02
 Prob > chi2 = 0.9904
```

There is no evidence of variation by cohort in these data.

## □ Technical note

Note the intentional absence of a likelihood-ratio test for  $\alpha = 0$  in `gnbreg`. The test is affected by the same boundary condition that affects the comparison test in `nbreg`; however, when  $\alpha$  is parameterized by more than a constant term, the null distribution becomes intractable. For this reason, we recommend using `nbreg` to test for overdispersion and, if you have reason to believe that overdispersion exists, only then modeling the overdispersion using `gnbreg`.

□

## Stored results

`nbreg` stores the following in `e()`:

### Scalars

|                            |                                                   |
|----------------------------|---------------------------------------------------|

e(predict) program used to implement predict  
 e(asbalanced) factor variables fvset as asbalanced  
 e(asobserved) factor variables fvset as asobserved

Matrices

e(b) coefficient vector  
 e(Cns) constraints matrix  
 e(iilog) iteration log (up to 20 iterations)  
 e(gradient) gradient vector  
 e(V) variance–covariance matrix of the estimators  
 e(V\_modelbased) model-based variance

Functions

e(sample) marks estimation sample

In addition to the above, the following is stored in `r()`:

Matrices

r(table) matrix containing the coefficients with their standard errors, test statistics, *p*-values, and confidence intervals

Note that results stored in `r()` are updated when the command is replayed and will be replaced when any *r*-class command is run after the estimation command.

## Methods and formulas

See [R] [poisson](#) and Johnson, Kemp, and Kotz (2005, chap. 4) for an introduction to the Poisson distribution.

Methods and formulas are presented under the following headings:

*Mean-dispersion model*  
*Constant-dispersion model*

### Mean-dispersion model

A negative binomial distribution can be regarded as a gamma mixture of Poisson random variables. The number of times something occurs,  $y_j$ , is distributed as  $\text{Poisson}(\nu_j \mu_j)$ . That is, its conditional likelihood is

$$f(y_j | \nu_j) = \frac{(\nu_j \mu_j)^{y_j} e^{-\nu_j \mu_j}}{\Gamma(y_j + 1)}$$

where  $\mu_j = \exp(\mathbf{x}_j \boldsymbol{\beta} + \text{offset}_j)$  and  $\nu_j$  is an unobserved parameter with a  $\text{Gamma}(1/\alpha, \alpha)$  density:

$$g(\nu) = \frac{\nu^{(1-\alpha)/\alpha} e^{-\nu/\alpha}}{\alpha^{1/\alpha} \Gamma(1/\alpha)}$$

This gamma distribution has mean 1 and variance  $\alpha$ , where  $\alpha$  is our ancillary parameter.

The unconditional likelihood for the  $j$ th observation is therefore

$$f(y_j) = \int_0^\infty f(y_j | \nu) g(\nu) d\nu = \frac{\Gamma(m + y_j)}{\Gamma(y_j + 1) \Gamma(m)} p_j^m (1 - p_j)^{y_j}$$

where  $p_j = 1/(1 + \alpha \mu_j)$  and  $m = 1/\alpha$ . Solutions for  $\alpha$  are handled by searching for  $\ln \alpha$  because  $\alpha$  must be greater than zero.

The log likelihood (with weights  $w_j$  and offsets) is given by

$$m = 1/\alpha \quad p_j = 1/(1 + \alpha\mu_j) \quad \mu_j = \exp(\mathbf{x}_j\boldsymbol{\beta} + \text{offset}_j)$$

$$\ln L = \sum_{j=1}^n w_j \left[ \ln\{\Gamma(m + y_j)\} - \ln\{\Gamma(y_j + 1)\} \right. \\ \left. - \ln\{\Gamma(m)\} + m \ln(p_j) + y_j \ln(1 - p_j) \right]$$

For `gnbreg`,  $\alpha$  can vary across the observations according to the parameterization  $\ln\alpha_j = \mathbf{z}_j\boldsymbol{\gamma}$ .

## Constant-dispersion model

The constant-dispersion model assumes that  $y_j$  is conditionally distributed as  $\text{Poisson}(\mu_j^*)$ , where  $\mu_j^* \sim \text{Gamma}(\mu_j/\delta, \delta)$  for some dispersion parameter  $\delta$  (by contrast, the mean-dispersion model assumes that  $\mu_j^* \sim \text{Gamma}(1/\alpha, \alpha\mu_j)$ ). The log likelihood is given by

$$m_j = \mu_j/\delta \quad p = 1/(1 + \delta)$$

$$\ln L = \sum_{j=1}^n w_j \left[ \ln\{\Gamma(m_j + y_j)\} - \ln\{\Gamma(y_j + 1)\} \right. \\ \left. - \ln\{\Gamma(m_j)\} + m_j \ln(p) + y_j \ln(1 - p) \right]$$

with everything else defined as before in the calculations for the mean-dispersion model.

`nbreg` and `gnbreg` support the Huber/White/sandwich estimator of the variance and its clustered version using `vce(robust)` and `vce(cluster clustvar)`, respectively. See [P] [\\_robust](#), particularly [Maximum likelihood estimators](#) and [Methods and formulas](#).

These commands also support estimation with survey data. For details on VCEs with survey data, see [SVY] [Variance estimation](#).

## Postestimation commands

The following postestimation commands are available after nbreg and gnbreg:

| Command                      | Description                                                                                                                             |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <code>contrast</code>        | contrasts and ANOVA-style joint tests of parameters                                                                                     |
| <code>estat ic</code>        | Akaike's, consistent Akaike's, corrected Akaike's, and Schwarz's Bayesian information criteria (AIC, CAIC, AICc, and BIC, respectively) |
| <code>estat summarize</code> | summary statistics for the estimation sample                                                                                            |
| <code>estat vce</code>       | variance–covariance matrix of the estimators (VCE)                                                                                      |
| <code>estat (svy)</code>     | postestimation statistics for survey data                                                                                               |
| <code>estimates</code>       | cataloging estimation results                                                                                                           |
| <code>etable</code>          | table of estimation results                                                                                                             |
| * <code>forecast</code>      | dynamic forecasts and simulations                                                                                                       |
| * <code>hausman</code>       | Hausman's specification test                                                                                                            |
| <code>lincom</code>          | point estimates, standard errors, testing, and inference for linear combinations of parameters                                          |
| <code>linktest</code>        | link test for model specification                                                                                                       |
| * <code>lrtest</code>        | likelihood-ratio test                                                                                                                   |
| <code>margins</code>         | marginal means, predictive margins, marginal effects, and average marginal effects                                                      |
| <code>marginsplot</code>     | graph the results from margins (profile plots, interaction plots, etc.)                                                                 |
| <code>nlcom</code>           | point estimates, standard errors, testing, and inference for nonlinear combinations of parameters                                       |
| <code>predict</code>         | number of events, incidence rates, probabilities, etc.                                                                                  |
| <code>predictnl</code>       | point estimates, standard errors, testing, and inference for generalized predictions                                                    |
| <code>pwcompare</code>       | pairwise comparisons of parameters                                                                                                      |
| <code>suest</code>           | seemingly unrelated estimation                                                                                                          |
| <code>test</code>            | Wald tests of simple and composite linear hypotheses                                                                                    |
| <code>testnl</code>          | Wald tests of nonlinear hypotheses                                                                                                      |

\*`forecast`, `hausman`, and `lrtest` are not appropriate with `svy` estimation results. `forecast` is also not appropriate with `mi` estimation results.

# predict

## Description for predict

predict creates a new variable containing predictions such as numbers of events, incidence rates, probabilities, linear predictions, standard errors, and predicted values.

## Menu for predict

Statistics > Postestimation

## Syntax for predict

```
predict [type] newvar [if] [in] [, statistic noffset]
```

```
predict [type] stub* [if] [in] , scores
```

| <i>statistic</i>  | Description                                           |
|-------------------|-------------------------------------------------------|
| Main              |                                                       |
| n                 | number of events; the default                         |
| ir                | incidence rate (equivalent to predict ..., n noffset) |
| pr( <i>n</i> )    | probability $\Pr(y_j = n)$                            |
| pr( <i>a, b</i> ) | probability $\Pr(a \leq y_j \leq b)$                  |
| xb                | linear prediction                                     |
| stdp              | standard error of the linear prediction               |

In addition, relevant only after gnbreg are the following:

| <i>statistic</i> | Description                               |
|------------------|-------------------------------------------|
| Main             |                                           |
| <u>a</u> lpha    | predicted values of $\alpha_j$            |
| <u>l</u> nalpha  | predicted values of $\ln\alpha_j$         |
| <u>s</u> tdplna  | standard error of predicted $\ln\alpha_j$ |

These statistics are available both in and out of sample; type predict ... if e(sample) ... if wanted only for the estimation sample.

## Options for predict

Main

n, the default, calculates the predicted number of events, which is  $\exp(\mathbf{x}_j\beta)$  if neither `offset(varnameo)` nor `exposure(varnamee)` was specified when the model was fit;  $\exp(\mathbf{x}_j\beta + \text{offset}_j)$  if `offset()` was specified; or  $\exp(\mathbf{x}_j\beta) \times \text{exposure}_j$  if `exposure()` was specified.

ir calculates the incidence rate  $\exp(\mathbf{x}_j\beta)$ , which is the predicted number of events when exposure is 1. This is equivalent to specifying both the n and the noffset options.

`pr(n)` calculates the probability  $\Pr(y_j = n)$ , where  $n$  is a nonnegative integer that may be specified as a number or a variable.

`pr(a,b)` calculates the probability  $\Pr(a \leq y_j \leq b)$ , where  $a$  and  $b$  are nonnegative integers that may be specified as numbers or variables;

$b$  missing ( $b \geq .$ ) means  $+\infty$ ;

`pr(20,.)` calculates  $\Pr(y_j \geq 20)$ ;

`pr(20,b)` calculates  $\Pr(y_j \geq 20)$  in observations for which  $b \geq .$  and calculates  $\Pr(20 \leq y_j \leq b)$  elsewhere.

`pr(.,b)` produces a syntax error. A missing value in an observation of the variable  $a$  causes a missing value in that observation for `pr(a,b)`.

`xb` calculates the linear prediction, which is  $\mathbf{x}_j\beta$  if neither `offset()` nor `exposure()` was specified;  $\mathbf{x}_j\beta + \text{offset}_j$  if `offset()` was specified; or  $\mathbf{x}_j\beta + \ln(\text{exposure}_j)$  if `exposure()` was specified; see `nooffset` below.

`stdp` calculates the standard error of the linear prediction.

`alpha`, `lnalpha`, and `stdplna` are relevant after `gnbreg` estimation only; they produce the predicted values of  $\alpha_j$ ,  $\ln\alpha_j$ , and the standard error of the predicted  $\ln\alpha_j$ , respectively.

`nooffset` is relevant only if you specified `offset()` or `exposure()` when you fit the model. It modifies the calculations made by `predict` so that they ignore the offset or exposure variable; the linear prediction is treated as  $\mathbf{x}_j\beta$  rather than as  $\mathbf{x}_j\beta + \text{offset}_j$  or  $\mathbf{x}_j\beta + \ln(\text{exposure}_j)$ . Specifying `predict ..., nooffset` is equivalent to specifying `predict ..., ir`.

`scores` calculates equation-level score variables.

The first new variable will contain  $\partial \ln L / \partial (\mathbf{x}_j\beta)$ .

The second new variable will contain  $\partial \ln L / \partial (\ln\alpha_j)$  for `dispersion(mean)` and `gnbreg`.

The second new variable will contain  $\partial \ln L / \partial (\ln\delta)$  for `dispersion(constant)`.

# margins

## Description for margins

`margins` estimates margins of response for numbers of events, incidence rates, probabilities, linear predictions, and predicted values.

## Menu for margins

Statistics > Postestimation

## Syntax for margins

```
margins [marginlist] [, options]
```

```
margins [marginlist] , predict(statistic ...) [predict(statistic ...) ...] [options]
```

| <i>statistic</i>             | Description                                                          |
|------------------------------|----------------------------------------------------------------------|
| <code>n</code>               | number of events; the default                                        |
| <code>ir</code>              | incidence rate (equivalent to <code>predict ..., n nooffset</code> ) |
| <code>pr(<i>n</i>)</code>    | probability $\Pr(y_j = n)$                                           |
| <code>pr(<i>a, b</i>)</code> | probability $\Pr(a \leq y_j \leq b)$                                 |
| <code>xb</code>              | linear prediction                                                    |
| <code>stdp</code>            | not allowed with <code>margins</code>                                |

In addition, relevant only after `gnbreg` are the following:

| <i>statistic</i>            | Description                           |
|-----------------------------|---------------------------------------|
| <code><u>alpha</u></code>   | predicted values of $\alpha_j$        |
| <code><u>lnalpha</u></code> | predicted values of $\ln\alpha_j$     |
| <code><u>stdplna</u></code> | not allowed with <code>margins</code> |

Statistics not allowed with `margins` are functions of stochastic quantities other than  $e(b)$ .

For the full syntax, see [\[R\] margins](#).

## Remarks and examples

After `nbreg` and `gnbreg`, `predict` returns the expected number of deaths per cohort and the probability of observing the number of deaths recorded or fewer.

```
. use https://www.stata-press.com/data/r19/rod93
. nbreg deaths i.cohort, nolog
Negative binomial regression Number of obs = 21
 LR chi2(2) = 0.14
Dispersion: mean Prob > chi2 = 0.9307
Log likelihood = -108.48841 Pseudo R2 = 0.0007
```

| deaths    | Coefficient | Std. err. | z     | P> z  | [95% conf. interval] |           |
|-----------|-------------|-----------|-------|-------|----------------------|-----------|
| cohort    |             |           |       |       |                      |           |
| 1960–1967 | .0591305    | .2978419  | 0.20  | 0.843 | -.5246289            | .64289    |
| 1968–1976 | -.0538792   | .2981621  | -0.18 | 0.857 | -.6382662            | .5305077  |
| _cons     | 4.435906    | .2107213  | 21.05 | 0.000 | 4.0229               | 4.848912  |
| /lnalpha  | -1.207379   | .3108622  |       |       | -1.816657            | -.5980999 |
| alpha     | .29898      | .0929416  |       |       | .1625683             | .5498555  |

LR test of alpha=0:  $\text{chibar2}(01) = 434.62$       Prob  $\geq$   $\text{chibar2} = 0.000$

```
. predict count
(option n assumed; predicted number of events)
. predict p, pr(0, deaths)
. summarize deaths count p
```

| Variable | Obs | Mean     | Std. dev. | Min      | Max      |
|----------|-----|----------|-----------|----------|----------|
| deaths   | 21  | 84.66667 | 48.84192  | 10       | 197      |
| count    | 21  | 84.66667 | 4.00773   | 80       | 89.57143 |
| p        | 21  | .4991542 | .2743702  | .0070255 | .9801285 |

The expected number of deaths ranges from 80 to 90. The probability  $\Pr(y_i \leq \text{deaths})$  ranges from 0.007 to 0.98.

The estimated expected and observed mean number of deaths, 84.67, happen to be the same in our example because our model included only a categorical predictor. In general, in the presence of other continuous predictors, the two estimates may not always be the same.

## Methods and formulas

In the following, we use the same notation as in [R] `nbreg`.

Methods and formulas are presented under the following headings:

*Mean-dispersion model*  
*Constant-dispersion model*

## Mean-dispersion model

The equation-level scores are given by

$$\begin{aligned}\text{score}(\mathbf{x}\boldsymbol{\beta})_j &= p_j(y_j - \mu_j) \\ \text{score}(\tau)_j &= -m \left\{ \frac{\alpha_j(\mu_j - y_j)}{1 + \alpha_j\mu_j} - \ln(1 + \alpha_j\mu_j) + \psi(y_j + m) - \psi(m) \right\}\end{aligned}$$

where  $\tau_j = \ln\alpha_j$  and  $\psi(z)$  is the digamma function.

## Constant-dispersion model

The equation-level scores are given by

$$\begin{aligned}\text{score}(\mathbf{x}\boldsymbol{\beta})_j &= m_j \{ \psi(y_j + m_j) - \psi(m_j) + \ln(p) \} \\ \text{score}(\tau)_j &= y_j - (y_j + m_j)(1 - p) - \text{score}(\mathbf{x}\boldsymbol{\beta})_j\end{aligned}$$

where  $\tau_j = \ln\delta_j$ .

## Description

`nestreg` fits nested models by sequentially adding blocks of variables and then reports comparison tests between the nested models.

## Quick start

Fit nested (hierarchical) models sequentially, including covariates `x1` and `x2` first and then adding `x3` and `x4`

```
nestreg: regress y (x1 x2) (x3 x4)
```

Also fit third model including indicators for categorical variable `a`

```
nestreg: regress y (x1 x2) (x3 x4) (i.a)
```

Report table of likelihood-ratio tests instead of Wald tests comparing models

```
nestreg, lrtable: regress y (x1 x2) (x3 x4) (i.a)
```

Fit nested models and adjust for complex survey design using `svyset` data

```
nestreg: svy: regress y (x1 x2) (x3 x4) (i.a)
```

Note: In the above examples, `regress` could be replaced with any estimation command allowing the `nestreg` prefix.

## Menu

Statistics > Other > Nested model statistics

## Syntax

Standard estimation command syntax

```
nestreg [, options]: command_name depvar (varlist) [(varlist) ...]
 [if] [in] [weight] [, command_options]
```

Survey estimation command syntax

```
nestreg [, options]: svy [vcetype] [, svy_options]: command_name depvar
 (varlist) [(varlist) ...] [if] [in] [, command_options]
```

| <i>options</i>                  | Description                                                       |
|---------------------------------|-------------------------------------------------------------------|
| Reporting                       |                                                                   |
| <code>waldtable</code>          | report Wald test results; the default                             |
| <code>lrtable</code>            | report likelihood-ratio test results                              |
| <code>quietly</code>            | suppress any output from <i>command_name</i>                      |
| <code>store(<i>stub</i>)</code> | store nested estimation results in <code>_est_<i>stub</i>#</code> |

by is allowed; see [U] 11.1.10 Prefix commands.

Weights are allowed if *command\_name* allows them; see [U] 11.1.6 weight.

A *varlist* in parentheses indicates that this list of variables is to be considered as a block. Each variable in *varlist* not bound in parentheses will be treated as its own block.

All postestimation commands behave as they would after *command\_name* without the `nestreg` prefix; see the postestimation manual entry for *command\_name*.

## Options

### Reporting

`waldtable` specifies that the table of Wald test results be reported. `waldtable` is the default.

`lrtable` specifies that the table of likelihood-ratio tests be reported. This option is not allowed if `pweights`, the `vce(robust)` option, or the `vce(cluster clustvar)` option is specified. `lrtable` is also not allowed with the `svy` prefix.

`quietly` suppresses the display of any output from *command\_name*.

`store(stub)` specifies that each model fit by `nestreg` be stored under the name `_est_stub#`, where `#` is the nesting order from first to last.

## Remarks and examples

Remarks are presented under the following headings:

- [Estimation commands](#)
- [Wald tests](#)
- [Likelihood-ratio tests](#)
- [Programming for nestreg](#)

## Estimation commands

nestreg removes collinear predictors and observations with missing values from the estimation sample before calling *command\_name*.

The following Stata commands are supported by nestreg:

betareg, clogit, cloglog, glm, intreg, logistic, logit, nbreg, ologit, oprobit, poisson, probit, qreg, regress, scobit, stcox, stcrreg, stintreg, streg, and tobit

You do not supply *depvar* for stcox, stintreg, stcrreg, or streg; otherwise, *depvar* is required. You must supply two *devars* for intreg.

## Wald tests

Use nestreg to test the significance of blocks of predictors, building the regression model one block at a time. Using the data from [example 1](#) of [\[R\] test](#), we wish to test the significance of the following predictors of birthrate: median age (medage), median age squared (c.medage#c.medage), and indicators of the census region (i.region).

```
. use https://www.stata-press.com/data/r19/census4
(Census data on birthrate, median age)
. nestreg: regress brate (medage) (c.medage#c.medage) (i.region)
note: 1.region omitted because of estimability.
```

nestreg collected the  $F$  statistic for the corresponding block of predictors and the model  $R^2$  statistic from each model fit.

The  $F$  statistic for the first block, 164.72, is for a test of the joint significance of the first block of variables; it is simply the  $F$  statistic from the regression of `brate` on `medage`. The  $F$  statistic for the second block, 35.25, is for a test of the joint significance of the second block of variables in a regression of both the first and second blocks of variables. In our example, it is an  $F$  test of `c.medage#c.medage` in the regression of `brate` on `medage` and `c.medage#c.medage`. Similarly, the third block's  $F$  statistic of 8.85 corresponds to a joint test of the indicators for the `N Cntrl`, `South`, and `West` regions in the final regression.

## Likelihood-ratio tests

The nestreg command provides a simple syntax for performing likelihood-ratio tests for nested model specifications; also see lrtest. Using the data from [example 1](#) of [\[R\] lrtest](#), we wish to jointly test the significance of the following predictors of low birthweight: age, lwt, ptl, and ht.

```
. use https://www.stata-press.com/data/r19/lbw
(Hosmer & Lemeshow data)
. nestreg, lr: logistic low (i.race smoke ui) (age lwt ptl ht)
note: 1.race omitted because of estimability.
Block 1: 2.race 3.race smoke ui
Logistic regression
Log likelihood = -107.93404
Number of obs = 189
LR chi2(4) = 18.80
Prob > chi2 = 0.0009
Pseudo R2 = 0.0801
```

| low   | Odds ratio | Std. err. | z     | P> z  | [95% conf. interval] |          |

| ht    | 6.249602   | 4.322408  | 2.65  | 0.008 | 1.611152             | 24.24199 |
| _cons | 1.586014   | 1.910496  | 0.38  | 0.702 | .1496092             | 16.8134  |

Note: **\_cons** estimates baseline odds.

| Block | LL       | LR    | df | Pr > LR | AIC      | BIC      |
|-------|----------|-------|----|---------|----------|----------|
| 1     | -107.934 | 18.80 | 4  | 0.0009  | 225.8681 | 242.0768 |
| 2     | -100.724 | 14.42 | 4  | 0.0061  | 219.448  | 248.6237 |

The estimation results from the full model are left in `e()`, so we can later use `estat` and other post-estimation commands.

```
. estat gof
Goodness-of-fit test after logistic model
Variable: low
 Number of observations = 189
Number of covariate patterns = 182
 Pearson chi2(173) = 179.24
 Prob > chi2 = 0.3567
```

## Programming for nestreg

If you want your community-contributed command (*command\_name*) to work with `nestreg`, it must follow standard Stata syntax and allow the `if` qualifier. Furthermore, *command\_name* must have `sw` or `swml` as a program property; see [P] [program properties](#). If *command\_name* has `swml` as a property, *command\_name* must store the log-likelihood value in `e(l1)` and the model degrees of freedom in `e(df_m)`.

## Stored results

`nestreg` stores the following in `r()`:

```
Matrices
 r(wald) matrix corresponding to the Wald table
 r(lr) matrix corresponding to the likelihood-ratio table
```

## Acknowledgment

We thank Paul H. Bern of Syracuse University for developing the hierarchical regression command that inspired `nestreg`.

## Description

`net` downloads and installs additions to Stata. The additions can be obtained from the internet or from physical media. The additions can be ado-files (new commands), help files, or even datasets. Collections of files that may be installed as a group are bound together into a *package*.

`ado` manages the packages you have installed by using `net`. The `ado` command lets you list and uninstall previously installed packages.

You can also access the `net` and `ado` features by selecting **Help > SJ and community-contributed features**; this is the recommended method to find and install additions to Stata.

## Syntax

*Set current location for net*

```
net from directory_or_url
```

*Change to a different net directory*

```
net cd path_or_url
```

*Change to a different net site*

```
net link linkname
```

*Search for installed packages*

```
net search (see [R] net search)
```

*Report current net location*

```
net
```

*Describe a package*

```
net describe pkgname [, from(directory_or_url)]
```

*Set location where packages will be installed*

```
net set ado dirname
```

*Set location where ancillary files will be installed*

```
net set other dirname
```

Report net ‘from’, ‘ado’, and ‘other’ settings

```
net query
```

Install ado-files and help files from a package

```
net install pkgname [, all replace force from(directory_or_url)]
```

Install ancillary files from a package

```
net get pkgname [, all replace force from(directory_or_url)]
```

Shortcut to access Stata Journal (SJ) net site

```
net sj vol-issue [insert]
```

List installed packages

```
ado [, find(string) from(dirname)]
ado dir [pkgid] [, find(string) from(dirname)]
```

Describe installed packages

```
ado describe [pkgid] [, find(string) from(dirname)]
```

Update installed packages

```
ado update (see [R] ado update)
```

Uninstall an installed package

```
ado uninstall pkgid [, from(dirname)]
```

where

```
pkgname is name of a package
pkgid is name of a package
 or a number in square brackets: [#]
dirname is a directory name
 or PLUS (default)
 or PERSONAL
 or SITE
```

## Options

`all` is used with `net install` and `net get`. Typing it with either one makes the command equivalent to typing `net install` followed by `net get`.

`replace` is for use with `net install` and `net get`. It specifies that the downloaded files replace existing files if any of the files already exists.

`force` specifies that the downloaded files replace existing files if any of the files already exists, even if Stata thinks all the files are the same. `force` implies `replace`.

`find(string)` is for use with `ado`, `ado dir`, and `ado describe`. It specifies that the descriptions of the packages installed on your computer be searched, and that the package descriptions containing *string* be listed.

`from(dirname)`, when used with `ado`, specifies where the packages are installed. The default is `from(PLUS)`. PLUS is a code word that Stata understands to correspond to a particular directory on your computer that was set at installation time. On Windows computers, PLUS probably means the directory `c:\ado\plus`, but it might mean something else. You can find out what it means by typing `sysdir`, but doing so is irrelevant if you use the defaults.

`from(directory_or_url)`, when used with `net`, specifies the directory or URL where installable packages may be found. The directory or URL is the same as the one that would have been specified with `net from`.

## Remarks and examples

For an introduction to using `net` and `ado`, see [\[U\] 29 Using the internet to keep up to date](#). The purpose of this documentation is

- to briefly, but accurately, describe `net` and `ado` and all their features and
- to provide documentation to those who wish to set up their own sites to distribute additions to Stata.

Remarks are presented under the following headings:

*Definition of a package*

*The purpose of the net and ado commands*

*Content pages*

*Package-description pages*

*Where packages are installed*

*A summary of the net command*

*A summary of the ado command*

*Relationship of net and ado to the point-and-click interface*

*Creating your own site*

*Format of content and package-description files*

*Example 1*

*Example 2*

*Additional package directives*

*SMCL in content and package-description files*

*Error-free file delivery*

## Definition of a package

A *package* is a collection of files—typically, `.ado` and `.sthlp` files—that together provide a new feature in Stata. Packages contain additions that you wish had been part of Stata at the outset. For instance, the package named `zz49` might add the `xyz` command to Stata. At a minimum, such a package would contain `xyz.ado`, the code to implement the new command, and `xyz.sthlp`, the system help to describe it. We write such additions, and so do other users.

One source of these additions is the *Stata Journal*, a printed and electronic journal with corresponding software. If you want the journal, you must subscribe, but the software is available for free from our website.

## The purpose of the net and ado commands

The `net` command makes it easy to distribute and install packages. The goal is to get you quickly to a package-description page that summarizes the addition, for example,

---

```
. net describe rte_stat, from(http://www.wemakeitupaswego.edu/faculty/sgazer/)
```

---

```
package rte_stat from http://www.wemakeitupaswego.edu/faculty/sgazer/
```

---

### TITLE

```
rte_stat. The robust-to-everything statistic; update.
```

### DESCRIPTION/AUTHOR(S)

```
S. Gazer, Dept. of Applied Theoretical Mathematics, WMIUAWG Univ.
Aleph-0 100% confidence intervals proved too conservative for some
applications; Aleph-1 confidence intervals have been substituted.
The new robust-to-everything supplants the previous robust-to-
everything-conceivable statistic. See "Inference in the absence
of data" (forthcoming). After installation, see help rte.
```

### INSTALLATION FILES

```
rte.ado
rte.sthlp
nullset.ado
random.ado
```

---

```
(type net install rte_stat)
```

If you decide that the addition might prove useful, `net` makes the installation easy:

```
. net install rte_stat
checking rte_stat consistency and verifying not already installed...
installing into c:\ado\plus\ ...
installation complete.
```

A content page tells you about other content pages and package-description pages. The example above lists other content pages only. Below, we follow one of the links for the *Stata Journal*:

```
. net link sj

---

dm0027, st0119, ..., st0121 are links to package-description pages.

1. When you type `net from`, you follow that with a location to display the location's content page.
  - a. The location could be a URL, such as <https://www.stata.com>. The content page at that location would then be listed.
  - b. The location could be `e:` on a Windows computer or a mounted volume on a Mac computer. The content page on that source would be listed. That would work if you had special media obtained from StataCorp or special media prepared by another user.

- c. The location could even be a directory on your computer, but that would work only if that directory contained the right kind of files.
2. Once you have specified a location, typing `net cd` will take you into subdirectories of that location, if there are any. Typing

```
. net from https://www.stata-journal.com
. net cd software
```

is equivalent to typing

```
. net from https://www.stata-journal.com/software
```

Typing `net cd` displays the content page from that location.

3. Typing `net` without arguments redisplay the current content page, which is the content page last displayed.
4. `net link` is similar to `net cd` in that the result is to change the location, but rather than changing to subdirectories of the current location, `net link` jumps to another location:

```
. net from https://www.stata-journal.com
```

---

```
https://www.stata-journal.com/
```

**The Stata Journal**

---

The Stata Journal is a refereed, quarterly journal containing articles of interest to Stata users. For more details and subscription information, visit the Stata Journal website at <https://www.stata-journal.com>.

PLACES you could **-net link-** to:

|       |                   |
|-------|-------------------|

## Package-description pages

Package-description pages describe what could be installed:

```
. net from https://www.stata-journal.com/software/sj7-1
```

---

```
https://www.stata-journal.com/software/sj7-1/
(output omitted)
```

```
. net describe st0119
```

---

```
package st0119 from https://www.stata-journal.com/software/sj7-1
```

---

### TITLE

SJ7-1 st0119. Rasch analysis

### DESCRIPTION/AUTHOR(S)

Rasch analysis

by Jean-Benoit Hardouin, University of Nantes, France

Support: jean-benoit.hardouin@univ-nantes.fr

After installation, type help **gammasy**, **gausshermite**,  
**geekel2d**, **raschtest**, and **raschtestv7**

### INSTALLATION FILES

(type **net install st0119**)

```
st0119/raschtest.ado
st0119/raschtest.hlp
st0119/raschtestv7.ado
st0119/raschtestv7.hlp
st0119/gammasy.ado
st0119/gammasy.hlp
st0119/gausshermite.ado
st0119/gausshermite.hlp
st0119/geekel2d.ado
st0119/geekel2d.hlp
```

### ANCILLARY FILES

(type **net get st0119**)

```
st0119/data.dta
st0119/outrasch.do
```

---

A package-description page describes the package and tells you how to install the component files. Package-description pages potentially describe two types of files:

1. Installation files: files that you type `net install` to install and that are required to make the addition work.
2. Ancillary files: additional files that you might want to install—you type `net get` to install them—but that you can ignore. Ancillary files are typically datasets that are useful for demonstration purposes. Ancillary files are not really installed in the sense of being copied to an official place for use by Stata itself. They are merely copied into the current directory so that you may use them if you wish.

You install the official files by typing `net install` followed by the package name. For example, to install `st0119`, you would type

```
. net install st0119
checking st0119 consistency and verifying not already installed...
installing into c:\ado\plus\ ...
installation complete.
```

You get the ancillary files—if there are any and if you want them—by typing `net get` followed by the package name:

```
. net get st0119
checking st0119 consistency and verifying not already installed...
copying into current directory...
 copying data.dta
 copying outrasch.do
ancillary files successfully copied.
```

Most users ignore the ancillary files.

Once you have installed a package—by typing `net install`—use `ado` to redisplay the package-description page whenever you wish:

```
. ado describe st0119
```

---

```
[1] package st0119 from https://www.stata-journal.com/software/sj7-1
```

---

**INSTALLED ON**

24 Feb 2025

---

The package-description page shown by `ado` includes the location from which we got the package and when we installed it. It does not mention the ancillary files that were originally part of this package because they are not tracked by `ado`.

## Where packages are installed

Packages should be installed in PLUS or SITE; these are code words that Stata understands and correspond to real directories on your computer. Typing `sysdir` will tell you where these are, if you care.

```
. sysdir
 STATA: C:\Program Files\Stata19\
 BASE: C:\Program Files\Stata19\ado\base\
 SITE: C:\Program Files\Stata19\ado\site\
 PLUS: c:\ado\plus\
 PERSONAL: c:\ado\personal\
 OLDPLACE: c:\ado\
```

If you type `sysdir`, you may obtain different results.

By default, `net` installs in the PLUS directory, and `ado` tells you about what is installed there. If you are on a multiple-user system, you may wish to install some packages in the SITE directory. This way, they will be available to other Stata users. To do that, before using `net install`, type

```
. net set ado SITE
```

and when reviewing what is installed or removing packages, redirect `ado` to that directory:

```
. ado ..., from(SITE)
```

In both cases, you type SITE because Stata will understand that SITE means the site `ado`-directory as defined by `sysdir`. To install into SITE, you must have write access to that directory.

If you reset where `net` installs and then, in the same session, wish to install into your private `ado`-directory, type

```
. net set ado PLUS
```

That is how things were originally. If you are confused as to where you are, type `net query`.

## A summary of the net command

The `net` command displays content pages and package-description pages. Such pages are provided over the internet, and most users get them there. We recommend that you start at <https://www.stata.com> and work out from there. We also recommend using `net search` to find packages of interest to you; see [R] [net search](#).

`net from` moves you to a location and displays the content page.

`net cd` and `net link` change from your current location to other locations. `net cd` enters subdirectories of the original location. `net link` jumps from one location to another, depending on the code on the content page.

`net describe` lists a package-description page. Packages are named, and you type `net describe pkgname`.

`net install` installs a package into your copy of Stata. `net get` copies any additional files (ancillary files) to your current directory.

net sj simplify loading files from the *Stata Journal*.

```
net sj vol-issue
```

is a synonym for typing

```
net from https://www.stata-journal.com/software/sjvol-issue
```

whereas

```
net sj vol-issue insert
```

is a synonym for typing

```
net from https://www.stata-journal.com/software/sjvol-issue
net describe insert
```

net set controls where net installs files. By default, net installs in the PLUS directory; see [P] **sysdir**. net set ado SITE would cause subsequent net commands to install in the SITE directory. net set other sets where ancillary files, such as .dta files, are installed. The default is the current directory.

net query displays the current net from, net set ado, and net set other settings.

## A summary of the ado command

The ado command lists the package descriptions of previously installed packages.

Typing ado without arguments is the same as typing ado dir. Both list the names and titles of the packages you have installed.

ado describe lists full package-description pages.

ado uninstall removes packages from your computer.

Because you can install packages from a variety of sources, the package names may not always be unique. Thus the packages installed on your computer are numbered sequentially, and you may refer to them by name or by number. For instance, say that you wanted to get rid of the robust-to-everything statistic command you installed. Type

```
. ado, find("robust-to-everything")
[15] package rte_stat from http://www.wemakeitupaswego.edu/faculty/sgazer
rte_stat. The robust-to-everything statistic; update.
```

You could then type

```
. ado uninstall rte_stat
```

or

```
. ado uninstall [15]
```

Typing ado uninstall rte\_stat would work only if the name rte\_stat were unique; otherwise, ado would refuse, and you would have to type the number.

The `find()` option is allowed with `ado dir` and `ado describe`. It searches the package description for the word or phrase you specify, ignoring case (alpha matches Alpha). The complete package description is searched, including the author's name and the name of the files. Thus if `rte` was the name of a command that you wanted to eliminate, but you could not remember the name of the package, you could type

```
. ado, find(rte)
[15] package rte_stat from http://www.wemakeitupaswego.edu/faculty/sgazer
rte_stat. The robust-to-everything statistic; update.
```

## Relationship of net and ado to the point-and-click interface

Users may instead select **Help > SJ and community-contributed features**. There are advantages and disadvantages:

1. Flipping through content and package-description pages is easier; it is much like a browser. See [\[GSM\] 19 Updating and extending Stata—internet functionality](#), [\[GSU\] 19 Updating and extending Stata—internet functionality](#), or [\[GSW\] 19 Updating and extending Stata—internet functionality](#).
2. When browsing a product-description page, note that the `.sthlp` files are highlighted. You may click on `.sthlp` files to review them before installing the package.
3. You may not redirect from where `ado` searches for files.

## Creating your own site

Users who wish to share content with the Stata community often do so via the Statistical Software Components (SSC) Archive. See [\[R\] ssc](#) and also see <http://repec.org/bocode/s/sscsubmit.html>.

The rest of this entry concerns how to create your own site to distribute additions to Stata. The idea is that you have written additions for use with Stata—say, `xyz.ado` and `xyz.sthlp`—and you wish to make them available so that others can easily install them. Or, perhaps you just have a dataset that you and others want to share.

In any case, all you need is a webpage. You place the files that you want to distribute on your webpage, and you add two more files—a content file and a package-description file—and you are done.

## Format of content and package-description files

The content file describes the content page. It must be named `stata.toc`:

---

```

OFF (to make site unavailable temporarily)
* lines starting with * are comments; they are ignored
* blank lines are ignored, too
* v indicates version---specify v 3, which is the current version of .toc files
v 3
* d lines display description text
* the first d line is the title, and the remaining ones are text
* blank d lines display a blank line
d title
d text
d text
d
...
* l lines display links
l word-to-show path-or-url [description]
l word-to-show path-or-url [description]
...
* t lines display other directories within the site
t path [description]
t path [description]
...
* p lines display packages
p pkgname [description]
p pkgname [description]
...

```

---

end stata.toc

Package files describe packages and are named `pkgname.pkg`:

---

```

* lines starting with * are comments; they are ignored
* blank lines are ignored, too
* v indicates version---specify v 3, which is the current version of .toc files
v 3
* d lines display package description text
* the first d line is the title, and the remaining ones are text
* blank d lines display a blank line
d title
d text
d Distribution-Date: date
d text
d
...
* f identifies the component files
f [path/]filename [description]
f [path/]filename [description]
...
* e line is optional; it means stop reading
e

```

---

end pkgname.pkg

Note the Distribution-Date description line. This line is optional but recommended. Stata can look for updates to community-contributed programs with the `ado update` command if the package files from which those programs were installed contain a Distribution-Date description line.

## Example 1

Say that we want the user to see the following:

```
. net from http://www.university.edu/~me

http://www.university.edu/~me
Chris Farrar, Uni University

PACKAGES you could -net describe-:
 xyz interval-truncated survival

. net describe xyz

package xyz from http://www.university.edu/~me

TITLE
 xyz. interval-truncated survival.
DESCRIPTION/AUTHOR(S)
 C. Farrar, Uni University.
INSTALLATION FILES (type net install xyz)
 xyz.ado
 xyz.sthlp
ANCILLARY FILES (type net get xyz)
 sample.dta

```

The files needed to do this would be

```
-----begin stata.toc-----
v 3
d Chris Farrar, Uni University
p xyz interval-truncated survival
-----end stata.toc-----
-----begin xyz.pkg-----
v 3
d xyz. interval-truncated survival.
d C. Farrar, Uni University.
f xyz.ado
f xyz.sthlp
f sample.dta
-----end xyz.pkg-----
```

On his homepage, Chris would place the following files:

|            |                                                             |
|------------|-------------------------------------------------------------|
| stata.toc  | (shown above)                                               |
| xyz.pkg    | (shown above)                                               |
| xyz.ado    | file to be delivered (for use by <code>net install</code> ) |
| xyz.sthlp  | file to be delivered (for use by <code>net install</code> ) |
| sample.dta | file to be delivered (for use by <code>net get</code> )     |

Chris does nothing to distinguish ancillary files from installation files.

## Example 2

S. Gazer wants to create a more complex site:

```
. net from http://www.wemakeitupaswego.edu/faculty/sgazer
```

---

```
http://www.wemakeitupaswego.edu/faculty/sgazer
```

```
Data-free inference materials
```

---

S. Gazer, Department of Applied Theoretical Mathematics

Also see my homepage for the preprint of "Irrefutable inference".

| rte.sthlp    | (file to be delivered)                              |
| nullset.ado  | (file to be delivered)                              |
| random.ado   | (file to be delivered)                              |
| empty.dta    | (file to be delivered)                              |
| rtec.pkg     | the other package referred to in stata.toc          |
| rtec.ado     | the corresponding files to be delivered             |
| rtec.sthlp   |                                                     |
| ir/stata.toc | the contents file for when the user types net cd ir |
| ir/...       | whatever other .pkg files are referred to           |
| ir/...       | whatever other files are to be delivered            |

If Mr. Gazer later updated the `rte` package, he could change the Distribution-Date description line in his package. Then, if someone who had previously installed the `rte` packaged wanted to obtain the latest version, that person could use the `ado update` command; see [R] [ado update](#).

For complex sites, a different structure may prove more convenient:

|                              |                                                                  |
|------------------------------|------------------------------------------------------------------|
| <code>stata.toc</code>       | (shown above)                                                    |
| <code>rte.pkg</code>         | (shown above)                                                    |
| <code>rtec.pkg</code>        | the other package referred to in <code>stata.toc</code>          |
| <code>rte/</code>            | directory containing <code>rte</code> files to be delivered:     |
| <code>rte/rte.ado</code>     | (file to be delivered)                                           |
| <code>rte/rte.sthlp</code>   | (file to be delivered)                                           |
| <code>rte/nullset.ado</code> | (file to be delivered)                                           |
| <code>rte/random.ado</code>  | (file to be delivered)                                           |
| <code>rte/empty.dta</code>   | (file to be delivered)                                           |
| <code>rtec/</code>           | directory containing <code>rtec</code> files to be delivered:    |
| <code>rtec/...</code>        | (files to be delivered)                                          |
| <code>ir/stata.toc</code>    | the contents file for when the user types <code>net cd ir</code> |
| <code>ir/*.pkg</code>        | whatever other package files are referred to                     |
| <code>ir/*/...</code>        | whatever other files are to be delivered                         |

If you prefer this structure, it is simply a matter of changing the bottom of the `rte.pkg` from

```
f rte.ado
f rte.sthlp
f nullset.ado
f random.ado
f empty.dta
```

to

```
f rte/rte.ado
f rte/rte.sthlp
f rte/nullset.ado
f rte/random.ado
f rte/empty.dta
```

In writing paths and files, the directory separator forward slash (/) is used, regardless of operating system, because this is what the internet uses.

It does not matter whether the files you put out are in Windows, Mac, or Unix format (how lines end is recorded differently). When Stata reads the files over the internet, it will figure out the file format on its own and will automatically translate the files to what is appropriate for the receiver.

## Additional package directives

*F filename* is similar to *f filename*, except that, when the file is installed, it will always be copied to the system directories (and not the current directory).

With *f filename*, the file is installed into a directory according to the file's suffix. For instance, `xyz.ado` would be installed in the system directories, whereas `xyz.dta` would be installed in the current directory.

Coding `F xyz.ado` would have the same result as coding `f xyz.ado`.

Coding `F xyz.dta`, however, would state that `xyz.dta` is to be installed in the system directories.

*g platformname filename* is also a variation on *f filename*. It specifies that the file be installed only if the user's operating system is of type *platformname*; otherwise, the file is ignored. The platform names are WIN64 (64-bit x86-64) for Windows; MACARM64 (Apple Silicon, GUI) and OSX.ARM64 (Apple Silicon, console), MACINTEL64 (64-bit Intel, GUI) and OSX.X8664 (64-bit Intel, console) for Mac;

and LINUX64 (64-bit x86-64) and LINUX64P (64-bit x86-64, libpng v1.6) for Linux. For LINUX64P, the LINUX64-specific version of a file will be installed if no LINUX64P-specific one exists. LINUX64 will not install a LINUX64P-specific version of a file because of possible changes in system libraries.

*G platformname filename* is a variation on *F filename*. The file, if not ignored, is to be installed in the system directories.

*g platformname filename1 filename2* is a more detailed version of *g platformname filename*. In this case, *filename1* is the name of the file on the server (the file to be copied), and *filename2* is to be the name of the file on the user's system; for example, you might code

```
g WIN64 mydll.forwin mydll.plugin
g LINUX64 mydll.forlinux mydll.plugin
```

When you specify one *filename*, the result is the same as specifying two identical *filenames*.

*G platformname filename1 filename2* is the install-in-system-directories version of *g platformname filename1 filename2*.

*h filename* asserts that *filename* must be loaded, or this package is not to be installed; for example, you might code

```
g WIN64 mydll.forwin mydll.plugin
g LINUX64 mydll.forlinux mydll.plugin
h mydll.plugin
```

if you were offering the plugin `mydll.plugin` for Windows and Linux only.

## SMCL in content and package-description files

The text listed on the second and subsequent `d` lines in both `stata.toc` and `pkgname.pkg` may contain SMCL as long as you include `v 3`; see [P] [smcl](#).

Thus, in `rte.pkg`, S. Gazer coded the third line as

```
d {bf:S. Gazer, Dept. of Applied Theoretical Mathematics, WMIUAWG Univ.}
```

## Error-free file delivery

Most people transport files over the internet and never worry about the file being corrupted in the process because corruption rarely occurs. If, however, the files must be delivered perfectly or not at all, you can include checksum files in the directory.

For instance, say that `big.dta` is included in your package and that it must be sent perfectly. First, use Stata to make the checksum file for `big.dta`

```
. checksum big.dta, save
```

That command creates a small file called `big.sum`; see [D] [checksum](#). Then, copy both `big.dta` and `big.sum` to your homepage.

If you do this, be cautious. If you put `big.dta` and `big.sum` on your homepage and then later change `big.dta` without changing `big.sum`, people will think that there are transmission errors when they try to download `big.dta`.

[Description](#)[Quick start](#)[Syntax](#)[Options](#)[Remarks and examples](#)[Also see](#)

## Description

`net search` searches the internet for community-contributed additions to Stata, including, but not limited to, community-contributed additions published in the *Stata Journal* (SJ). `net search` lists the available additions that contain the specified keywords.

The community-contributed materials found are available for immediate download by using the `net` command or by clicking on the link.

In addition to typing `net search`, you may select **Help > Search...** and choose **Search net resources**. This is the recommended way to search for community-contributed additions to Stata.

## Quick start

Search community-contributed commands for all terms `word1`, `word2`, and `word3`

```
net search word1 word2 word3
```

Same as above, but search for any term

```
net search word1 word2 word3, or
```

Search internet sources other than the *Stata Journal*

```
net search word1 word2 word3, nosj
```

## Syntax

```
net search word [word ...] [, options]
```

| <i>options</i>          | Description                                                    |
|-------------------------|----------------------------------------------------------------|
| <code>or</code>         | list packages that contain any of the keywords; default is all |
| <code>nosj</code>       | search non-SJ sources                                          |
| <code>tocpkg</code>     | search both tables of contents and packages; the default       |
| <code>toc</code>        | search tables of contents only                                 |
| <code>pkg</code>        | search packages only                                           |
| <code>everywhere</code> | search packages for match                                      |
| <code>filenames</code>  | search filenames associated with package for match             |
| <code>errnone</code>    | make return code 111 instead of 0 when no matches found        |

## Options

`or` is relevant only when multiple keywords are specified. By default, `net search` lists only packages that include all the keywords. `or` changes the command to list packages that contain any of the keywords.

`nosj` specifies that `net search` not list matches that were published in the SJ.

`tocpkg`, `toc`, and `pkg` determine what is searched. `tocpkg` is the default, meaning that both tables of contents (tocs) and packages (pkgs) are searched. `toc` restricts the search to tables of contents. `pkg` restricts the search to packages.

`everywhere` and `filenames` determine where in packages `net search` looks for *keywords*. The default is `everywhere`. `filenames` restricts `net search` to search for matches only in the filenames associated with a package. Specifying `everywhere` implies `pkg`.

`errnone` is a programmer's option that causes the return code to be 111 instead of 0 when no matches are found.

## Remarks and examples

`net search` searches the internet for community-contributed additions to Stata. If you want to search the Stata documentation for a particular topic, command, or author, see [\[R\] search](#). `net search word [word ...]` (without options) is equivalent to typing `search word [word ...]`, `net`.

Remarks are presented under the following headings:

*Topic searches*  
*Author searches*  
*Command searches*  
*Where does net search look?*  
*How does net search work?*

## Topic searches

### Example: Find what is available about random effects

```
. net search random effect
```

Comments:

- It is best to search using the singular form of a word. `net search random effect` will find both “random effect” and “random effects”.
- `net search random effect` will also find “random-effect” because `net search` performs a string search and not a word search.
- `net search random effect` lists all packages containing the words “random” and “effect”, not necessarily used together.
- If you wanted all packages containing the word “random” or the word “effect”, you would type `net search random effect, or`.

## Author searches

### Example: Find what is available by author Jeroen Weesie

```
. net search weesie
```

Comments:

- You could type `net search jeroen weesie`, but that might list fewer results because sometimes the last name is used without the first.
- You could type `net search Weesie`, but it would not matter. Capitalization is ignored in the search.

### Example: Find what is available by Jeroen Weesie, excluding SJ materials

```
. net search weesie, nosj
```

- The SJ tends to dominate search results because so much has been published in it. If you know that what you are looking for is not in the SJ, specifying the `nosj` option will narrow the search.
- `net search weesie` lists everything that `net search weesie, nosj` lists, and more. If you just type `net search weesie`, look down the list. SJ materials are listed first, and non-SJ materials are listed last.

## Command searches

### Example: Find the community-contributed command kursus

```
. net search kursus, file
```

- You could just type `net search kursus`, and that will list everything `net search kursus, file` lists, and more. Because you know `kursus` is a command, however, there must be a `kursus.ado` file associated with the package. Typing `net search kursus, file` narrows the search.
- You could also type `net search kursus.ado, file` to narrow the search even more.

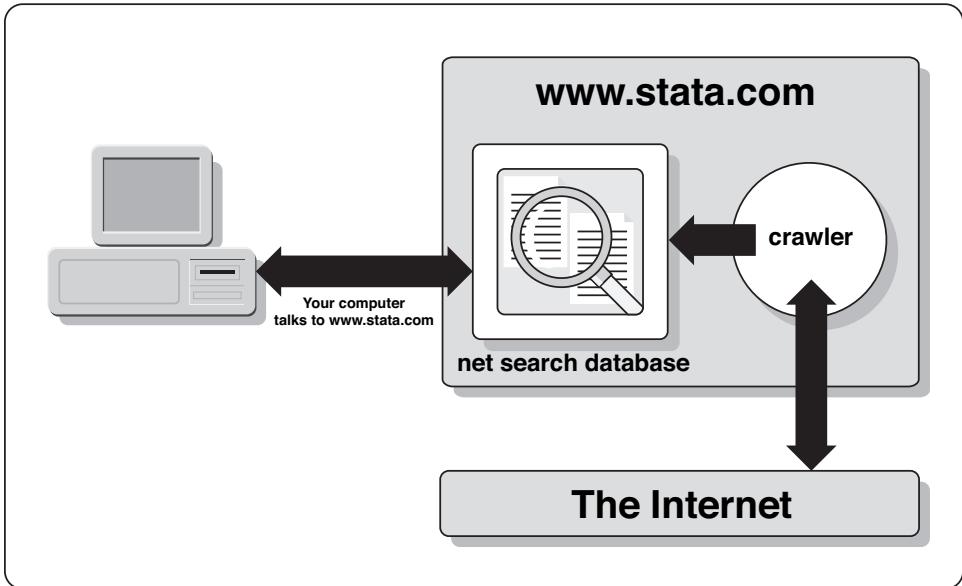

## Where does net search look?

`net search` looks everywhere, not just at <https://www.stata.com>.

`net search` begins by looking at <https://www.stata.com>, but then follows every link, which takes it to other places, and then follows every link again, which takes it to even more places, and so on.

Authors: Please let us know if you have a site that we should include in our search by sending an email to [webmaster@stata.com](mailto:webmaster@stata.com). We will then link to your site from ours to ensure that `net search` finds your materials. That is not strictly necessary, however, as long as your site is directly or indirectly linked from some site that is linked to ours.

## How does net search work?

Our website maintains a database of Stata resources. When you use `net search`, it contacts <https://www.stata.com> with your request, <https://www.stata.com> searches its database, and Stata returns the results to you.

Another part of the system is called the crawler, which searches the web for new Stata resources to add to the `net search` database and verifies that the resources already found are still available. When a new resource becomes available, the crawler takes about two days to add it to the database, and, similarly, if a resource disappears, the crawler takes roughly two days to remove it from the database.

## Description

Some commands (for example, `net` and `update`) are designed specifically for use over the internet. Many other Stata commands that read a file (for example, `copy`, `type`, and `use`) can also read directly from a URL. All of these commands will usually work without your ever needing to concern yourself with the `set` commands discussed here. These `set` commands provide control over network system parameters.

If you experience problems when using Stata's network features, ask your system administrator if your site uses a proxy. A proxy is a server between your computer and the rest of the internet, and your computer may need to communicate with other computers on the internet through this proxy. If your site uses a proxy, your system administrator can provide you with its host name and the port your computer can use to communicate with it. If your site's proxy requires you to log in to it before it will respond, your system administrator will provide you with a user ID and password.

`set httpproxyhost` sets the name of the host to be used as a proxy server. `set httpproxyport` sets the port number. `set httpproxy` turns on or off the use of a proxy server, leaving the proxy host name and port intact, even when not in use.

Under the Mac and Windows operating systems, when you `set httpproxy on`, Stata will attempt to obtain the values of `httpproxyhost` and `httpproxyport` from the operating system if they have not been previously set. `set httpproxy on, init` attempts to obtain these values from the operating system, even if they have been previously set.

If the proxy requires authorization (user ID and password), `set authorization on` via `set httpproxyauth on`. The proxy user and proxy password must also be set to the appropriate user ID and password by using `set httpproxyuser` and `set httpproxypw`.

Stata remembers the various proxy settings between sessions and does not need a permanently option.

## Syntax

*Turn on or off the use of a proxy server*

```
set httpproxy {on | off} [, init]
```

*Set proxy host name*

```
set httpproxyhost ["name"]
```

*Set the proxy port number*

```
set httpproxyport #
```

*Turn on or off proxy authorization*

```
set httpproxyauth {on | off}
```

*Set proxy authorization user ID*

```
set httpproxyuser ["name"]
```

*Set proxy authorization password*

```
set httpproxypw ["password"]
```

## Options

`init` specifies that `set httpproxy` on attempts to initialize `httpproxyhost` and `httpproxyport` from the operating system (Mac and Windows only).

## Remarks and examples

If you receive an error message, see <https://www.stata.com/support/faqs/web/> for the latest information.

[Description](#)[Options](#)[Acknowledgments](#)[Quick start](#)[Remarks and examples](#)[References](#)[Menu](#)[Stored results](#)[Also see](#)[Syntax](#)[Methods and formulas](#)

## Description

`nl` fits an arbitrary nonlinear regression function by least squares. With the interactive version of the command, you enter the function directly on the command line or in the dialog box by using a *substitutable expression*. If you have a function that you use regularly, you can write a *substitutable expression program* and use the second syntax to avoid having to reenter the function every time. The function evaluator program version gives you the most flexibility in exchange for increased complexity; with this version, your program is given a vector of parameters and a variable list, and your program computes the regression function.

When you write a substitutable expression program or function evaluator program, the first two letters of the name must be `nl`. *sexp\_prog* and *func\_prog* refer to the name of the program without the first two letters. For example, if you wrote a function evaluator program named `nlregss`, you would type `nl regss @ . . .` to estimate the parameters.

## Quick start

Linear model of  $y$  as a function of  $x_1$  and a constant

```
nl (y = {b0} + {b1}*x1)
```

Same as above, but defining the linear combination `lc`

```
nl (y = {lc: x1, xb})
```

Same as above, but specify starting values

```
nl (y = {b0=.5} + {b1=2}*x1)
```

Add variables  $x_2$  and  $x_3$  to the linear combination

```
nl (y = {lc: x1 x2 x3})
```

Same as above, but explicitly specify a constant term `b0` with starting value

```
nl (y = {b0=.5} + {lc: x1 x2 x3, noconstant})
```

An exponential model

```
nl (y = {b0} + {b1}*{b2}^x1)
```

Same as above, but use `nl`'s built-in function `exp3` to specify the model

```
nl exp3: y x1
```

## Menu

Statistics > Linear models and related > Nonlinear least-squares estimation

## Syntax

### Interactive version

```
nl (devar = <sexp>) [if] [in] [weight] [, options]
```

### Programmed substitutable expression version

```
nl sexp_prog : devar [varlist] [if] [in] [weight] [, options]
```

### Function evaluator program version

```
nl func_prog @ devar [varlist] [if] [in] [weight] ,
 { parameters(namelist) | nparameters(#) } [options]
```

where

*devar* is the dependent variable;

<*sexp*> is a substitutable expression;

*sexp\_prog* is a substitutable expression program; and

*func\_prog* is a function evaluator program.

| <i>options</i>                                                                                                                                                                                                                                                                                                         | Description                                                                                                                                                                     |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Model                                                                                                                                                                                                                                                                                                                  |                                                                                                                                                                                 |

## Options

### Model

`define(name:<subexpr>)` defines a function of model parameters, <subexpr>, and labels it as *name*.

This option can be repeated to define multiple functions. The `define()` option is useful for expressions that appear multiple times in the main nonlinear specification of the command: you define the expression once and then simply refer to it by using `{name}`: in the nonlinear specification. This option can be used for notational convenience. See [Substitutable expressions](#) for how to specify <subexpr>.

`parameters(namelist)` specifies the names of the parameters in the model. This option applies only to the function evaluator program version. The names of the parameters must adhere to the naming conventions of Stata's variables; see [\[U\] 11.3 Naming conventions](#). If `parameters()` and `nparameters()` are both specified, the number in `nparameters()` must match the number of names specified in `parameters()`.

`nparameters(#)` specifies the number of parameters in the model. If you do not specify names with the `parameters()` option, `nl` names them `b1`, `b2`, ..., `b#`. This option applies only to the function evaluator program version. If `nparameters()` and `parameters()` are both specified, the number in `nparameters()` must match the number of names specified in `parameters()`.

`variables(varlist)` specifies computational variables used in a function evaluator program other than `depvar` and `varlist`. `nl` ignores observations for which any of these variables, in addition to variables in `depvar` and `varlist`, have missing values. This option is necessary only for the function evaluator program version and only when using variables other than `depvar` and `varlist`. In all other cases, the substitutable expression parser considers all the variables in your expressions. If you do not declare these extra computational variables in function evaluators programs, then `nl` exits with an error if the computed `depvar` contains missing values.

*sexp\_options* refer to any options allowed by your *sexp\_prog*.

*func\_options* refer to any options allowed by your *func\_prog*.

### Model 2

`lnlsq(#)` fits the model by using log least-squares, which we define as least squares with shifted log-normal errors. In other words,  $\ln(\text{depvar} - \#)$  is assumed to be normally distributed. Sums of squares and deviance are adjusted to the same scale as `depvar`.

`noconstant` indicates that the function does not include a constant term. By default, Stata will use a parameter as a constant if the coefficient of variation (over observations) of the partial derivative of our function with respect to the parameter is less than `ltolerance()`. The `noconstant` option overrides this default and is generally not needed.

`hasconstant(name)` indicates that parameter *name* be treated as the constant term in the model and that `nl` should not use its default algorithm to find a constant term. As with `noconstant`, this option is seldom used.

`constraints(constraints)`; see [\[R\] Estimation options](#).

## SE/Robust

`vce(vctype)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory (`gnr`), that are robust to some kinds of misspecification (`robust`), that allow for intragroup correlation (`cluster clustvar`), and that use bootstrap or jackknife methods (`bootstrap`, `jackknife`); see [R] [vce\\_option](#).

`vce(gnr)`, the default, uses the conventionally derived variance estimator for nonlinear models fit using Gauss–Newton regression.

`nl` also allows the following:

`vce(hac kernel [#])` specifies that a heteroskedasticity- and autocorrelation-consistent (HAC) variance estimate be used. HAC refers to the general form for combining weighted matrices to form the variance estimate. There are three kernels available for `nl`:

`nwest | gallant | anderson`

`#` specifies the number of lags. If `#` is not specified,  $N - 2$  is assumed.

`vce(hac kernel [#])` is not allowed if weights are specified.

`vce(hc2)` and `vce(hc3)` specify alternative bias corrections for the robust variance calculation. `vce(hc2)` and `vce(hc3)` may not be specified with the `svy` prefix. By default, `vce(robust)` uses  $\hat{\sigma}_j^2 = \{n/(n - k)\}u_j^2$  as an estimate of the variance of the  $j$ th observation, where  $u_j$  is the calculated residual and  $n/(n - k)$  is included to improve the overall estimate's small-sample properties.

`vce(hc2)` instead uses  $u_j^2/(1 - h_{jj})$  as the observation's variance estimate, where  $h_{jj}$  is the  $j$ th diagonal element of the hat (projection) matrix. This produces an unbiased estimate of the covariance matrix if the model is homoskedastic. `vce(hc2)` tends to produce slightly more conservative confidence intervals than `vce(robust)`.

`vce(hc3)` uses  $u_j^2/(1 - h_{jj})^2$  as suggested by Davidson and MacKinnon (1993 and 2004), who report that this often produces better results when the model is heteroskedastic. `vce(hc3)` produces confidence intervals that tend to be even more conservative.

See, in particular, Davidson and MacKinnon (2004, 239), who advocate the use of `vce(hc2)` or `vce(hc3)` instead of the plain robust estimator for nonlinear least squares.

## Reporting

`level(#)`; see [R] [Estimation options](#).

`leave` leaves behind after estimation a set of new variables with the same names as the estimated parameters containing the derivatives of  $E(y)$  with respect to the parameters. If the dataset contains an existing variable with the same name as a parameter, then using `leave` causes `nl` to issue an error message with return code 110.

`leave` may not be specified with `vce(cluster clustvar)` or the `svy` prefix.

`title(string)` specifies an optional title that will be displayed just above the table of parameter estimates.

`title2(string)` specifies an optional subtitle that will be displayed between the title specified in `title()` and the table of parameter estimates. If `title2()` is specified but `title()` is not, `title2()` has the same effect as `title()`.

*display\_options*: `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `nolstretch`; see [R] [Estimation options](#).

### Optimization

*optimization\_options*: `iterate(#)`, `[no]log`, `trace`, `showstep`, `gradient`, `hessian`, `showtolerance`, `tolerance(#)`, `ltolerance(#)`, `nrtolerance(#)`, `nonrntolerance`, `difficult`, `search(on|off[, rseed(#)])`, `from(init_specs)`, `epsilon(#)`, `minderiv(#)`; see [R] [Maximize](#). Those that require special mention for `nl` are listed below.

`ltolerance(#)` specifies the tolerance for the residual sum of squares (RSS) of the Gauss–Newton algorithm. When the relative change in the RSS from one (alternating) iteration to the next is less than or equal to `ltolerance(#)`, the RSS convergence is satisfied. The default is `ltolerance(1e-7)`.

`difficult` specifies that a different stepping algorithm be used in nonconcave regions.

`search(on|off[, rseed(#)])` specifies whether an initial value search should be done. The default is `search(off)`. Use `rseed(#)` for reproducible results when searching for initial values. `search(on)` manipulates the values of the entire coefficient vector and will replace any initial values set in the expression.

`epsilon(#)` specifies the relative change in a parameter to be used in computing the numeric derivatives. The centered derivative for parameter  $\beta_i$  is computed as  $\{f(\mathbf{X}, \dots, \beta_i + \delta_i, \dots) - f(\mathbf{X}, \dots, \beta_i - \delta_i, \dots)\} / (2\delta_i)$ , where  $\delta_i = \epsilon(|\beta_i| + \epsilon)$ . The default is  $\epsilon = c(\text{epsdouble})^{1/3}$  (Press et al. 2007).

`minderiv(#)` specifies the minimum value for the derivative step  $\delta_i = \epsilon(|\beta_i| + \epsilon)$ . The default is  $\epsilon^2$ .

The following option is available with `nl` but is not shown in the dialog box:

`coeflegend`; see [R] [Estimation options](#).

## Remarks and examples

Remarks are presented under the following headings:

- [Substitutable expressions](#)
- [Substitutable expression programs](#)
- [Built-in functions](#)
- [Lognormal errors](#)
- [Other uses](#)
- [Weights](#)
- [Potential errors](#)
- [General comments on fitting nonlinear models](#)
- [Function evaluator programs](#)

`nl` fits an arbitrary nonlinear function by least squares. The interactive version allows you to enter the function directly on the command line or dialog box using *substitutable expressions*. You can write a *substitutable expression program* for functions that you fit frequently to save yourself time. Finally, *function evaluator programs* give you the most flexibility in defining your nonlinear function, though they are more complicated to use.

The next section explains the substitutable expressions that are used to define the regression function, and the section thereafter explains how to write substitutable expression program files so that you do not need to type in commonly used functions over and over. Later sections highlight other features of `nl`.

The final section discusses function evaluator programs. If you find substitutable expressions adequate to define your nonlinear function, then you can skip that section entirely. Function evaluator programs are generally needed only for complicated problems, such as multistep estimators. The program receives a vector of parameters at which it is to compute the function and a variable into which the results are to be placed.

## Substitutable expressions

You define the nonlinear function to be fit by `nl` by using a substitutable expression. Substitutable expressions are just like any other mathematical expressions involving scalars and variables, such as those you would use with Stata's `generate` command, except that the parameters to be estimated are bound in braces. See [U] 13.2 Operators and [U] 13.3 Functions for more information on expressions.

For example, suppose that you wish to fit the function

$$y_i = \beta_0(1 - e^{-\beta_1 x_i}) + \epsilon_i$$

where  $\beta_0$  and  $\beta_1$  are the parameters to be estimated and  $\epsilon_i$  is an error term. You would simply type

```
. nl (y = {b0}*(1 - exp(-{b1}*x)))
```

You must enclose the entire equation in parentheses. Because `b0` and `b1` are enclosed in braces, `nl` knows that they are parameters in the model. `nl` will initialize `b0` and `b1` to zero by default. To request that `nl` initialize `b0` to 1 and `b1` to 0.25, you would type

```
. nl (y = {b0=1}*(1 - exp(-{b1=0.25}*x)))
```

That is, inside the braces denoting a parameter, you put the parameter name followed by an equal sign and the initial value. If a parameter appears in your function multiple times, you need only specify an initial value only once (or never, if you wish to set the initial value to zero). If you do specify more than one initial value for the same parameter, `nl` will use the *last* value given. Parameter names must follow the same conventions as variable names. See [U] 11.3 Naming conventions.

Frequently, even nonlinear functions contain linear combinations of variables. As an example, suppose that you wish to fit the function

$$y_i = \beta_0 \{1 - e^{-(\beta_1 x_{1i} + \beta_2 x_{2i} + \beta_3 x_{3i})}\} + \epsilon_i$$

`nl` allows you to declare the linear combination of variables by using the shorthand notation

```
. nl (y = {b0=1}*(1 - exp(-{lc: x1 x2 x3, noconstant})))
```

In the syntax `{lc: x1 x2 x3, noconstant}`, you are telling `nl` that you are declaring a linear combination named `lc` that is a function of three variables, `x1`, `x2`, and `x3`. `nl` will create three parameters, named `lc:x1`, `lc:x2`, and `lc:x3`, and initialize them to zero. Instead of typing the previous command, you could have typed

```
. nl (y = {b0=1}*(1 - exp(-({b1}*x1 + {b2}*x2 + {b3}*x3))))
```

or

```
. nl (y = {b0=1}*(1 - exp(-{lc:}))), define(lc: x1 x2 x3, noconstant)
```

and yielded the same result. Having defined this linear combination, you can refer to its individual parameters elsewhere in the function by using `{lc:x1}`, `{lc:x2}`, and `{lc:x3}` or, more generally, `{eqname:varname}`. When creating linear combinations, `nl` ensures that the parameter names it chooses are unique and have not yet been used in the function.

You may also refer to a “subset” of a previously defined linear combination. For example, suppose we wish to fit

$$y_i = \beta_0 \{1 - e^{-(\beta_1 x_{1i} + \beta_2 x_{2i} + \beta_3 x_{3i})}\} + \beta_1 x_{1i} + \beta_3 x_{3i} + \epsilon_i$$

We can refer to it as

```
. nl (y = {b0=1}*(1 - exp(-{lc: x1 x2 x3, noconstant})) + {lc:x1}*x1 + {lc:x3}*x3)
```

To refer to an entire linear combination, you can simply use its name. For example, you can type

```
. nl (y = {b0=1}*(1 - exp(-{lc: x1 x2 x3, noconstant})) + {lc:})
```

The general syntax for defining a linear combination is

```
{eqname: varspec[, xb noconstant]}
```

The `xb` option is used to distinguish between, on the one hand, a linear combination of only one variable and, on the other, a free parameter that has the same name as its covariate and the same group name as the linear combination. For example, `{lc: x1, xb}` is equivalent to `{lc:_cons} + {lc:x1}*x1`, whereas `{lc:x1}` refers to either a free parameter `x1` with a group name `lc` or the coefficient of the `x1` variable, if `{lc:}` has been previously defined in the expression as a linear combination that involves variable `x1`. Thus, the `xb` option indicates that the specification is a linear combination rather than a single parameter to be estimated.

In general, there are three rules to follow when defining substitutable expressions:

1. Parameters of the model are bound in braces: `{b0}`, `{param}`, etc.
2. Initial values for parameters are given by including an equal sign and the initial value inside the braces: `{b0=1}`, `{param=3.571}`, etc.
3. Linear combinations of variables can be included using the notation `{eqname:varlist}`, for example, `{xb: mpg price weight}`, `{score: w x z}`, etc. Parameters of linear combinations are initialized to zero.

If you specify initial values by using the `from()` option, they override whatever initial values are given within the substitutable expression. Substitutable expressions are so named because, once values are assigned to the parameters, the resulting expression can be handled by `generate` and `replace`.

## ▷ Example 1

We wish to fit the CES production function

$$\ln Q_i = \beta_0 - \frac{1}{\rho} \ln \{ \delta K_i^{-\rho} + (1 - \delta) L_i^{-\rho} \} + \epsilon_i \quad (1)$$

where  $\ln Q_i$  is the log of output for firm  $i$ ;  $K_i$  and  $L_i$  are firm  $i$ 's capital and labor usage, respectively; and  $\epsilon_i$  is a regression error term. Because  $\rho$  appears in the denominator of a fraction, zero is not a feasible initial value; for a CES production function,  $\rho = 1$  is a reasonable choice. Setting  $\delta = 0.5$  implies that labor and capital have equal impacts on output, which is also a reasonable choice for an initial value. We type

```
. use https://www.stata-press.com/data/r19/production
. summarize lnoutput, meanonly
. local b0 = round(r(mean),.1)
. di "b0 = 'b0'"
b0 = 3
. nl (lnoutput = {b0='b0'} - ln({capital:} + {labor:})/{rho=1}),
> define(capital:{delta=0.5}*capital^{-(rho)})
> define(labor:(1 - {delta})*labor^{-(rho)})
Iteration 0: Residual SS = 80.334811
Iteration 1: Residual SS = 29.387341
Iteration 2: Residual SS = 29.36601
Iteration 3: Residual SS = 29.365808
Iteration 4: Residual SS = 29.365806
```

| Source   | SS        | df | MS         |                 |          |  |
|----------|-----------|----|------------|-----------------|----------|--|
| Model    | 91.144992 | 2  | 45.5724962 | Number of obs = | 100      |  |
| Residual | 29.365806 | 97 | .302740263 | R-squared =     | 0.7563   |  |
|          |           |    |            | Adj R-squared = | 0.7513   |  |
|          |           |    |            | Root MSE =      | .5502184 |  |
| Total    | 120.5108  | 99 | 1.21728079 | Res. dev. =     | 161.2538 |  |

| lnoutput | Coefficient | Std. err. | t     | P> t  | [95% conf. interval] |          |
|----------|-------------|-----------|-------|-------|----------------------|----------|
| /b0      | 3.792143    | .0996809  | 38.04 | 0.000 | 3.594303             | 3.989982 |
| /delta   | .4823479    | .0519785  | 9.28  | 0.000 | .379185              | .5855109 |
| /rho     | 1.386944    | .4725595  | 2.93  | 0.004 | .4490446             | 2.324844 |

Note: Parameter **b0** is used as a constant term during estimation.

`nl` will attempt to find a constant term in the model and, if one is found, mention it at the bottom of the output. `nl` found `b0` to be a constant because the partial derivative  $\partial \ln Q_i / \partial b_0$  has a coefficient of variation less than `tolerance()` in the estimation sample.

The elasticity of substitution for the CES production function is  $\sigma = 1/(1 + \rho)$ ; and, having fit the model, we can use `nlcom` to estimate it:

```
. nlcom (1/(1 + _b[/rho]))
 _nl_1: 1/(1 + _b[/rho])
```

| lnoutput | Coefficient | Std. err. | z    | P> z  | [95% conf. interval] |         |
|----------|-------------|-----------|------|-------|----------------------|---------|
| _nl_1    | .4189457    | .0829415  | 5.05 | 0.000 | .2563833             | .581508 |

See [R] `nlcom` and [U] 13.5 Accessing coefficients and standard errors for more information.

nl's output closely mimics that of regress; see [R] regress for more information. The  $R^2$ , sums of squares, and similar statistics are calculated in the same way that regress calculates them. If no "constant" term is specified, the usual caveats apply to the interpretation of the  $R^2$  statistic; see the comments and references in Goldstein (1992). Unlike regress, nl does not report a model  $F$  statistic, because a test of the joint significance of all the parameters except the constant term may not be relevant in a nonlinear model.

## Substitutable expression programs

If you fit the same model often or if you want to write an estimator that will operate on whatever variables you specify, then you will want to write a substitutable expression program. That program will return a macro containing a substitutable expression that nl can then evaluate, and it may optionally calculate initial values as well. The name of the program must begin with the letters nl.

To illustrate, suppose that you use the CES production function often in your work. Instead of typing in the formula each time, you can write a program like this:

```

program nlces, rclass
 version 19.5 // (or version 19 if you do not have StataNow)
 syntax varlist(min=3 max=3) [if]
 local logout : word 1 of `varlist'
 local capital : word 2 of `varlist'
 local labor : word 3 of `varlist'
 // Initial value for b0 given delta=0.5 and rho=1
 tempvar y
 generate double `y' = `logout' + ln(0.5*`capital'^-1 + 0.5*`labor'^-1)
 summarize `y' `if', meanonly
 local b0val = r(mean)
 // Terms for substitutable expression
 local capterm "{delta=0.5}*`capital'^(-1*{rho})"
 local labterm "(1-{delta})*`labor'^(-1*{rho})"
 local term2 "1/{rho=1}*ln(`capterm' + `labterm')
 // Return substitutable expression and title
 return local eq "logout' = {b0=`b0val}' - `term2'"
 return local title "CES ftn., ln Q=`logout', K=`capital', L=`labor'"
end

```

The program accepts three variables for log output, capital, and labor, and it accepts an *if exp* qualifier to restrict the estimation sample. All programs that you write to use with nl must accept an *if exp* qualifier because, when nl calls the program, it passes a binary variable that marks the estimation sample (the variable equals one if the observation is in the sample and zero otherwise). When calculating initial values, you will want to restrict your computations to the estimation sample, and you can do so by using *if* with any commands that accept *if exp* qualifiers. Even if your program does not calculate initial values or otherwise use the *if* qualifier, the *syntax* statement must still allow it. See [P] syntax for more information on the *syntax* command and the use of *if*.

As in the previous example, reasonable initial values for  $\delta$  and  $\rho$  are 0.5 and 1, respectively. Conditional on those values, (1) can be rewritten as

$$\beta_0 = \ln Q_i + \ln(0.5K_i^{-1} + 0.5L_i^{-1}) - \epsilon_i \quad (2)$$

so a good initial value for  $\beta_0$  is the mean of the right-hand side of (2) ignoring  $\epsilon_i$ . Lines 7–10 of the function evaluator program calculate that mean and store it in a local macro. Notice the use of *if* in the *summarize* statement so that the mean is calculated only for the estimation sample.

The final part of the program returns two macros. The macro `title` is optional and defines a short description of the model that will be displayed in the output immediately above the table of parameter estimates. The macro `eq` is required and defines the substitutable expression that `nl` will use. If the expression is short, you can define it all at once. However, because the expression used here is somewhat lengthy, defining local macros and then building up the final expression from them is easier.

To verify that there are no errors in your program, you can call it directly and then use `return list`:

```
. use https://www.stata-press.com/data/r19/production
. nlces lnoutput capital labor
 (output omitted)
. return list
macros:
 r(title) : "CES ftn., ln Q=lnoutput, K=capital, L=labor"
 r(eq) : "lnoutput = {b0=3.711606264663641} - 1/{rho=1}*
> ln({delta=0.5}*capital^{-1*{rho}} + (1-{delta})*labor^{-1*{rho}})"
```

The macro `r(eq)` contains the same substitutable expression that we specified at the command line in the [preceding example](#), except for the initial value for `b0`. In short, an `nl` substitutable expression program should return in `r(eq)` the same substitutable expression you would type at the command line. The only difference is that when writing a substitutable expression program, you do not bind the entire expression inside parentheses.

Having written the program, you can use it by typing

```
. nl ces: lnoutput capital labor
```

(There is a space between `nl` and `ces`.) The output is identical to that shown in [example 1](#), save for the title defined in the function evaluator program that appears immediately above the table of parameter estimates.

## □ Technical note

You will want to store `nlces` as an ado-file called `nlces.ado`. The alternative is to type the code into Stata interactively or to place the code in a do-file. While those alternatives are adequate for occasional use, if you save the program as an ado-file, you can use the function anytime you use Stata without having to redefine the program. When `nl` attempts to execute `nlces`, if the program is not in Stata's memory, Stata will search the disk(s) for an ado-file of the same name and, if found, automatically load it. All you have to do is name the file with the `.ado` suffix and then place it in a directory where Stata will find it. You should put the file in the directory Stata reserves for user-written ado-files, which, depending on your operating system, is `c:\ado\personal` (Windows), `~/ado/personal` (Unix), or `~:ado:personal` (Mac). See [\[U\] 17 Ado-files](#).

□

Sometimes you may want to pass additional options to the substitutable expression program. You can modify the `syntax` statement of your program to accept whatever options you wish. Then when you call `nl` with the `syntax`

```
. nl func_prog: varlist, options
```

any *options* that are not recognized by `nl` (see the table of options at the beginning of this entry) are passed on to your function evaluator program. The only other restriction is that your program cannot accept an option named `at` because `nl` uses that option with function evaluator programs.

## Built-in functions

Some functions are used so often that `nl` has them built in so that you do not need to write them yourself. `nl` automatically chooses initial values for the parameters, though you can use the `initial()` option to override them.

Three alternatives are provided for exponential regression with one asymptote:

$$\text{exp3} \quad y_i = \beta_0 + \beta_1 \beta_2^{x_i} + \epsilon_i$$

$$\text{exp2} \quad y_i = \beta_1 \beta_2^{x_i} + \epsilon_i$$

$$\text{exp2a} \quad y_i = \beta_1 (1 - \beta_2^{x_i}) + \epsilon_i$$

For instance, typing `nl exp3: ras dv1` fits the three-parameter exponential model (parameters  $\beta_0$ ,  $\beta_1$ , and  $\beta_2$ ) using  $y_i = \text{ras}$  and  $x_i = \text{dv1}$ .

Two alternatives are provided for the logistic function (symmetric sigmoid shape; not to be confused with logistic regression):

$$\text{log4} \quad y_i = \beta_0 + \beta_1 / [1 + \exp\{-\beta_2(x_i - \beta_3)\}] + \epsilon_i$$

$$\text{log3} \quad y_i = \beta_1 / [1 + \exp\{-\beta_2(x_i - \beta_3)\}] + \epsilon_i$$

Finally, two alternatives are provided for the Gompertz function (asymmetric sigmoid shape):

$$\text{gom4} \quad y_i = \beta_0 + \beta_1 \exp[-\exp\{-\beta_2(x_i - \beta_3)\}] + \epsilon_i$$

$$\text{gom3} \quad y_i = \beta_1 \exp[-\exp\{-\beta_2(x_i - \beta_3)\}] + \epsilon_i$$

## Lognormal errors

A nonlinear model with errors that are independent and identically distributed normal may be written as

$$y_i = f(\mathbf{x}_i, \boldsymbol{\beta}) + u_i, \quad u_i \sim N(0, \sigma^2) \quad (3)$$

for  $i = 1, \dots, n$ . If the  $y_i$  are thought to have a  $k$ -shifted lognormal instead of a normal distribution—that is,  $\ln(y_i - k) \sim N(\zeta_i, \tau^2)$ , and the systematic part  $f(\mathbf{x}_i, \boldsymbol{\beta})$  of the original model is still thought appropriate for  $y_i$ —the model becomes

$$\ln(y_i - k) = \zeta_i + v_i = \ln\{f(\mathbf{x}_i, \boldsymbol{\beta}) - k\} + v_i, \quad v_i \sim N(0, \tau^2) \quad (4)$$

This model is fit if `lnlsq(k)` is specified.

If model (4) is correct, the variance of  $(y_i - k)$  is proportional to  $\{f(\mathbf{x}_i, \boldsymbol{\beta}) - k\}^2$ . Probably the most common case is  $k = 0$ , sometimes called “proportional errors” because the standard error of  $y_i$  is proportional to its expectation,  $f(\mathbf{x}_i, \boldsymbol{\beta})$ . Assuming that the value of  $k$  is known, (4) is just another nonlinear model in  $\boldsymbol{\beta}$ , and it may be fit as usual. However, we may wish to compare the fit of (3) with that of (4) using the residual sum of squares (RSS) or the deviance  $D$ ,  $D = -2 \times \log\text{-likelihood}$ , from each model. To do so, we must allow for the change in scale introduced by the log transformation.

Assuming, then, the  $y_i$  to be normally distributed, [Atkinson \(1985, 85–87, 184\)](#), by considering the Jacobian  $\prod |\partial \ln(y_i - k) / \partial y_i|$ , showed that multiplying both sides of (4) by the geometric mean of  $y_i - k$ ,  $\dot{y}$ , gives residuals on the same scale as those of  $y_i$ . The geometric mean is given by

$$\dot{y} = e^{n^{-1} \sum \ln(y_i - k)}$$

which is a constant for a given dataset. The residual deviance for (3) and for (4) may be expressed as

$$D(\hat{\beta}) = \left\{ 1 + \ln(2\pi\hat{\sigma}^2) \right\} n \quad (5)$$

where  $\hat{\beta}$  is the maximum likelihood estimate (MLE) of  $\beta$  for each model and  $n\hat{\sigma}^2$  is the RSS from (3), or that from (4) multiplied by  $\dot{y}^2$ .

Because (3) and (4) are models with different error structures but the same functional form, the arithmetic difference in their RSS or deviances is not easily tested for statistical significance. However, if the deviance difference is large ( $>4$ , say), we would naturally prefer the model with the smaller deviance. Of course, the residuals for each model should be examined for departures from assumptions (nonconstant variance, nonnormality, serial correlations, etc.) in the usual way.

Alternatively, consider modeling

$$E(y_i) = 1/(C + Ae^{Bx_i}) \quad (6)$$

$$E(1/y_i) = E(\tilde{y}_i) = C + Ae^{Bx_i} \quad (7)$$

where  $C$ ,  $A$ , and  $B$  are parameters to be estimated. Using the data  $(y, x) = (0.04, 5)$ ,  $(0.06, 12)$ ,  $(0.08, 25)$ ,  $(0.1, 35)$ ,  $(0.15, 42)$ ,  $(0.2, 48)$ ,  $(0.25, 60)$ ,  $(0.3, 75)$ , and  $(0.5, 120)$  ([Danuso 1991](#)), fitting the models yields

| Model                          | $C$   | $A$   | $B$      | RSS       | Deviance |
|--------------------------------|-------|-------|----------|-----------|----------|
| (6)                            | 1.781 | 25.74 | -0.03926 | -0.001640 | -51.95   |
| (6) with <code>lnlsq(0)</code> | 1.799 | 25.45 | -0.04051 | -0.001431 | -53.18   |
| (7)                            | 1.781 | 25.74 | -0.03926 | 8.197     | 24.70    |
| (7) with <code>lnlsq(0)</code> | 1.799 | 27.45 | -0.04051 | 3.651     | 17.42    |

There is little to choose between the two versions of the logistic model (6), whereas for the exponential model (7), the fit using `lnlsq(0)` is much better (a deviance difference of 7.28). The reciprocal transformation has introduced heteroskedasticity into  $\tilde{y}_i$ , which is countered by the proportional errors property of the lognormal distribution implicit in `lnlsq(0)`. The deviances are not comparable between the logistic and exponential models because the change of scale has not been allowed for, although in principle it could be.

## Other uses

Even if you are fitting linear regression models, you may find that `nl` can save you some typing. Because you specify the parameters of your model explicitly, you can impose constraints on them directly.

## ▷ Example 2

In [example 2](#) of [\[R\] cnsreg](#), we showed how to fit the model

$$\text{mpg} = \beta_0 + \beta_1 \text{price} + \beta_2 \text{weight} + \beta_3 \text{displ} + \beta_4 \text{gear\_ratio} + \beta_5 \text{foreign} + \beta_6 \text{length} + u$$

subject to the constraints

$$\begin{aligned} \beta_1 &= \beta_2 = \beta_3 = \beta_6 \\ \beta_4 &= -\beta_5 = \beta_0/20 \end{aligned}$$

An alternative way is to use `nl`:

```
. use https://www.stata-press.com/data/r19/auto, clear
(1978 automobile data)
. nl (mpg = {b0} + {b1}*price + {b1}*weight + {b1}*displ +
> {b0}/20*gear_ratio - {b0}/20*foreign + {b1}*length)
Iteration 0: Residual SS = 36008
Iteration 1: Residual SS = 1578.5223
Iteration 2: Residual SS = 1578.5223
```

| Source   | SS        | df | MS         |                 |          |
|----------|-----------|----|------------|-----------------|----------|
| Model    | 34429.478 | 2  | 17214.7389 | Number of obs = | 74       |
| Residual | 1578.5223 | 72 | 21.9239203 | R-squared =     | 0.9562   |
|          |           |    |            | Adj R-squared = | 0.9549   |
|          |           |    |            | Root MSE =      | 4.682299 |
| Total    | 36008     | 74 | 486.594595 | Res. dev. =     | 436.4562 |

| mpg | Coefficient | Std. err. | t     | P> t  | [95% conf. interval] |           |
|-----|-------------|-----------|-------|-------|----------------------|-----------|
| /b0 | 26.52229    | 1.375178  | 19.29 | 0.000 | 23.78092             | 29.26365  |
| /b1 | -.000923    | .0001534  | -6.02 | 0.000 | -.0012288            | -.0006172 |

The point estimates and standard errors for  $\beta_0$  and  $\beta_1$  are identical to those reported in [example 2](#) of [\[R\] cnsreg](#). To get the estimate for  $\beta_4$ , we can use `nlcom`:

```
. nlcom _b[/b0]/20
 _nl_1: _b[/b0]/20
```

| mpg   | Coefficient | Std. err. | z     | P> z  | [95% conf. interval] |          |
|-------|-------------|-----------|-------|-------|----------------------|----------|
| _nl_1 | 1.326114    | .0687589  | 19.29 | 0.000 | 1.191349             | 1.460879 |

The advantage to using `nl` is that we do not need to use the `constraint` command six times. ◀

`nl` is also a useful tool when doing exploratory data analysis. For example, you may want to run a regression of  $y$  on a function of  $x$ , though you have not decided whether to use  $\sqrt{x}$  or  $\ln(x)$ . You can use `nl` to run both regressions without having first to generate two new variables:

```
. nl (y = {b0} + {b1}*ln(x))
. nl (y = {b0} + {b1}*sqrt(x))
```

[Poi \(2008\)](#) shows the advantages of using `nl` when marginal effects of transformed variables are desired as well.

## Weights

Weights are specified in the usual way—analytic and frequency weights as well as `iweights` are supported; see [U] 20.24 **Weighted estimation**. Use of analytic weights implies that the  $y_i$  have different variances. Therefore, model (3) may be rewritten as

$$y_i = f(\mathbf{x}_i, \boldsymbol{\beta}) + u_i, \quad u_i \sim N(0, \sigma^2/w_i) \quad (3a)$$

where  $w_i$  are (positive) weights, assumed to be known and normalized such that their sum equals the number of observations. The residual deviance for (3a) is

$$D(\widehat{\boldsymbol{\beta}}) = \{1 + \ln(2\pi\widehat{\sigma}^2)\}n - \sum \ln(w_i) \quad (5a)$$

[compare with (5)], where

$$n\widehat{\sigma}^2 = \text{RSS} = \sum w_i \{y_i - f(\mathbf{x}_i, \widehat{\boldsymbol{\beta}})\}^2$$

Defining and fitting a model equivalent to (4) when weights have been specified as in (3a) is not straightforward and has not been attempted. Thus, deviances using and not using the `lnlsq()` option may not be strictly comparable when analytic weights (other than 0 and 1) are used.

You do not need to modify your substitutable expression in any way to use weights. If, however, you write a substitutable expression program, then you should account for weights when obtaining initial values. When `nl` calls your program, it passes whatever weight expression (if any) was specified by the user. Here is an outline of a substitutable expression program that accepts weights:

```

program nl name, rclass
 version 19.5 // (or version 19 if you do not have StataNow)
 syntax varlist [aw fw iw pw] if
 ...
 // Obtain initial values allowing weights
 // Use the syntax ['weight' 'exp']. For example,
 summarize varname ['weight' 'exp'] 'if'
 regress depvar varlist ['weight' 'exp'] 'if'
 ...
 // Return substitutable expression
 return local eq "substitutable expression"
 return local title "description of estimator"
end

```

For details on how the `syntax` command processes weight expressions, see [P] **syntax**.

## Potential errors

`nl` is reasonably robust to the inability of your nonlinear function to be evaluated at some parameter values. `nl` does assume that your function can be evaluated at the initial values of the parameters. If your function cannot be evaluated at the initial values, an error message is issued with return code 480. Recall that if you do not specify an initial value for a parameter, then `nl` initializes it to zero. Many nonlinear functions cannot be evaluated when some parameters are zero, so in those cases specifying alternative initial values is crucial.

Thereafter, as `nl` changes the parameter values, it monitors your function for unexpected missing values. If these are detected, `nl` backs up. That is, `nl` finds a point between the previous, known-to-be-good parameter vector and the new, known-to-be-bad vector at which the function can be evaluated and continues its iterations from that point.

`nl` requires that once a parameter vector is found where the predictions can be calculated, small changes to the parameter vector be made to calculate numeric derivatives. If a boundary is encountered at this point, an error message is issued with return code 481.

When specifying `lnlsq()`, an attempt to take logarithms of  $y_i - k$  when  $y_i \leq k$  results in an error message with return code 482.

If `iterate()` iterations are performed and estimates still have not converged, results are presented with a warning, and the return code is set to 430.

If you use the programmed substitutable expression version of `nl` with a function evaluator program, or vice versa, Stata issues an error message. Verify that you are using the syntax appropriate for the program you have.

## General comments on fitting nonlinear models

Achieving convergence is often problematic. For example, a unique minimum of the sum-of-squares function may not exist. Much literature exists on different algorithms that have been used, on strategies for obtaining good initial parameter values, and on tricks for parameterizing the model to make its behavior as linear-like as possible. Selected references are [Kennedy and Gentle \(1980, chap. 10\)](#) for computational matters and [Ross \(1990\)](#) and [Ratkowsky \(1983\)](#) for all three aspects. Ratkowsky's book is particularly clear and approachable, with useful discussion on the meaning and practical implications of intrinsic and parameter-effects nonlinearity. An excellent text on nonlinear estimation is [Gallant \(1987\)](#). Also see [Davidson and MacKinnon \(1993 and 2004\)](#).

To enhance the success of `nl`, pay attention to the form of the model fit, along the lines of [Ratkowsky and Ross](#). For example, [Ratkowsky \(1983, 49–59\)](#) analyzes three possible three-parameter yield-density models for plant growth:

$$E(y_i) = \begin{cases} (\alpha + \beta x_i)^{-1/\theta} \\ (\alpha + \beta x_i + \gamma x_i^2)^{-1} \\ (\alpha + \beta x_i^\phi)^{-1} \end{cases}$$

All three models give similar fits. However, he shows that the second formulation is dramatically more linear-like than the other two and therefore has better convergence properties. In addition, the parameter estimates are virtually unbiased and normally distributed, and the asymptotic approximation to the standard errors, correlations, and confidence intervals is much more accurate than for the other models. Even within a given model, the way the parameters are expressed (for example,  $\phi^{x_i}$  or  $e^{\theta x_i}$ ) affects the degree of linearity and convergence behavior.

## Function evaluator programs

Occasionally, a nonlinear function may be so complex that writing a substitutable expression for it is impractical. For example, there could be many parameters in the model. Alternatively, if you are implementing a two-step estimator, writing a substitutable expression may be altogether impossible. Function evaluator programs can be used in these situations.

`nl` will pass to your function evaluator program a list of variables, a weight expression, a variable marking the estimation sample, and a vector of parameters. Your program is to replace the dependent variable, which is the first variable in the variables list, with the values of the nonlinear function evaluated at those parameters. As with substitutable expression programs, the first two letters of the name must be `nl`.

To focus on the mechanics of the function evaluator program, again let's compare the CES production function to the previous examples. The function evaluator program is

```

program nlces2
 version 19.5 // (or version 19 if you do not have StataNow)
 syntax varlist(min=3 max=3) if, at(name)
 local logout : word 1 of `varlist'
 local capital : word 2 of `varlist'
 local labor : word 3 of `varlist'

 // Retrieve parameters out of at matrix
 tempname b0 rho delta
 scalar `b0' = `at'[1, 1]
 scalar `rho' = `at'[1, 2]
 scalar `delta' = `at'[1, 3]

 tempvar kterm lterm
 generate double `kterm' = `delta'*`capital'^(-1*`rho') `if'
 generate double `lterm' = (1-`delta')*`labor'^(-1*`rho') `if'

 // Fill in dependent variable
 replace `logout' = `b0' - 1/`rho'*ln(`kterm' + `lterm') `if'

end

```

Unlike the previous `nlces` program, this one is not declared to be `r-class`. The `syntax` statement again accepts three variables: one for log output, one for capital, and one for labor. An `if exp` is again required because `nl` will pass a binary variable marking the estimation sample. All function evaluator programs must accept an option named `at()` that takes a name as an argument—that is how `nl` passes the parameter vector to your program.

The next part of the program retrieves the output, labor, and capital variables from the variables list. It then breaks up the temporary matrix `at` and retrieves the parameters `b0`, `rho`, and `delta`. Pay careful attention to the order in which the parameters refer to the columns of the `at` matrix because that will affect the syntax you use with `nl`. The temporary names you use inside this program are immaterial, however.

The rest of the program computes the nonlinear function, using some temporary variables to hold intermediate results. The final line of the program then replaces the dependent variable with the values of the function. Notice the use of `'if'` to restrict attention to the estimation sample. `nl` makes a copy of your dependent variable so that when the command is finished your data are left unchanged.

To use the program and fit your model, you type

```

. use https://www.stata-press.com/data/r19/production, clear
. nl ces2 @ lnoutput capital labor, parameters(b0 rho delta)
> initial(b0 0 rho 1 delta 0.5)

```

The output is again identical to that shown in [example 1](#). The order in which the parameters were specified in the `parameters()` option is the same in which they are retrieved from the `at` matrix in the program. To initialize them, you simply list the parameter name, a space, the initial value, and so on.

If you use the `nparameters()` option instead of the `parameters()` option, the parameters are named `b1`, `b2`, ..., `bk`, where `k` is the number of parameters. Thus, you could have typed

```
. nl ces2 @ lnoutput capital labor, nparameters(3) initial(b1 0 b2 1 b3 0.5)
```

With that syntax, the parameters called `b0`, `rho`, and `delta` in the program will be labeled `b1`, `b2`, and `b3`, respectively. In programming situations or if there are many parameters, instead of listing the parameter names and initial values in the `initial()` option, you may find it more convenient to pass a column vector. In those cases, you could type

```
. matrix myvals = (0, 1, 0.5)
. nl ces2 @ lnoutput capital labor, nparameters(3) initial(myvals, copy)
```

or by name

```
. matrix colnames myvals = b1 b2 b3
. nl ces2 @ lnoutput capital labor, nparameters(3) initial(myvals)
```

In summary, a function evaluator program receives a list of variables, the first of which is the dependent variable that you are to replace with the values of your nonlinear function. Additionally, it must accept an *if exp*, as well as an option named `at` that will contain the vector of parameters at which `nl` wants the function evaluated. You are then free to do whatever is necessary to evaluate your function and replace the dependent variable.

If you wish to use weights, your function evaluator program's `syntax` statement must accept them. If your program consists only of, for example, `generate` statements, you need not do anything with the weights passed to your program. However, if in calculating the nonlinear function you use commands such as `summarize` or `regress`, then you will want to use the weights with those commands.

As with substitutable expression programs, `nl` will pass to it any options specified that `nl` does not accept, providing you with a way to pass more information to your function.

## □ Technical note

Before version 9 of Stata, the `nl` command used a different syntax, which required you to write an *nlfcn* program, and it did not have a syntax for interactive use other than the seven functions that were built-in. The old syntax of `nl` still works, and you can still use those *nlfcn* programs. If `nl` does not see a colon, an `at` sign, or a set of parentheses surrounding the equation in your command, it assumes that the old syntax is being used.

The current version of `nl` uses scalars and matrices to store intermediate calculations instead of local and global macros as the old version did, so the current version produces more accurate results. In practice, however, any discrepancies are likely to be small.

□

## Stored results

nl stores the following in `e()`:

### Scalars

|                            |                                                                           |
|----------------------------|---------------------------------------------------------------------------|
| <code>e(N)</code>          | number of observations                                                    |
| <code>e(k)</code>          | number of parameters                                                      |
| <code>e(k_eq_model)</code> | number of equations in overall model test; always 0                       |
| <code>e(df_m)</code>       | model degrees of freedom                                                  |
| <code>e(df_r)</code>       | residual degrees of freedom                                               |
| <code>e(df_t)</code>       | total degrees of freedom                                                  |
| <code>e(mss)</code>        | model sum of squares                                                      |
| <code>e(rss)</code>        | residual sum of squares                                                   |
| <code>e(tss)</code>        | total sum of squares                                                      |

| <code>e(marginsnotok)</code> | predictions disallowed by <code>margins</code>                                                                                                                             |

|                 |                                              |
|-----------------|----------------------------------------------|
| Matrices        |                                              |
| e(b)            | coefficient vector                           |
| e(Cns)          | constraints matrix                           |
| e(from)         | initial values vector                        |
| e(V)            | variance-covariance matrix of the estimators |
| e(V_modelbased) | model-based variance                         |
| Functions       |                                              |
| e(sample)       | marks estimation sample                      |

In addition to the above, the following is stored in `r()`:

|          |                                                                                                                       |
|----------|-----------------------------------------------------------------------------------------------------------------------|
| Matrices |                                                                                                                       |
| r(table) | matrix containing the coefficients with their standard errors, test statistics, $p$ -values, and confidence intervals |

Note that results stored in `r()` are updated when the command is replayed and will be replaced when any `r-class` command is run after the estimation command.

## Methods and formulas

The derivation here is based on Davidson and MacKinnon (2004, chap. 6). Let  $\beta$  denote the  $k \times 1$  vector of parameters, and write the regression function using matrix notation as  $\mathbf{y} = \mathbf{f}(\mathbf{x}, \beta) + \mathbf{u}$  so that the objective function can be written as

$$\text{SSR}(\beta) = \{\mathbf{y} - \mathbf{f}(\mathbf{x}, \beta)\}' \mathbf{D} \{\mathbf{y} - \mathbf{f}(\mathbf{x}, \beta)\}$$

The  $\mathbf{D}$  matrix contains the weights and is defined in `[R] regress`; if no weights are specified, then  $\mathbf{D}$  is the  $N \times N$  identity matrix. Taking a second-order Taylor series expansion centered at  $\beta_0$  yields

$$\text{SSR}(\beta) \approx \text{SSR}(\beta_0) + \mathbf{g}'(\beta_0)(\beta - \beta_0) + \frac{1}{2}(\beta - \beta_0)'\mathbf{H}(\beta_0)(\beta - \beta_0) \quad (8)$$

where  $\mathbf{g}(\beta_0)$  denotes the  $k \times 1$  gradient of  $\text{SSR}(\beta)$  evaluated at  $\beta_0$  and  $\mathbf{H}(\beta_0)$  denotes the  $k \times k$  Hessian of  $\text{SSR}(\beta)$  evaluated at  $\beta_0$ . Letting  $\mathbf{X}$  denote the  $N \times k$  Jacobian matrix, the matrix of derivatives of  $\mathbf{f}(\mathbf{x}, \beta)$  with respect to  $\beta$ , the gradient  $\mathbf{g}(\beta)$  is

$$\mathbf{g}(\beta) = -2\mathbf{X}'\mathbf{D}\mathbf{u} \quad (9)$$

$\mathbf{X}$  and  $\mathbf{u}$  are obviously functions of  $\beta$ , though for notational simplicity that dependence is not shown explicitly. The  $(m, n)$  element of the Hessian can be written as

$$H_{mn}(\beta) = -2 \sum_{i=1}^{i=N} d_{ii} \left[ \frac{\partial^2 f_i}{\partial \beta_m \partial \beta_n} u_i - X_{im} X_{in} \right] \quad (10)$$

where  $d_{ii}$  is the  $i$ th diagonal element of  $\mathbf{D}$ . As discussed in Davidson and MacKinnon (2004, chap. 6), the first term inside the brackets of (10) has expectation zero, so the Hessian can be approximated as

$$\mathbf{H}(\beta) = 2\mathbf{X}'\mathbf{D}\mathbf{X} \quad (11)$$

Differentiating the Taylor series expansion of  $\text{SSR}(\beta)$  shown in (8) yields the first-order condition for a minimum

$$\mathbf{g}(\beta_0) + \mathbf{H}(\beta_0)(\beta - \beta_0) = \mathbf{0}$$

which suggests the iterative procedure

$$\beta_{j+1} = \beta_j - \alpha \mathbf{H}^{-1}(\beta_j) \mathbf{g}(\beta_j) \quad (12)$$

where  $\alpha$  is a “step size” parameter chosen at each iteration to improve convergence. Using (9) and (11), we can write (12) as

$$\beta_{j+1} = \beta_j + \alpha(\mathbf{X}'\mathbf{D}\mathbf{X})^{-1}\mathbf{X}'\mathbf{D}\mathbf{u} \quad (13)$$

where  $\mathbf{X}$  and  $\mathbf{u}$  are evaluated at  $\beta_j$ . Apart from the scalar  $\alpha$ , the second term on the right-hand side of (13) can be computed via a (weighted) regression of the columns of  $\mathbf{X}$  on the errors. This is implemented using Mata’s `moptimize()` function and the Gauss–Newton algorithm. Derivatives are computed numerically using Mata’s `deriv()` function. Convergence is declared when `mreldif( $\beta_{j+1}, \beta_j$ ) < tolerance()` or `reldif(SSR( $\beta_{j+1}$ ), SSR( $\beta_j$ )) < ltolerance()`, and  $\mathbf{g}'_{j+1}(\mathbf{H}_{j+1})^{-1}\mathbf{g}_{j+1} < \text{nrtolerance}()$ .

As derived, for example, in Davidson and MacKinnon (2004, chap. 6), an expedient way to obtain the covariance matrix is to compute  $\mathbf{u}$  and the columns of  $\mathbf{X}$  at the final estimate  $\hat{\beta}$  and then regress that  $\mathbf{u}$  on  $\mathbf{X}$ . The covariance matrix of the estimated parameters of that regression serves as an estimate of  $\text{Var}(\hat{\beta})$ . If that regression employs a robust covariance matrix estimator, then the covariance matrix for the parameters of the nonlinear regression will also be robust.

All other statistics are calculated analogously to those in linear regression, except that the nonlinear function  $f(\mathbf{x}_i, \beta)$  plays the role of the linear function  $\mathbf{x}'_i\beta$ . See [R] [regress](#).

This command supports estimation with survey data. For details on VCEs with survey data, see [SVY] [Variance estimation](#).

## Acknowledgments

The original version of `nl` was written by Patrick Royston of the MRC Clinical Trials Unit, London, and coauthor of the Stata Press book *Flexible Parametric Survival Analysis Using Stata: Beyond the Cox Model*. Francesco Danuso’s menu-driven nonlinear regression program (1991) provided the inspiration.

## Postestimation commands

The following postestimation commands are available after `nl`:

| Command                      | Description                                                                                                                             |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <code>estat ic</code>        | Akaike's, consistent Akaike's, corrected Akaike's, and Schwarz's Bayesian information criteria (AIC, CAIC, AICc, and BIC, respectively) |
| <code>estat summarize</code> | summary statistics for the estimation sample                                                                                            |
| <code>estat vce</code>       | variance–covariance matrix of the estimators (VCE)                                                                                      |
| <code>estat (svy)</code>     | postestimation statistics for survey data                                                                                               |
| <code>estimates</code>       | cataloging estimation results                                                                                                           |
| <code>etable</code>          | table of estimation results                                                                                                             |
| * <code>forecast</code>      | dynamic forecasts and simulations                                                                                                       |
| * <code>hausman</code>       | Hausman's specification test                                                                                                            |
| <code>lincom</code>          | point estimates, standard errors, testing, and inference for linear combinations of parameters                                          |
| * <code>lrtest</code>        | likelihood-ratio test                                                                                                                   |
| † <code>margins</code>       | marginal means, predictive margins, marginal effects, and average marginal effects                                                      |
| <code>marginsplot</code>     | graph the results from margins (profile plots, interaction plots, etc.)                                                                 |
| <code>nlcom</code>           | point estimates, standard errors, testing, and inference for nonlinear combinations of parameters                                       |
| <code>predict</code>         | fitted values, residuals, etc.                                                                                                          |
| <code>predictnl</code>       | point estimates, standard errors, testing, and inference for generalized predictions                                                    |
| <code>test</code>            | Wald tests of simple and composite linear hypotheses                                                                                    |
| <code>testnl</code>          | Wald tests of nonlinear hypotheses                                                                                                      |

\*`forecast`, `hausman`, and `lrtest` are not appropriate with `svy` estimation results.

†You must specify the `variables()` option with `nl`.

# predict

## Description for predict

`predict` creates a new variable containing predictions such as fitted values, residuals, probabilities, and expected values. It can also create multiple new variables containing predicted, named substitutable expressions.

## Menu for predict

Statistics > Postestimation

## Syntax for predict

*Syntax for predicting without named substitutable expressions (parameters)*

```
predict [type] newvar [if] [in] [, statistic]
```

```
predict [type] stub* [if] [in] , scores
```

*Syntax for predicting with named substitutable expressions (parameters)*

*Predict all parameters*

```
predict [type] { stub* | newvarlist } [if] [in] , parameters
```

*Predict specific parameters*

```
predict [type] (newvar = {param:}) [(newvar = {param:}) [...]] [if] [in]
```

```
predict [type] { stub* | newvarlist } [if] [in] , parameters(paramnames)
```

| <i>statistic</i>                     | Description                                 |
|--------------------------------------|---------------------------------------------|
| <u>y</u> hat                         | fitted values; the default                  |
| <u>r</u> esiduals                    | residuals                                   |
| <u>pr</u> ( <i>a</i> , <i>b</i> )    | $\Pr(y_j   a < y_j < b)$                    |
| <u>e</u> ( <i>a</i> , <i>b</i> )     | $E(y_j   a < y_j < b)$                      |
| <u>ys</u> tar( <i>a</i> , <i>b</i> ) | $E(y_j^*), y_j^* = \max\{a, \min(y_j, b)\}$ |

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

## Options for predict

Main

`yhat`, the default, calculates the fitted values.

`residuals` calculates the residuals.

`pr(a,b)` calculates  $\Pr(a < f(\mathbf{x}_j, \mathbf{b}) + u_j < b)$ , the probability that  $y_j|\mathbf{x}_j$  would be observed in the interval  $(a, b)$ .

$a$  and  $b$  may be specified as numbers or variable names;  $lb$  and  $ub$  are variable names;

`pr(20,30)` calculates  $\Pr(20 < f(\mathbf{x}_j, \mathbf{b}) + u_j < 30)$ ;

`pr(lb,ub)` calculates  $\Pr(lb < f(\mathbf{x}_j, \mathbf{b}) + u_j < ub)$ ; and

`pr(20,ub)` calculates  $\Pr(20 < f(\mathbf{x}_j, \mathbf{b}) + u_j < ub)$ .

$a$  missing ( $a \geq .$ ) means  $-\infty$ ; `pr(. ,30)` calculates  $\Pr(-\infty < f(\mathbf{x}_j, \mathbf{b}) + u_j < 30)$ ;

`pr(lb,30)` calculates  $\Pr(-\infty < f(\mathbf{x}_j, \mathbf{b}) + u_j < 30)$  in observations for which  $lb \geq .$  and calculates  $\Pr(lb < f(\mathbf{x}_j, \mathbf{b}) + u_j < 30)$  elsewhere.

$b$  missing ( $b \geq .$ ) means  $+\infty$ ; `pr(20, .)` calculates  $\Pr(+\infty > f(\mathbf{x}_j, \mathbf{b}) + u_j > 20)$ ;

`pr(20,ub)` calculates  $\Pr(+\infty > f(\mathbf{x}_j, \mathbf{b}) + u_j > 20)$  in observations for which  $ub \geq .$  and calculates  $\Pr(20 < f(\mathbf{x}_j, \mathbf{b}) + u_j < ub)$  elsewhere.

`e(a,b)` calculates  $E(f(\mathbf{x}_j, \mathbf{b}) + u_j | a < f(\mathbf{x}_j, \mathbf{b}) + u_j < b)$ , the expected value of  $y_j|\mathbf{x}_j$  conditional on  $y_j|\mathbf{x}_j$  being in the interval  $(a, b)$ , meaning that  $y_j|\mathbf{x}_j$  is truncated.  $a$  and  $b$  are specified as they are for `pr()`.

`ystar(a,b)` calculates  $E(y_j^*)$ , where  $y_j^* = a$  if  $f(\mathbf{x}_j, \mathbf{b}) + u_j \leq a$ ,  $y_j^* = b$  if  $f(\mathbf{x}_j, \mathbf{b}) + u_j \geq b$ , and  $y_j^* = f(\mathbf{x}_j, \mathbf{b}) + u_j$  otherwise, meaning that  $y_j^*$  is censored.  $a$  and  $b$  are specified as they are for `pr()`.

`scores` calculates the scores. The  $j$ th new variable created will contain the score for the  $j$ th parameter in `e(b)`.

`parameters` and `parameters(paramnames)` calculate predictions for all or a subset of the named substitutable expressions in the model. `parameters()` does not appear in the dialog box.

`paramnames` is `param [param [ . . . ]]`, and `param` is a name of a substitutable expression as specified in one of `nl`'s `define()` options.

# margins

## Description for margins

`margins` estimates margins of response for fitted values.

## Menu for margins

Statistics > Postestimation

## Syntax for margins

```
margins [marginlist] [, options]
margins [marginlist] , predict(statistic ...) [options]
```

| <i>statistic</i>                      | Description                                            |
|---------------------------------------|--------------------------------------------------------|
| <code>yhat</code>                     | fitted values; the default                             |
| <code>pr(a,b)</code>                  | not allowed with margins                               |
| <code>e(a,b)</code>                   | not allowed with margins                               |
| <code>ystar(a,b)</code>               | not allowed with margins                               |
| <code>residuals</code>                | not allowed with margins                               |
| <code>parameters</code>               | predicted parameters                                   |
| <code>parameters(<i>param</i>)</code> | predicted, named substitutable expression <i>param</i> |

Statistics not allowed with margins are functions of stochastic quantities other than `e(b)`.

For the full syntax, see [R] [margins](#).

## Remarks and examples

### ▷ Example 1: Basic usage of predict and margins

Obtaining predictions after fitting a nonlinear regression model with `nl` is no more difficult than obtaining predictions after fitting a linear regression model with `regress`. Here we fit a model of `mpg` on `weight`, allowing for a nonlinear relationship:

```
. use https://www.stata-press.com/data/r19/auto
(1978 automobile data)
. nl (mpg = {b0} + {b1}*weight^{gamma=-.5}), variables(weight) nolog
```

| Source   | SS        | df | MS         |                 |          |  |
|----------|-----------|----|------------|-----------------|----------|--|
| Model    | 1646.4376 | 2  | 823.218805 | Number of obs = | 74       |  |
| Residual | 797.02185 | 71 | 11.2256599 | R-squared =     | 0.6738   |  |
|          |           |    |            | Adj R-squared = | 0.6646   |  |
|          |           |    |            | Root MSE =      | 3.350472 |  |
| Total    | 2443.4595 | 73 | 33.4720474 | Res. dev. =     | 385.8874 |  |

  

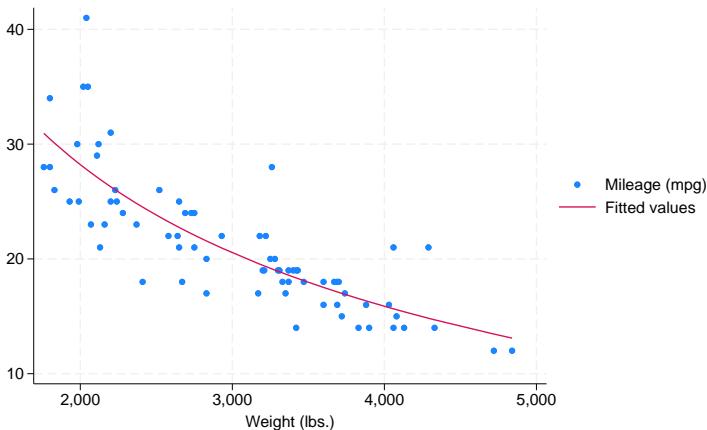

| mpg    | Coefficient | Std. err. | t     | P> t  | [95% conf. interval] |          |
|--------|-------------|-----------|-------|-------|----------------------|----------|
| /b0    | -18.17687   | 60.62086  | -0.30 | 0.765 | -139.0514            | 102.6977 |
| /b1    | 1377.163    | 5291.956  | 0.26  | 0.795 | -9174.697            | 11929.02 |
| /gamma | -.4460793   | .6763682  | -0.66 | 0.512 | -1.794719            | .9025606 |

Note: Parameter **b0** is used as a constant term during estimation.

Now, we obtain the predicted values of `mpg` and plot them in a graph along with the observed values:

```
. predict mpghat
(option yhat assumed; fitted values)
. scatter mpg weight || line mpghat weight, sort
```

Suppose we wanted to know how sensitive mpg is to changes in weight for cars that weigh 3,000 pounds. We can use margins to find out:

```
. margins, eyex(weight) at(weight = 3000)
Conditional marginal effects Number of obs = 74
Model VCE: GNR
Expression: Fitted values, predict()
ey/ex wrt: weight
At: weight = 3000
```

|        | ey/ex     | Delta-method<br>std. err. | z      | P> z  | [95% conf. interval] |          |
|--------|-----------|---------------------------|--------|-------|----------------------|----------|
| weight | -.8408143 | .0804327                  | -10.45 | 0.000 | -.9984596            | -.683169 |

With the `eyex()` option, margins reports elasticities. These results show that if we increase weight by 1%, then mpg decreases by about 0.84%.

◀

## □ Technical note

Observant readers will notice that margins issued a warning message stating that it could not perform its usual check for estimable functions. In the case of `nl`, as long as you do not specify the `predict()` option of margins or specify the default `predict(yhat)`, you can safely ignore that message. The predicted values that `nl` produces are suitable for use with margins. However, if you specify any `predict()` options other than `yhat`, then the output from margins after using `nl` will not be correct.

□

## ▷ Example 2: Predictions from named expressions

Continuing with [example 1](#), consider now a logistic regression that explains the origin of the cars as a function of their price, their fuel efficiency, and their length.

```
. logit foreign price mpg length
Iteration 0: Log likelihood = -45.03321
Iteration 1: Log likelihood = -27.130212
Iteration 2: Log likelihood = -23.885718
Iteration 3: Log likelihood = -23.468167
Iteration 4: Log likelihood = -23.460272
Iteration 5: Log likelihood = -23.460253
Iteration 6: Log likelihood = -23.460253

Logistic regression Number of obs = 74
LR chi2(3) = 43.15
Prob > chi2 = 0.0000
Pseudo R2 = 0.4790

Log likelihood = -23.460253
```

| foreign | Coefficient | Std. err. | z     | P> z  | [95% conf. interval] |           |
|---------|-------------|-----------|-------|-------|----------------------|-----------|
| price   | .0005602    | .0001889  | 2.97  | 0.003 | .0001899             | .0009306  |
| mpg     | -.0606663   | .0854276  | -0.71 | 0.478 | -.2281012            | .1067687  |
| length  | -.1718435   | .0538215  | -3.19 | 0.001 | -.2773316            | -.0663553 |
| _cons   | 27.7666     | 9.860407  | 2.82  | 0.005 | 8.440557             | 47.09264  |

After fitting this model, the `predict` command computes predicted probabilities by default or the linear prediction if we use the `xb` option:

```
. predict p_logit
(option pr assumed; Pr(foreign))
. predict xb_logit, xb
```

Next recall that logistic regression fits the logistic cumulative density function to our data via maximum likelihood. We could instead fit this (nonlinear) function via nonlinear least squares using the `nl` command:

```
. nl (foreign = 1/(1 + exp(-{lp: price mpg length})))
Iteration 0: Residual SS = 18.5
Iteration 1: Residual SS = 7.7385558
Iteration 2: Residual SS = 7.6199595
Iteration 3: Residual SS = 7.6149448
Iteration 4: Residual SS = 7.6143961
Iteration 5: Residual SS = 7.6143036
Iteration 6: Residual SS = 7.6142876
Iteration 7: Residual SS = 7.6142848
Iteration 8: Residual SS = 7.6142843
```

| Source   | SS        | df | MS         |                 |          |
|----------|-----------|----|------------|-----------------|----------|
| Model    | 7.8451752 | 3  | 2.61505839 | Number of obs = | 74       |
| Residual | 7.6142843 | 70 | .10877549  | R-squared =     | 0.5075   |
|          |           |    |            | Adj R-squared = | 0.4864   |
|          |           |    |            | Root MSE =      | .3298113 |
| Total    | 15.459459 | 73 | .211773417 | Res. dev. =     | 41.72401 |

| foreign | Coefficient | Std. err. | t     | P> t  | [95% conf. interval] |           |
|---------|-------------|-----------|-------|-------|----------------------|-----------|
| price   | .0006768    | .0002826  | 2.39  | 0.019 | .0001131             | .0012405  |
| mpg     | -.0703169   | .0704894  | -1.00 | 0.322 | -.2109036            | .0702698  |
| length  | -.2241772   | .0912304  | -2.46 | 0.016 | -.4061305            | -.0422224 |
| _cons   | 36.6067     | 15.28359  | 2.40  | 0.019 | 6.124531             | 67.08886  |

Note: Parameter `_cons` is used as a constant term during estimation.

Computing predicted probabilities from this model is still the default for `predict` because these are simply the values our model predicts for the dependent variable:

```
. predict p_nl
(option yhat assumed; fitted values)
```

To obtain the linear prediction, we need the predicted values of the named linear combination `{lp:}` we created. We can compute those using the `parameters()` option:

```
. predict xb_nl, parameters(lp)
```

## Description

`nlcom` computes point estimates, standard errors, test statistics, significance levels, and confidence intervals for (possibly) nonlinear combinations of parameter estimates after any Stata estimation command, including survey estimation. Results are displayed in the usual table format used for displaying estimation results. Standard error calculations are based on the “delta method”, an approximation appropriate in large samples.

## Quick start

Estimate the ratio of the coefficient of `x2` to the coefficient of `x1`

```
nlcom _b[x2]/_b[x1]
```

Also estimate the ratio of the coefficient of `x3` to coefficient of `x1`

```
nlcom (_b[x2]/_b[x1]) (_b[x3]/_b[x1])
```

Add labels to the ratios

```
nlcom (r21:_b[x2]/_b[x1]) (r31:_b[x3]/_b[x1])
```

Same as above, but post estimates and use the `test` command to test that both ratios are equal to 1

```
nlcom (r21:_b[x2]/_b[x1]) (r31:_b[x3]/_b[x1]), post
test (r21 = 1) (r31 = 1)
```

Estimate the ratio of the coefficients of factor indicators 2.a and 3.a

```
nlcom _b[2.a]/_b[3.a]
```

Estimate the ratio of the coefficients of `x1` in the equations for `y1` and `y2` in a multiequation model

```
nlcom _b[y1:x1]/_b[y2:x1]
```

## Menu

Statistics > Postestimation

## Syntax

Nonlinear combination of parameters—*one expression*

```
nlcom [name:]exp [, options]
```

Nonlinear combinations of parameters—*more than one expression*

```
nlcom ([name:]exp) ([[name:]exp) ... [, options]
```

| <i>options</i>               | Description                                                                                                 |
|------------------------------|-------------------------------------------------------------------------------------------------------------|
| <code>level(#)</code>        | set confidence level; default is <code>level(95)</code>                                                     |
| <code>iterate(#)</code>      | maximum number of iterations                                                                                |
| <code>display_options</code> | control column formats and line width                                                                       |
| <code>post</code>            | post estimation results                                                                                     |
| <code>eform</code>           | report exponentiated estimates; column title is “exp(b)”                                                    |
| <code>eform(string)</code>   | report exponentiated estimates; column title is “string”                                                    |
| <code>noheader</code>        | suppress output header                                                                                      |
| <code>df(#)</code>           | use <i>t</i> distribution with # degrees of freedom for computing <i>p</i> -values and confidence intervals |

`collect` is allowed; see [\[U\] 11.1.10 Prefix commands](#).

Only one of `eform` or `eform()` is allowed.

`noheader` and `df(#)` do not appear in the dialog box.

The second syntax means that if more than one expression is specified, each must be surrounded by parentheses. The optional *name* is any valid Stata name and labels the transformations.

*exp* is a possibly nonlinear expression containing

```
_b[coef]
_b[eqno:coef]
[eqno]coef
[eqno]_b[coef]
```

*eqno* is

```
##
name
```

*coef* identifies a coefficient in the model. *coef* is typically a variable name, a level indicator, an interaction indicator, or an interaction involving continuous variables. Level indicators identify one level of a factor variable and interaction indicators identify one combination of levels of an interaction; see [\[U\] 11.4.3 Factor variables](#). *coef* may contain time-series operators; see [\[U\] 11.4.4 Time-series varlists](#).

Distinguish between `[]`, which are to be typed, and `[_]`, which indicate optional arguments.

## Options

`level(#)` specifies the confidence level, as a percentage, for confidence intervals. The default is `level(95)` or as set by `set level`; see [\[U\] 20.8 Specifying the width of confidence intervals](#).

`iterate(#)` specifies the maximum number of iterations used to find the optimal step size in calculating numerical derivatives of the transformation(s) with respect to the original parameters. By default, the maximum number of iterations is 100, but convergence is usually achieved after only a few iterations. You should rarely have to use this option.

`display_options:` `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `no1stretch`; see [R] [Estimation options](#).

`post` causes `nlcom` to behave like a Stata estimation (`eclass`) command. When `post` is specified, `nlcom` will post the vector of transformed parameters and its estimated variance–covariance matrix to `e()`. This option, in essence, makes the transformation permanent. Thus you could, after posting, treat the transformed estimation results in the same way as you would treat results from other Stata estimation commands. For example, after posting, you could redisplay the results by typing `nlcom` without any arguments, or use `test` to perform simultaneous tests of hypotheses on linear combinations of the transformed parameters; see [R] [test](#).

Specifying `post` clears out the previous estimation results, which can be recovered only by refitting the original model or by storing the estimation results before running `nlcom` and then restoring them; see [R] [estimates store](#).

`eform` and `eform(string)` specify that the table of estimates be displayed in exponentiated form: for each estimate,  $e^b$  rather than  $b$  is displayed, where  $b$  is the nonlinear combination of parameters. `eform` labels the exponentiated results `exp(b)`, whereas `eform(string)` uses `string` to label them. Standard errors and confidence intervals are also transformed; see [R] [eform\\_option](#).

The following options are available with `nlcom` but are not shown in the dialog box:

`noheader` suppresses the output header.

`df(#)` specifies that the  $t$  distribution with  $\#$  degrees of freedom be used for computing  $p$ -values and confidence intervals.

## Remarks and examples

Remarks are presented under the following headings:

[Introduction](#)

[Basics](#)

[Using the post option](#)

[Reparameterizing ML estimates for univariate data](#)

[nlcom versus eform](#)

## Introduction

`nlcom` and `predictnl` both use the delta method. They take nonlinear transformations of the estimated parameter vector from some fitted model and apply the delta method to calculate the variance, standard error, Wald test statistic, etc., of the transformations. `nlcom` is designed for functions of the parameters, and `predictnl` is designed for functions of the parameters and of the data, that is, for predictions.

`nlcom` generalizes `lincom` (see [R] [lincom](#)) in two ways. First, `nlcom` allows the transformations to be nonlinear. Second, `nlcom` can be used to simultaneously estimate many transformations (whether linear or nonlinear) and to obtain the estimated variance–covariance matrix of these transformations.

## Basics

In [R] `lincom`, the following regression was performed:

```
. use https://www.stata-press.com/data/r19/regress
. regress y x1 x2 x3
```

| Source   | SS         | df  | MS         | Number of obs | = | 148    |
|----------|------------|-----|------------|---------------|---|--------|
| Model    | 3259.3561  | 3   | 1086.45203 | F(3, 144)     | = | 96.12  |
| Residual | 1627.56282 | 144 | 11.3025196 | Prob > F      | = | 0.0000 |
|          |            |     |            | R-squared     | = | 0.6670 |
|          |            |     |            | Adj R-squared | = | 0.6600 |
| Total    | 4886.91892 | 147 | 33.2443464 | Root MSE      | = | 3.3619 |

| y     | Coefficient | Std. err. | t      | P> t  | [95% conf. interval] |           |
|-------|-------------|-----------|--------|-------|----------------------|-----------|
| x1    | 1.457113    | 1.07461   | 1.36   | 0.177 | -.666934             | 3.581161  |
| x2    | 2.221682    | .8610358  | 2.58   | 0.011 | .5197797             | 3.923583  |
| x3    | -.006139    | .0005543  | -11.08 | 0.000 | -.0072345            | -.0050435 |
| _cons | 36.10135    | 4.382693  | 8.24   | 0.000 | 27.43863             | 44.76407  |

Then, `lincom` was used to estimate the difference between the coefficients of `x1` and `x2`:

```
. lincom _b[x2] - _b[x1]
(1) - x1 + x2 = 0
```

| y   | Coefficient | Std. err. | t    | P> t  | [95% conf. interval] |          |
|-----|-------------|-----------|------|-------|----------------------|----------|
| (1) | .7645682    | .9950282  | 0.77 | 0.444 | -1.20218             | 2.731316 |

It was noted, however, that nonlinear expressions are not allowed with `lincom`:

```
. lincom _b[x2]/_b[x1]
not possible with test
r(131);
```

Nonlinear transformations are instead estimated using `nlcom`:

```
. nlcom _b[x2]/_b[x1]
 _nl_1: _b[x2]/_b[x1]
```

| y     | Coefficient | Std. err. | z    | P> z  | [95% conf. interval] |          |
|-------|-------------|-----------|------|-------|----------------------|----------|
| _nl_1 | 1.524714    | .9812848  | 1.55 | 0.120 | -.3985686            | 3.447997 |

### □ Technical note

The notation `_b[name]` is the standard way in Stata to refer to regression coefficients; see [U] 13.5 [Accessing coefficients and standard errors](#). Some commands, such as `lincom` and `test`, allow you to drop the `_b[]` and just refer to the coefficients by *name*. `nlcom`, however, requires the full specification `_b[name]`.

□

Returning to our linear regression example, `nlcom` also allows simultaneous estimation of more than one combination:

```
. nlcom (_b[x2]/_b[x1]) (_b[x3]/_b[x1]) (_b[x3]/_b[x2])
 _nl_1: _b[x2]/_b[x1]
 _nl_2: _b[x3]/_b[x1]
 _nl_3: _b[x3]/_b[x2]
```

| y     | Coefficient | Std. err. | z     | P> z  | [95% conf. interval] |          |
|-------|-------------|-----------|-------|-------|----------------------|----------|
| _nl_1 | 1.524714    | .9812848  | 1.55  | 0.120 | -.3985686            | 3.447997 |
| _nl_2 | -.0042131   | .0033483  | -1.26 | 0.208 | -.0107756            | .0023494 |
| _nl_3 | -.0027632   | .0010695  | -2.58 | 0.010 | -.0048594            | -.000667 |

We can also label the transformations to produce more informative names in the estimation table:

```
. nlcom (ratio21:_b[x2]/_b[x1]) (ratio31:_b[x3]/_b[x1]) (ratio32:_b[x3]/_b[x2])
 ratio21: _b[x2]/_b[x1]
 ratio31: _b[x3]/_b[x1]
 ratio32: _b[x3]/_b[x2]
```

| y       | Coefficient | Std. err. | z     | P> z  | [95% conf. interval] |          |
|---------|-------------|-----------|-------|-------|----------------------|----------|
| ratio21 | 1.524714    | .9812848  | 1.55  | 0.120 | -.3985686            | 3.447997 |
| ratio31 | -.0042131   | .0033483  | -1.26 | 0.208 | -.0107756            | .0023494 |
| ratio32 | -.0027632   | .0010695  | -2.58 | 0.010 | -.0048594            | -.000667 |

`nlcom` stores the vector of estimated combinations and its estimated variance–covariance matrix in `r()`.

```
. matrix list r(b)
r(b)[1,3]
 ratio21 ratio31 ratio32
c1 1.5247143 -.00421315 -.00276324
. matrix list r(V)
symmetric r(V)[3,3]
 ratio21 ratio31 ratio32
ratio21 .96291982
ratio31 -.00287781 .00001121
ratio32 -.00014234 2.137e-06 1.144e-06
```

## Using the post option

When used with the `post` option, `nlcom` stores the estimation vector and variance–covariance matrix in `e()`, making the transformation permanent:

```
. quietly nlcom (ratio21:_b[x2]/_b[x1]) (ratio31:_b[x3]/_b[x1])
> (ratio32:_b[x3]/_b[x2]), post
. matrix list e(b)
e(b) [1,3]
 ratio21 ratio31 ratio32
y1 1.5247143 -.00421315 -.00276324
. matrix list e(V)
symmetric e(V) [3,3]
 ratio21 ratio31 ratio32
ratio21 .96291982
ratio31 -.00287781 .00001121
ratio32 -.00014234 2.137e-06 1.144e-06
```

After posting, we can proceed as if we had just run a Stata estimation (`eclass`) command. For instance, we can replay the results,

```
. nlcom
```

| y       | Coefficient | Std. err. | z     | P> z  | [95% conf. interval] |          |
|---------|-------------|-----------|-------|-------|----------------------|----------|
| ratio21 | 1.524714    | .9812848  | 1.55  | 0.120 | -.3985686            | 3.447997 |
| ratio31 | -.0042131   | .0033483  | -1.26 | 0.208 | -.0107756            | .0023494 |
| ratio32 | -.0027632   | .0010695  | -2.58 | 0.010 | -.0048594            | -.000667 |

or perform other postestimation tasks in the transformed metric, this time making reference to the new “coefficients”:

```
. display _b[ratio31]
-.00421315
. estat vce, correlation
Correlation matrix of coefficients of nlcom model
 e(V) | ratio21 ratio31 ratio32
-----|-----
ratio21 | 1.0000
ratio31 | -0.8759 1.0000
ratio32 | -0.1356 0.5969 1.0000
. test _b[ratio21] = 1
(1) ratio21 = 1
 chi2(1) = 0.29
 Prob > chi2 = 0.5928
```

We see that testing `_b[ratio21]=1` in the transformed metric is equivalent to testing using `testnl _b[x2]/_b[x1]=1` in the original metric:

```
. quietly regress y x1 x2 x3
. testnl _b[x2]/_b[x1] = 1
(1) _b[x2]/_b[x1] = 1
 chi2(1) = 0.29
 Prob > chi2 = 0.5928
```

We needed to refit the regression model to recover the original parameter estimates.

## □ Technical note

In a previous technical note, we mentioned that commands such as `lincom` and `test` permit reference to *name* instead of `_b[name]`. This is not the case when `lincom` and `test` are used after `nlcom`, `post`. In the above, we used

```
. test _b[ratio21] = 1
```

rather than

```
. test ratio21 = 1
```

which would have returned an error. Consider this a limitation of Stata. For the shorthand notation to work, you need a variable named *name* in the data. In `nlcom`, however, *name* is just a coefficient label that does not necessarily correspond to any variable in the data. □

## Reparameterizing ML estimates for univariate data

When run using only a response and no covariates, Stata's maximum likelihood (ML) estimation commands will produce ML estimates of the parameters of some assumed univariate distribution for the response. The parameterization, however, is usually not one we are used to dealing with in a nonregression setting. In such cases, `nlcom` can be used to transform the estimation results from a regression model to those from a maximum likelihood estimation of the parameters of a univariate probability distribution in a more familiar metric.

### ▷ Example 1

Consider the following univariate data on  $Y = \#$  of traffic accidents at a certain intersection in a given year:

```
. use https://www.stata-press.com/data/r19/trafint
```

```
. summarize accidents
```

| Variable  | Obs | Mean     | Std. dev. | Min | Max |
|-----------|-----|----------|-----------|-----|-----|
| accidents | 12  | 13.83333 | 14.47778  | 0   | 41  |

A quick glance of the output from `summarize` leads us to quickly reject the assumption that  $Y$  is distributed as Poisson because the estimated variance of  $Y$  is much greater than the estimated mean of  $Y$ .

Instead, we choose to model the data as univariate negative binomial, of which a common parameterization is

$$\Pr(Y = y) = \frac{\Gamma(r + y)}{\Gamma(r)\Gamma(y + 1)} p^r (1 - p)^y \quad 0 \leq p \leq 1, \quad r > 0, \quad y = 0, 1, \dots$$

with

$$E(Y) = \frac{r(1 - p)}{p} \quad \text{Var}(Y) = \frac{r(1 - p)}{p^2}$$

There exist no closed-form solutions for the maximum likelihood estimates of  $p$  and  $r$ , yet they may be estimated by the iterative method of Newton–Raphson. One way to get these estimates would be to write our own Newton–Raphson program for the negative binomial. Another way would be to write our own ML evaluator; see [R] ml.

The easiest solution, however, would be to use Stata’s existing negative binomial ML regression command, nbreg. The only problem with this solution is that nbreg estimates a different parameterization of the negative binomial, but we can worry about that later.

```
. nbreg accidents
Fitting Poisson model:
Iteration 0: Log likelihood = -105.05361
Iteration 1: Log likelihood = -105.05361
Fitting constant-only model:
Iteration 0: Log likelihood = -43.948619
Iteration 1: Log likelihood = -43.891483
Iteration 2: Log likelihood = -43.89144
Iteration 3: Log likelihood = -43.89144
Fitting full model:
Iteration 0: Log likelihood = -43.89144
Iteration 1: Log likelihood = -43.89144
Negative binomial regression Number of obs = 12
 LR chi2(0) = 0.00
Dispersion: mean Prob > chi2 = .
Log likelihood = -43.89144 Pseudo R2 = 0.0000
```

| accidents | Coefficient | Std. err. | z    | P> z  | [95% conf. interval] |          |
|-----------|-------------|-----------|------|-------|----------------------|----------|
| _cons     | 2.627081    | .3192233  | 8.23 | 0.000 | 2.001415             | 3.252747 |
| /lnalpha  | .1402425    | .4187147  |      |       | -.6804233            | .9609083 |
| alpha     | 1.150553    | .4817534  |      |       | .5064026             | 2.61407  |

```
LR test of alpha=0: chibar2(01) = 122.32 Prob >= chibar2 = 0.000
```

```
. nbreg, coeflegend
Negative binomial regression Number of obs = 12
 LR chi2(0) = 0.00
Dispersion: mean Prob > chi2 = .
Log likelihood = -43.89144 Pseudo R2 = 0.0000
```

| accidents | Coefficient | Legend       |
|-----------|-------------|--------------|
| _cons     | 2.627081    | _b[_cons]    |
| /lnalpha  | .1402425    | _b[/lnalpha] |
| alpha     | 1.150553    |              |

```
LR test of alpha=0: chibar2(01) = 122.32 Prob >= chibar2 = 0.000
```

From this output, we see that, when used with univariate data, nbreg estimates a regression intercept,  $\beta_0$ , and the logarithm of some parameter  $\alpha$ . This parameterization is useful in regression models:  $\beta_0$  is the intercept meant to be augmented with other terms of the linear predictor, and  $\alpha$  is an overdispersion parameter used for comparison with the Poisson regression model.

However, we need to transform  $(\beta_0, \ln\alpha)$  to  $(p, r)$ . Examining *Methods and formulas* of [R] `nbreg` reveals the transformation as

$$p = \{1 + \alpha \exp(\beta_0)\}^{-1} \quad r = \alpha^{-1}$$

which we apply using `nlcom`:

```
. nlcom (p:1/(1 + exp(_b[/lnalpha] + _b[_cons])))
> (r:exp(-_b[/lnalpha]))
 p: 1/(1 + exp(_b[/lnalpha] + _b[_cons]))
 r: exp(-_b[/lnalpha])
```

| accidents | Coefficient | Std. err. | z    | P> z  | [95% conf. interval] |          |
|-----------|-------------|-----------|------|-------|----------------------|----------|
| p         | .0591157    | .0292857  | 2.02 | 0.044 | .0017168             | .1165146 |
| r         | .8691474    | .3639248  | 2.39 | 0.017 | .1558679             | 1.582427 |

Given the invariance of maximum likelihood estimators and the properties of the delta method, the above parameter estimates, standard errors, etc., are precisely those we would have obtained had we instead performed the Newton–Raphson optimization in the  $(p, r)$  metric.

◀

## □ Technical note

Note how we referred to the estimate of  $\ln\alpha$  above as `_b[/lnalpha]`. This is not entirely evident from the output of `nbreg`, which is why we redisplayed the results using the `coeflegend` option so that we would know how to refer to the coefficients; [U] [13.5 Accessing coefficients and standard errors](#). □

## nlcom versus eform

Many Stata estimation commands allow you to display exponentiated regression coefficients, some by default, some optionally. Known as “`eform`” in Stata terminology, this reparameterization serves many uses: it gives odds ratios for logistic models, hazard ratios in survival models, incidence-rate ratios in Poisson models, and relative-risk ratios in multinomial logit models, to name a few.

For example, consider the following estimation taken directly from the [technical note](#) in [R] `poisson`:

```
. use https://www.stata-press.com/data/r19/airline
. generate lnN = ln(n)
. poisson injuries XYZowned lnN
Iteration 0: Log likelihood = -22.333875
Iteration 1: Log likelihood = -22.332276
Iteration 2: Log likelihood = -22.332276

Poisson regression Number of obs = 9
LR chi2(2) = 19.15
Prob > chi2 = 0.0001
Pseudo R2 = 0.3001

Log likelihood = -22.332276
```

| injuries | Coefficient | Std. err. | z    | P> z  | [95% conf. interval] |          |
|----------|-------------|-----------|------|-------|----------------------|----------|
| XYZowned | .6840667    | .3895877  | 1.76 | 0.079 | -.0795111            | 1.447645 |
| lnN      | 1.424169    | .3725155  | 3.82 | 0.000 | .6940517             | 2.154285 |
| _cons    | 4.863891    | .7090501  | 6.86 | 0.000 | 3.474178             | 6.253603 |

When we replay results and specify the `irr` (incidence-rate ratios) option,

```
. poisson, irr
Poisson regression Number of obs = 9
 LR chi2(2) = 19.15
 Prob > chi2 = 0.0001
 Pseudo R2 = 0.3001

Log likelihood = -22.332276
```

| injuries | IRR      | Std. err. | z    | P> z  | [95% conf. interval] |          |
|----------|----------|-----------|------|-------|----------------------|----------|
| XYZowned | 1.981921 | .7721322  | 1.76 | 0.079 | .9235678             | 4.253085 |
| lnN      | 4.154402 | 1.547579  | 3.82 | 0.000 | 2.00181              | 8.621728 |
| _cons    | 129.5272 | 91.84126  | 6.86 | 0.000 | 32.2713              | 519.8828 |

Note: `_cons` estimates baseline incidence rate.

we obtain the exponentiated regression coefficients and their estimated standard errors.

Contrast this with what we obtain if we exponentiate the coefficients manually by using `nlcom`:

```
. nlcom (E_XYZowned:exp(_b[XYZowned])) (E_lnN:exp(_b[lnN]))
 E_XYZowned: exp(_b[XYZowned])
 E_lnN: exp(_b[lnN])
```

| injuries   | Coefficient | Std. err. | z    | P> z  | [95% conf. interval] |          |
|------------|-------------|-----------|------|-------|----------------------|----------|
| E_XYZowned | 1.981921    | .7721322  | 2.57 | 0.010 | .4685701             | 3.495273 |
| E_lnN      | 4.154402    | 1.547579  | 2.68 | 0.007 | 1.121203             | 7.187602 |

There are three things to note when comparing an estimation command specified with an *eform\_option* with the `nlcom` command specified with coefficients that are exponentiated manually:

1. The exponentiated coefficients and standard errors are identical. This is certainly good news.
2. The Wald test statistic ( $z$ ) and level of significance are different. When using *eform\_option* with an estimation command, the Wald test does not change from what you would have obtained without the *eform\_option*. You can see this by comparing both versions of the `poisson` output given [previously](#).

When you use *eform*, Stata knows that what is usually desired is a test of

$$H_0: \exp(\beta) = 1$$

and not the uninformative-by-comparison

$$H_0: \exp(\beta) = 0$$

The test of  $H_0: \exp(\beta) = 1$  is asymptotically equivalent to a test of  $H_0: \beta = 0$ , the Wald test in the original metric, but the latter has better small-sample properties. Thus if you specify *eform*, you get a test of  $H_0: \beta = 0$ .

`nlcom`, however, is general. It does not attempt to infer the test of greatest interest for a given transformation, and so a test of

$$H_0: \text{transformed coefficient} = 0$$

is always given, regardless of the transformation.

3. You may be surprised to see that, even though the coefficients and standard errors are identical, the confidence intervals (both 95%) are different.

iform confidence intervals reported by an estimation command are standard confidence intervals with the endpoints transformed. For example, the confidence interval for the coefficient on `lnN` is `[0.694, 2.154]`, whereas the confidence interval for the incidence-rate ratio due to `lnN` is `[exp(0.694), exp(2.154)] = [2.002, 8.619]`, which, except for some roundoff error, is what we see from the `output` of `poisson, irr`. For exponentiated coefficients, confidence intervals based on transform-the-endpoints methodology generally have better small-sample properties than their asymptotically equivalent counterparts.

The transform-the-endpoints method, however, gives valid coverage only when the transformation is monotonic. `nlcom` uses a more general and asymptotically equivalent method for calculating confidence intervals, as described in [Methods and formulas](#).

Notice that `nlcom` has an `iform` option that behaves the same way as the `iform` option of any estimation command. Thus, we could have obtained the exponentiated coefficients and confidence intervals after `poisson` by specifying the `iform` option with `nlcom`; that is, we would type

```
. nlcom (E_XYZowned: _b[XYZowned]) (E_lnN: _b[lnN]), iform
 E_XYZowned: _b[XYZowned]
 E_lnN: _b[lnN]
```

| injuries   | exp(b)   | Std. err. | z    | P> z  | [95% conf. interval] |          |
|------------|----------|-----------|------|-------|----------------------|----------|
| E_XYZowned | 1.981921 | .7721322  | 1.76 | 0.079 | .9235678             | 4.253085 |
| E_lnN      | 4.154402 | 1.547579  | 3.82 | 0.000 | 2.00181              | 8.621728 |

We obtain the same results as we did using `poisson` with the `irr` option. The interpretation of the coefficients and confidence intervals follows the discussion above.

## Stored results

`nlcom` stores the following in `r()`:

### Scalars

`r(N)` number of observations  
`r(df_r)` residual degrees of freedom

### Matrices

`r(b)` vector of transformed coefficients  
`r(V)` estimated variance–covariance matrix of the transformed coefficients  
`r(table)` matrix containing the estimates with their standard errors, test statistics, *p*-values, and confidence intervals

If `post` is specified, `nlcom` also stores the following in `e()`:

### Scalars

`e(N)` number of observations  
`e(df_r)` residual degrees of freedom  
`e(N_strata)` number of strata *L*, if used after `svy`  
`e(N_psu)` number of sampled PSUs *n*, if used after `svy`  
`e(rank)` rank of `e(V)`

### Macros

`e(cmd)` `nlcom`  
`e(predict)` program used to implement `predict`  
`e(properties)` `b V`

## Matrices

|            |                                                                                                      |

## Methods and formulas

Given a  $1 \times k$  vector of parameter estimates,  $\widehat{\boldsymbol{\theta}} = (\widehat{\theta}_1, \dots, \widehat{\theta}_k)$ , consider the estimated  $p$ -dimensional transformation

$$g(\widehat{\boldsymbol{\theta}}) = [g_1(\widehat{\boldsymbol{\theta}}), g_2(\widehat{\boldsymbol{\theta}}), \dots, g_p(\widehat{\boldsymbol{\theta}})]$$

The estimated variance–covariance of  $g(\widehat{\boldsymbol{\theta}})$  is given by

$$\widehat{\text{Var}}\{g(\widehat{\boldsymbol{\theta}})\} = \mathbf{G}\mathbf{V}\mathbf{G}'$$

where  $\mathbf{G}$  is the  $p \times k$  matrix of derivatives for which

$$\mathbf{G}_{ij} = \left. \frac{\partial g_i(\boldsymbol{\theta})}{\partial \theta_j} \right|_{\boldsymbol{\theta}=\widehat{\boldsymbol{\theta}}} \quad i = 1, \dots, p \quad j = 1, \dots, k$$

and  $\mathbf{V}$  is the estimated variance–covariance matrix of  $\widehat{\boldsymbol{\theta}}$ . Standard errors are obtained as the square roots of the variances.

The Wald test statistic for testing

$$H_0: g_i(\boldsymbol{\theta}) = 0$$

versus the two-sided alternative is given by

$$Z_i = \frac{g_i(\widehat{\boldsymbol{\theta}})}{[\widehat{\text{Var}}_{ii}\{g(\widehat{\boldsymbol{\theta}})\}]^{1/2}}$$

When the variance–covariance matrix of  $\widehat{\boldsymbol{\theta}}$  is an asymptotic covariance matrix,  $Z_i$  is approximately distributed as Gaussian. For linear regression,  $Z_i$  is taken to be approximately distributed as  $t_{1,r}$  where  $r$  is the residual degrees of freedom from the original fitted model.

A  $(1 - \alpha) \times 100\%$  confidence interval for  $g_i(\boldsymbol{\theta})$  is given by

$$g_i(\widehat{\boldsymbol{\theta}}) \pm z_{\alpha/2} [\widehat{\text{Var}}_{ii}\{g(\widehat{\boldsymbol{\theta}})\}]^{1/2}$$

for those cases where  $Z_i$  is Gaussian and

$$g_i(\widehat{\boldsymbol{\theta}}) \pm t_{\alpha/2,r} [\widehat{\text{Var}}_{ii}\{g(\widehat{\boldsymbol{\theta}})\}]^{1/2}$$

for those cases where  $Z_i$  is  $t$  distributed.  $z_p$  is the  $1 - p$  quantile of the standard normal distribution, and  $t_{p,r}$  is the  $1 - p$  quantile of the  $t$  distribution with  $r$  degrees of freedom.

## Description

`nlsur` fits a system of nonlinear equations by feasible generalized nonlinear least squares (FGNLS). With the interactive version of the command, you enter the system of equations on the command line or in the dialog box by using *substitutable expressions*. If you have a system that you use regularly, you can write a *substitutable expression program* and use the second syntax to avoid having to reenter the system every time. The function evaluator program version gives you the most flexibility in exchange for increased complexity; with this version, your program is given a vector of parameters and a variable list, and your program computes the system of equations.

When you write a substitutable expression program or a function evaluator program, the first five letters of the name must be `nlsur`. *sexp\_prog* and *func\_prog* refer to the name of the program without the first five letters. For example, if you wrote a function evaluator program named `nlsurregss`, you would type `nlsur regss @ ...` to estimate the parameters.

## Quick start

Two-parameter exponential model regressing  $y_1$  on  $x$  using the default FGNLS estimator

```
nlsur (y1 = {b1}*{b2}^x)
```

Add the `variables()` option to allow for missing values of  $y_1$  and  $x$

```
nlsur (y1 = {b1}*{b2}^x), variables(y1 x)
```

Two-equation, two-parameter exponential model

```
nlsur (y1 = {b1}*{b2}^x) (y2 = {g1}*{g2}^x), variables(y1 y2 x)
```

Same as above, but use the iterative FGNLS estimator

```
nlsur (y1 = {b1}*{b2}^x) (y2 = {g1}*{g2}^x), variables(y1 y2 x) ifgnls
```

Specify starting values for parameters  $b_1$  and  $g_2$

```
nlsur (y1 = {b1=.5}*{b2}^x) (y2 = {g1}*{g2=1}^x), variables(y1 y2 x)
```

Same as above

```
nlsur (y1 = {b1}*{b2}^x) (y2 = {g1}*{g2}^x), variables(y1 y2 x) ///
initial(b1 .5 g2 1)
```

Same as above, but specify starting values using the matrix `i`

```
matrix i = (.5,0,0,1)
nlsur (y1 = {b1}*{b2}^x) (y2 = {g1}*{g2}^x), variables(y1 y2 x) ///
initial(i)
```

## Menu

Statistics > Linear models and related > Multiple-equation models > Nonlinear seemingly unrelated regression

## Syntax

### Interactive version

```
nlsur (deivar_1 = <sexp_1>) (deivar_2 = <sexp_2>) ... [if] [in] [weight]
 [, options]
```

### Programmed substitutable expression version

```
nlsur sexp_prog : deivar_1 deivar_2 ... [varlist] [if] [in] [weight] [, options]
```

### Function evaluator program version

```
nlsur func_prog @ deivar_1 deivar_2 ... [varlist] [if] [in] [weight] ,
 nequations(#) { parameters(namelist) | nparameters(#) } [options]
```

where

*deivar*<sub>*j*</sub> is the dependent variable for equation *j*;  
 <*sexp*><sub>*j*</sub> is the substitutable expression for equation *j*;  
*sexp\_prog* is a substitutable expression program; and  
*func\_prog* is a function evaluator program.

| <i>options</i>                                | Description                                                                                                                                              |

| <code>coeflegend</code>                       | display legend instead of statistics                                                                                                                     |

\*You must specify `nequations(#)` and one of `parameters(namelist)` or `nparameters(#)` or both.

`bayesboot`, `bootstrap`, `by`, `collect`, `jackknife`, `rolling`, and `statsby` are allowed; see [U] 11.1.10 [Prefix commands](#).

Weights are not allowed with the `bootstrap` prefix; see [R] [bootstrap](#).

`aweights` are not allowed with the `jackknife` prefix; see [R] [jackknife](#).

`aweights`, `fweights`, `iweights`, and `pweights` are allowed; see [U] 11.1.6 [weight](#).

`coeflegend` does not appear in the dialog box.

See [U] 20 [Estimation and postestimation commands](#) for more capabilities of estimation commands.

## Options

### Model

`fgnls` requests the two-step FGNLS estimator; this is the default.

`ifgnls` requests the iterative FGNLS estimator. For the nonlinear systems estimator, this is equivalent to maximum likelihood estimation.

`nls` requests the nonlinear least-squares (NLS) estimator.

`variables(varlist)` specifies the variables in the system. `nlsur` ignores observations for which any of these variables has missing values. If you do not specify `variables()`, `nlsur` issues an error message if the estimation sample contains any missing values.

`initial(initial_values)` specifies the initial values to begin the estimation. You can specify a  $1 \times k$  matrix, where  $k$  is the total number of parameters in the system, or you can specify a parameter name, its initial value, another parameter name, its initial value, and so on. For example, to initialize `alpha` to 1.23 and `delta` to 4.57, you would type

```
. nlsur ..., initial(alpha 1.23 delta 4.57) ...
```

Initial values declared using this option override any that are declared within substitutable expressions. If you specify a matrix, the values must be in the same order in which the parameters are declared in your model. `nlsur` ignores the row and column names of the matrix.

`nequations(#)` specifies the number of equations in the system.

`parameters(namelist)` specifies the names of the parameters in the system. The names of the parameters must adhere to the naming conventions of Stata's variables; see [U] 11.3 [Naming conventions](#). If you specify both `parameters()` and `nparameters()`, the number of names in the former must match the number specified in the latter.

`nparameters(#)` specifies the number of parameters in the system. If you do not specify names with the `parameters()` option, `nlsur` names them `b1`, `b2`, ..., `b#`. If you specify both `parameters()` and `nparameters()`, the number of names in the former must match the number specified in the latter.

`sexp_options` refer to any options allowed by your `sexp_prog`.

`func_options` refer to any options allowed by your `func_prog`.

### SE/Robust

`vce(vcetype)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory (`gnr`), that are robust to some kinds of misspecification (`robust`), that allow for intragroup correlation (`cluster clustvar`), and that use bootstrap or jackknife methods (`bootstrap`, `jackknife`); see [R] [vce\\_option](#).

`vce(gnr)`, the default, uses the conventionally derived variance estimator for nonlinear models fit using Gauss–Newton regression.

#### Reporting

`level(#)`; see [R] [Estimation options](#).

`title(string)` specifies an optional title that will be displayed just above the table of parameter estimates.

`title2(string)` specifies an optional subtitle that will be displayed between the title specified in `title()` and the table of parameter estimates. If `title2()` is specified but `title()` is not, `title2()` has the same effect as `title()`.

`display_options`: `noci`, `nopvalues`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `no1stretch`; see [R] [Estimation options](#).

#### Optimization

`optimization_options`: `iterate(#)`, `[no]log`, `trace`, `eps(#)`, `ifgnlsiterate(#)`, `ifgnlseps(#)`, `delta(#)`, `noconstants`, and `hasconstants(namelist)`.

`iterate()` specifies the maximum number of iterations to use for NLS at each round of FG-NLS estimation. This option is different from `ifgnlsiterate()`, which controls the maximum rounds of FG-NLS estimation to use when the `ifgnls` option is specified.

`log` and `nolog` specify whether to show the iteration log; see `set iterlog` in [R] [set iter](#).

`trace` specifies that the iteration log should include the current parameter vector.

`eps(#)` specifies the convergence criterion for successive parameter estimates and for the residual sum of squares (RSS). The default is `eps(1e-5)` (0.00001). `eps()` also specifies the convergence criterion for successive parameter estimates between rounds of iterative FG-NLS estimation when `ifgnls` is specified.

`ifgnlsiterate(#)` specifies the maximum number of FG-NLS iterations to perform. The default is the number set using `set maxiter`, which is 300 by default. To use this option, you must also specify the `ifgnls` option.

`ifgnlseps(#)` specifies the convergence criterion for successive estimates of the error covariance matrix during iterative FG-NLS estimation. The default is `ifgnlseps(1e-10)`. To use this option, you must also specify the `ifgnls` option.

`delta(#)` specifies the relative change in a parameter,  $\delta$ , to be used in computing the numeric derivatives. The derivative for parameter  $\beta_i$  is computed as

$$\{f_i(\mathbf{x}_i, \beta_1, \beta_2, \dots, \beta_i + d, \beta_{i+1}, \dots) - f_i(\mathbf{x}_i, \beta_1, \beta_2, \dots, \beta_i, \beta_{i+1}, \dots)\} / d$$

where  $d = \delta(|\beta_i| + \delta)$ . The default is `delta(4e-7)`.

`noconstants` indicates that none of the equations in the system includes constant terms. This option is generally not needed, even if there are no constant terms in the system; though in rare cases without this option, `nlsur` may claim that there is one or more constant terms even if there are none.

`hasconstants(namelist)` indicates the parameters that are to be treated as constant terms in the system of equations. The number of elements of `namelist` must equal the number of equations in the system. The  $i$ th entry of `namelist` specifies the constant term in the  $i$ th equation. If an equation

does not include a constant term, specify a period (.) instead of a parameter name. This option is seldom needed with the interactive and programmed substitutable expression versions, because in those cases nlshr can almost always find the constant terms automatically.

The following options are available with nlshr but are not shown in the dialog box:

coeflegend; see [R] [Estimation options](#).

## Remarks and examples

Remarks are presented under the following headings:

*Introduction*  
*Substitutable expression programs*  
*Function evaluator programs*

### Introduction

nlshr fits a system of nonlinear equations by FGNLS. It can be viewed as a nonlinear variant of Zellner's seemingly unrelated regression model (Zellner 1962; Zellner and Huang 1962; Zellner 1963) and is therefore commonly called nonlinear SUR or nonlinear SURE. The model is also discussed in textbooks such as Davidson and MacKinnon (1993) and Greene (2012, 305–306). Formally, the model fit by nlshr is

$$\begin{aligned}y_{i1} &= f_1(\mathbf{x}_i, \boldsymbol{\beta}) + u_{i1} \\y_{i2} &= f_2(\mathbf{x}_i, \boldsymbol{\beta}) + u_{i2} \\&\vdots = \vdots \\y_{iM} &= f_M(\mathbf{x}_i, \boldsymbol{\beta}) + u_{iM}\end{aligned}$$

for  $i = 1, \dots, N$  observations and  $m = 1, \dots, M$  equations. The errors for the  $i$ th observation,  $u_{i1}, u_{i2}, \dots, u_{iM}$ , may be correlated, so fitting the  $m$  equations jointly may lead to more efficient estimates. Moreover, fitting the equations jointly allows us to impose cross-equation restrictions on the parameters. Not all elements of the parameter vector  $\boldsymbol{\beta}$  and data vector  $\mathbf{x}_i$  must appear in all the equations, though each element of  $\boldsymbol{\beta}$  must appear in at least one equation for  $\boldsymbol{\beta}$  to be identified. For this model, iterative FGNLS estimation is equivalent to maximum likelihood estimation with multivariate normal disturbances.

The syntax you use with nlshr closely mirrors that used with nl. In particular, you use substitutable expressions with the interactive and programmed substitutable expression versions to define the functions in your system. See [R] [nl](#) for more information on substitutable expressions. Here we reiterate the three rules that you must follow:

1. Parameters of the model are bound in braces: {b0}, {param}, etc.
2. Initial values for parameters are given by including an equal sign and the initial value inside the braces: {b0=1}, {param=3.571}, etc. If you do not specify an initial value, that parameter is initialized to zero. The `initial()` option overrides initial values in substitutable expressions.
3. Linear combinations of variables can be included using the notation {eqname:varlist}, for example, {xb: mpg price weight}, {score: w x z}, etc. Parameters of linear combinations are initialized to zero.

▷ Example 1: Interactive version using two-step FGNLS estimator

We have data from an experiment in which two closely related types of bacteria were placed in a Petri dish, and the number of each type of bacteria were recorded every hour. We suspect a two-parameter exponential growth model can be used to model each type of bacteria, but because they shared the same dish, we want to allow for correlation in the error terms. We want to fit the system of equations

$$p_1 = \beta_1 \beta_2^t + u_1$$

$$p_2 = \gamma_1 \gamma_2^t + u_2$$

where  $p_1$  and  $p_2$  are the two populations and  $t$  is time, and we want to allow for nonzero correlation between  $u_1$  and  $u_2$ . We type

```
. use https://www.stata-press.com/data/r19/petridish
. nlstur (p1 = {b1}*{b2}^t) (p2 = {g1}*{g2}^t)
(obs = 25)
```

Calculating NLS estimates:

```
Iteration 0: Residual SS = 335.5286
Iteration 1: Residual SS = 333.8583
Iteration 2: Residual SS = 219.9233
Iteration 3: Residual SS = 127.9355
Iteration 4: Residual SS = 14.86765
Iteration 5: Residual SS = 8.628459
Iteration 6: Residual SS = 8.281268
Iteration 7: Residual SS = 8.28098
Iteration 8: Residual SS = 8.280979
Iteration 9: Residual SS = 8.280979
```

Calculating FGNLS estimates:

```
Iteration 0: Scaled RSS = 49.99892
Iteration 1: Scaled RSS = 49.99892
Iteration 2: Scaled RSS = 49.99892
```

FGNLS regression

| Equation |    | Obs | Parms | RMSE     | R-sq    | Constant |
|----------|----|-----|-------|----------|---------|----------|
| 1        | p1 | 25  | 2     | .4337019 | 0.9734* | (none)   |
| 2        | p2 | 25  | 2     | .3783479 | 0.9776* | (none)   |

\* Uncentered R-sq

|     | Coefficient | Std. err. | z      | P> z  | [95% conf. interval] |          |
|-----|-------------|-----------|--------|-------|----------------------|----------|
| /b1 | .3926631    | .064203   | 6.12   | 0.000 | .2668275             | .5184987 |
| /b2 | 1.119593    | .0088999  | 125.80 | 0.000 | 1.102149             | 1.137036 |
| /g1 | .5090441    | .0669495  | 7.60   | 0.000 | .3778256             | .6402626 |
| /g2 | 1.102315    | .0072183  | 152.71 | 0.000 | 1.088167             | 1.116463 |

The header of the output contains a summary of each equation, including the number of observations and parameters and the root mean squared error of the residuals. `nlstur` checks to see whether each equation contains a constant term, and if an equation does contain a constant term, an  $R^2$  statistic is presented. If an equation does not have a constant term, an uncentered  $R^2$  is instead reported. The  $R^2$  statistic for each equation measures the percentage of variance explained by the nonlinear function and may be useful for descriptive purposes, though it does not have the same formal interpretation in the context of FGNLS as it does with NLS estimation. As we would expect,  $\beta_2$  and  $\gamma_2$  are both greater than one, indicating the two bacterial populations increased in size over time.

The model we fit in the next three examples is in fact linear in the parameters, so it could be fit using the `sureg` command. However, we will fit the model using `nlshr` so that we can focus on the mechanics of using the command. Moreover, using `nlshr` will obviate the need to generate several variables as well as the need to use the `constraint` command to impose parameter restrictions.

► **Example 2: Interactive version using iterative FGNLS estimator—the translog production function**

Greene (1997, sec. 15.6) discusses the transcendental logarithmic (translog) cost function and provides cost and input price data for capital, labor, energy, and materials for the US economy. One way to fit the translog production function to these data is to fit the system of three equations

$$s_k = \beta_k + \delta_{kk} \ln \left( \frac{p_k}{p_m} \right) + \delta_{kl} \ln \left( \frac{p_l}{p_m} \right) + \delta_{ke} \ln \left( \frac{p_e}{p_m} \right) + u_1$$

$$s_l = \beta_l + \delta_{kl} \ln \left( \frac{p_k}{p_m} \right) + \delta_{ll} \ln \left( \frac{p_l}{p_m} \right) + \delta_{le} \ln \left( \frac{p_e}{p_m} \right) + u_2$$

$$s_e = \beta_e + \delta_{ke} \ln \left( \frac{p_k}{p_m} \right) + \delta_{le} \ln \left( \frac{p_l}{p_m} \right) + \delta_{ee} \ln \left( \frac{p_e}{p_m} \right) + u_3$$

where  $s_k$  is capital's cost share,  $s_l$  is labor's cost share, and  $s_e$  is energy's cost share;  $p_k$ ,  $p_l$ ,  $p_e$ , and  $p_m$  are the prices of capital, labor, energy, and materials, respectively; the  $u$ 's are regression error terms; and the  $\beta$ 's and  $\delta$ 's are parameters to be estimated. There are three cross-equation restrictions on the parameters:  $\delta_{kl}$ ,  $\delta_{ke}$ , and  $\delta_{le}$  each appear in two equations. To fit this model by using the iterative FGNLS estimator, we type

```
. use https://www.stata-press.com/data/r19/mfgcost
(Manufacturing cost)
. nlshr (s_k = {bk} + {dkk}*ln(pk/pm) + {dkl}*ln(pl/pm) + {dke}*ln(pe/pm))
> (s_l = {bl} + {dkl}*ln(pk/pm) + {dll}*ln(pl/pm) + {dle}*ln(pe/pm))
> (s_e = {be} + {dke}*ln(pk/pm) + {dle}*ln(pl/pm) + {dee}*ln(pe/pm)),
> ifgnls

We draw your attention to the iteration log at the top of the output. When iterative FGNLS estimation is used, the final scaled RSS will equal the product of the number of observations in the estimation sample and the number of equations; see *Methods and formulas* for details. Because the RSS is scaled by the error covariance matrix during each round of FGNLS estimation, the scaled RSS is not comparable from one FGNLS iteration to the next.

### □ Technical note

You may have noticed that we mentioned having data for four factors of production, yet we fit only three share equations. Because the four shares sum to one, we must drop one of the equations to avoid having a singular error covariance matrix. The iterative FGNLS estimator is equivalent to maximum likelihood estimation, and thus it is invariant to which one of the four equations we choose to drop. The (linearly restricted) parameters of the fourth equation can be obtained using the `lincom` command. Nonlinear functions of the parameters, such as the elasticities of substitution, can be computed using `nlcom`.

## Substitutable expression programs

If you fit the same model repeatedly or you want to share code with colleagues, you can write a *substitutable expression program* to define your system of equations and avoid having to retype the system every time. The first five letters of the program's name must be `nlsur`, and the program must set the `r`-class macro `r(n_eq)` to the number of equations in your system. The first equation's substitutable expression must be returned in `r(eq_1)`, the second equation's in `r(eq_2)`, and so on. You may optionally set `r(title)` to label your output; that has the same effect as specifying the `title()` option.

### ► Example 3: Programmed substitutable expression version

We return to our translog cost function, for which a substitutable expression program is

```

program nlsurtranslog, rclass
 version 19.5 // (or version 19 if you do not have StataNow)
 syntax varlist(min=7 max=7) [if]
 tokenize `varlist'
 args sk sl se pk pl pe pm
 local pkpm ln(`pk'/'pm')
 local plpm ln(`pl'/'pm')
 local pepm ln(`pe'/'pm')
 return scalar n_eq = 3
 return local eq_1 "'sk'= {bk} + {dkk}*`pkpm' + {dkl}*`plpm' + {dke}*`pepm'"
 return local eq_2 "'s1'= {b1} + {dkl}*`pkpm' + {dll}*`plpm' + {dle}*`pepm'"
 return local eq_3 "'se'= {be} + {dke}*`pkpm' + {dle}*`plpm' + {dee}*`pepm'"
 return local title "4-factor translog cost function"
end

```

We made our program accept seven variables, for the three dependent variables  $s_k$ ,  $s_l$ , and  $s_e$ , and the four factor prices  $p_k$ ,  $p_l$ ,  $p_m$ , and  $p_e$ . The `tokenize` command assigns to macros '1', '2', ..., '7' the seven variables stored in 'varlist', and the `args` command transfers those numbered macros to macros 'sk', 's1', ..., 'pm'. Because we knew our substitutable expressions were going to be somewhat long, we created local macros to hold the log price ratios. These are simply macros that hold strings such as `ln(pk/pm)`, not variables, and they will save us some repetitious typing when we define our substitutable expressions. Our program returns the number of equations in `r(n_eq)`, and we defined our substitutable expressions in `eq_1`, `eq_2`, and `eq_3`. We do not bind the expressions in parentheses as we do with the interactive version of `nlsur`. Finally, we put a title in `r(title)` to label our output.

Our `syntax` command also accepts an `if` clause, and that is how `nlsur` indicates the estimation sample to our program. In this application, we can safely ignore it because our program does not compute initial values. However, had we used commands such as `summarize` or `regress` to obtain initial values, then we would need to restrict those commands to analyze only the estimation sample. In those cases, typically, you simply need to include 'if' with the commands you are using. For example, instead of the command

```
summarize `depvar', meanonly
```

you would use

```
summarize `depvar' `if', meanonly
```

We can check our program by typing

```

. nlsurtranslog s_k s_l s_e pk pl pe pm
. return list
scalars:
 r(n_eq) = 3
macros:
 r(title) : "4-factor translog cost function"
 r(eq_3) : "s_e= {be} + {dke}*ln(pk/pm) + {dle}*ln(pl/pm) + {..}"
 r(eq_2) : "s_l= {b1} + {dkl}*ln(pk/pm) + {dll}*ln(pl/pm) + {..}"
 r(eq_1) : "s_k= {bk} + {dkk}*ln(pk/pm) + {dkl}*ln(pl/pm) + {..}"

```

Now that we know that our program works, we fit our model by typing

```
. nlstur translog: s_k s_l s_e pk pl pe pm, ifgnls
(obs = 25)

Because we set `r(title)` in our substitutable expression program, the coefficient table has a title attached to it. The estimates are identical to those we obtained in [example 2](#).

## □ Technical note

`nlsur` accepts frequency and analytic weights as well as `pweights` (sampling weights) and `iweights` (importance weights). You do not need to modify your substitutable expressions in any way to perform weighted estimation, though you must make two changes to your substitutable expression program. The general outline of a *sexp-prog* program is

```

program nlsur name, rclass
 version 19.5 // (or version 19 if you do not have StataNow)
 syntax varlist [fw aw pw iw] [if]
 // Obtain initial values incorporating weights. For example,
 summarize varname ['weight' 'exp' 'if'
 ...
 // Return n_eqn and substitutable expressions
 return scalar n_eq = #
 return local eq_1 = ...
 ...
end

```

First, we wrote the `syntax` statement to accept a weight expression. Here we allow all four types of weights, but if you know that your estimator is valid, say, for only frequency weights, then you should modify the `syntax` line to accept only `fweights`. Second, if your program computes starting values, then any commands you use must incorporate the weights passed to the program; you do that by including `['weight' 'exp']` when calling those commands.

□

## Function evaluator programs

Although substitutable expressions are extremely flexible, there are some problems for which the nonlinear system cannot be defined using them. You can use the function evaluator program version of `nlsur` in these cases. We present two examples, a simple one to illustrate the mechanics of function evaluator programs and a more complicated one to illustrate the power of `nlsur`.

### ► Example 4: Function evaluator program version

Here we write a function evaluator program to fit the translog cost function used in examples 2 and 3. The function evaluator program is

```

program nlsurtranslog2
 version 19.5 // (or version 19 if you do not have StataNow)
 syntax varlist(min=7 max=7) [if], at(name)
 tokenize `varlist'
 args sk sl se pk pl pe pm
 tempname bk dkk dkl dke bl dll dle be dee
 scalar `bk' = `at'[1,1]
 scalar `dkk' = `at'[1,2]
 scalar `dkl' = `at'[1,3]
 scalar `dke' = `at'[1,4]
 scalar `bl' = `at'[1,5]
 scalar `dll' = `at'[1,6]
 scalar `dle' = `at'[1,7]
 scalar `be' = `at'[1,8]
 scalar `dee' = `at'[1,9]
 local pkpm ln(`pk'/'pm')
 local plpm ln(`pl'/'pm')
 local pepm ln(`pe'/'pm')
 quietly {
 replace `sk' = `bk' + `dkk'*`pkpm' + `dkl'*`plpm' + ///
 `dke'*`pepm' `if'
 replace `sl' = `bl' + `dkl'*`pkpm' + `dll'*`plpm' + ///
 `dle'*`pepm' `if'
 replace `se' = `be' + `dke'*`pkpm' + `dle'*`plpm' + ///
 `dee'*`pepm' `if'
 }
end

```

Unlike the substitutable expression program we wrote in [example 3](#), `nlsurtranslog2` is not declared as `r-class` because we will not be returning any stored results. We are again expecting seven variables: three shares and four factor prices, and `nlsur` will again mark the estimation sample with an `if` expression.

Our function evaluator program also accepts an option named `at()`, which will receive a parameter vector at which we are to evaluate the system of equations. All function evaluator programs must accept this option. Our model has nine parameters to estimate, and we created nine temporary scalars to hold the elements of the `'at'` matrix.

Because our model has three equations, the first three variables passed to our program are the dependent variables that we are to fill in with the function values. We replaced only the observations in our estimation sample by including the `'if'` qualifier in the `replace` statements. Here we could have ignored the `'if'` qualifier because `nlsur` will skip over observations not in the estimation sample and we did not perform any computations requiring knowledge of the estimation sample. However, including the `'if'` is good practice and may result in a slight speed improvement if the functions of your model are complicated and the estimation sample is much smaller than the dataset in memory.

We could have avoided creating temporary scalars to hold our individual parameters by writing the replace statements as, for example,

```
replace 'sk' = 'at'[1,1] + 'at'[1,2]*'pkpm' + 'at'[1,3]*'plpm' + 'at'[1,4]*'pepm' 'if'
```

You can use whichever method you find more appealing, though giving the parameters descriptive names reduces the chance for mistakes and makes debugging easier.

To fit our model by using the function evaluator program version of nlsur, we type

```
. nlsur translog2 @ s_k s_l s_e pk pl pe pm, ifgnls nequations(3)
> parameters(bk dkk dkl dke bl dll dle be dee)
> hasconstants(bk bl be)
(obs = 25)

| /dee | .0183415    | .0049858  | 3.68   | 0.000 | .0085694             | .0281135  |

When we use the function evaluator program version, `nlsur` requires us to specify the number of equations in `nequations()`, and it requires us to specify either the names for each of our parameters or the number of parameters in the model. Here we used the `parameters()` option to name our parameters; the order in which we specified them in this option is the same as the order in which we extracted them from the ‘at’ matrix in our program. Had we instead specified `nparameters(9)`, our parameters would have been labeled `/b1`, `/b2`, ..., `/b9` in the output.

`nlsur` has no way of telling how many parameters appear in each equation, so the `Parms` column in the header contains missing values. Moreover, the function evaluator program version of `nlsur` does not attempt to identify constant terms, so we used the `hasconstant` option to tell `nlsur` which parameter in each equation is a constant term.

The estimates are identical to those we obtained in examples 2 and 3.

### □ Technical note

As with substitutable expression programs, if you intend to do weighted estimation with a function evaluator program, you must modify your `func_prog` program’s `syntax` statement to accept weights. Moreover, if you use any statistical commands when computing your nonlinear functions, then you must include the weight expression with those commands.

► Example 5: Fitting the basic AIDS model using nlstur

Deaton and Muellbauer (1980) introduce the almost ideal demand system (AIDS), and Poi (2012) presents a set of commands and several extensions for fitting the AIDS automatically. Here we show how to fit the basic AIDS model, which is a common example of a nonlinear system of equations, by manually using `nlstur`. The dataset `food.dta` contains household expenditures, expenditure shares, and log prices for four broad food groups. For a four-good demand system, we need to fit the following system of three equations:

$$\begin{aligned}
 w_1 &= \alpha_1 + \gamma_{11} \ln p_1 + \gamma_{12} \ln p_2 + \gamma_{13} \ln p_3 + \beta_1 \ln \left\{ \frac{m}{P(\mathbf{p})} \right\} + u_1 \\
 w_2 &= \alpha_2 + \gamma_{12} \ln p_1 + \gamma_{22} \ln p_2 + \gamma_{23} \ln p_3 + \beta_2 \ln \left\{ \frac{m}{P(\mathbf{p})} \right\} + u_2 \\
 w_3 &= \alpha_3 + \gamma_{13} \ln p_1 + \gamma_{23} \ln p_2 + \gamma_{33} \ln p_3 + \beta_3 \ln \left\{ \frac{m}{P(\mathbf{p})} \right\} + u_3
 \end{aligned}$$

where  $w_k$  denotes a household's fraction of expenditures on good  $k$ ,  $\ln p_k$  denotes the logarithm of the price paid for good  $k$ ,  $m$  denotes a household's total expenditure on all four goods, the  $u$ 's are regression error terms, and

$$\ln P(\mathbf{p}) = \alpha_0 + \sum_{i=1}^4 \alpha_i \ln p_i + \frac{1}{2} \sum_{i=1}^4 \sum_{j=1}^4 \gamma_{ij} \ln p_i \ln p_j$$

The parameters for the fourth good's share equation can be recovered from the following constraints that are imposed by economic theory:

$$\sum_{i=1}^4 \alpha_i = 1 \quad \sum_{i=1}^4 \beta_i = 0 \quad \gamma_{ij} = \gamma_{ji} \quad \text{and} \quad \sum_{i=1}^4 \gamma_{ij} = 0 \quad \text{for all } j$$

Our model has a total of 12 unrestricted parameters. We will not estimate  $\alpha_0$  directly. Instead, we will set it equal to 5; see Deaton and Muellbauer (1980) for a discussion of why treating  $\alpha_0$  as fixed is acceptable.

Our function evaluator program is

```

 }
end

```

The syntax statement accepts eight variables: three expenditure share variables, all four log-price variables, and a variable for log expenditures ( $\ln m$ ). Most of the code simply extracts the parameters from the 'at' matrix. Although we are estimating only 12 parameters, to calculate the price index term and the expenditure share equations, we need the restricted parameters as well. Notice how we impose the constraints on the parameters. We then created a temporary variable to hold  $\ln P(\mathbf{p})$ , and we filled the three dependent variables with the predicted expenditure shares.

To fit our model, we type

```
. use https://www.stata-press.com/data/r19/food
(Four food groups)
. nlsur aids @ w1 w2 w3 lnp1 lnp2 lnp3 lnp4 lnexp,

To get the restricted parameters for the fourth share equation, we can use `lincom`. For example, to obtain  $\alpha_4$ , we type

```
. lincom 1 - [a1]_cons - [a2]_cons - [a3]_cons
(1) - [a1]_cons - [a2]_cons - [a3]_cons = -1
```

|     | Coefficient | Std. err. | z     | P> z  | [95% conf. interval] |          |
|-----|-------------|-----------|-------|-------|----------------------|----------|
| (1) | .3083643    | .0052611  | 58.61 | 0.000 | .2980528             | .3186758 |

For more information on `lincom`, see [\[R\] lincom](#).

## Stored results

`nlsur` stores the following in `e()`:

### Scalars

- `e(N)` number of observations
- `e(k)` number of parameters
- `e(k_#)` number of parameters for equation #
- `e(k_eq)` number of equation names in `e(b)`
- `e(k_eq_model)` number of equations in overall model test
- `e(n_eq)` number of equations
- `e(mss_#)` model sum of squares for equation #
- `e(rss_#)` RSS for equation #
- `e(rmse_#)` root mean squared error for equation #
- `e(r2_#)`  $R^2$  for equation #
- `e(ll)` Gaussian log likelihood (`iflgs` version only)
- `e(N_clust)` number of clusters
- `e(rank)` rank of `e(V)`
- `e(converged)` 1 if converged, 0 otherwise

### Macros

- `e(cmd)` `nlsur`
- `e(cmdline)` command as typed
- `e(method)` `fgnls`, `ifgnls`, or `nls`
- `e(depvar)` names of dependent variables
- `e(depvar_#)` dependent variable for equation #
- `e(wtype)` weight type
- `e(wexp)` weight expression

In addition to the above, the following is stored in `r()`:

|          |                                                                                                                            |
|----------|----------------------------------------------------------------------------------------------------------------------------|
| Matrices |                                                                                                                            |
| r(table) | matrix containing the coefficients with their standard errors, test statistics, <i>p</i> -values, and confidence intervals |

Note that results stored in `r()` are updated when the command is replayed and will be replaced when any *r*-class command is run after the estimation command.

## Methods and formulas

Write the system of equations for the *i*th observation as

$$\mathbf{y}_i = \mathbf{f}(\mathbf{x}_i, \boldsymbol{\beta}) + \mathbf{u}_i \quad (1)$$

where  $\mathbf{y}_i$  and  $\mathbf{u}_i$  are  $1 \times M$  vectors, for  $i = 1, \dots, N$ ;  $\mathbf{f}$  is a function that returns a  $1 \times M$  vector;  $\mathbf{x}_i$  represents all the exogenous variables in the system; and  $\boldsymbol{\beta}$  is a  $1 \times k$  vector of parameters. The generalized nonlinear least-squares system estimator is defined as

$$\widehat{\boldsymbol{\beta}} \equiv \operatorname{argmin}_{\boldsymbol{\beta}} \sum_{i=1}^N \{\mathbf{y}_i - \mathbf{f}(\mathbf{x}_i, \boldsymbol{\beta})\} \boldsymbol{\Sigma}^{-1} \{\mathbf{y}_i - \mathbf{f}(\mathbf{x}_i, \boldsymbol{\beta})\}'$$

where  $\boldsymbol{\Sigma} = E(\mathbf{u}_i' \mathbf{u}_i)$  is an  $M \times M$  positive-definite weight matrix. Let  $\mathbf{T}$  be the Cholesky decomposition of  $\boldsymbol{\Sigma}^{-1}$ ; that is,  $\mathbf{T}\mathbf{T}' = \boldsymbol{\Sigma}^{-1}$ . Postmultiply (1) by  $\mathbf{T}$ :

$$\mathbf{y}_i \mathbf{T} = \mathbf{f}(\mathbf{x}_i, \boldsymbol{\beta}) \mathbf{T} + \mathbf{u}_i \mathbf{T} \quad (2)$$

Because  $E(\mathbf{T}'\mathbf{u}'_i\mathbf{u}_i\mathbf{T}) = \mathbf{I}$ , we can “stack” the columns of (2) and write

$$\begin{aligned}
 \mathbf{y}_1\mathbf{T}_1 &= \mathbf{f}(\mathbf{x}_1, \boldsymbol{\beta})\mathbf{T}_1 + \tilde{u}_{11} \\
 \mathbf{y}_1\mathbf{T}_2 &= \mathbf{f}(\mathbf{x}_1, \boldsymbol{\beta})\mathbf{T}_2 + \tilde{u}_{12} \\
 &\vdots \\
 \mathbf{y}_1\mathbf{T}_M &= \mathbf{f}(\mathbf{x}_1, \boldsymbol{\beta})\mathbf{T}_M + \tilde{u}_{1M} \\
 &\vdots \\
 \mathbf{y}_N\mathbf{T}_1 &= \mathbf{f}(\mathbf{x}_N, \boldsymbol{\beta})\mathbf{T}_1 + \tilde{u}_{N1} \\
 \mathbf{y}_N\mathbf{T}_2 &= \mathbf{f}(\mathbf{x}_N, \boldsymbol{\beta})\mathbf{T}_2 + \tilde{u}_{N2} \\
 &\vdots \\
 \mathbf{y}_N\mathbf{T}_M &= \mathbf{f}(\mathbf{x}_N, \boldsymbol{\beta})\mathbf{T}_M + \tilde{u}_{NM}
 \end{aligned} \tag{3}$$

where  $\mathbf{T}_j$  denotes the  $j$ th column of  $\mathbf{T}$ . By construction, all  $\tilde{u}_{ij}$  are independently distributed with unit variance. As a result, by transforming the model in (1) to that shown in (3), we have reduced the multivariate generalized nonlinear least-squares system estimator to a univariate nonlinear least-squares problem; and the same parameter estimation technique used by `nls` can be used here. See [R] `nls` for the details. Moreover, because the  $\tilde{u}_{ij}$  all have variance 1, the final scaled RSS reported by `nlsur` is equal to  $NM$ .

To make the estimator feasible, we require an estimate  $\widehat{\boldsymbol{\Sigma}}$  of  $\boldsymbol{\Sigma}$ . `nlsur` first sets  $\widehat{\boldsymbol{\Sigma}} = \mathbf{I}$ . Although not efficient, the resulting estimate,  $\widehat{\boldsymbol{\beta}}_{\text{NLS}}$ , is consistent. If the `nls` option is specified, estimation is complete. Otherwise, the residuals

$$\hat{\mathbf{u}}_i = \mathbf{y}_i - \mathbf{f}(\mathbf{x}_i, \widehat{\boldsymbol{\beta}}_{\text{NLS}})$$

are calculated and used to compute

$$\widehat{\boldsymbol{\Sigma}} = \frac{1}{N} \sum_{i=1}^N \hat{\mathbf{u}}_i' \hat{\mathbf{u}}_i$$

With  $\widehat{\boldsymbol{\Sigma}}$  in hand, a new estimate  $\widehat{\boldsymbol{\beta}}$  is then obtained.

If the `ifgnls` option is specified, the new  $\widehat{\boldsymbol{\beta}}$  is used to recompute the residuals and obtain a new estimate of  $\widehat{\boldsymbol{\Sigma}}$ , from which  $\widehat{\boldsymbol{\beta}}$  can then be reestimated. Iterations stop when the relative change in  $\widehat{\boldsymbol{\beta}}$  is less than `eps()`, the relative change in  $\widehat{\boldsymbol{\Sigma}}$  is less than `ifgnlseps()`, or if `ifgnlsiterate()` iterations have been performed.

If the `vce(robust)` and `vce(cluster clustvar)` options were not specified, then

$$V(\widehat{\boldsymbol{\beta}}) = \left( \sum_{i=1}^N \mathbf{X}'_i \widehat{\boldsymbol{\Sigma}}^{-1} \mathbf{X}_i \right)^{-1}$$

where the  $M \times k$  matrix  $\mathbf{X}_i$  has typical element  $X_{ist}$ , the derivative of the  $s$ th element of  $\mathbf{f}$  with respect to the  $t$ th element of  $\boldsymbol{\beta}$ , evaluated at  $\mathbf{x}_i$  and  $\widehat{\boldsymbol{\beta}}$ . As a practical matter, once the model is written in the form of (3), the variance–covariance matrix can be calculated via a Gauss–Newton regression; see Davidson and MacKinnon (1993, chap. 6).

If `robust` is specified, then

$$V_R(\widehat{\boldsymbol{\beta}}) = \left( \sum_{i=1}^N \mathbf{X}'_i \widehat{\boldsymbol{\Sigma}}^{-1} \mathbf{X}_i \right)^{-1} \sum_{i=1}^N \mathbf{X}'_i \widehat{\boldsymbol{\Sigma}}^{-1} \hat{\mathbf{u}}_i' \hat{\mathbf{u}}_i \widehat{\boldsymbol{\Sigma}}^{-1} \mathbf{X}_i \left( \sum_{i=1}^N \mathbf{X}'_i \widehat{\boldsymbol{\Sigma}}^{-1} \mathbf{X}_i \right)^{-1}$$

The cluster–robust variance matrix is

$$V_C(\widehat{\beta}) = \left( \sum_{i=1}^N \mathbf{X}'_i \widehat{\Sigma}^{-1} \mathbf{X}_i \right)^{-1} \sum_{c=1}^{N_C} \mathbf{w}_c \mathbf{w}'_c \left( \sum_{i=1}^N \mathbf{X}'_i \widehat{\Sigma}^{-1} \mathbf{X}_i \right)^{-1}$$

where  $N_C$  is the number of clusters and

$$\mathbf{w}_c = \sum_{j \in C_k} \mathbf{X}'_j \widehat{\Sigma}^{-1} \widehat{\mathbf{u}}'_j$$

with  $C_k$  denoting the set of observations in the  $k$ th cluster. In evaluating these formulas, we use the value of  $\widehat{\Sigma}$  used in calculating the final estimate of  $\widehat{\beta}$ . That is, we do not recalculate  $\widehat{\Sigma}$  after we obtain the final value of  $\widehat{\beta}$ .

The RSS for the  $j$ th equation,  $\text{RSS}_j$ , is

$$\text{RSS}_j = \sum_{i=1}^N (\widehat{y}_{ij} - y_{ij})^2$$

where  $\widehat{y}_{ij}$  is the predicted value of the  $i$ th observation on the  $j$ th dependent variable; the total sum of squares (TSS) for the  $j$ th equation,  $\text{TSS}_j$ , is

$$\text{TSS}_j = \sum_{i=1}^N (y_{ij} - \bar{y}_j)^2$$

if there is a constant term in the  $j$ th equation, where  $\bar{y}_j$  is the sample mean of the  $j$ th dependent variable, and

$$\text{TSS}_j = \sum_{i=1}^N y_{ij}^2$$

if there is no constant term in the  $j$ th equation; and the model sum of squares (MSS) for the  $j$ th equation,  $\text{MSS}_j$ , is  $\text{TSS}_j - \text{RSS}_j$ .

The  $R^2$  for the  $j$ th equation is  $\text{MSS}_j/\text{TSS}_j$ . If an equation does not have a constant term, then the reported  $R^2$  for that equation is “uncentered” and based on the latter definition of  $\text{TSS}_j$ .

Under the assumption that the  $\mathbf{u}_i$  are independent and identically distributed  $N(\mathbf{0}, \widehat{\Sigma})$ , the log likelihood for the model is

$$\ln L = -\frac{MN}{2} \{1 + \ln(2\pi)\} - \frac{N}{2} \ln |\widehat{\Sigma}|$$

The log likelihood is reported only when the `ifgnls` option is specified.

## Postestimation commands

The following postestimation commands are available after `nlsur`:

| Command                      | Description                                                                                                                             |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <code>estat ic</code>        | Akaike's, consistent Akaike's, corrected Akaike's, and Schwarz's Bayesian information criteria (AIC, CAIC, AICc, and BIC, respectively) |
| <code>estat summarize</code> | summary statistics for the estimation sample                                                                                            |
| <code>estat vce</code>       | variance–covariance matrix of the estimators (VCE)                                                                                      |
| <code>estimates</code>       | cataloging estimation results                                                                                                           |
| <code>etable</code>          | table of estimation results                                                                                                             |
| <code>forecast</code>        | dynamic forecasts and simulations                                                                                                       |
| <code>hausman</code>         | Hausman's specification test                                                                                                            |
| <code>lincom</code>          | point estimates, standard errors, testing, and inference for linear combinations of parameters                                          |
| <code>lrtest</code>          | likelihood-ratio test                                                                                                                   |
| * <code>margins</code>       | marginal means, predictive margins, marginal effects, and average marginal effects                                                      |
| <code>marginsplot</code>     | graph the results from margins (profile plots, interaction plots, etc.)                                                                 |
| <code>nlcom</code>           | point estimates, standard errors, testing, and inference for nonlinear combinations of parameters                                       |
| <code>predict</code>         | fitted values, residuals, etc.                                                                                                          |
| <code>predictnl</code>       | point estimates, standard errors, testing, and inference for generalized predictions                                                    |
| <code>test</code>            | Wald tests of simple and composite linear hypotheses                                                                                    |
| <code>testnl</code>          | Wald tests of nonlinear hypotheses                                                                                                      |

\*You must specify the `variables()` option with `nlsur`.

# predict

## Description for predict

`predict` creates a new variable containing predictions such as fitted values and residuals.

## Menu for predict

Statistics > Postestimation

## Syntax for predict

```
predict [type] newvar [if] [in] [, equation(eqno) yhat residuals]
```

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

## Options for predict

Main

`equation(eqno)` specifies to which equation you are referring. `equation(#1)` would mean that the calculation is to be made for the first equation, `equation(#2)` would mean the second, and so on. If you do not specify `equation()`, results are the same as if you had specified `equation(#1)`.

`yhat`, the default, calculates the fitted values for the specified equation.

`residuals` calculates the residuals for the specified equation.

# margins

## Description for margins

`margins` estimates margins of response for fitted values.

## Menu for margins

Statistics > Postestimation

## Syntax for margins

```
margins [marginlist] [, options]
```

```
margins [marginlist] , predict(statistic ...) [options]
```

| <i>statistic</i>  | Description                           |
|-------------------|---------------------------------------|
| <u>y</u> hat      | fitted values; the default            |
| <u>r</u> esiduals | not allowed with <code>margins</code> |

Statistics not allowed with `margins` are functions of stochastic quantities other than `e(b)`.

For the full syntax, see [R] [margins](#).

## Remarks and examples

### ▷ Example 1

In [example 2](#) of [R] [nlsur](#), we fit a four-factor translog cost function to data for the US economy. The own-price elasticity for a factor measures the percentage change in its usage as a result of a 1% increase in the factor's price, assuming that output is held constant. For the translog production function, the own-price factor elasticities are

$$\eta_i = \frac{\delta_{ii} + s_i(s_i - 1)}{s_i}$$

Here we compute the elasticity for capital at the sample mean of capital's factor share. First, we use `summarize` to get the mean of `s_k` and store that value in a scalar:

```
. use https://www.stata-press.com/data/r19/mfgcost
(Manufacturing cost)
. nlsur (s_k = {bk} + {dkk}*ln(pk/pm) + {dkl}*ln(pl/pm) + {dke}*ln(pe/pm))
> (s_l = {bl} + {dkl}*ln(pk/pm) + {dll}*ln(pl/pm) + {dle}*ln(pe/pm))
> (s_e = {be} + {dke}*ln(pk/pm) + {dle}*ln(pl/pm) + {dee}*ln(pe/pm)),
> ifgnls
(output omitted)
. summarize s_k
Variable	Obs Mean Std. dev. Min Max
 s_k | 25 .053488 .0044795 .04602 .06185
. scalar kmean = r(mean)
```

Now, we can use `nlcom` to calculate the elasticity:

```
. nlcom (([dkk]_cons + kmean*(kmean-1)) / kmean)
 _nl_1: ([dkk]_cons + kmean*(kmean-1)) / kmean
```

|       | Coefficient | Std. err. | z     | P> z  | [95% conf. interval] |           |
|-------|-------------|-----------|-------|-------|----------------------|-----------|
| _nl_1 | -.3952986   | .1083535  | -3.65 | 0.000 | -.6076676            | -.1829295 |

If the price of capital increases by 1%, its usage will decrease by about 0.4%. To maintain its current level of output, a firm would increase its usage of other inputs to compensate for the lower capital usage. The standard error reported by `nlcom` reflects the sampling variance of the estimated parameter  $\widehat{\delta}_{kk}$ , but `nlcom` treats the sample mean of `s_k` as a fixed parameter that does not contribute to the sampling variance of the estimated elasticity.

## Description

Nonparametric regression models the mean of an outcome given the covariates without making assumptions about its functional form. This makes nonparametric regression estimates robust to functional form misspecification. `npregress` implements the two most common nonparametric regression estimators: series regression and kernel regression.

Nonparametric series estimation regresses the outcome on a function of the covariates. The function of the covariates is known as a basis function. A basis is a collection of terms that approximates smooth functions arbitrarily well. A basis function includes a subset of these terms. The bases used by `npregress series` are polynomials, piecewise polynomial splines, and B-splines.

Nonparametric kernel estimation computes a weighted average of the outcome. The weights are functions called kernels, which give rise to the name of the method. `npregress kernel` performs local-linear and local-constant kernel regression.

Whether we choose to approximate the mean of our outcome using series regression or kernel regression, we obtain estimates that are robust to assumptions about functional form. This robustness comes at a cost; we need many observations and perhaps a long computation time to estimate the elements of the approximating function.

This entry introduces the intuition behind the nonparametric regression estimators implemented in `npregress`. If you are familiar with these methods, you may want to skip to [\[R\] npregress kernel](#) or [\[R\] npregress series](#).

## Remarks and examples

Remarks are presented under the following headings:

*[Overview](#)*

*[Nonparametric series regression](#)*

*[Runge's phenomenon](#)*

*[Piecewise polynomial splines and B-splines](#)*

*[Nonparametric kernel regression](#)*

*[Limitations of nonparametric methods](#)*

## Overview

Nonparametric regression is used when we are uncertain about the functional form of the mean of the outcome given the covariates. For example, when we estimate a linear regression, we assume that the functional form for the mean of the outcome is a linear combination of the specified covariates. Both parametric (linear) regression and nonparametric regression provide an estimate of the mean for the different values of the covariates. Consider the simulated data in figure 1. The mean of the outcome for all values of  $x$  is overlaid on these points.

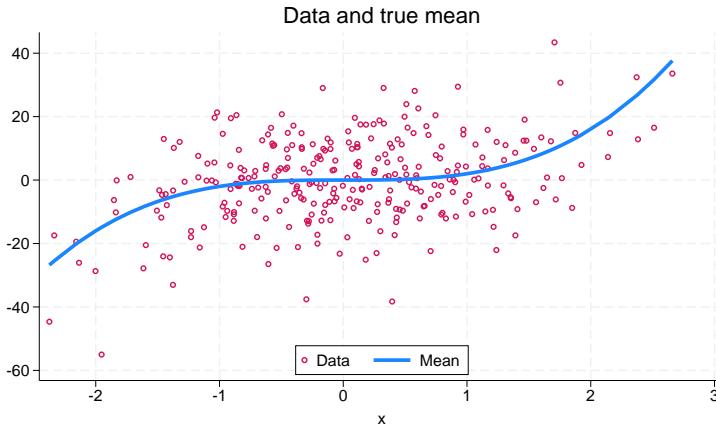

Figure 1.

Because the mean of the data in figure 1 is not linear in  $x$ , using a simple linear regression will not give us a correct picture about the effect of covariate  $x$  on the outcome. For example, if we perform a linear regression of the outcome on  $x$  for the data, we obtain the plot shown in figure 2.

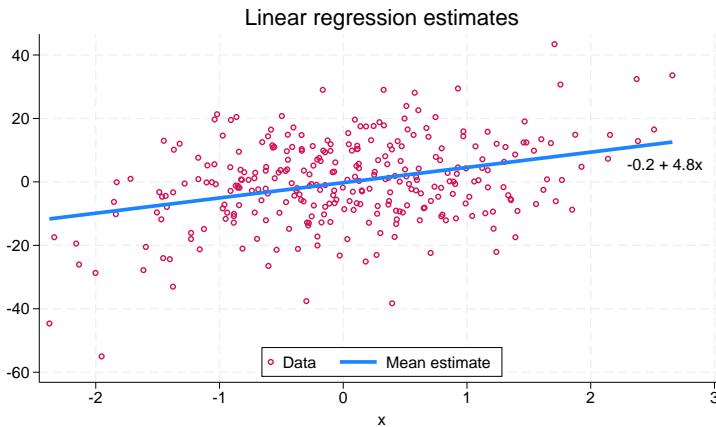

Figure 2.

The change in the predicted outcome when  $x$  changes is positive and constant, yet the true mean is nonlinear. If the assumption about the functional form of the mean is incorrect, the estimates we obtain are inconsistent. If we instead fit the model using `npregress` and graph the estimates, we obtain figure 3.

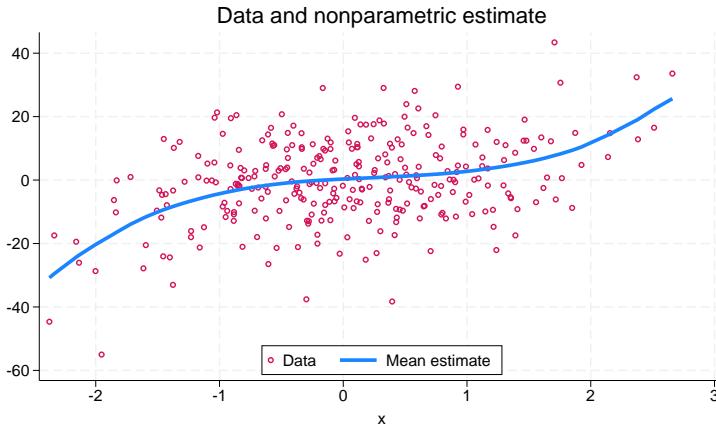

Figure 3.

`npregress` gives us the correct relationship between the outcome and the covariates. The nonparametric regression estimates are consistent as long as the true function is sufficiently smooth. If the linear regression assumptions are true, nonparametric regression is still consistent but less efficient.

Although nonparametric regression is a way to obtain estimates that are robust to functional form misspecification, this robustness comes at a cost. You need many observations and more time to compute the estimates. The cost increases with the number of covariates; this is referred to as the curse of dimensionality.

## Nonparametric series regression

The basis and the basis function are concepts essential to understanding series regression. A basis is a collection of terms that can approximate a smooth function arbitrarily well. A basis function uses a subset of these terms to approximate the mean function. `npregress series` allows you to use a polynomial basis, a piecewise polynomial spline basis, or a B-spline basis. For each basis, `npregress series` selects the basis function for you.

We use an example to illustrate the use of a basis and a basis function. Suppose a researcher has data on the outcome  $y$  and a covariate  $x$ . We plot their relationship in the figure 4 below.

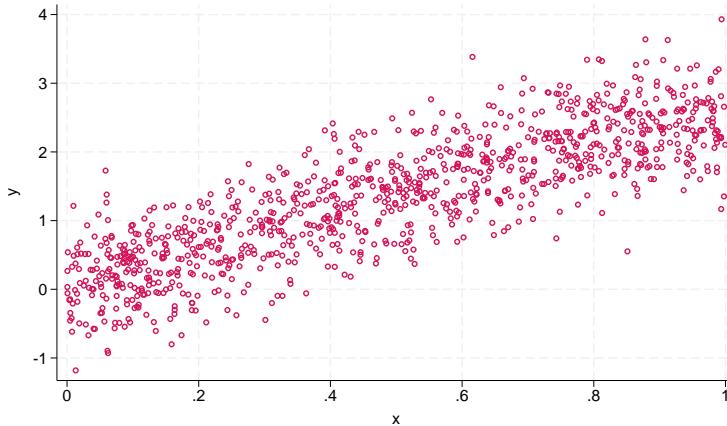

Figure 4.

In this case, a regression of  $y$  on  $x$  will do a good job of approximating the true function. If our data looked like the data in figure 5, however, a regression of  $y$  on  $x$  would be inadequate.

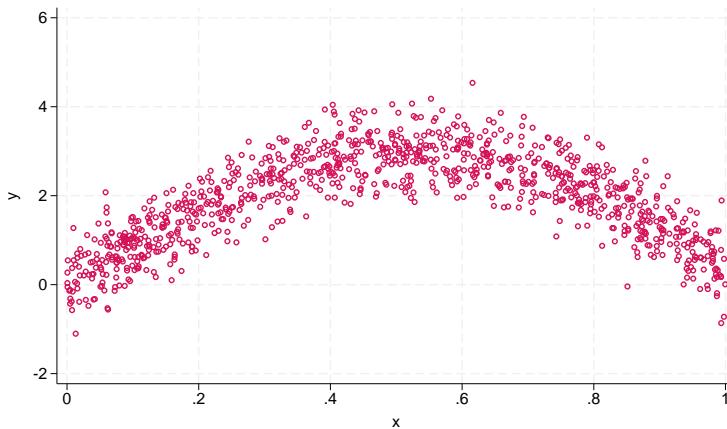

Figure 5.

In this case, a regression of  $y$  on  $x$  and  $x^2$  is more appropriate.

In each case, we include terms from a polynomial basis. In the first case, we need a constant and the linear term  $x$ . In the second case, we need a constant, the linear term  $x$ , and the quadratic term  $x^2$ . A more complex function would require a basis function that includes more terms from the polynomial basis.

If we want to use a polynomial basis function, `npregress` will select a degree of the polynomial for us. Additional terms reduce bias but increase the variance of the estimator. `npregress` will select the terms that optimally tradeoff bias and variance. In other words, `npregress` selects a basis function that includes the terms that minimize the mean squared error. Our example above used a polynomial basis function, but `npregress` can also select terms from a piecewise polynomial spline or B-spline basis.

## Runge's phenomenon

Polynomials are the most intuitive basis but not the preferred basis for nonparametric series estimation. The reason is that they are poor at interpolating. This problem shows up at the boundaries of the support of the covariates, where, as you increase the order of the polynomial, the polynomial approximation oscillates frequently, even when the true function does not behave this way.

Let us demonstrate. Below is an example for which we model a mean function using a third-order polynomial. We plot the data and the estimate of the mean function:

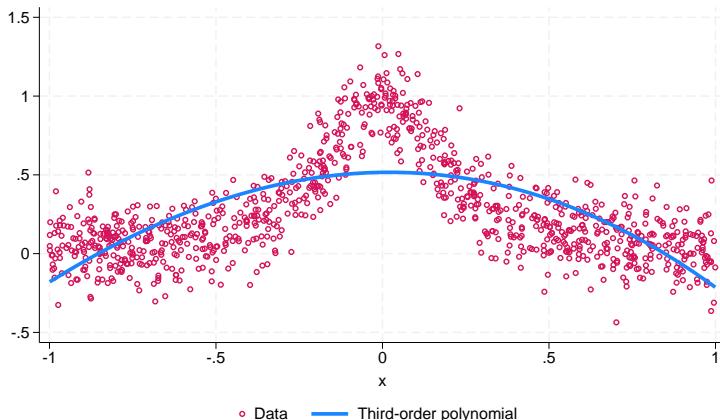

Figure 6.

Looking at the data, it appears that a higher-order polynomial would be a better fit for the data. Below is the mean function we get using a sixth-order and a tenth-order polynomial:

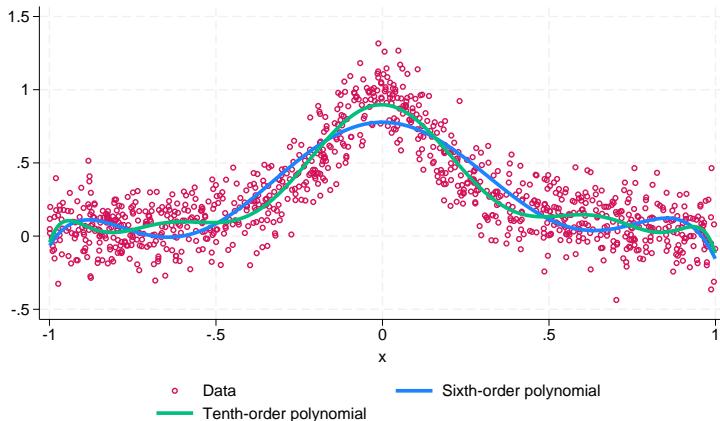

Figure 7.

The predictions improve at values near the middle of the range of  $x$  but become more variable at the edges of the parameter space.

What we illustrated above is referred to as Runge’s phenomenon. Increasing the complexity of the polynomial order did not improve our approximation. In fact, as we increased the polynomial order, the behavior at the edges of the parameter space became more variable. The way to address this is to use a basis that does a better job of interpolating: piecewise polynomial splines or B-splines.

## Piecewise polynomial splines and B-splines

Piecewise polynomial splines and B-splines are preferred to a polynomial basis because they are better at approximation. We discuss piecewise polynomial splines to provide intuition for both the piecewise polynomial spline basis and the B-spline basis.

Low-order polynomials do a great job of approximating functions in regions where the true function does not change too much. Splines continuously connect a set of low-order polynomials to create a basis to approximate a smooth function. The graph below illustrates what this definition means. We show in maroon a piecewise polynomial spline estimate of the mean function for the data in the example above.

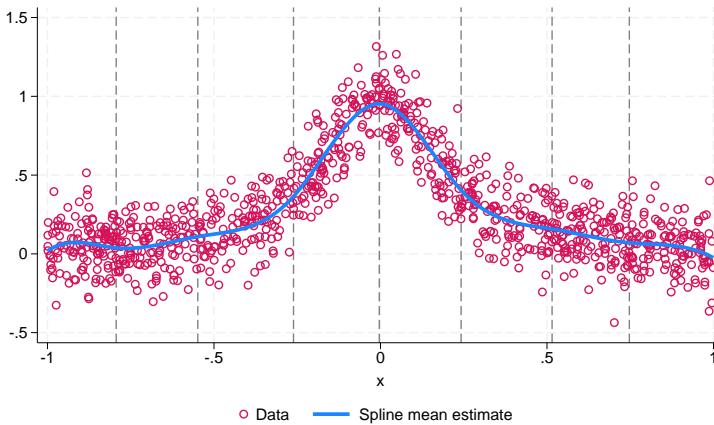

Figure 8.

To see that splines are better than polynomials, note that the spline approximation of the mean function fits the data well and that there are no regions where the approximation wiggles wildly.

Now, we delve into the definition above. The vertical lines in the graph partition the support of  $x$  into subregions. The piecewise polynomial spline basis allows for a different low-order polynomial in each subregion, and it forces the polynomials in neighboring regions to be continuously connected. In figure 8 above, the basis used is a third-order polynomial in each subregion. The graph illustrates that the polynomials are smoothly connected at the subregion boundaries. The subregion boundaries are known as the knot points, or just the knots, because they are where the different polynomials are tied together.

By default, `npregress` selects the number of knots for you. Alternatively, you may specify the number of knots yourself.

We now look at how the mean function at each region was computed. We show this mathematically and graphically.

Defining the seven knots as  $t_1, \dots, t_7$ , where  $t_1 < t_2 < \dots < t_6 < t_7$ , the third-order piecewise polynomial spline estimate is given by

$$\widehat{E}(y_i|x_i) = \widehat{\beta}_0 + \widehat{\beta}_1 x_i + \widehat{\beta}_2 x_i^2 + \widehat{\beta}_3 x_i^3 + \sum_{j=1}^7 \beta_{j+3} \max(x_i - t_j, 0)^3$$

Thus, for all  $x_i$  that are less than the smallest knot,  $t_1$ , the mean estimate is given by the third-order polynomial

$$\widehat{E}(y_i|x_i \leq t_1) = \widehat{\beta}_0 + \widehat{\beta}_1 x_i + \widehat{\beta}_2 x_i^2 + \widehat{\beta}_3 x_i^3$$

Here it is graphically:

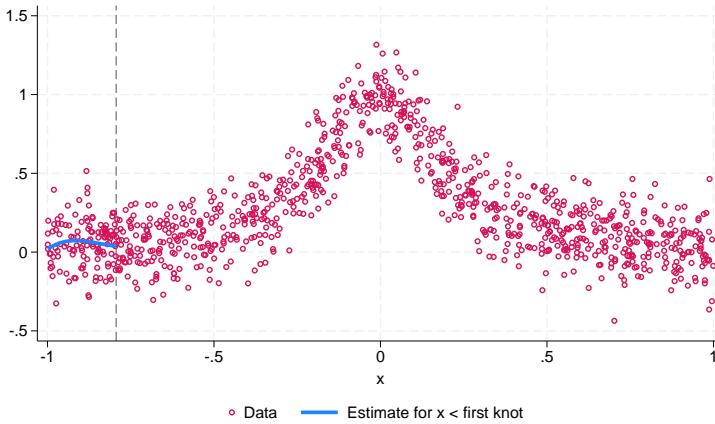

Figure 9.

Likewise, if  $x$  is less than the second knot,  $t_2$ , then the mean estimate for that region is different if  $x_i > t_1$  than if  $x_i \leq t_1$ , and is given by

$$\widehat{E}(y_i|x_i \leq t_2) = \widehat{\beta}_0 + \widehat{\beta}_1 x_i + \widehat{\beta}_2 x_i^2 + \widehat{\beta}_3 x_i^3 + \beta_4 (x_i - t_1)^3 (x_i > t_1)$$

Here it is graphically:

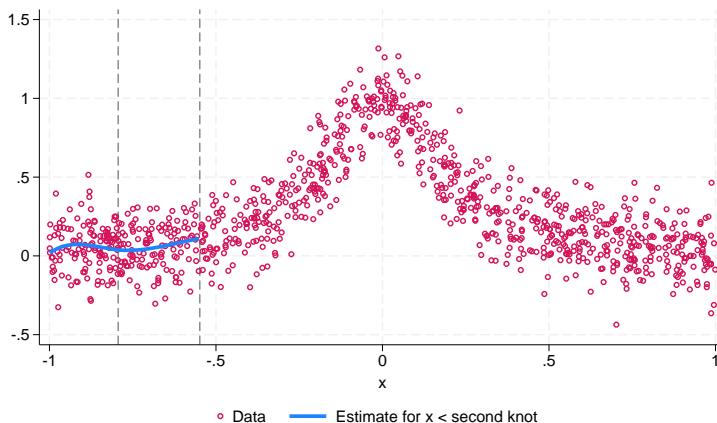

Figure 10.

As  $x$  increases, there are additional contributions from each subregion. If we continue plotting the resulting mean estimates, the following graphs would be what we would obtain:

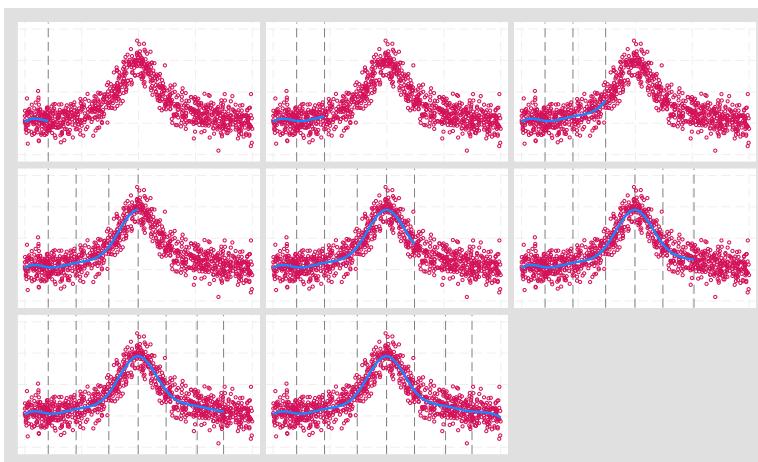

Figure 11.

This example illustrates how the terms in the spline basis approximate the mean function. Both the graph of the estimated function and the intuition in the example illustrate why the spline basis is better than the polynomial basis.

In the examples above, we used a piecewise polynomial spline basis. Specifically, we used a third-order piecewise polynomial spline basis function to obtain our estimates of the conditional mean. We could have also used second-order or first-order piecewise polynomial splines, where the order of the splines is defined by the order of the polynomial terms in the covariates used in each subregion.

As mentioned before, piecewise polynomial splines are preferred to a polynomial basis because they are better at approximation. However, piecewise polynomial splines also have some issues. In particular, they can be highly collinear and therefore numerically unstable. You can see this in the regions delineated in figure 11, which are defined by terms of the form  $\max(x_i - t_j, 0)$  that may overlap.

B-splines avoid this problem, so each term that goes into the conditional mean approximation is orthogonal. It is for this reason that B-splines are the default basis for `npregress` series. However, the intuition we obtain from piecewise polynomial splines and B-splines is equivalent. In fact, B-spline and piecewise polynomial spline bases can approximate the same functions. For a more detailed explanation of B-splines, see *Methods and formulas* in [R] `npregress` series.

In this section, we provided an intuitive and brief introduction to nonparametric series estimation. For detailed introductions to series estimators and the methods implemented by `npregress` series, see [de Boor \(2001\)](#), [Schumaker \(2007\)](#), [Eubank \(1999\)](#), [Schoenberg \(1969\)](#), [Newey \(1997\)](#), and [Chen \(2007\)](#).

## Nonparametric kernel regression

`npregress` `kernel` approximates the mean by using a kernel function. In [Overview](#), we plotted the following data and nonparametric estimate of the mean function:

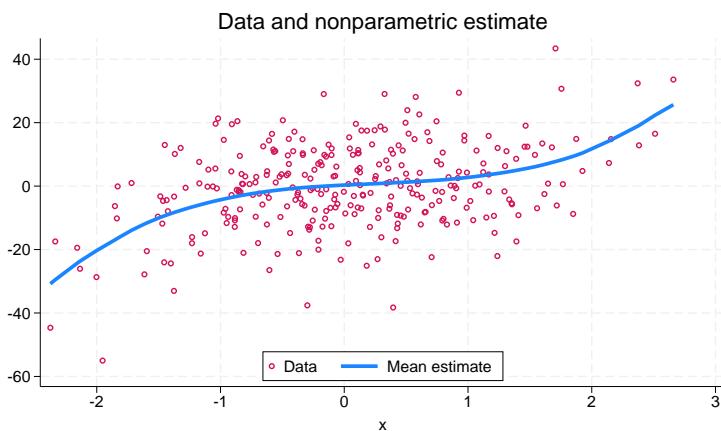

Figure 12.

We used kernel regression to estimate this mean function. With this method, we estimate the mean of the outcome at different values of the covariate  $x$ . In this section, we build our intuition for how kernel regression estimates these means, and we demonstrate this graphically.

Suppose covariate  $x$  is discrete. In this case, a consistent estimator of the mean of outcome  $y$  given that  $x = a$  is the average of the values of  $y$  for which  $x$  is equal to a given value  $a$ . For instance, the sample average of the yearly income for married individuals is a consistent estimator for the population mean yearly income for married individuals.

Now, consider estimating the mean of  $y$  given that  $x = a$  when  $x$  is continuous and  $a$  is a value observed for  $x$ . Because  $x$  is continuous, the probability of any observed value being exactly equal to  $a$  is 0. Therefore, we cannot compute an average for the values of  $y$  for which  $x$  is equal to a given value  $a$ . We use the average of  $y$  for the observations in which  $x$  is close to  $a$  to estimate the mean of  $y$  given that  $x = a$ . Specifically, we use the observations for which  $|x - a| < h$ , where  $h$  is small. The parameter  $h$  is called a bandwidth. In nonparametric kernel regression, a bandwidth determines the amount of information we use to estimate the conditional mean at each point  $a$ . We demonstrate how this works graphically.

For the simulated data in our example, we choose  $h = 0.25$  and  $a = -0.19$ . The vertical lines in figure 13 delimit the values of  $x$  around  $a$  for which we are computing the mean of  $y$ . The light blue square is our estimate of the conditional mean using the observations between the vertical lines.

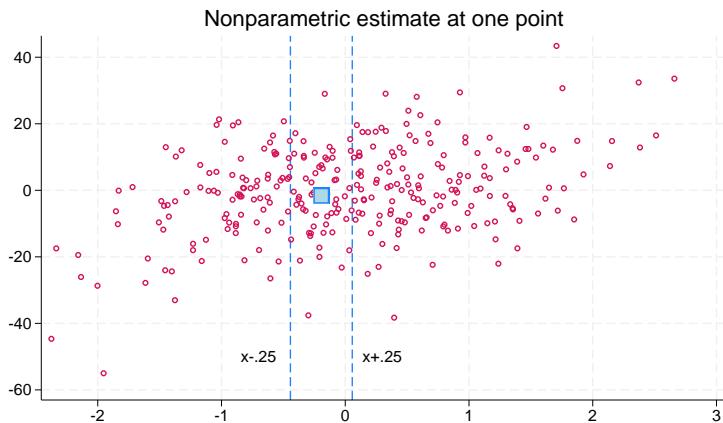

Figure 13.

Repeating this estimation when  $a = 2.66$  produces figure 14.

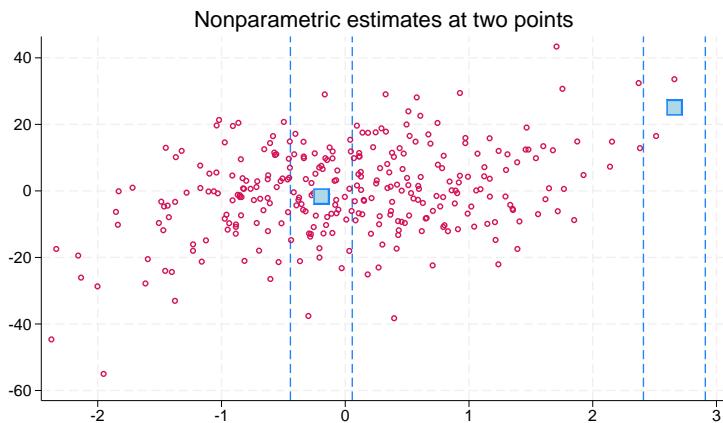

Figure 14.

Doing this estimation for each point in our data produces a nonparametric estimate of the mean for a given value of the covariates (see figure 15).

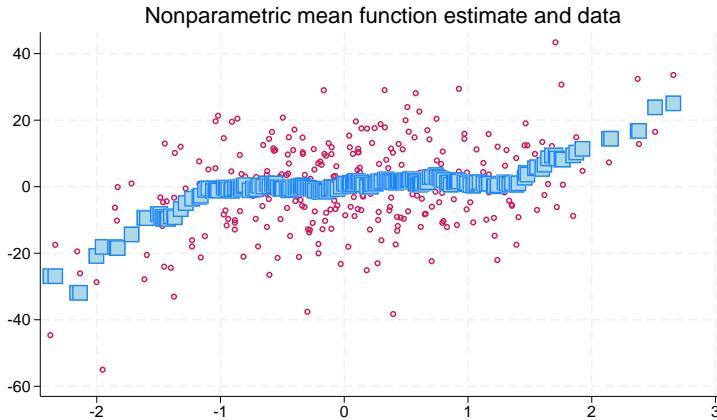

Figure 15.

The plotted blue squares in figure 15 form what is known as the conditional mean function. Because these are simulated data, we can compare our estimate with the true conditional mean function, a comparison we show in figure 16.

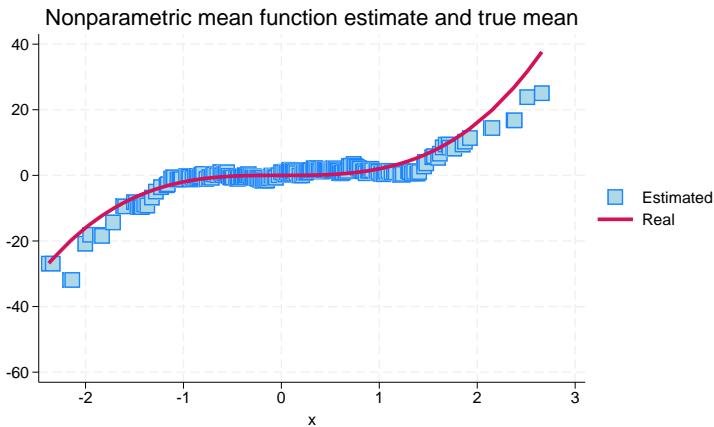

Figure 16.

We see that the estimate is a bit less smooth than the true function. The size of the bandwidth  $h$  determines the shape and smoothness of the estimated conditional mean function, because the bandwidth defines how many observations around each point are used. For example, if  $h$  is arbitrarily large—say,  $h = 300$ —then we get figure 17.

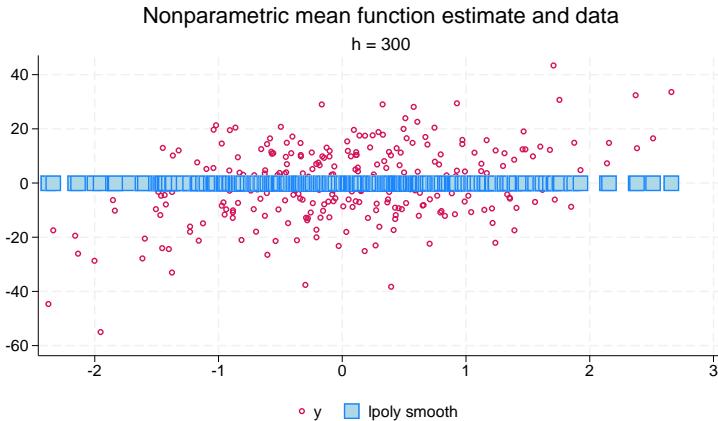

Figure 17.

In this case, all observations are used to estimate the conditional mean at each point, and the estimate is therefore a constant. On the other hand, a too-small bandwidth produces a jagged function with high variability, as illustrated in figure 18.

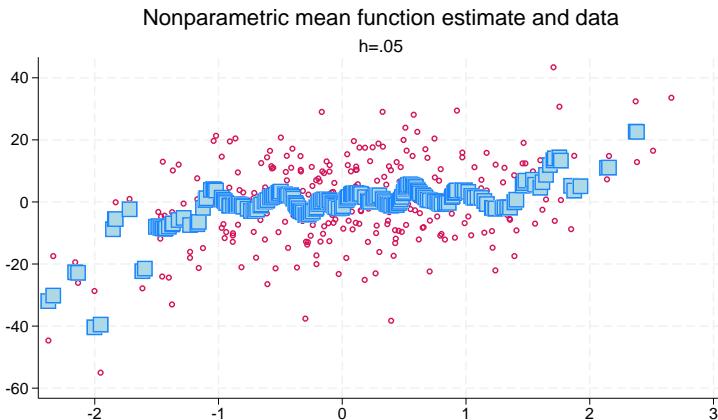

Figure 18.

The optimal bandwidth is somewhere in between. A too-large bandwidth includes too many observations, so the estimate is biased but it has a low variance. A too-small bandwidth includes too few observations, so the estimate has little bias but the variance is large. In other words, the optimal bandwidth trades off bias and variance. In the case of `npregress kernel`, the bandwidth is chosen to minimize the cost of this tradeoff by using either cross-validation, as suggested by [Li and Racine \(2004\)](#), or an improved Akaike information criterion proposed by [Hurvich, Simonoff, and Tsai \(1998\)](#).

How we average the observations around a point is also important. In the examples above, we gave the same weight to each observation for which  $|x - a| < h$ . However, we might weight each observation differently. The weights that observations receive are determined by functions called kernels. We could have used any of the weights in `[R] kdensity`. For a nice introduction to kernel weighting, see [Silverman \(1986\)](#).

The estimator described above uses only nearby observations and is thus a local estimator. It uses a sample average, which is a regression on a constant, and is thus a locally constant estimator. For these reasons, the estimator described above fits what is known as a local-constant regression.

The generalization that uses the prediction from a local-linear regression on covariates is known as local-linear regression. Local-linear regression estimates the derivative of the conditional mean function in addition to the function itself. Understanding how the conditional mean changes when covariates change is sometimes the research question of interest, for example, how income changes for different levels of taxes. Local-linear regression provides an estimate for these changes for continuous and discrete variables.

See [Fan and Gijbels \(1996\)](#) and [Li and Racine \(2007\)](#) for detailed introductions to the kernel estimators implemented in `npregress kernel`.

## Limitations of nonparametric methods

As discussed above, series regression and kernel regression approximate an unknown mean function. Series regression uses least squares on the basis function. Kernel regression uses a kernel-weighted average of nearby observations.

Series estimators are considered to be global estimators because they approximate the mean function at each point using the value of one overall approximating function. Kernel regression is considered a local estimator because it only uses nearby observations to approximate the mean for a given covariate pattern.

Although piecewise polynomial splines and B-splines are considered to be global estimators, in fact, they are local estimators. They are local because they fit a polynomial in each region defined by the knots. Like kernel estimators, piecewise polynomial spline and B-spline estimators require that there are enough data in each region. Suppose our data look like the data below.

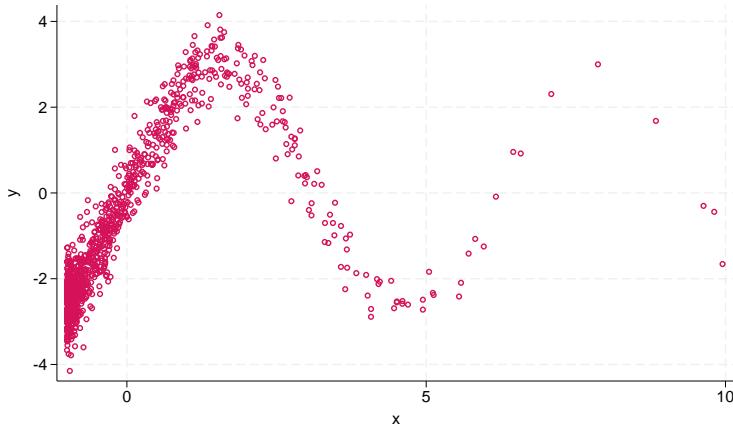

Figure 19.

Using a method to select knots optimally at percentiles of the data will give us figure 20.

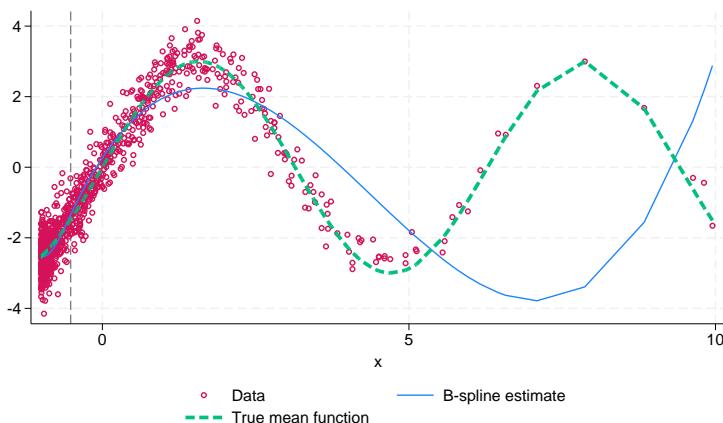

Figure 20.

The vertical line denotes the point at which the knot is placed. The blue line is the B-spline estimate, and the dotted green line is the true mean function. We see that our estimate of the mean function is not good, especially for higher positive values of the covariate. The reason is that data are sparse for these values. An alternative is to place the knots uniformly over the values of  $x$ . In this case, our estimate of the mean function improves. However, this does not change the fact that we have regions with insufficient data to make reliable inferences.

Thus, for kernel, piecewise polynomial spline, and B-spline estimators, we must have enough data points for all ranges of the data. In particular, piecewise polynomial spline and B-spline estimates should not be used to predict outside the support of the data.

Another important consideration is model selection. `npregress` selects the number of terms from a basis for series estimation and the bandwidth for kernel estimation. After model selection, the models are taken as given without accounting for model-selection error. You can find an in-depth discussion and references of some of the issues that arise when performing model selection in [\[LASSO\] Lasso intro](#).

## Description

`npregress kernel` performs nonparametric local–linear and local–constant kernel regression. Like linear regression, nonparametric regression models the mean of the outcome conditional on the covariates, but unlike linear regression, it makes no assumptions about the functional form of the relationship between the outcome and the covariates. `npregress kernel` may be used to model the mean of a continuous, count, or binary outcome.

## Quick start

Nonparametric regression of  $y$  on  $x$  and discrete covariate  $a$  using the Epanechnikov kernel for  $x$  and the Li–Racine kernel for  $a$

```
npregress kernel y x i . a
```

Same as above, but use 500 replications and compute bootstrap standard errors and percentile confidence intervals

```
npregress kernel y x i . a, reps(500)
```

Same as above, but use a Gaussian kernel for  $x$

```
npregress kernel y x i . a, reps(500) kernel(gaussian)
```

Same as above, but use the improved AIC to find the optimal bandwidth

```
npregress kernel y x i . a, reps(500) kernel(gaussian) imaic
```

Same as above, but additionally specify that only the mean of the outcome be computed

```
npregress kernel y x i . a, reps(500) kernel(gaussian) imaic noderivatives
```

Specify  $h$  as the vector of bandwidths

```
npregress kernel y x i . a, bwidth(h)
```

## Options

### Model

`estimator`(`linear` | `constant`) specifies whether the local-constant or local-linear kernel estimator should be used. The default is `estimator`(`linear`).

`kernel` (*kernel*) specifies the kernel density function for continuous covariates for use in calculating the local-constant or local-linear estimator. The default is `kernel`(`epanechnikov`).

`dkernel` (*dkernel*) specifies the kernel density function for discrete covariates for use in calculating the local-constant or local-linear estimator. The default is `dkernel`(`liracine`); see [Methods and formulas](#) for details on the Li–Racine kernel. When `dkernel`(`cellmean`) is specified, discrete covariates are weighted by their cell means.

`predict` (*prspec*) specifies that `npregress kernel` store the predicted values for the mean and derivatives of the mean with the specified names. *prspec* is the following:

```
predict(varlist | stub* [, replace noderivatives])
```

The option takes a variable list or a *stub*. The first variable name corresponds to the predicted outcome mean. The second name corresponds to the derivatives of the mean. There is one derivative for each *indepvar*.

When `replace` is used, variables with the names in *varlist* or *stub*\* are replaced by those in the new computation. If *noderivatives* is specified, only a variable for the mean is created. This will increase computation speed but will add to the computation burden if you want to obtain marginal effects after estimation.

`noderivatives` suppresses the computation of the derivatives. In this case, only the mean function is computed.

`imaic` specifies to use the improved AIC instead of cross-validation to compute optimal bandwidths.

`unident``sample`(*newvar*) specifies the name of a variable that is 1 if the observation violates the model identification assumptions and is 0 otherwise. By default, this variable is a system variable (`_unident_sample`).

`npregress kernel` computes a weighted regression for each observation in our data. An observation violates identification assumptions if the regression cannot be performed at that point. The regression formula, which is discussed in detail in *Methods and formulas*, is given by

$$\hat{\gamma} = (\mathbf{Z}'\mathbf{W}\mathbf{Z})^{-1} \mathbf{Z}'\mathbf{W}\mathbf{y}$$

`npregress kernel` verifies that the matrix  $(\mathbf{Z}'\mathbf{W}\mathbf{Z})$  is full rank for each observation to determine identification. Identification problems commonly arise when the bandwidth is too small, resulting in too few observations within a bandwidth. Independent variables that are collinear within the bandwidth can also cause a problem with identification at that point.

Observations that violate identification assumptions are reported as missing for the predicted means and derivatives.

---

#### Bandwidth

`bwidth`(*specs*) specifies the half-width of the kernel at each point for the computation of the mean and the derivatives of the mean function. If no bandwidth is specified, one is chosen by minimizing the integrated mean squared error of the prediction.

*specs* specifies bandwidths for the mean and derivative for each *indepvar* in one of three ways: by specifying the name of a vector containing the bandwidths (for example, `bwidth(H)`, where H is a properly labeled vector); by specifying the equation and coefficient names with the corresponding values (for example, `bwidth(Mean:x1=0.5 Effect:x1=0.9)`); or by specifying a list of values for the means, standard errors, and derivatives for *indepvars* given in the order of the corresponding *indepvars* and specifying the copy suboption (for example, `bwidth(0.5 0.9, copy)`).

`skip` specifies that any parameters found in the specified vector that are not also found in the model be ignored. The default action is to issue an error message.

`copy` specifies that the list of values or the vector be copied into the bandwidth vector by position rather than by name.

`meanbwidth`(*specs*) specifies the half-width of the kernel at each point for the computation of the mean function. If no bandwidth is specified, one is chosen by minimizing the integrated mean squared error of the prediction. For details on how to specify the bandwidth, see the description of `bwidth()`, [above](#).

`derivbwidth`(*specs*) specifies the half-width of the kernel at each point for the computation of the derivatives of the mean. If no bandwidth is specified, one is chosen by minimizing the integrated mean squared error of the prediction. For details on how to specify the bandwidth, see the description of `bwidth()`, [above](#).

---

#### SE

`vce`(*vcetype*) specifies the type of standard error reported, which may be either that no standard errors are reported (`none`; the default) or that bootstrap standard errors are reported (`bootstrap`); see [\[R\] vce\\_option](#).

We recommend that you select the number of replications using `reps(#)` instead of specifying `vce(bootstrap)`, which defaults to 50 replications. Be aware that the number of replications needed to produce good estimates of the standard errors varies depending on the problem.

When `vce(bootstrap)` is specified, `npregress kernel` reports percentile confidence intervals as recommended by [Cattaneo and Jansson \(2018\)](#) instead of reporting the normal-based confidence intervals that are reported when `vce(bootstrap)` is specified with other commands. Other types of confidence intervals can be obtained by using the `citype(citype)` option.

`reps(#)` specifies the number of bootstrap replications to be performed. Specifying this option is equivalent to specifying `vce(bootstrap, reps(#))`.

`seed(#)` sets the random-number seed. You must specify `reps(#)` with `seed(#)`.

`bwreplace` computes a different bandwidth for each bootstrap replication. The default is to compute the bandwidth once and keep it fixed for each bootstrap replication. This option is seldom used.

#### Reporting

`level(#)`; see [\[R\] Estimation options](#).

`display_options`: `nocl`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `no1stretch`; see [\[R\] Estimation options](#).

`citype(citype)` specifies the type of confidence interval to be computed. By default, bootstrap percentile confidence intervals are reported as recommended by [Cattaneo and Jansson \(2018\)](#). `citype` may be one of `percentile`, `bc`, or `normal`.

#### Maximization

`maximize_options`: `iterate(#)`, `[no]log`, `trace`, `showstep`, `tolerance(#)`, `ltolerance(#)`, `from(init_specs)`; see [\[R\] Maximize](#). These options are seldom used.

The following option is available with `npregress kernel` but is not shown in the dialog box:

`coeflegend`; see [\[R\] Estimation options](#).

## Remarks and examples

This entry assumes that you are already familiar with nonparametric regression. For an introduction to the nonparametric kernel regression methods used in `npregress kernel`, see [\[R\] npregress intro](#).

Remarks are presented under the following headings:

- [Overview](#)
- [Estimation and effects](#)
- [Visualizing covariate effects](#)

## Overview

`npregress kernel` implements local-constant and local-linear regression. The covariates may be continuous or discrete. You can use `npregress kernel` to nonparametrically estimate a conditional mean. `npregress kernel` also allows you to estimate covariate effects after estimation and, in models with one covariate, to plot the mean function by using `nprgraph` after estimation.

The word “nonparametric” refers to the fact that the parameter of interest, the mean as a function of the covariates, is given by the unknown function  $g(\mathbf{x}_i)$ , which is an element of an infinite-dimensional space of functions. In contrast, in a parametric model, the mean for a given value of the covariates,  $E(y_i|\mathbf{x}_i) = f(\mathbf{x}_i, \beta)$ , is a known function that is fully characterized by the parameter of interest,  $\beta$ , which is a finite-dimensional real vector (Shao 2003).

The regression model of outcome  $y_i$  given the  $k$ -dimensional vector of covariates  $\mathbf{x}_i$  is given by

$$y_i = g(\mathbf{x}_i) + \varepsilon_i \tag{1}$$

$$E(\varepsilon_i|\mathbf{x}_i) = 0 \tag{2}$$

where  $\varepsilon_i$  is the error term. The covariates may include discrete and continuous variables. Equations (1) and (2) imply that

$$E(y_i|\mathbf{x}_i) = g(\mathbf{x}_i)$$

Once we account for the information in the covariates, the error term provides no information about the mean of our outcome. The conditional mean function is therefore given by  $g(\mathbf{x}_i)$ . By estimating  $E(y_i|\mathbf{x}_i = \mathbf{x})$  for all points  $\mathbf{x}$  in our data, we obtain an estimate of  $E(y_i|\mathbf{x}_i)$ .

`npregress kernel`, by default, estimates a local-linear regression. Local-linear regression estimates a regression for a subset of observations for each point in our data. See Fan and Gijbels (1996) for a good reference on local-linear regression. Local-linear regression, for each point  $\mathbf{x}$ , solves the minimization problem given by

$$\min_{\gamma} \sum_{i=1}^n \{y_i - \gamma_0 - \gamma_1'(\mathbf{x}_i - \mathbf{x})\}^2 K(\mathbf{x}_i, \mathbf{x}, \mathbf{h}) \tag{3}$$

where  $\gamma = (\gamma_0, \gamma_1)'$ .

Equation (3) and its solution are similar to parametric ordinary least squares. The slope and the constant in (3), however, have a different interpretation. The constant in (3),  $\gamma_0$ , is the conditional mean at a specific point  $\mathbf{x}$ . The slope parameter,  $\gamma_1$ , is the derivative of the mean function with respect to  $\mathbf{x}$ . The solution to this least-squares problem gives us the mean function and its derivative for each one of the elements of  $\mathbf{x}$ . Repeating this optimization for each point  $\mathbf{x}$  gives us the entire mean function and its derivatives.

Another difference between (3) and the minimization problem of parametric ordinary least squares is how the optimization is weighted. The weights are given by the kernel function  $K(\mathbf{x}_i, \mathbf{x}, \mathbf{h})$ . The kernel function assigns weights to observations  $\mathbf{x}_i$  based on how much they differ from  $\mathbf{x}$  and based on the bandwidth,  $\mathbf{h}$ . The smaller  $\mathbf{h}$  is, the larger the weight assigned to points between  $\mathbf{x}_i$  and  $\mathbf{x}$ .

The bandwidth also determines the bias and variance of the mean function estimator. `npregress kernel` selects the bandwidth using cross-validation, as suggested by Li and Racine (2004), or if the `imaic` option is specified, with the improved AIC proposed by Hurvich, Simonoff, and Tsai (1998). Both methods minimize the tradeoff between bias and variance.

`npregress kernel` computes a conditional mean for each observation in the data and, for each one of these computations, verifies whether identification conditions are fulfilled. The observations for which the regression identification assumptions are not satisfied are dropped from the estimation sample. Additionally, whenever there is a violation of the identification assumption, `npregress kernel` generates a system variable or a variable with a name provided in `noidsample(newvar)`. This variable is 1 for observations violating the identification assumption and is 0 otherwise. `npregress kernel` also issues a warning, letting you know the number of observations for which the identification assumption is not satisfied.

## Estimation and effects

The output of `npregress kernel` reports averages of the mean function and the effects of the mean function. An average effect from nonparametric regression may be either 1) an average marginal effect, in the case of the mean of derivatives for continuous covariates or 2) the mean of contrasts for discrete covariates.

Some well-established literature estimates these average effects directly and uses an optimal bandwidth for this computation; see [Powell, Stock, and Stoker \(1989\)](#) and [Powell and Stoker \(1996\)](#). By taking averages of the local-linear estimates, `npregress kernel` is more in line with the approach in [Li, Lu, and Ullah \(2003\)](#). Intuitively, choosing the optimal bandwidth for the derivative produces a more efficient estimator than using the bandwidth that is optimal for the function. Both estimators are consistent for the average effect. [Cattaneo and Jansson \(2018\)](#) formally justify the average effect using the function-optimal bandwidth.

`npregress kernel` also reports an approximation of  $n|\mathbf{h}|$  as the expected kernel observations. This statistic rounds the product of the continuous kernel bandwidth values and the number of observations used for estimation. For instance, if the estimation sample was 500 and the bandwidth was 0.246, the expected kernel observations would be 123 ( $= 500 \times 0.246$ ). The expected kernel observation number of 123 tells us that, on average, 123 observations are used to compute each one of the 500 regressions performed by `npregress kernel`.

### ► Example 1: Nonparametric regression estimation and graphing

`dui.dta` contains information about the number of monthly drunk driving citations in a local jurisdiction (`citations`). Suppose we want to know the effect of increasing fines on the number of citations. Because `citations` is a count variable, we could consider fitting the model with `poisson` or `nbreg`. However, both of these estimators make assumptions about the distribution of the data. If these assumptions are not true, we will obtain inconsistent estimates.

By using npregress kernel, we do not have to make any assumptions about how citations is distributed. We use npregress kernel to estimate the mean of citations as a function of the value of the fines imposed for drunk driving (fines).

```
. use https://www.stata-press.com/data/r19/dui
(Fictional data on monthly drunk driving citations)
. npregress kernel citations fines
Computing mean function

Minimizing cross-validation function:

Iteration 0: Cross-validation criterion = 35.478784
Iteration 1: Cross-validation criterion = 4.0147129
Iteration 2: Cross-validation criterion = 4.0104176
Iteration 3: Cross-validation criterion = 4.0104176
Iteration 4: Cross-validation criterion = 4.0104176
Iteration 5: Cross-validation criterion = 4.0104176
Iteration 6: Cross-validation criterion = 4.0104006
```

```
Computing optimal derivative bandwidth

Iteration 0: Cross-validation criterion = 6.1648059
Iteration 1: Cross-validation criterion = 4.3597488
Iteration 2: Cross-validation criterion = 4.3597488
Iteration 3: Cross-validation criterion = 4.3597488
Iteration 4: Cross-validation criterion = 4.3597488
Iteration 5: Cross-validation criterion = 4.3597488
Iteration 6: Cross-validation criterion = 4.3595842
Iteration 7: Cross-validation criterion = 4.3594713
Iteration 8: Cross-validation criterion = 4.3594713
```

Bandwidth

|       | Mean     | Effect  |
|-------|----------|---------|
| fines | .5631079 | .924924 |

```
Local-linear regression Number of obs = 500
Kernel : epanechnikov E(Kernel obs) = 282
Bandwidth: cross-validation R-squared = 0.4380
```

| citations      | Estimate  |
|----------------|-----------|
| Mean citations | 22.33999  |
| Effect fines   | -7.692388 |

Note: Effect estimates are averages of derivatives.  
 Note: You may compute standard errors using vce(bootstrap) or reps().

The first table displays the bandwidths used to estimate the mean function and the derivative of the mean function. Each of these bandwidths is estimated by minimizing a function that trades off bias and variance; the corresponding iteration logs are displayed also. The expected number of observations used to estimate the mean function at each point is reported in E(Kernel obs) as 282.

Unlike other estimation commands, `npregress kernel` does not report standard errors, test statistics, and confidence intervals by default. In [example 2](#), we demonstrate how to obtain these statistics and further discuss the output.

▷ Example 2: Bootstrapping standard errors

We can estimate the standard errors by using the bootstrap; see [Cattaneo and Jansson \(2018\)](#) for formal results. We use the `reps(400)` option, which is equivalent to `vce(bootstrap, reps(400))` and specifies that 400 bootstrap replications be used instead of the default 50 replications that are used when we specify `vce(bootstrap)`.

Each estimation problem requires a different number of replications to produce good estimates of the standard errors. In [example 3](#), we explain how we decided to use 400 replications. Note that nonparametric estimation and the bootstrap are computationally intensive, so running this example and others that compute bootstrap standard errors will take a while.

```
. npregress kernel citations fines, reps(400) seed(12)
(running npregress on estimation sample)

Bootstrap replications (400):10.....20.....30.....40.....
> ...50.....60.....70.....80.....90.....100.....110...
>120.....130.....140.....150.....160.....170.....
> .180.....190.....200.....210.....220.....230.....240.
>250.....260.....270.....280.....290.....300.....
> ...310.....320.....330.....340.....350.....360.....37
> 0.....380.....390.....400 done
```

Bandwidth

|       | Mean     | Effect  |
|-------|----------|---------|
| fines | .5631079 | .924924 |

```
Local-linear regression Number of obs = 500
Kernel : epanechnikov E(Kernel obs) = 282
Bandwidth: cross-validation R-squared = 0.4380
```

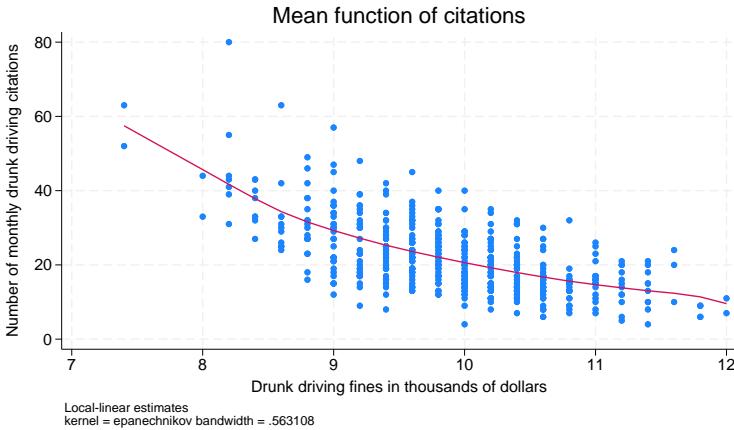

|                | Observed estimate | Bootstrap std. err. | z      | P> z  | Percentile [95% conf. interval] |           |
|----------------|-------------------|---------------------|--------|-------|---------------------------------|-----------|
| Mean citations | 22.33999          | .4588298            | 48.69  | 0.000 | 21.48622                        | 23.35956  |
| Effect fines   | -7.692388         | .491884             | -15.64 | 0.000 | -8.693068                       | -6.757721 |

Note: Effect estimates are averages of derivatives.

The coefficient table now reports the average of the predicted means and the average of the predicted derivatives of the mean function with bootstrap standard errors. The average of the observation-level predicted (`citations`) is 22.34. The average of the observation-level marginal effects is  $-7.69$ , which indicates that increasing `fines` reduces the mean number of citations.

We use `npggraph` to graph the estimated conditional mean function.

```
. npggraph
```

The graph shows the negative association between fines and the number of drunk driving citations. ◀

`npregress kernel` generates system variables for the mean function and the derivative of the mean function. To see the variables that `npregress kernel` generated for [example 1](#), we type

```
. describe *_*, fullnames
```

| Variable name                          | Storage type | Display format | Value label | Variable label                          |
|----------------------------------------|--------------|----------------|-------------|-----------------------------------------|
| <code>_Mean_citations</code>           | double       | %10.0g         |             | Mean function                           |
| <code>_d_Mean_citations_d fines</code> | double       | %10.0g         |             | derivative of mean function w.r.t fines |

To specify a name for each system variable, we can use the `predict()` option.

```
. npregress kernel citations fines, predict(mean deriv)
(output omitted)
```

```
. describe mean deriv
```

| Variable name      | Storage type | Display format | Value label | Variable label                          |
|--------------------|--------------|----------------|-------------|-----------------------------------------|
| <code>mean</code>  | double       | %10.0g         |             | Mean function                           |
| <code>deriv</code> | double       | %10.0g         |             | derivative of mean function w.r.t fines |

Alternatively, we can use the same *stub* for all the variable names by typing `predict(hatvar*)`, which would generate variables `hatvar1` and `hatvar2`.

You may add `noderivatives` to the option, as in `predict(hatvar*, noderivatives)`, to specify that no derivatives be generated. You save memory when you use `noderivatives`, but you add to the computational burden. As you will see below, an important feature of `npregress kernel` is the availability of the `margins` command after estimation. `margins` must compute the derivatives and their optimal bandwidth.

▷ Example 3: Selecting the number of bootstrap replications

We start by fitting the model using 200 bootstrap replications. We want to find the number of replications for which the confidence intervals do not change much.

```
. nprogress kernel citations fines, reps(200) seed(12)
(running nprogress on estimation sample)
Bootstrap replications (200):10.....20.....30.....40.....
>50.....60.....70.....80.....90.....100.....110...
>120.....130.....140.....150.....160.....170.....
> .180.....190.....200 done
```

Bandwidth

|       | Mean     | Effect  |
|-------|----------|---------|
| fines | .5631079 | .924924 |

```
Local-linear regression Number of obs = 500
Kernel : epanechnikov E(Kernel obs) = 282
Bandwidth: cross-validation R-squared = 0.4380
```

| citations      | Observed estimate | Bootstrap std. err. | z      | P> z  | Percentile [95% conf. interval] |          |
|----------------|-------------------|---------------------|--------|-------|---------------------------------|----------|
| Mean citations | 22.33999          | .4769389            | 46.84  | 0.000 | 21.49744                        | 23.42156 |
| Effect fines   | -7.692388         | .5088819            | -15.12 | 0.000 | -8.742081                       | -6.77816 |

Note: Effect estimates are averages of derivatives.

For 200 replications, the confidence interval for the mean ranges from 21.50 to 23.42. For the effect of fines, this range is  $-8.74$  to  $-6.78$ .

We repeat the estimation using 300 replications and the same seed as in the previous case.

```
. nprogress kernel citations fines, reps(300) seed(12)
(running nprogress on estimation sample)
Bootstrap replications (300):10.....20.....30.....40.....
>50.....60.....70.....80.....90.....100.....110...
>120.....130.....140.....150.....160.....170.....
> .180.....190.....200.....210.....220.....230.....240...
>250.....260.....270.....280.....290.....300 done
```

Bandwidth

|       | Mean     | Effect  |
|-------|----------|---------|
| fines | .5631079 | .924924 |

```
Local-linear regression Number of obs = 500
Kernel : epanechnikov E(Kernel obs) = 282
Bandwidth: cross-validation R-squared = 0.4380
```

| citations      | Observed estimate | Bootstrap std. err. | z      | P> z  | Percentile [95% conf. interval] |           |
|----------------|-------------------|---------------------|--------|-------|---------------------------------|-----------|
| Mean citations | 22.33999          | .4570611            | 48.88  | 0.000 | 21.49359                        | 23.36299  |
| Effect fines   | -7.692388         | .4981956            | -15.44 | 0.000 | -8.673813                       | -6.720508 |

Note: Effect estimates are averages of derivatives.

The confidence interval for the mean ranges from 21.49 to 23.36. For the effect of fines, this range is -8.67 to -6.72. There are some differences so we try estimation with 400 replications.

```
. npregress kernel citations fines, reps(400) seed(12)
(running npregress on estimation sample)
Bootstrap replications (400):10.....20.....30.....40.....
>50.....60.....70.....80.....90.....100.....110....
>120.....130.....140.....150.....160.....170.....
>180.....190.....200.....210.....220.....230.....240.
>250.....260.....270.....280.....290.....300.....
>310.....320.....330.....340.....350.....360.....37
> 0.....380.....390.....400 done
```

Bandwidth

|       | Mean     | Effect  |
|-------|----------|---------|
| fines | .5631079 | .924924 |

```
Local-linear regression Number of obs = 500
Kernel : epanechnikov E(Kernel obs) = 282
Bandwidth: cross-validation R-squared = 0.4380
```

| citations      | Observed estimate | Bootstrap std. err. | z      | P> z  | Percentile [95% conf. interval] |           |
|----------------|-------------------|---------------------|--------|-------|---------------------------------|-----------|
| Mean citations | 22.33999          | .4588298            | 48.69  | 0.000 | 21.48622                        | 23.35956  |
| Effect fines   | -7.692388         | .491884             | -15.64 | 0.000 | -8.693068                       | -6.757721 |

Note: Effect estimates are averages of derivatives.

The confidence interval for the mean ranges from 21.49 to 23.36. In the case of the effect of fines, these ranges are -8.69 to -6.76. The changes are small so we decide to use 400 replications.

▷ Example 4: Estimating the effect of a percentage change in a covariate

Nonparametric estimation and the bootstrap are computationally intensive, so we use only 200 replications here.

We now extend [example 2](#). In addition to `finest`, we model `citations` as a function of whether the jurisdiction taxes alcoholic beverages (`taxes`); whether the city is small, medium, or large (`csize`); and whether there is a college in the jurisdiction (`college`).

```
. nprogress kernel citations finest i.taxes i.csize i.college, nolog
> reps(200) seed(12)
(running nprogress on estimation sample)
Bootstrap replications (200):10.....20.....30.....40.....
>50.....60.....70.....80.....90.....100.....110...
>120.....130.....140.....150.....160.....170.....
>180.....190.....200 done
```

Bandwidth

|                      | Mean     | Effect   |
|----------------------|----------|----------|
| <code>finest</code>  | .4471373 | .6537197 |
| <code>taxes</code>   | .4375656 | .4375656 |
| <code>csize</code>   | .3938759 | .3938759 |
| <code>college</code> | .554583  | .554583  |

```
Local-linear regression Number of obs = 500
Continuous kernel : epanechnikov E(Kernel obs) = 224
Discrete kernel : liracine R-squared = 0.8010
Bandwidth : cross-validation
```

| citations                                          | Observed estimate | Bootstrap std. err. | z      | P> z  | Percentile [95% conf. interval] |           |
|----------------------------------------------------|-------------------|---------------------|--------|-------|---------------------------------|-----------|
| Mean citations                                     | 22.26306          | .4642464            | 47.96  | 0.000 | 21.46204                        | 23.2516   |
| Effect                                             |                   |                     |        |       |                                 |           |

| <code>csize</code><br>(Medium vs<br>Small)         | 5.300524          | .2687413            | 19.72  | 0.000 | 4.758121                        | 5.797119  |
| (Large vs<br>Small)                                | 11.05053          | .502633             | 21.99  | 0.000 | 10.00169                        | 11.94311  |
| <code>college</code><br>(College vs<br>Not coll..) | 5.953188          | .461057             | 12.91  | 0.000 | 5.086511                        | 6.88612   |

Note: Effect estimates are averages of derivatives for continuous covariates and averages of contrasts for factor covariates.

The mean number of citations predicted by the mean estimates is 22.26. The average marginal effect of fines is  $-7.33$ , slightly less in magnitude than the  $-7.69$  that we estimated in [example 2](#).

The average marginal effect tells us the result of an infinitesimal change in fines on citations. Instead of talking about infinitesimal changes, we want to know the effect of increasing fines by 15%. We can use margins to estimate the mean number of citations that would occur if fines were increased by 15%.

```
. margins, at(fines=generate(fines*1.15)) reps(200) seed(12)
(running margins on estimation sample)
Bootstrap replications (200):10.....20.....30.....40.....
>50.....60.....70.....80.....90.....100.....110...
>120.....130.....140.....150.....160.....170.....
> .180.....190.....200 done
Predictive margins Number of obs = 500
 Replications = 200
Expression: Mean function, predict()
At: fines = fines*1.15
```

|       | Observed margin | Bootstrap std. err. | z     | P> z  | Percentile [95% conf. interval] |          |
|-------|-----------------|---------------------|-------|-------|---------------------------------|----------|
| _cons | 14.00818        | .866694             | 16.16 | 0.000 | 11.39967                        | 15.00145 |

The estimated mean number of citations with the new level of fines is 14.01, which is smaller than the mean 22.26 that was estimated with the observed fines. We can formally compare this estimate with the mean at the original level of fines. We use the contrast() option with margins to estimate the difference in these means.

```
. margins, at(fines=generate(fines)) at(fines=generate(fines*1.15))
> contrast(atcontrast(r) nowald) reps(200) seed(12)
(running margins on estimation sample)
Bootstrap replications (200):10.....20.....30.....40.....
>50.....60.....70.....80.....90.....100.....110...
>120.....130.....140.....150.....160.....170.....
> .180.....190.....200 done
Contrasts of predictive margins Number of obs = 500
 Replications = 200
Expression: Mean function, predict()
1._at: fines = fines
2._at: fines = fines*1.15
```

|                 | Observed contrast | Bootstrap std. err. | Percentile [95% conf. interval] |           |
|-----------------|-------------------|---------------------|---------------------------------|-----------|
| _at<br>(2 vs 1) | -8.254875         | .8058215            | -10.44121                       | -7.381583 |

We find that increasing fines by 15% reduces the average number of drunk driving citations by 8.25.

▷ Example 5: Estimating the effect of a change in level

Now, we estimate the effect of increasing `fin`es from \$10,000 to \$11,000 for fixed levels of the other covariates. The other covariate values identify a jurisdiction with a set of characteristics of interest: of medium size, with a college, and taxes alcohol.

First, we use `margins` to estimate the means for a jurisdiction with the characteristics of interest for the two levels of `fin`es.

```
. margins, at(fin=10 taxes=1 csize=2 college=1)
> at(fin=11 taxes=1 csize=2 college=1) reps(200) seed(12)
(running margins on estimation sample)

Bootstrap replications (200):10.....20.....30.....40.....
>50.....60.....70.....80.....90.....100.....110...
>120.....130.....140.....150.....160.....170.....
> .180.....190.....200 done

Adjusted predictions Number of obs = 500
 Replications = 200

Expression: Mean function, predict()
1._at: fin = 10
 taxes = 1
 csize = 2
 college = 1
2._at: fin = 11
 taxes = 1
 csize = 2
 college = 1
```

|     | Observed margin | Bootstrap std. err. | z     | P> z  | Percentile [95% conf. interval] |          |
|-----|-----------------|---------------------|-------|-------|---------------------------------|----------|
| _at |                 |                     |       |       |                                 |          |
| 1   | 23.17242        | .5746008            | 40.33 | 0.000 | 21.95222                        | 24.30412 |
| 2   | 15.90157        | .972558             | 16.35 | 0.000 | 13.87449                        | 17.7134  |

For a medium-sized jurisdiction that taxes alcohol and has a college, the estimated mean of citations when `fin`es are \$10,000 is 23.17, and the estimated mean of citations when `fin`es are \$11,000 is 15.90.

We now use margins to estimate the difference in these means.

```
. margins, at(fines=10 taxes=1 csize=2 college=1)
> at(fines=11 taxes=1 csize=2 college=1)
> contrast(atcontrast(r) nowald) reps(200) seed(12)
(running margins on estimation sample)

Bootstrap replications (200):10.....20.....30.....40.....
>50.....60.....70.....80.....90.....100.....110.....
>120.....130.....140.....150.....160.....170.....
> .180.....190.....200 done
Contrasts of predictive margins
```

Number of obs = 500  
Replications = 200

Expression: Mean function, predict()

```
1._at: fines = 10
 taxes = 1
 csize = 2
 college = 1
2._at: fines = 11
 taxes = 1
 csize = 2
 college = 1
```

|                 | Observed contrast | Bootstrap std. err. | Percentile [95% conf. interval] |           |
|-----------------|-------------------|---------------------|---------------------------------|-----------|
| _at<br>(2 vs 1) | -7.270858         | 1.003861            | -9.096777                       | -5.162513 |

In these jurisdictions, increasing fines from \$10,000 to \$11,000 reduces the average number of citations by 7.27.

### ➤ Example 6: Population-averaged covariate effects

In [example 5](#), we estimated the means for two values of fines for a medium-sized jurisdiction with a college and taxes on alcohol. We specified values for each covariate in our model. In this example, we will now estimate population-averaged means instead of means at specific levels of all covariates.

We first estimate the means for two levels of fines. We do not specify values for `csize`, `college`, or `taxes`, so the estimated means are unconditional on these covariates. We use `margins` to estimate means of citations when fines are \$10,000 and when fines are \$11,000:

```
. margins, at(fines=10) at(fines=11) reps(200) seed(12)
(running margins on estimation sample)
Bootstrap replications (200):10.....20.....30.....40.....
>50.....60.....70.....80.....90.....100.....110...
>120.....130.....140.....150.....160.....170.....
> .180.....190.....200 done
Predictive margins Number of obs = 500
 Replications = 200
Expression: Mean function, predict()
1._at: fines = 10
2._at: fines = 11
```

|     | Observed margin | Bootstrap std. err. | z     | P> z  | Percentile [95% conf. interval] |          |
|-----|-----------------|---------------------|-------|-------|---------------------------------|----------|
| _at |                 |                     |       |       |                                 |          |
| 1   | 20.50161        | .3281821            | 62.47 | 0.000 | 19.90257                        | 21.08954 |
| 2   | 14.97432        | .3815647            | 39.24 | 0.000 | 14.14858                        | 15.59955 |

The estimated mean of citations when fines are \$10,000 is 20.50, and the estimated mean of citations when fines are \$11,000 is 14.97. We now use margins to estimate the difference in these means:

```
. margins, at(fines=10) at(fines=11)
> contrast(atcontrast(r) nowald) reps(200) seed(12)
(running margins on estimation sample)
Bootstrap replications (200):10.....20.....30.....40.....
>50.....60.....70.....80.....90.....100.....110...
>120.....130.....140.....150.....160.....170.....
> .180.....190.....200 done
Contrasts of predictive margins Number of obs = 500
 Replications = 200
Expression: Mean function, predict()
1._at: fines = 10
2._at: fines = 11
```

|                 | Observed contrast | Bootstrap std. err. | Percentile [95% conf. interval] |           |
|-----------------|-------------------|---------------------|---------------------------------|-----------|
| _at<br>(2 vs 1) | -5.527288         | .3529352            | -6.277903                       | -4.925523 |

When fines increase from \$10,000 to \$11,000, the mean number of citations is estimated to decrease by 5.53.

Next, we consider the effect of taxing alcoholic beverages. We first estimate the population-averaged number of citations with and without such taxes.

```
. margins taxes, reps(200) seed(12)
(running margins on estimation sample)
Bootstrap replications (200):10.....20.....30.....40.....
>50.....60.....70.....80.....90.....100.....110...
>120.....130.....140.....150.....160.....170.....
> .180.....190.....200 done
Predictive margins Number of obs = 500
 Replications = 200
Expression: Mean function, predict()
```

|        | Observed margin | Bootstrap std. err. | z     | P> z  | Percentile [95% conf. interval] |          |
|--------|-----------------|---------------------|-------|-------|---------------------------------|----------|
| taxes  |                 |                     |       |       |                                 |          |
| No tax | 25.47052        | .6445729            | 39.52 | 0.000 | 24.17515                        | 26.6114  |
| Tax    | 20.96781        | .4448277            | 47.14 | 0.000 | 20.17071                        | 21.88565 |

The estimated mean number of citations is 25.47 when there are no alcohol taxes and 20.97 when there are alcohol taxes. We again use margins to estimate the difference in these means.

```
. margins r.taxes, reps(200) seed(12)
(running margins on estimation sample)
Bootstrap replications (200):10.....20.....30.....40.....
>50.....60.....70.....80.....90.....100.....110...
>120.....130.....140.....150.....160.....170.....
> .180.....190.....200 done
Contrasts of predictive margins Number of obs = 500
 Replications = 200
Expression: Mean function, predict()
```

|       | df | chi2  | P>chi2 |
|-------|----|-------|--------|
| taxes | 1  | 80.71 | 0.0000 |

|                          | Observed contrast | Bootstrap std. err. | Percentile [95% conf. interval] |           |
|--------------------------|-------------------|---------------------|---------------------------------|-----------|
| taxes<br>(Tax vs No tax) | -4.502719         | .5011999            | -5.437733                       | -3.544934 |

The mean number of citations is estimated to decrease by 4.50 when alcohol sales are taxed.

## Visualizing covariate effects

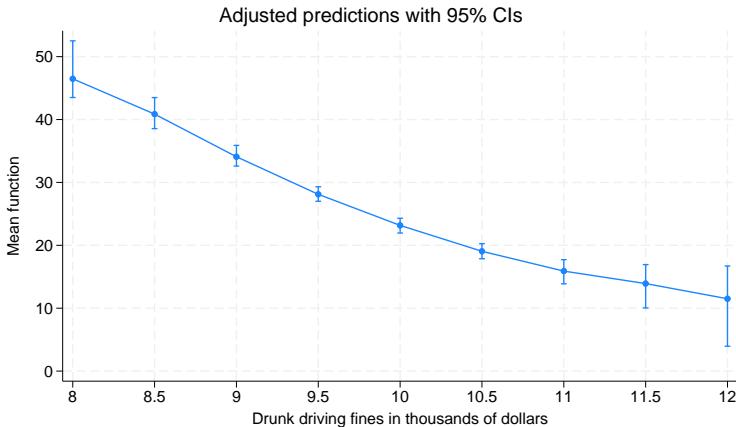

### ▷ Example 7: Using margins to visualize the mean function and covariate effects

We can also estimate the mean function for the jurisdiction with characteristics of interest over a range of observed fines. We simply add a range of fines to our margins specification from [example 4](#).

```
. margins, at(fines=(8(0.5)12) taxes=1 csize=2 college=1) reps(200) seed(12)
(output omitted)
```

We graph these results using `marginsplot`.

```
. marginsplot
(output omitted)
```

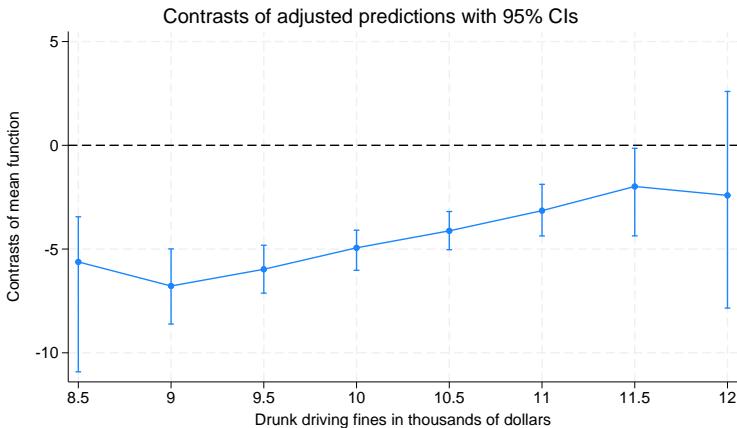

We estimated the mean when fines are \$8,000, \$8,500, and so on. From these estimated means, we can estimate the effect of a \$500 increase for each of these levels of fines.

We simply reissue our `margins` command and specify a reverse adjacent contrast that subtracts the current level from the next level for each level of fines.

```
. margins, at(fines=(8(0.5)12) taxes=1 csize=2 college=1)
> contrast(atcontrast(ar)) reps(200) seed(12)
(output omitted)
```

We again graph the results, adding a reference line at 0 that designates no change in citations:

```
. marginsplot, yline(0)
 (output omitted)
```

For each level of fines between \$8,500 and \$11,500, the effect of a \$500 increase reduces the mean number of drunk driving incidents. Between \$11,500 and \$12,000, the difference of a \$500 increase is not statistically different from 0.

It would be easy to construct a similar graph for the population-averaged effects in [example 6](#). Simply omit the terms that set the other covariates at fixed values.

## Stored results

npregress kernel stores the following in `e()`:

### Scalars

|                                  |                                                          |

|------------------------|-------------------------|
| <code>e(sample)</code> | marks estimation sample |
|------------------------|-------------------------|

In addition to the above, the following is stored in `r()`:

### Matrices

|                       |                                                                                                                            |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------|
| <code>r(table)</code> | matrix containing the coefficients with their standard errors, test statistics, <i>p</i> -values, and confidence intervals |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------|

Note that results stored in `r()` are updated when the command is replayed and will be replaced when any `r-class` command is run after the estimation command.

## Methods and formulas

The regression model of outcome  $y_i$  given the  $k$ -dimensional vector of covariates  $\mathbf{x}_i$  was defined in (1) and (2) of *Remarks and examples* and repeated here:

$$y_i = g(\mathbf{x}_i) + \varepsilon_i \tag{4}$$

$$E(\varepsilon_i | \mathbf{x}_i) = 0 \tag{5}$$

where  $\varepsilon_i$  is the error term. The covariates may include discrete and continuous variables. Equations (4) and (5) imply that

$$E(y_i | \mathbf{x}_i) = g(\mathbf{x}_i)$$

npregress kernel, by default, estimates a local-linear regression; see [Fan and Gijbels \(1996\)](#) for a good reference on local-linear regression. As we discussed in *Remarks and examples*, local-linear regression estimates a regression for a subset of observations for each point in our data and solves the minimization problem given by

$$\min_{\boldsymbol{\gamma}} \sum_{i=1}^n \{y_i - \gamma_0 - \boldsymbol{\gamma}'_1 (\mathbf{x}_i - \mathbf{x})\}^2 K(\mathbf{x}_i, \mathbf{x}, \mathbf{h}) \tag{6}$$

where  $\boldsymbol{\gamma} = (\gamma_0, \boldsymbol{\gamma}'_1)'$  and  $K(\mathbf{x}_i, \mathbf{x}, \mathbf{h})$  is the product of the kernels for each covariate.

$$K(\mathbf{x}_i, \mathbf{x}, \mathbf{h}) = \prod_{j=1}^k K_j(x_{ij}, x_j, h_j)$$

The kernel for a continuous covariate is of the form

$$K_j(x_{ij}, x_j, h_j) = k_j \left( \frac{x_{ij} - x_j}{h_j} \right)$$

where  $k_j(\cdot)$  is one of the [kernels](#) listed in [\[R\] kdensity](#). For discrete covariates, npregress kernel uses the Li–Racine kernel given by

$$K_j(x_{ij}, x_j, h_j) = \begin{cases} 1 & \text{if } x_{ij} = x_j \\ h_j & \text{otherwise} \end{cases}$$

By estimating  $E(y_i | \mathbf{x}_i = \mathbf{x})$  for all points  $\mathbf{x}$  in our data, we obtain an estimate of  $E(y_i | \mathbf{x}_i)$ . For a given  $\mathbf{x}$ , the solution to the minimization problem in (6) is given by

$$\widehat{\boldsymbol{\gamma}} = (\mathbf{Z}'\mathbf{W}\mathbf{Z})^{-1} \mathbf{Z}'\mathbf{W}\mathbf{y}$$

where  $\widehat{\boldsymbol{\gamma}} = (\widehat{\gamma}_0, \widehat{\boldsymbol{\gamma}}'_1)'$ ,  $\mathbf{Z}$  is an  $n \times (k + 1)$  matrix with an  $i$ th row given by  $\{1, (\mathbf{x}_i - \mathbf{x})'\}$ ,  $\mathbf{W}$  is an  $n \times n$  diagonal matrix with an  $i$ th diagonal given by  $K(\mathbf{x}_i, \mathbf{x}, \mathbf{h})$ , and  $\mathbf{y}$  is the  $n \times 1$  outcome vector.  $\widehat{\gamma}_0$  is an estimate of  $g(\mathbf{x})$ , whereas  $\widehat{\boldsymbol{\gamma}}_1$  is an estimate of the derivative of  $g(\mathbf{x})$  with respect to  $\mathbf{x}$ . When the matrix  $(\mathbf{Z}'\mathbf{W}\mathbf{Z})$  is not full rank, the parameter  $\boldsymbol{\gamma}$  is not identified. The observations for which this is true are dropped from the estimation sample.

The local-constant estimator of  $g(\mathbf{x})$  is a special case of (6) with  $\gamma_1 = \mathbf{0}$ . In this case, the solution to the optimization problem is given by

$$\frac{\sum_{i=1}^n y_i K(\mathbf{x}_i, \mathbf{x}, \mathbf{h})}{\sum_{i=1}^n K(\mathbf{x}_i, \mathbf{x}, \mathbf{h})}$$

This is also known as the Nadaraya–Watson kernel estimator, for [Nadaraya \(1965\)](#) and [Watson \(1964\)](#).

`npregress kernel` and `margins`, when used after `npregress kernel`, use a bootstrap estimate of the standard errors for all the estimated effects and report percentile confidence intervals by default. [Cattaneo and Jansson \(2018\)](#) formally justify this use of the bootstrap and provide a definitive reference for semiparametric estimation and inference using kernel-based estimators. Their work demonstrates that the percentile bootstrap provides better coverage than a normal-based confidence interval for statistics based on kernel estimates. See *Methods and formulas* in `[R] bootstrap` for confidence interval formulas.

The rate of convergence of nonparametric regression estimates is given by the product of the sample size and the bandwidths  $\sqrt{n|\mathbf{h}|}$ , where  $|\mathbf{h}|$  is the product of the bandwidths for each covariate. As the sample size increases, the bandwidth decreases. Thus, the rate of convergence of the estimator is slower than the parametric rate  $\sqrt{n}$ . Another way of thinking about  $n|\mathbf{h}|$  is that, because we are not using all our observations to estimate the mean at each point, we require more data to get more reliable estimates; the convergence rate is thus slower. The rate of convergence also decreases as the number of covariates increases, because  $|\mathbf{h}|$  decreases. This is referred to as the curse of dimensionality; see [Li and Racine \(2007, chap. 2\)](#) and [Stinchcombe and Drukker \(2013\)](#) for details.

The convergence rate for the derivative of the mean function is different from the convergence rate of the mean function. Therefore, the bandwidth and bandwidth computation for the derivative are different. `npregress kernel` computes the bandwidth for the derivative function by using cross-validation, as suggested by [Henderson et al. \(2015\)](#).

## Acknowledgments

We thank Matias Cattaneo of Princeton University and Qi Li of Texas A&M University for many helpful conversations. We thank Xinrong Li of Central University of Finance and Economics in China for research assistance during her summer internship at StataCorp during the summer of 2008.

## Postestimation commands

The following postestimation command is of special interest after `nprogress kernel`:

| Command                 | Description               |
|-------------------------|---------------------------|
| <a href="#">npgraph</a> | plot of conditional means |

The following standard postestimation commands are also available:

| Command                         | Description                                                                                       |
|---------------------------------|---------------------------------------------------------------------------------------------------|
| <a href="#">estat summarize</a> | summary statistics for the estimation sample                                                      |
| <a href="#">estat vce</a>       | variance–covariance matrix of the estimators (VCE)                                                |
| <a href="#">estimates</a>       | cataloging estimation results                                                                     |
| <a href="#">etable</a>          | table of estimation results                                                                       |
| <a href="#">lincom</a>          | point estimates, standard errors, testing, and inference for linear combinations of parameters    |
| <a href="#">margins</a>         | marginal means, predictive margins, marginal effects, and average marginal effects                |
| <a href="#">marginsplot</a>     | graph the results from margins (profile plots, interaction plots, etc.)                           |
| <a href="#">nlcom</a>           | point estimates, standard errors, testing, and inference for nonlinear combinations of parameters |
| <a href="#">predict</a>         | conditional means and residuals                                                                   |
| <a href="#">predictnl</a>       | point estimates, standard errors, testing, and inference for generalized predictions              |
| <a href="#">test</a>            | Wald tests of simple and composite linear hypotheses                                              |
| <a href="#">testnl</a>          | Wald tests of nonlinear hypotheses                                                                |

# predict

## Description for predict

`predict` creates a new variable containing predictions such as conditional mean of the outcome, residuals, or derivatives of the mean function.

## Menu for predict

Statistics > Postestimation

## Syntax for predict

```
predict [type] newvar [if] [in] [, statistic]
```

```
predict [type] { stub* | newvarlist } [if] [in] , derivatives
```

| <i>statistic</i> | Description |
|------------------|-------------|
|------------------|-------------|

---

Main

|                        |                                              |
|------------------------|----------------------------------------------|
| <code>mean</code>      | conditional mean of the outcome; the default |
| <code>residuals</code> | residuals                                    |

---

These statistics are calculated only for the estimation sample.

## Options for predict

Main

`mean`, the default, calculates the conditional mean of the outcome variable.

`residuals` calculates the residuals.

`derivatives` calculates the derivatives of the conditional mean.

## margins

### Description for margins

`margins` estimates margins of the conditional mean.

### Menu for margins

Statistics > Postestimation

### Syntax for margins

```
margins [marginlist] [, options]
```

```
margins [marginlist] , predict(statistic ...) [options]
```

| <i>statistic</i> | Description |
|------------------|-------------|
|------------------|-------------|

Main

|                                 |                                              |
|---------------------------------|----------------------------------------------|
| <code>mean</code>               | conditional mean of the outcome; the default |
| <code><u>r</u>esiduals</code>   | not allowed with margins                     |
| <code><u>d</u>erivatives</code> | not allowed with margins                     |

| <i>options</i> | Description |
|----------------|-------------|
|----------------|-------------|

SE

|                             |                                                                     |
|-----------------------------|---------------------------------------------------------------------|
| <code>nose</code>           | do not estimate standard errors; the default                        |
| <code>vce(bootstrap)</code> | estimate bootstrap standard errors                                  |
| <code><u>r</u>eps(#)</code> | equivalent to <code>vce(bootstrap, reps(#))</code>                  |
| <code>seed(#)</code>        | set random-number seed to #; must also specify <code>reps(#)</code> |

Reporting

|                                           |                                                                                                     |
|-------------------------------------------|-----------------------------------------------------------------------------------------------------|
| <code><u>c</u>itype(<i>citype</i>)</code> | method to compute bootstrap confidence intervals; default is <code><u>c</u>itype(percentile)</code> |
|-------------------------------------------|-----------------------------------------------------------------------------------------------------|

| <i>citype</i> | Description |
|---------------|-------------|
|---------------|-------------|

|                                |                                              |
|--------------------------------|----------------------------------------------|
| <code><u>p</u>ercentile</code> | percentile confidence intervals; the default |
| <code>bc</code>                | bias-corrected confidence intervals          |
| <code><u>n</u>ormal</code>     | normal-based confidence intervals            |

Statistics not allowed with `margins` are functions of stochastic quantities other than `e(b)`.

For the full syntax, see [\[R\] margins](#).

## Options for margins

### SE

`nose` suppresses calculation of the VCE and standard errors. This is the default.

`vce(bootstrap)` specifies that bootstrap standard errors are reported; see [R] [vce\\_option](#).

We recommend that you select the number of replications using `reps(#)` instead of specifying `vce(bootstrap)`, which defaults to 50 replications. Be aware that the number of replications needed to produce good estimates of the standard errors varies depending on the problem.

`reps(#)` specifies the number of bootstrap replications to be performed. Specifying this option is equivalent to specifying `vce(bootstrap, reps(#))`.

`seed(#)` sets the random-number seed. You must specify `reps(#)` with `seed(#)`.

### Reporting

`ci(type(citype))` specifies the type of confidence interval to be computed. By default, bootstrap percentile confidence intervals are reported as recommended by [Cattaneo and Jansson \(2018\)](#). *citype* may be one of `percentile`, `bc`, or `normal`.

## npgraph

### Description for npgraph

`npgraph` plots the conditional mean estimated by `npregress kernel` overlaid on a scatterplot of the data. `npgraph` is available only after fitting models with one covariate.

### Syntax for npgraph

```
npgraph [if] [in] [, options]
```

| <i>options</i>                                 | Description                                                                    |
|------------------------------------------------|--------------------------------------------------------------------------------|
| Plot                                           |                                                                                |
| <a href="#">marker_options</a>                 | change look of markers (color, size, etc.)                                     |
| <a href="#">marker_label_options</a>           | add marker labels; change look or position                                     |
| <code>nosscatter</code>                        | suppress scatterplot                                                           |
| Smoothed line                                  |                                                                                |
| <a href="#">lineopts(<i>cline_options</i>)</a> | affect rendition of the smoothed line                                          |
| Add plots                                      |                                                                                |
| <code>addplot(<i>plot</i>)</code>              | add other plots to the generated graph                                         |
| Y axis, X axis, Titles, Legend, Overall        |                                                                                |
| <a href="#">twoway_options</a>                 | any options other than by() documented in [G-3] <a href="#">twoway_options</a> |

## Options for npregraph

### Plot

*marker\_options* affect the rendition of markers drawn at the plotted points, including their shape, size, color, and outline; see [G-3] *marker\_options*.

*marker\_label\_options* specify if and how the markers are to be labeled; see [G-3] *marker\_label\_options*.

*noscatter* suppresses superimposing a scatterplot of the observed data over the smooth. This option is useful when the number of resulting points would be so large as to clutter the graph.

### Smoothed line

*lineopts* (*cline\_options*) affects the rendition of the smoothed line; see [G-3] *cline\_options*.

### Add plots

*addplot* (*plot*) provides a way to add other plots to the generated graph; see [G-3] *addplot\_option*.

### Y axis, X axis, Titles, Legend, Overall

*twoway\_options* are any of the options documented in [G-3] *twoway\_options*, excluding *by()*. These include options for titling the graph (see [G-3] *title\_options*) and for saving the graph to disk (see [G-3] *saving\_option*).

## Remarks and examples

For examples of margins after *npregress kernel*, see [example 4](#), [example 5](#), and [example 6](#) in [R] *npregress kernel*.

For examples of *marginsplot*, see [example 7](#) in [R] *npregress kernel*.

For an example of *npregraph*, see [example 2](#) in [R] *npregress kernel*.

## Methods and formulas

The formulas used by *predict* and *margins* for the conditional mean function and the mean marginal effect of a covariate are given in *Methods and formulas* of [R] *npregress kernel*.

## Description

`nprogress series` performs nonparametric series estimation using a B-spline, piecewise polynomial spline, or polynomial basis. Like linear regression, nonparametric regression models the mean of the outcome conditional on the covariates, but unlike linear regression, it makes no assumptions about the functional form of the relationship between the outcome and the covariates. `nprogress series` may be used to model the mean of a continuous, count, or binary outcome.

## Quick start

Nonparametric regression of  $y$  on  $x$  and discrete covariate  $a$  using the default B-spline basis

```
nprogress series y x i.a
```

Same as above, but use a polynomial basis

```
nprogress series y x i.a, polynomial
```

Same as above, but use a piecewise polynomial spline basis

```
nprogress series y x i.a, spline
```

Same as above, but use AIC to find the optimal basis function

```
nprogress series y x i.a, criterion(aic) spline
```

Interpolate using three knots

```
nprogress series y x i.a, knots(3)
```

Specify values of knots in matrix  $K$

```
nprogress series y x i.a, knotsmat(K)
```

## Menu

Statistics > Nonparametric analysis > Nonparametric series regression

## Syntax

```
npregress series depvar indepvarsseries [if] [in] [weight] [, options]
```

*indepvars*<sub>series</sub> is the list of independent variables for which a basis function will be formed.

| <i>options</i>                                       | Description                                                                                                                                      |
|------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Model</b>                                         |                                                                                                                                                  |
| <code>bspline</code>                                 | use a third-order B-spline basis; the default                                                                                                    |
| <code>bspline(#)</code>                              | use a B-spline basis of order #                                                                                                                  |
| <code>spline</code>                                  | use a third-order piecewise polynomial spline basis                                                                                              |
| <code>spline(#)</code>                               | use a piecewise polynomial spline basis of order #                                                                                               |
| <code>polynomial</code>                              | use a polynomial basis                                                                                                                           |
| <code>polynomial(#)</code>                           | use a polynomial basis of order #                                                                                                                |
| <code>asis(<i>varlist</i>)</code>                    | include <i>varlist</i> in model as specified; do not use in basis                                                                                |
| <code>nointeract(<i>seriesvarlist</i>)</code>        | use <i>seriesvarlist</i> in basis without interactions                                                                                           |
| <code>criterion(<i>crittype</i>)</code>              | criterion to use; <i>crittype</i> may be <code>cv</code> , <code>gcv</code> , <code>aic</code> , <code>bic</code> , or <code>mallows</code>      |
| <code>knots(#)</code>                                | use a piecewise polynomial spline or B-spline basis function with # knots                                                                        |
| <code>knotsmat(<i>matname</i>)</code>                | use knots in matrix <i>matname</i> for piecewise polynomial spline or B-spline estimation                                                        |
| <code>distinct(#)</code>                             | minimum number of distinct values allowed in continuous covariates; default is <code>distinct(10)</code>                                         |
| <code>basis(<i>stub</i> [, <i>replace</i>])</code>   | store elements of piecewise polynomial spline or B-spline basis function using <i>stub</i>                                                       |
| <code>rescale(<i>stub</i> [, <i>replace</i>])</code> | store rescaled values of covariates using <i>stub</i>                                                                                            |
| <b>SE</b>                                            |                                                                                                                                                  |
| <code>vce(<i>vcetype</i>)</code>                     | <i>vcetype</i> may be <code>robust</code> , <code>ols</code> , or <code>bootstrap</code>                                                         |
| <b>Reporting</b>                                     |                                                                                                                                                  |
| <code>level(#)</code>                                | set confidence level; default is <code>level(95)</code>                                                                                          |
| <code>aequations</code>                              | display auxiliary regression coefficients                                                                                                        |
| <code>display_options</code>                         | control columns and column formats, row spacing, line width, display of omitted variables and base and empty cells, and factor-variable labeling |
| <b>Maximization</b>                                  |                                                                                                                                                  |
| <code>maximize_options</code>                        | control the maximization process                                                                                                                 |
| <code>coeflegend</code>                              | display legend instead of statistics                                                                                                             |

*indepvars* and *varlist* may contain factor variables; see [U] 11.4.3 **Factor variables**.

`bayesboot`, `bootstrap`, `by`, `collect`, and `jackknife` are allowed; see [U] 11.1.10 **Prefix commands**.

Weights are not allowed with the `bootstrap` prefix; see [R] **bootstrap**.

`fweights` and `iweights` are allowed; see [U] 11.1.6 **weight**.

`coeflegend` does not appear in the dialog box.

See [U] 20 **Estimation and postestimation commands** for more capabilities of estimation commands.

## Options

### Model

`bspline` specifies that a third-order B-spline be selected. It is the default basis.

`bspline(#)` specifies that a B-spline of order `#` be used as the basis. The order may be 1, 2, or 3.

`spline` specifies that a third-order piecewise polynomial spline be selected as the basis.

`spline(#)` specifies that a piecewise polynomial spline of order `#` be used as the basis. The order may be 1, 2, or 3.

`polynomial` specifies that a polynomial be selected as the basis.

`polynomial(#)` specifies that a polynomial of order `#` be used as the basis. The order may be an integer between 1 and 16.

`asis(varlist)` specifies that variables in *varlist* be included as independent variables in the model without any transformation. No B-spline, piecewise polynomial spline, or polynomial basis function will be formed from these variables. Variables in *varlist* may not be specified in *indepvars*<sub>series</sub>.

`nointeract(seriesvarlist)` specifies that the terms in the basis function formed from variables in *seriesvarlist* not be interacted with the terms of the basis function formed from other variables in *indepvars*<sub>series</sub>. Covariates specified in *seriesvarlist* must be in *indepvars*<sub>series</sub>.

`criterion(crittype)` specifies that *crittype* be used to select the optimal number of terms in the basis function. *crittype* may be one of the following: *cv* (cross-validation), *gcv* (generalized cross-validation), *aic* (Akaike's information criterion), *bic* (Schwarz's Bayesian information criterion), or *mallows* (Mallows's  $C_p$ ). The default is `criterion(cv)`.

`knots(#)` specifies that a piecewise polynomial spline or B-spline basis function with `#` knots be used. The minimum number of knots must be an integer greater than or equal to 1. The maximum number of knots is either 4,096 or two-thirds of the sample size, whichever is smaller.

`knotsmat(matname)` specifies that the knots for each continuous covariate be the values in each row of *matname*. The number of knots should be the same for each covariate, and there must be as many rows as there are continuous covariates. If rows of *matname* are not labeled with *varnames*, then rows are assumed to be in the order of *indepvars*<sub>series</sub>.

`distinct(#)` specifies the minimum number of distinct values allowed in continuous variables. By default, continuous variables that enter the basis through either *indepvars*<sub>series</sub> or *seriesvarlist* are required to have at least 10 distinct values. Continuous variables with few distinct values provide little information for determining an appropriate basis function and may produce unreliable estimates.

`basis(stub [, replace])` specifies that the elements of the basis function generated by `npregress series` be stored with the specified names.

The option argument *stub* is the prefix used to generate enumerated variables for each element of the basis.

When `replace` is used, existing variables named with *stub* are replaced by those from the new computation.

`rescale(stub [, replace])` specifies that the rescaled covariates used to generate the basis function be stored with the specified names.

The option argument *stub* is the prefix used to generate enumerated variable names for the covariates.

When `replace` is used, existing covariates named with *stub* are replaced by those from the new computation.

---

#### SE

`vce(vcetype)` specifies the type of standard error reported, which includes types that are robust to some kinds of misspecification (`robust`), that assume homoskedasticity (`ols`), and that use bootstrap methods (`bootstrap`); see [R] [vce\\_option](#).

---

#### Reporting

`level(#)`; see [R] [Estimation options](#).

`aequations` specifies that the auxiliary regression coefficients be reported. By default, only the average marginal effects of the covariates on the outcome are reported.

`display_options`: `nocl`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `no!stretch`; see [R] [Estimation options](#).

---

#### Maximization

`maximize_options`: `iterate(#)`, `[no]log`, `tolerance(#)`; see [R] [Maximize](#). These options are seldom used.

The following option is available with `npregress series` but is not shown in the dialog box:

`coeflegend`; see [R] [Estimation options](#).

## Remarks and examples

This entry assumes that you are already familiar with nonparametric regression. Below, we discuss nonparametric series estimation; see [R] [npregress intro](#) for an overview of nonparametric regression and the models fit by `npregress series` and `npregress kernel`.

Remarks are presented under the following headings:

[Overview](#)  
[Estimation and effects](#)

## Overview

`npregress series` implements nonparametric series estimation using a B-spline, piecewise polynomial spline, or polynomial basis. The covariates may be continuous or discrete. `npregress series` allows you to estimate covariate effects and other counterfactuals related to the unknown mean function after estimation.

The word “nonparametric” refers to the fact that the parameter of interest—the mean as a function of the covariates—is given by the unknown function  $g(\mathbf{x}_i)$ , which is an element of an infinite-dimensional space of functions. In contrast, in a parametric model, the mean for a given value of the covariates,  $E(y_i|\mathbf{x}_i) = f(\mathbf{x}_i, \beta)$ , is a known function that is fully characterized by the parameter of interest,  $\beta$ , which is a finite-dimensional real vector (Shao 2003).

The nonparametric regression model of outcome  $y_i$  given the  $k$ -dimensional vector of covariates  $\mathbf{x}_i$  is given by

$$y_i = g(\mathbf{x}_i) + \varepsilon_i \tag{1}$$

$$E(\varepsilon_i|\mathbf{x}_i) = 0 \tag{2}$$

where  $\varepsilon_i$  is the error term. Equations (1) and (2) imply that

$$E(y_i|\mathbf{x}_i) = g(\mathbf{x}_i)$$

Once we account for the information in the covariates, the error term provides no information about the mean of our outcome. The conditional mean function is therefore given by  $g(\mathbf{x}_i)$ .

The mean estimate we obtain using nonparametric series estimation has the same form of the mean function estimate we obtain using linear regression. The regressors, however, are not variables in the data but functions of the variables. An example would be a  $k$ th-order polynomial. Suppose we have one covariate. The elements of the polynomial in this case would be  $(x_i, x_i^2, \dots, x_i^k)$ . If we define  $\mathbf{z}_i$  as a vector with elements  $(x_i, x_i^2, \dots, x_i^k)$ , we may write the estimate of the mean function as

$$\mathbf{z}'_i \hat{\beta}$$

where  $\hat{\beta}$  has the form of an ordinary least-squares estimate.

npregress series allows us to specify other functional forms for  $\mathbf{z}_i$  depending on the basis we select: B-spline, piecewise polynomial spline, or polynomial. See [Methods and formulas](#) for the formulas for each basis.

Although the estimate of the mean function has the form of a linear regression, the individual coefficients are not easily interpretable. For instance, in our  $k$ th-order polynomial example, if  $x_i$  is continuous, the marginal effect of  $x_i$  is not a single coefficient but rather is a function of  $k$  elements of  $\beta$  and the covariate  $x_i$ .

In the example above, we had only one covariate,  $x_i$ . If we have more than one covariate, we approximate the mean function by using interactions of the terms in the basis function for each covariate. For instance, a polynomial of  $x_i$  and  $w_i$  would have terms  $(x_i, w_i, x_i w_i, x_i^2, w_i^2, \dots, w_i^k x_i^k)$ . As the number of covariates increases, the number of terms in the basis function increases exponentially. This is referred to in the literature as the curse of dimensionality.

npregress series allows us to reduce the dimensionality by using the `nointeract()` option to request that some covariates not be interacted with others. For the example above, this is equivalent to specifying a model of the form

$$y_i = g_1(x_i) + g_2(w_i) + \varepsilon_i \tag{3}$$

In (3),  $g_1(x_i)$  and  $g_2(w_i)$  are unknown functions, but there are no interactions between  $x_i$  and  $w_i$ . This ameliorates the curse of dimensionality but imposes more structure to the model.

You may also want to reduce the curse of dimensionality by requesting a parametric component, by using the `asis()` option, to fit models like this:

$$y_i = g(x_i) + w_i\beta + \varepsilon_i \tag{4}$$

In (4),  $g(x_i)$  is unknown but we assume that  $w_i$  enters the model linearly.

As mentioned above, the regression coefficients are not easily interpretable. We can, however, estimate marginal effects, as reported in the `nprogress series` output, and use `margins` to answer specific questions about the effects of covariates on the conditional mean,  $g(\mathbf{x}_i)$ . We demonstrate this in the examples below.

For detailed introductions to series estimators and the methods implemented by `nprogress series`, see [de Boor \(2001\)](#), [Schumaker \(2007\)](#), [Eubank \(1999\)](#), [Schoenberg \(1969\)](#), [Newey \(1997\)](#), and [Chen \(2007\)](#).

## Estimation and effects

### ▷ Example 1: Nonparametric series regression estimation

`dui.dta` contains information about the number of monthly drunk driving citations in a local jurisdiction (`citations`). Suppose we want to know the effect of increasing fines on the number of citations. Because `citations` is a count variable, we could consider fitting the model with `poisson` or `nbreg`. However, both of these estimators make assumptions about the distribution of the data. If these assumptions are not true, we will obtain inconsistent estimates.

By using `nprogress series`, we do not have to make any assumptions about how `citations` is distributed. We use `nprogress series` to estimate the average marginal effect of drunk driving penalties (`fines`) on citations.

```
. use https://www.stata-press.com/data/r19/dui
(Fictional data on monthly drunk driving citations)
. nprogress series citations fines
Computing approximating function
Minimizing cross-validation criterion
Iteration 0: Cross-validation criterion = 55.15697
Iteration 1: Cross-validation criterion = 55.11413
Computing average derivatives
Cubic B-spline estimation Number of obs = 500
Criterion: cross-validation Number of knots = 3
```

|           | Effect    | Robust<br>std. err. | z      | P> z  | [95% conf. interval] |           |
|-----------|-----------|---------------------|--------|-------|----------------------|-----------|
| citations |           |                     |        |       |                      |           |
| fines     | -8.020769 | .464836             | -17.26 | 0.000 | -8.931831            | -7.109707 |

Note: Effect estimates are averages of derivatives.

The iteration log first tells us that the approximating function is being computed. At this stage, the number of knots of the cubic B-spline is selected using cross-validation. Three knots were selected.

After the approximating function is computed, average marginal effects are computed. This second step is computationally expensive. The computation time increases with the number of elements in the basis function, which in turn increases with the complexity of the mean function we are trying to compute.

The table reports that the average marginal effect of fines on the mean number of citations is  $-8.02$ . Increasing fines, on average, reduces the number of citations.

◀

`npregress series` generates a system variable for each element of the basis function. Additionally, variables are generated with the rescaled values of the continuous covariates used to construct the basis function. To see the variables that `npregress series` generated for [example 1](#), we type

```
. describe *_*, fullnames
```

| Variable name | Storage type | Display format | Value label | Variable label          |
|---------------|--------------|----------------|-------------|-------------------------|
| __x1rs        | double       | %10.0g         |             | fines rescaled to [0,1] |
| _x1__b1       | double       | %10.0g         |             | Basis term 1 for fines  |
| _x1__b2       | double       | %10.0g         |             | Basis term 2 for fines  |
| _x1__b3       | double       | %10.0g         |             | Basis term 3 for fines  |
| _x1__b4       | double       | %10.0g         |             | Basis term 4 for fines  |
| _x1__b5       | double       | %10.0g         |             | Basis term 5 for fines  |
| _x1__b6       | double       | %10.0g         |             | Basis term 6 for fines  |
| _x1__b7       | double       | %10.0g         |             | Basis term 7 for fines  |

To specify a name for each of the elements of the basis function, we can use the `basis()` option with a *stub*.

```
. npregress series citations fines, basis(basis)
(output omitted)
```

We get the following set of names for the elements of the basis function:

```
. describe basis*, fullnames
```

| Variable name | Storage type | Display format | Value label | Variable label         |
|---------------|--------------|----------------|-------------|------------------------|
| basis1        | double       | %10.0g         |             | Basis term 1 for fines |
| basis2        | double       | %10.0g         |             | Basis term 2 for fines |
| basis3        | double       | %10.0g         |             | Basis term 3 for fines |
| basis4        | double       | %10.0g         |             | Basis term 4 for fines |
| basis5        | double       | %10.0g         |             | Basis term 5 for fines |
| basis6        | double       | %10.0g         |             | Basis term 6 for fines |
| basis7        | double       | %10.0g         |             | Basis term 7 for fines |

We may also modify the name of the rescaled variable by using the `rescale()` option.

```
. npregress series citations fines, rescale(rescaled)
(output omitted)
```

This will give us

```
. describe rescaled*, fullnames
```

| variable name | storage type | display format | value label | variable label          |
|---------------|--------------|----------------|-------------|-------------------------|
| rescaled1     | double       | %10.0g         |             | fines rescaled to [0,1] |

▷ Example 2: Estimation with more than one regressor

We now extend [example 1](#). In addition to `finest`, we model citations as a function of whether the jurisdiction is small, medium, or large (`csize`) and whether there is a college in the jurisdiction (`college`).

```
. npregress series citations finest i.csize i.college
Computing approximating function
Minimizing cross-validation criterion
Iteration 0: Cross-validation criterion = 30.26251
Computing average derivatives
Cubic B-spline estimation Number of obs = 500
Criterion: cross-validation Number of knots = 1
```

| citations                                                  | Effect    | Robust<br>std. err. | z      | P> z  | [95% conf. interval] |           |
|------------------------------------------------------------|-----------|---------------------|--------|-------|----------------------|-----------|
| finest                                                     | -7.787386 | .2917941            | -26.69 | 0.000 | -8.359292            | -7.215481 |
| csize<br>(Medium<br>vs<br>Small)<br>(Large<br>vs<br>Small) | 4.732592  | .5087968            | 9.30   | 0.000 | 3.735368             | 5.729815  |
| college<br>(College<br>vs<br>Not coll..)                   | 6.514286  | .5958949            | 10.93  | 0.000 | 5.346353             | 7.682218  |

Note: Effect estimates are averages of derivatives for continuous covariates and averages of contrasts for factor covariates.

The average marginal effect of `finest` is  $-7.79$ , slightly less in magnitude than the  $-8.02$  that we estimated in [example 1](#). The output also shows effects for the variables `csize` and `college`. In these categorical variables, the effects are differences instead of derivatives. For example, if every jurisdiction in the population were a college town, we would expect 6.51 more citations than if none were college towns.

### ► Example 3: Expected citations for different levels of fines

The `npregress series` command reported that the average marginal effect of fines on number of citations is negative. We can use `margins` to further explore the relationship between level of fines and expected number of citations. What would we expect if all jurisdictions set fines to \$8,000? What if they all set fines to \$9,000? \$10,000? \$11,000? We use the `at(fines=(8 9 10 11))` option with `margins` to estimate these expected values.

```
. margins, at(fines=(8 9 10 11))
Predictive margins Number of obs = 500
Model VCE: Robust
Expression: Mean function, predict()
1._at: fines = 8
2._at: fines = 9
3._at: fines = 10
4._at: fines = 11
```

| _at | Delta-method |           |       |       | [95% conf. interval] |          |
|-----|--------------|-----------|-------|-------|----------------------|----------|
|     | Margin       | std. err. | z     | P> z  |                      |          |
| 1   | 49.58234     | 1.47392   | 33.64 | 0.000 | 46.69351             | 52.47117 |
| 2   | 28.35154     | .5730302  | 49.48 | 0.000 | 27.22842             | 29.47466 |
| 3   | 20.40163     | .3320855  | 61.43 | 0.000 | 19.75075             | 21.0525  |
| 4   | 14.78085     | .4297201  | 34.40 | 0.000 | 13.93862             | 15.62309 |

There appears to be a dramatic drop in the expected number of citations as fines increase from \$8,000 to \$9,000. We can visualize these results if we type `marginsplot`.

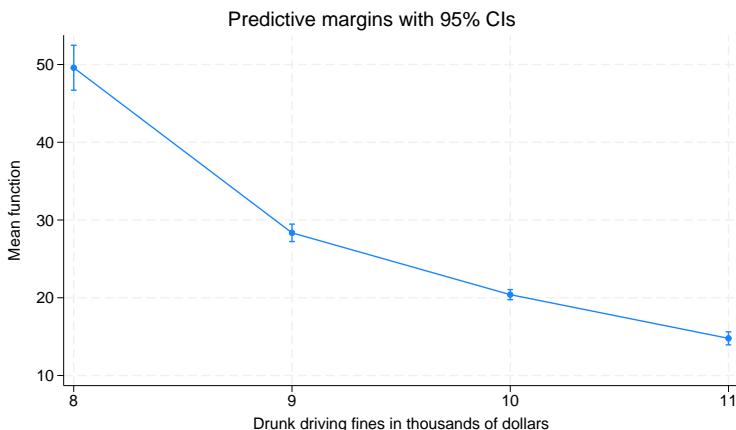

Figure 1.

Are there significant differences in the expected number of citations as we increase fines in increments of \$1,000? If we use the reverse-adjacent contrast operator, `ar.`, with margins, we can estimate these differences and perform tests.

```
. margins, at(fines=(8 9 10 11)) contrast(atcontrast(ar._at) nowald effects)
Contrasts of predictive margins Number of obs = 500
Model VCE: Robust

Expression: Mean function, predict()
1._at: fines = 8
2._at: fines = 9
3._at: fines = 10
4._at: fines = 11

Expression: Mean function, predict()
1._at: fines = 8
2._at: fines = 9
3._at: fines = 10
4._at: fines = 11
```

|          | Delta-method |           |        |       | [95% conf. interval] |           |
|----------|--------------|-----------|--------|-------|----------------------|-----------|
|          | Contrast     | std. err. | z      | P> z  |                      |           |
| _at      |              |           |        |       |                      |           |
| (2 vs 1) | -21.2308     | 1.610261  | -13.18 | 0.000 | -24.38685            | -18.07475 |
| (3 vs 2) | -7.94991     | .7085254  | -11.22 | 0.000 | -9.338595            | -6.561226 |
| (4 vs 3) | -5.620773    | .5683614  | -9.89  | 0.000 | -6.734741            | -4.506806 |

When fines are increased from \$8,000 to \$9,000, we expect a decrease of 21.23 in the number of citations. Smaller but still statistically significant decreases in the number of citations are expected as fines are increased from \$9,000 to \$10,000 and from \$10,000 to \$11,000.

► Example 4: Estimating the effect for different levels of jurisdiction size

Now, we estimate the effect of increasing `fines` for different jurisdiction sizes.

```
. margins csize, dydx(fines)
Average marginal effects Number of obs = 500
Model VCE: Robust

Expression: Mean function, predict()
dy/dx wrt: fines
```

| fines  | csize | Delta-method |           |        |       | [95% conf. interval] |           |
|--------|-------|--------------|-----------|--------|-------|----------------------|-----------|
|        |       | dy/dx        | std. err. | z      | P> z  |                      |           |
| Small  |       | -5.992484    | .4491224  | -13.34 | 0.000 | -6.872747            | -5.11222  |
| Medium |       | -7.740284    | .4366709  | -17.73 | 0.000 | -8.596144            | -6.884425 |
| Large  |       | -10.20492    | .564166   | -18.09 | 0.000 | -11.31067            | -9.099178 |

If all jurisdictions were small but other characteristics were as they are observed, then we expect that the marginal effect of `fines` would be  $-5.99$ . We see that the effect is more extreme as the size of the jurisdiction increases. If all jurisdictions were large, we expect that the average marginal effect of `fines` would be  $-10.20$ .

We can further explore the effects of fines for different jurisdiction sizes by estimating the expected number of citations with fines at specific levels.

```
. margins csize, at(fines=(8(1)11))
(output omitted)
```

To visualize the effect, we type marginsplot.

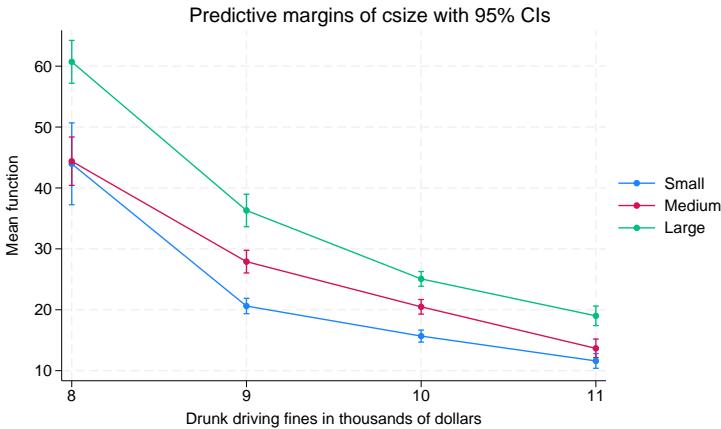

Figure 2.

For each jurisdiction size, we see that on average higher fines result in fewer citations. We also see that the effect of changing fine levels is nonlinear and differs across the counterfactual jurisdiction size. For instance, as fines increase from \$8,000 to \$9,000, the expected number of citations decreases faster for small jurisdictions than for medium ones.

## Stored results

npregress series stores the following in e():

### Scalars

|              |                             |

In addition to the above, the following is stored in `r()`:

|          |                                                                                                                       |
|----------|-----------------------------------------------------------------------------------------------------------------------|
| Matrices |                                                                                                                       |
| r(table) | matrix containing the coefficients with their standard errors, test statistics, $p$ -values, and confidence intervals |

Note that results stored in `r()` are updated when the command is replayed and will be replaced when any `r-class` command is run after the estimation command.

## Methods and formulas

Methods and formulas are presented under the following headings:

- [Overview](#)
- [Polynomials](#)
- [Piecewise polynomial splines](#)
- [B-splines](#)
- [Model selection](#)
  - [Cross-validation](#)
  - [Generalized cross-validation](#)
  - [Mallows's  \$C\_p\$](#)
  - [AIC and BIC](#)

## Overview

The regression model of outcome  $y_i$  given the  $k$ -dimensional vector of covariates  $\mathbf{x}_i$  was defined in (1) and (2) of *Remarks and examples* and is repeated here:

$$y_i = g(\mathbf{x}_i) + \varepsilon_i \quad (1)$$

$$E(\varepsilon_i | \mathbf{x}_i) = 0 \quad (2)$$

where  $\varepsilon_i$  is the error term. The covariates may include discrete and continuous variables. Equations (1) and (2) imply that

$$E(y_i | \mathbf{x}_i) = g(\mathbf{x}_i)$$

As discussed in *Remarks and examples*, series estimators have the form of ordinary least squares. Thus, we can write the estimate of the mean function as

$$\widehat{E}(y_i|\mathbf{x}_i) = \mathbf{z}(\mathbf{x}_i)\widehat{\boldsymbol{\beta}} \quad (5)$$

where  $\mathbf{z}(\mathbf{x}_i)$  is a known  $q$ -dimensional vector for which every one of the  $q$  terms is a function of the  $k$ -dimensional vector of covariates  $\mathbf{x}_i$ . Let  $n$  be the sample size. If we define  $\mathbf{Z}$  as the  $n \times q$  matrix formed by the  $\mathbf{z}(\mathbf{x}_i)$  for each individual  $i$ , then the  $q$ -dimensional coefficient vector  $\widehat{\boldsymbol{\beta}}$  is the ordinary least-squares vector that comes from regressing the  $n \times 1$  outcome vector  $\mathbf{y}$  on  $\mathbf{Z}$  and has the known form

$$\widehat{\boldsymbol{\beta}} = (\mathbf{Z}'\mathbf{Z})^{-1}(\mathbf{Z}'\mathbf{y}) \quad (6)$$

Each one of the series estimators has a different form for  $\mathbf{z}(\mathbf{x}_i)$ . Below, we define  $\mathbf{z}(\mathbf{x}_i)$  for polynomials, piecewise polynomial splines, and B-splines.

## Polynomials

For a polynomial of order 1 with  $k$  continuous covariates,  $\mathbf{x}_i \equiv (x_{i1}, x_{i2}, \dots, x_{ik})$ ,  $\mathbf{z}(\mathbf{x}_i)$  is

$$\mathbf{z}(\mathbf{x}_i) = (x_{i1}, x_{i2}, \dots, x_{ik}) \quad (P1)$$

For notational convenience, we will refer to the polynomial above as *P1*, which also corresponds to the name we gave to the equation. More formally, we could have written  $(x_{i1}, x_{i2}, \dots, x_{ik}) \equiv P1$ . We will maintain this notational convention below.

A polynomial of order 2 with  $k$  continuous covariates includes *P1* and second-order terms:

$$\mathbf{z}(\mathbf{x}_i) = (P1, x_{i1}^2, x_{i1}x_{i2}, \dots, x_{i1}x_{ik}, x_{i2}x_{i3}, \dots, x_{ik}^2) \quad (P2)$$

A third-order polynomial with  $k$  continuous covariates includes the terms in *P2* (which already includes *P1*) and third-order terms:

$$\mathbf{z}(\mathbf{x}_i) = (P2, x_{i1}^3, x_{i1}^2x_{i2}, \dots, x_{i1}^2x_{ik}, x_{i1}x_{i2}x_{i3}, \dots, x_{ik}^3) \quad (P3)$$

This recursive relationship continues. Thus, fourth-order polynomials includes the terms in *P3* (which already includes *P1* and *P2*) plus fourth-order terms.

For the polynomials above and all series estimators below, discrete covariates enter the model in levels, and each level is interacted with all other covariates in the model.

## Piecewise polynomial splines

Piecewise polynomial splines are formed by a polynomial and functions of the form

$$\max(x_{ik} - t_{1k}, 0)$$

In the expression above,  $t_{1k}$  is a constant that is called a knot. The subscript of  $t_{1k}$  indicates that it is the first knot of the continuous covariate  $\mathbf{x}_k$ . The  $\max(\cdot)$  function is 0 when  $x_{ik} < t_{1k}$  and is  $x_{ik} - t_{1k}$  otherwise. *npregress series* selects a set of knots for each one of the continuous covariates.

The regressors for npregress series using a piecewise polynomial spline of order 3 with one continuous covariate,  $\mathbf{x}_1$ , and  $k$  knots,  $t_{11} < t_{21} < \dots < t_{k1}$ , are given by

$$\mathbf{z}(x_{i1}) = \left\{ x_{i1}, x_{i1}^2, x_{i1}^3, \max(x_{i1} - t_{11}, 0)^3, \max(x_{i1} - t_{21}, 0)^3, \dots, \max(x_{i1} - t_{k1}, 0)^3 \right\} \quad (S1)$$

Equivalently, for another continuous covariate,  $\mathbf{x}_2$ , and  $k$  knots,  $t_{12} < t_{22} < \dots < t_{k2}$ , we have

$$\mathbf{z}(x_{i2}) = \left\{ x_{i2}, x_{i2}^2, x_{i2}^3, \max(x_{i2} - t_{12}, 0)^3, \max(x_{i2} - t_{22}, 0)^3, \dots, \max(x_{i2} - t_{k2}, 0)^3 \right\} \quad (S2)$$

To get  $\mathbf{z}(x_{i1}, x_{i2})$  for  $\mathbf{x}_1$  and  $\mathbf{x}_2$  and  $k$  knots, we include all terms in  $S1$  and  $S2$  as well as all the terms that result from the interaction of their terms. We write it succinctly as

$$\mathbf{z}(x_{i1}, x_{i2}) = \{S1, S2, (S1)(S2)\} \quad (S12)$$

The description above refers to the default third-order piecewise polynomial spline. Below, we describe the cases for piecewise polynomial splines of order 1 and order 2. Going back to the one covariate case, if we want a piecewise polynomial spline of order 1 with  $k$  knots, we have

$$\mathbf{z}(x_{i1}) = \{x_{i1}, \max(x_{i1} - t_{11}, 0), \max(x_{i1} - t_{21}, 0), \dots, \max(x_{i1} - t_{k1}, 0)\}$$

And for order 2 with  $k$  knots and one covariate, we have

$$\mathbf{z}(x_{i1}) = \{x_{i1}, x_{i1}^2, \max(x_{i1} - t_{11}, 0)^2, \max(x_{i1} - t_{21}, 0)^2, \dots, \max(x_{i1} - t_{k1}, 0)^2\}$$

If we have more than one covariate, the logic of interacting the expressions for each covariate is the same as the logic we used for the third-order piecewise polynomial spline in  $(S1)$ .

To construct  $\mathbf{z}(\mathbf{x}_i)$ , continuous covariates are rescaled to be between 0 and 1 with the expression

$$\{\mathbf{x}_i - \min(\mathbf{x}_i)\} \left\{ \frac{1}{\max(\mathbf{x}_i) - \min(\mathbf{x}_i)} \right\}$$

This rescaling is used to construct the piecewise polynomial spline and B-spline bases.

## B-splines

To construct a B-spline basis, we need to define knots that are on the interior of the range of the covariates and knots that are at the upper and lower limits of the range or outside the range. The number of knots that are not in the interior differs depending on the order of the B-spline. For a B-spline of order 1 with  $k$  interior knots,  $t_1, t_2, \dots, t_k$ , we need 4 additional knots. The set of knots for a first-order B-spline is therefore

$$t_{-1}, t_0, t_1, \dots, t_k, t_{k+1}, t_{k+2}$$

We added  $t_{-1}, t_0, t_{k+1}$ , and  $t_{k+2}$  to the interior knots. By convention,  $t_{-1} = t_0$  and  $t_{k+1} = t_{k+2}$ .

For a B-spline of order 2 with  $k$  interior knots, we need 6 additional knots. The set of knots is

$$t_{-2}, t_{-1}, t_0, t_1, \dots, t_k, t_{k+1}, t_{k+2}, t_{k+3}$$

For a B-spline of order 3, the set of knots is

$$t_{-3}, t_{-2}, t_{-1}, t_0, t_1, \dots, t_k, t_{k+1}, t_{k+2}, t_{k+3}, t_{k+4}$$

We first define a first-order B-spline for one continuous covariate  $\mathbf{x}$  with  $k$  interior knots. Let  $\mathbf{t}_j$  denote an  $n \times 1$  vector for which all elements take the value of the  $j$ th knot  $t_j$ . The B-spline basis is formed by  $k + 2$  functions of the form

$$B_{j,1} = \frac{(\mathbf{x} - t_j)}{t_{j+1} - t_j} \mathbf{1}(\mathbf{t}_j \leq \mathbf{x} < \mathbf{t}_{j+1}) + \frac{(t_{j+2} - \mathbf{x})}{t_{j+2} - t_{j+1}} \mathbf{1}(\mathbf{t}_{j+1} \leq \mathbf{x} < \mathbf{t}_{j+2}) \quad (7)$$

$$j = -1, 0, 1, 2, \dots, k$$

Above, we use the indicator function  $\mathbf{1}(\cdot)$ , which is 1 when the condition inside the parentheses is satisfied and is 0 otherwise. Also, any term for which  $t_{j+1} = t_j$  or  $t_{j+2} = t_{j+1}$  is considered to be a vector of 0s.

The function  $\mathbf{z}(\mathbf{x})$  used to estimate  $g(\mathbf{x})$  is given by

$$\mathbf{z}(\mathbf{x}) = (B_{-1,1}, B_{0,1}, B_{1,1}, \dots, B_{k,1})$$

We now define a second-order B-spline for one continuous covariate  $\mathbf{x}$  with  $k$  interior knots. The basis is constructed using the relationship given by

$$B_{j,2} = \frac{(\mathbf{x} - t_j)}{t_{j+2} - t_j} B_{j,1} + \frac{(t_{j+3} - \mathbf{x})}{t_{j+3} - t_{j+1}} B_{j+1,1}$$

$$j = -2, -1, 0, 1, 2, \dots, k$$

where  $B_{j,1}$  and  $B_{j+1,1}$  come from (7) above. Thus, second-order B-splines are a function of first-order B-splines, and as we will see below, third-order B-splines are a function of second-order B-splines. This recursion continues into higher orders, but nprogress series stops at B-splines of order 3.

The function  $\mathbf{z}(\mathbf{x})$  for the second-order B-spline is given by

$$\mathbf{z}(\mathbf{x}) = (B_{-2,2}, B_{-1,2}, B_{0,2}, B_{1,2}, \dots, B_{k,2})$$

The terms of the basis for a third-order B-spline are given by

$$B_{j,3} = \frac{(\mathbf{x} - t_j)}{t_{j+3} - t_j} B_{j,2} + \frac{(t_{j+4} - \mathbf{x})}{t_{j+4} - t_{j+1}} B_{j+1,2}$$

$$j = -3, -2, -1, 0, 1, 2, \dots, k$$

and the function  $\mathbf{z}(\mathbf{x})$  for the third-order B-spline is

$$\mathbf{z}(\mathbf{x}) = (B_{-3,3}, B_{-2,3}, B_{-1,3}, B_{0,3}, B_{1,3}, \dots, B_{k,3}) \tag{B1}$$

As was the case with piecewise polynomial splines, when there is more than one covariate, you include all functions of the form (B1) and their interactions to form expressions like the one in (S1).

### Model selection

Below, we define the criteria used for model selection. In the case of B-splines and piecewise polynomial splines, nprogress series selects the number of knots to be used for estimation. In the case of a polynomial basis, nprogress series selects the order of the polynomial.

Let us first define the squared residuals,  $e_i^2$ , where  $e_i = y_i - \hat{g}(\mathbf{x}_i)$  and  $\hat{g}(\cdot)$  is the mean function estimate defined in (5). We denote the residuals for the regressions below as  $e_i(\mathbf{t}_k)$  instead of  $e_i$  to signal that the estimates we obtain are a function of the set of knots,  $\mathbf{t}_k$ , used. In the case of polynomials,  $\mathbf{t}_k$  will refer to the degree of the polynomial instead of knots.

### Cross-validation

The cross-validation criterion,  $CV(\mathbf{t}_k)$ , is defined by

$$CV(\mathbf{t}_k) = \frac{1}{n} \sum_{i=1}^n \frac{e_i(\mathbf{t}_k)^2}{(1 - h_{ii})^2} \tag{8}$$

In (8),  $h_{ii}$  are the diagonal elements of the matrix  $\mathbf{Z}(\mathbf{Z}'\mathbf{Z})\mathbf{Z}'$ , where  $\mathbf{Z}$  is defined in (6) above and  $n$  is the size of the estimation sample.

nprogress series computes  $CV(\mathbf{t}_k)$  for different sets of knots,  $\mathbf{t}_1, \mathbf{t}_2, \dots, \mathbf{t}_k, \dots$ , where  $\mathbf{t}_1 \subset \mathbf{t}_2 \subset \dots \subset \mathbf{t}_k \subset \dots$ , and then selects the model with the smallest value for the cross-validation criterion.

## Generalized cross-validation

The generalized cross-validation criterion,  $GCV(\mathbf{t}_k)$ , is given by

$$GCV(\mathbf{t}_k) = \frac{1}{n} \sum_{i=1}^n \frac{e_i(\mathbf{t}_k)^2}{\{1 - (K/n)\}^2}$$

where  $K$  is the number of estimated parameters and the other arguments are equivalent to those defined in (8). As with cross-validation,  $GCV(\mathbf{t}_k)$  is computed for a set of models with an increasing number of nested knots, in the case of piecewise polynomial splines and B-splines, and of polynomial order in the case of polynomials. The minimum of the sequence is the selected model.

## Mallows's $C_p$

$$\text{Mallows}(\mathbf{t}_k) = \frac{1}{n} \sum_{i=1}^n e_i(\mathbf{t}_k)^2 \left(1 + \frac{2K}{n}\right)$$

As with cross-validation, Mallows ( $\mathbf{t}_k$ ) is computed for a set of models with an increasing number of nested knots, and the minimum of the sequence is the selected model.

## AIC and BIC

See *Methods and formulas* in [R] [estat ic](#).

## Postestimation commands

The following standard postestimation commands are available after `nprogress series`:

| Command                      | Description                                                                                       |
|------------------------------|---------------------------------------------------------------------------------------------------|
| <code>estat summarize</code> | summary statistics for the estimation sample                                                      |
| <code>estat vce</code>       | variance–covariance matrix of the estimators (VCE)                                                |
| <code>estimates</code>       | cataloging estimation results                                                                     |
| <code>etable</code>          | table of estimation results                                                                       |
| <code>lincom</code>          | point estimates, standard errors, testing, and inference for linear combinations of parameters    |
| <code>margins</code>         | marginal means, predictive margins, marginal effects, and average marginal effects                |
| <code>marginsplot</code>     | graph the results from margins (profile plots, interaction plots, etc.)                           |
| <code>nlcom</code>           | point estimates, standard errors, testing, and inference for nonlinear combinations of parameters |
| <code>predict</code>         | conditional means and residuals                                                                   |
| <code>predictnl</code>       | point estimates, standard errors, testing, and inference for generalized predictions              |
| <code>test</code>            | Wald tests of simple and composite linear hypotheses                                              |
| <code>testnl</code>          | Wald tests of nonlinear hypotheses                                                                |

# predict

## Description for predict

`predict` creates a new variable containing predictions such as conditional mean of the outcome, residuals, or score of the mean function.

## Menu for predict

Statistics > Postestimation

## Syntax for predict

```
predict [type] newvar [if] [in] [, statistic atsample tolerance(#)]
```

| <i>statistic</i> | Description |
|------------------|-------------|
|------------------|-------------|

---

Main

|                        |                                              |
|------------------------|----------------------------------------------|
| <code>mean</code>      | conditional mean of the outcome; the default |
| <code>residuals</code> | residuals                                    |
| <code>score</code>     | score; equivalent to <code>residuals</code>  |

---

These statistics are available for the estimation sample only.

## Options for predict

Main

`mean`, the default, calculates the conditional mean of the outcome variable.

`residuals` calculates the residuals.

`score` is a synonym for `residuals`.

`atsample` restricts predictions to the range of covariates in the data. If requested predictions extend beyond the range of the data, `atsample` will compute predictions only for observations within the range of the original data and will exclude those observations that are beyond the range of the data.

By default, predictions will not be computed if any covariate is set to a value outside the range of the data, unless `atsample` or `tolerance()` is specified.

`tolerance(#)` sets the tolerance for predictions outside the range of the covariates.

By default, predictions will not be computed if any covariate is set to a value outside the range of the data, unless `tolerance()` or `atsample` is specified.

## margins

### Description for margins

`margins` estimates margins of the conditional mean.

### Menu for margins

Statistics > Postestimation

### Syntax for margins

```
margins [marginlist] [, options]
```

```
margins [marginlist] , predict(statistic ...) [options]
```

| <i>statistic</i> | Description |
|------------------|-------------|
|------------------|-------------|

Main

|                               |                                              |
|-------------------------------|----------------------------------------------|
| <code>mean</code>             | conditional mean of the outcome; the default |
| <code><u>r</u>esiduals</code> | not allowed with margins                     |
| <code><u>s</u>core</code>     | not allowed with margins                     |

| <i>options</i> | Description |
|----------------|-------------|
|----------------|-------------|

SE

|                                  |                                                                                                   |
|----------------------------------|---------------------------------------------------------------------------------------------------|
| <code>vce(<i>vcetype</i>)</code> | <i>vcetype</i> may be <code>delta</code> , <code>unconditional</code> , or <code>bootstrap</code> |
| <code><u>r</u>eps(#)</code>      | equivalent to <code>vce(bootstrap, reps(#))</code>                                                |
| <code>seed(#)</code>             | set random-number seed to #; must also specify <code>reps(#)</code>                               |
| <code>nose</code>                | do not estimate standard errors                                                                   |

Reporting

|                                           |                                                                                              |
|-------------------------------------------|----------------------------------------------------------------------------------------------|
| <code><u>c</u>itype(<i>citype</i>)</code> | method to compute bootstrap confidence intervals; default is <code>citype(percentile)</code> |
|-------------------------------------------|----------------------------------------------------------------------------------------------|

| <i>citype</i> | Description |
|---------------|-------------|
|---------------|-------------|

|                                |                                              |
|--------------------------------|----------------------------------------------|
| <code><u>p</u>ercentile</code> | percentile confidence intervals; the default |
| <code>bc</code>                | bias-corrected confidence intervals          |
| <code><u>n</u>ormal</code>     | normal-based confidence intervals            |

Statistics not allowed with `margins` are functions of stochastic quantities other than `e(b)`.

For the full syntax, see [\[R\] margins](#).

## Options for margins

SE

`vce(delta)`, `vce(unconditional)`, and `vce(bootstrap)` specify how the VCE and, correspondingly, standard errors are calculated.

`vce(delta)` is the default. The delta method is applied to the formula for the response and the VCE of the estimation command. This method assumes that values of the covariates used to calculate the response are given or, if all covariates are not fixed using `at()`, that the data are given.

`vce(unconditional)` specifies that the covariates that are not fixed be treated in a way that accounts for their having been sampled. The VCE is estimated using the linearization method. This method allows for heteroskedasticity or other violations of distributional assumptions in the same manner as `vce(robust)`, which is the default for `npregress series`.

`vce(bootstrap)` specifies that bootstrap standard errors be reported; see [R] [vce\\_option](#). We recommend that you select the number of replications using `reps(#)` instead of specifying `vce(bootstrap)`, which defaults to 50 replications. Be aware that the number of replications needed to produce good estimates of the standard errors varies depending on the problem.

`reps(#)` specifies the number of bootstrap replications to be performed. Specifying this option is equivalent to specifying `vce(bootstrap, reps(#))`.

`seed(#)` sets the random-number seed. You must specify `reps(#)` with `seed(#)`.

`nose` suppresses calculation of the VCE and standard errors.

Reporting

`ctype(ctype)` specifies the type of confidence interval to be computed. By default, bootstrap percentile confidence intervals are reported as recommended by [Cattaneo and Jansson \(2018\)](#). *ctype* may be one of `percentile`, `bc`, or `normal`.

## Remarks and examples

For examples of margins after `npregress series`, see [example 3](#) and [example 4](#) in [R] [npregress series](#).

For an example of `marginsplot`, see [example 4](#) in [R] [npregress series](#).

## Methods and formulas

The formulas used by `predict` and `margins` for the conditional mean function and the mean marginal effect of a covariate are given in [Methods and formulas](#) of [R] [npregress series](#).

## Description

`nptrend` performs four different nonparametric tests for trend: the Cochran–Armitage test, the Jonckheere–Terpstra test, the linear-by-linear trend test, and a test using ranks developed by Cuzick.

## Quick start

Cochran–Armitage test for the association of a binary outcome in `y` and the ordered values of the categories of `x`

```
nptrend y, group(x) carmitage
```

Same as above, but report an exact  $p$ -value calculated using Monte Carlo permutations

```
nptrend y, group(x) carmitage exact
```

Same as above, but perform 100,000 Monte Carlo permutations rather than the default of 10,000, and set the random-number seed for reproducibility

```
nptrend y, group(x) carmitage exact(montecarlo, reps(100000) ///
rseed(1234))
```

Rather than testing the trend in `y` by the values of `x`, which are 1, 2, 3, test the trend by 1, 2, 4

```
nptrend y, group(x) carmitage scoregroup(1 2 4)
```

Jonckheere–Terpstra test for trend in `y` across ordered categories of `catvar`

```
nptrend y, group(catvar) jterpstra
```

Same as above, but perform the linear-by-linear trend test

```
nptrend y, group(catvar) linear
```

Same as above, but perform Cuzick’s test using ranks

```
nptrend y, group(catvar) cuzick
```

## Menu

Statistics > Nonparametric analysis > Tests of hypotheses > Trend test across ordered groups

## Syntax

```
nptrend varname [if] [in] [weight], group(groupvar) testopt [options]
```

| <i>options</i>                          | Description                                                          |

| <u>c</u> uzick                          | use ranks for the response scores in the test due to Cuzick          |

\* group(*groupvar*) and one of the choices for *testopt* are required.

collect is allowed; see [U] 11.1.10 Prefix commands.

fweights are allowed, except when exact is specified; see [U] 11.1.6 weight.

## Options

### Main

group(*groupvar*) defines the ordered groups across which differences in the response *varname* are to be tested. group() is required.

When option scoregroup() is not specified, the values of *groupvar* are the group scores. When scoregroup() is specified, *groupvar* defines the ordered categories, and the scores are the values specified in scoregroup(). When scoregroup() is specified, *groupvar* must be a positive integer (with gaps allowed).

*testopt* specifies the test that is reported. It is required and must be one of carmitage, jterpstra, linear, or cuzick.

carmitage specifies that the Cochran–Armitage test for trend be reported. Typically, the response *varname* is a 0/1 variable, and the values of *groupvar* represent a set of ordered categories. It gives a test of the trend of the proportions of positive responses in the groups, with the hypothesized trend given by the values of *groupvar* (or the values of scoregroup() if specified). If the response *varname* is not 0/1, it can be valued 1/2 and mapped to 0/1 or 1/0 using scoreresponse(0 1) or scoreresponse(1 0), respectively.

Response and group specifications for carmitage can be flipped. The *groupvar* variable can be a 0/1 predictor, and the response *varname* can contain ordered outcomes. If *groupvar* is not 0/1, it can be valued 1/2 and mapped to 0/1 or 1/0 using scoregroup(0 1) or scoregroup(1 0), respectively.

`jterpstra` specifies that the Jonckheere–Terpstra test for trend be reported. The response *varname* contains outcomes, which can be ordered categories or continuous values, and the *groupvar* variable is an ordered group indicator that is believed to be a predictor of outcome. The Jonckheere–Terpstra statistic is dependent on which is the response variable and which is the group variable. If response and group variables are interchanged, the value of the statistic will be different.

Only the orderings given by the response *varname* and *groupvar* are used to calculate the Jonckheere–Terpstra statistic. Different numerical values that give the same orderings produce the same statistic. Hence, this statistic is used when a test for trend dependent only on order is desired. Typically, the options `scorerresponse()` and `scoregroup()` are not specified. However, either or both of these options can be used to change the orderings given by *varname* and *groupvar*.

`linear` specifies that the linear-by-linear test for trend be reported. The linear-by-linear statistic is symmetric in the response variable *varname* and the group indicator *groupvar*. Interchanging response and group variables produces the same result. Despite the name “linear”, nonlinear trends can be tested. The trend, linear or nonlinear, is based on the numerical values of the response and group variables. `scorerresponse()` and `scoregroup()` can be specified to test different trends.

`cuzick` specifies that ranks be used for the responses and that the test for trend across ordered groups developed by [Cuzick \(1985\)](#) be reported. Because ranks are used, only the ordering given by response variable *varname* matters. The numerical values of *groupvar* are used in calculation, and different values, even those that give the same ordering, will result in different values of the statistic for Cuzick’s test. `scorerresponse()` can be specified to change the ordering of the responses. `scoregroup()` can be specified to test different trends by group.

`scorerresponse(numlist)` specifies scores for the responses in *varname*. When specified, *varname* must contain only positive integers (with gaps allowed), and the response score for *varname* = *i* is the *i*th number in *numlist*. When `scorerresponse()` is not specified, the response scores are the values of the response *varname*.

`scoregroup(numlist)` specifies scores for the groups specified by *groupvar*. When specified, *groupvar* must contain only positive integers (with gaps allowed), and the group score for *groupvar* = *i* is the *i*th number in *numlist*. When `scoregroup()` is not specified, the group scores are the values of *groupvar*.

`exact` and `exact(exact_specs)` specify that an exact *p*-value be reported.

`exact` specifies that an exact *p*-value from a Monte Carlo permutation test be reported. `exact` is a synonym for `exact(montecarlo)`.

`exact(montecarlo | enumerate[ , options ])` specifies that an exact *p*-value be reported in addition to the approximate or asymptotic *p*-value. Specifying `exact(montecarlo)` does a Monte Carlo permutation test. Specifying `exact(enumerate)` does an enumeration of all possible permutations. Because the number of all possible permutations is typically extremely large, enumeration is feasible only for very small datasets. The number of permutations will be displayed, and you can click on *Break* to stop the computation. The exact *p*-value is computed by `permute`.

`exact(montecarlo[ , options ])` allows *options* `show`, `reps(#)`, `rseed(#)`, `saving(filename[ , sav_options ])`, `level(#)`, `dots(#)`, `nodots`, and `eps(#)`. The `show` option specifies that the table produced by `permute` also be displayed. By default, 10,000 Monte Carlo permutations are done. That is, the default is the same as specifying `exact(montecarlo, reps(10000))`. The default for `dots()` is `dots(100)` when `reps()` is  $\geq 10,000$ ; otherwise, it is `dots(1)`. See [Options](#) in [\[R\] permute](#).

`exact(enumerate[, options])` allows *options* `show`, `saving(filename[, sav_options])`, `dots(#)`, `nodots`, and `eps(#)`. The `show` option specifies that the table produced by `permute` also be displayed. The default for `dots()` is `dots(100)`. See [Options](#) in [\[R\] permute](#).

`noLabel` causes numerical values of *groupvar* to be displayed in the table of mean response scores rather than value labels.

`notable` suppresses the display of the table of mean response scores by group.

## Remarks and examples

Remarks are presented under the following headings:

[Introduction](#)  
[Cochran–Armitage test](#)  
[Jonckheere–Terpstra test](#)  
[Linear-by-linear trend test](#)  
[Cuzick’s test](#)

## Introduction

`nptrend` performs four different nonparametric tests for trend: the Cochran–Armitage test, the Jonckheere–Terpstra test, the linear-by-linear trend test, and a test using ranks developed by Cuzick.

Data for these tests consist of two variables. The first variable, specified immediately after `nptrend`, contains responses. The second variable, specified in `group()`, identifies groups.

For the Cochran–Armitage test, the response is typically a 0/1 variable, and the values of the group variable are ordered categories. It tests the trend of the proportions of positive responses in the groups. The numerical values of the hypothesized trend are called “scores”. For this form of the test, we call the scores that specify the hypothesized trend “group scores” because it is the trend by group being tested. For example, group scores of 1, 2, 3 would test for a linear trend. Group scores of 1, 4, 9 would test for a quadratic trend.

The specification of the Cochran–Armitage test can be flipped. That is, the response variable can identify ordered outcome categories, and the group variable can be 0/1. In this case, we call the scores that specify the hypothesized trend “response scores”.

The Cochran–Armitage test requires either a 0/1 response variable or a 0/1 group variable. It cannot test responses with more than two levels when there are more than two groups.

The Jonckheere–Terpstra test is typically used when there are more than two groups and more than two response levels. The test assesses whether there is an association between the response scores and the group scores, but only the relative orders of the responses and groups matter. Because there is no need to specify a hypothesized trend, this test is in this sense “more nonparametric” than the other tests for trend reported by `nptrend`.

The linear-by-linear trend test uses response scores to specify the trend being tested. So it is typically used when the trend of the response scores, rather than just their ordering, is meaningful. The linear-by-linear statistic is asymptotically equivalent to the Pearson correlation coefficient (see [\[R\] correlate](#)).

The statistics for the Cochran–Armitage test (when the response is 0/1), the linear-by-linear trend test, and Cuzick’s test are based on the numerical values of the group scores. The linear-by-linear test requires numerical response scores as well. Different scores, even those that have the same ordering, produce different values of the statistic. For instance, group scores 1, 2, 3 would give a different result than 1, 2, 4. For the linear-by-linear test, the same holds for response scores.

The options `scorerresponse()` and `scoregroup()` are provided as convenience tools to test different response scores and group scores without having to modify the underlying variables. They do, however, require that the underlying variables be valued 1, 2, 3, ...

If your data are not grouped, you can test for trend with the `signtest` and `spearman` commands; see [R] [signrank](#) and [R] [spearman](#). With `signtest`, you can perform the Cox and Stuart test, a sign test applied to differences between equally spaced observations of `varname`. With `spearman`, you can perform the Daniels test, a test of zero Spearman correlation between `varname` and a time index. See [Conover \(1999, 169–175, 323\)](#) for a discussion of these tests.

## Cochran–Armitage test

The Cochran–Armitage test tests the trend in ordered groups of the probability of a positive response. As we stated earlier, response and group specifications can be flipped, and it can assess whether a trend based on ordered responses is associated with membership in one of two groups. In the discussion that follows we will consider only the former case: ordered groups with 0/1 responses.

The Cochran–Armitage test is based on a linear probability model for  $\theta_i$ , the probability of a positive response for subjects in the  $i$ th group,

$$\theta_i = \alpha + \beta(g_i - \bar{g})$$

where  $\alpha$  is the intercept,  $\beta$  is the slope,  $g_i$  are the group scores, and  $\bar{g}$  is the mean of the group scores.

The estimate for  $\beta$  is the ordinary least-squares (OLS) estimate  $\hat{\beta}$ , and this is the statistic for the Cochran–Armitage test.

However, the standard error of the statistic  $\hat{\beta}$  for the Cochran–Armitage test has a different formulation than that of the standard error from OLS regression—although they are the same asymptotically. The standard error  $\text{se}(\hat{\beta})$  for the Cochran–Armitage statistic is based on decomposing the Pearson statistic for independence.

The Pearson statistic  $X_{\text{Ind}}^2$  for independence can be written as

$$X_{\text{Ind}}^2 = z^2 + X_{\text{DL}}^2$$

where  $z = \hat{\beta}/\text{se}(\hat{\beta})$  is the  $z$  score for the Cochran–Armitage test and  $X_{\text{DL}}^2$  is a statistic for departure from the linear trend. Asymptotically,  $z$  has a standard normal distribution, and  $X_{\text{DL}}^2$  has a  $\chi^2$  distribution with  $I - 2$  degrees of freedom, where  $I$  is the number of ordered categories. See [Cochran–Armitage test for trend](#) in *Methods and formulas* below.

This is one of the advantages of performing the Cochran–Armitage test. We get not only a test for trend but also a test for departure from this trend. Let’s be clear about what we mean when we say “departure from this trend”. The Pearson statistic for independence is decomposed into two pieces. Either piece being large means that the test for independence is rejected. The linear piece  $z^2$  being large means there is a linear trend that rejects independence. The departure piece  $X_{\text{DL}}^2$  being large means there are differences other than the linear trend that reject independence.

We should also be clear about what we mean when we say “linear trend”. Linear trend means whatever trend is given by the group scores  $g_i$ , which do not have to be 1, 2, 3, ... They could be, for instance, 1, 3, 10, 12, ... It is linear in the scores but not necessarily linear by the ordering of the groups.

When the exact option is specified, a  $p$ -value from the permutation test of the null hypothesis  $\beta = 0$  is reported.

► Example 1

We have fictional data from a clinical trial of a new drug for treating migraines. The variable `dose` contains the dose of the drug given to a subject. The variable `relief` is 0/1 with 0 indicating no relief of the migraine and 1 indicating partial or total relief. Here is a tabulation of the data:

```
. use https://www.stata-press.com/data/r19/migraine
(Fictional migraine drug data)
. tabulate dose relief, row nokey
```

| Mycureit<br>dose in mg | Relief of migraine<br>after 2 hours |              | Total         |
|------------------------|-------------------------------------|--------------|---------------|
|                        | 0                                   | 1            |               |
| 10                     | 80<br>40.00                         | 120<br>60.00 | 200<br>100.00 |
| 20                     | 92<br>46.00                         | 108<br>54.00 | 200<br>100.00 |
| 30                     | 83<br>41.50                         | 117<br>58.50 | 200<br>100.00 |
| 40                     | 63<br>31.50                         | 137<br>68.50 | 200<br>100.00 |
| Total                  | 318<br>39.75                        | 482<br>60.25 | 800<br>100.00 |

There appears to be a trend of more subjects reporting relief at the higher doses. Let's calculate the Cochran–Armitage test for trend:

```
. nptrend relief, group(dose) carmitage
Cochran–Armitage test for trend
Number of observations = 800
Number of groups = 4
Number of response levels = 2
```

| Group | Group score | Mean<br>response<br>score | Number<br>of obs |
|-------|-------------|---------------------------|------------------|
| dose  |             |                           |                  |
| 10    | 10          | .6                        | 200              |
| 20    | 20          | .54                       | 200              |
| 30    | 30          | .585                      | 200              |
| 40    | 40          | .685                      | 200              |

```
Statistic = .003
Std. err. = .0015476
z = 1.939
Prob > |z| = 0.0526
Test of departure from trend:
chi2(2) = 5.45
Prob > chi2 = 0.0656
```

The asymptotic  $p$ -value for the test of a linear trend is 0.0526. The  $p$ -value for the test of departure from linearity is 0.0656.

The  $p$ -value for the test of a linear trend is close to 0.05. Rather than report the asymptotic  $p$ -value, we may want to report an exact  $p$ -value. We run `nptrend` again, this time specifying the exact option.

```
. nptrend relief, group(dose) carmitage exact
Permutations (10,000):1,000.....2,000.....3,000.....4,000
>5,000.....6,000.....7,000.....8,000.....9,000.....
> ..10,000 done
```

Cochran-Armitage test for trend

```
Number of observations = 800
Number of groups = 4
Number of response levels = 2
```

| Group | Group score | Mean response score | Number of obs |
|-------|-------------|---------------------|---------------|
| dose  |             |                     |               |
| 10    | 10          | .6                  | 200           |
| 20    | 20          | .54                 | 200           |
| 30    | 30          | .585                | 200           |
| 40    | 40          | .685                | 200           |

```
Statistic = .003
Std. err. = .0015476
z = 1.939
Prob > |z| = 0.0526
Exact prob = 0.0576 (10,000 Monte Carlo permutations)
```

Test of departure from trend:

```
chi2(2) = 5.45
Prob > chi2 = 0.0656
```

The exact  $p$ -value reported is 0.0576, larger than the asymptotic  $p$ -value of 0.0526. The exact  $p$ -value comes from a permutation test performed by computing 10,000 random permutations. This means that there is some random error associated with the reported exact  $p$ -value.

To see the Monte Carlo error in the exact  $p$ -value, we can use the `show` suboption of `exact`, which displays the full output of `permute`. The option we specify is

```
exact(montecarlo, show reps(100000) dots(1000) rseed(1234))
```

We increase the number of random permutations to 100,000. `dots(1000)` displays a dot after every 1,000th permutation rather than the default of every 100th. `rseed(1234)` sets the random-number seed so we can reproduce our result. We did not set the random-number seed when we ran `nptrend ... exact` earlier. If we were to run that again, we would get a different value for the exact  $p$ -value. Here are the results with `exact()` specified this new way:

```
. nptrend relief, group(dose) carmitage
> exact(montecarlo, show reps(100000) dots(1000) rseed(1234))
Permutations (100,000):10,000.....20,000.....30,000.....4
> 0,000.....50,000.....60,000.....70,000.....80,000.....90,
> 000.....100,000 done
Monte Carlo permutation results Number of observations = 800
Permutation variable: relief Number of permutations = 100,000
```

| T     | T(obs) | Test      | c     | n      | p     | Monte Carlo error |             |       |
|-------|--------|-----------|-------|--------|-------|-------------------|-------------|-------|
|       |        |           |       |        |       | SE(p)             | [95% CI(p)] |       |
| _pm_1 | .003   | lower     | 97435 | 100000 | .9744 | .0005             | .9734       | .9753 |
|       |        | upper     | 2959  | 100000 | .0296 | .0005             | .0285       | .0307 |
|       |        | two-sided |       |        | .0592 | .0007             | .0577       | .0606 |

Notes: For lower one-sided test,  $c = \#\{T \leq T(\text{obs})\}$  and  $p = p_{\text{lower}} = c/n$ .  
 For upper one-sided test,  $c = \#\{T \geq T(\text{obs})\}$  and  $p = p_{\text{upper}} = c/n$ .  
 For two-sided test,  $p = 2 \cdot \min(p_{\text{lower}}, p_{\text{upper}})$ ; SE and CI approximate.

Cochran-Armitage test for trend

```
Number of observations = 800
Number of groups = 4
Number of response levels = 2
```

| Group | Group score | Mean response score | Number of obs |
|-------|-------------|---------------------|---------------|
| dose  |             |                     |               |
| 10    | 10          | .6                  | 200           |
| 20    | 20          | .54                 | 200           |
| 30    | 30          | .585                | 200           |
| 40    | 40          | .685                | 200           |

```
Statistic = .003
Std. err. = .0015476
z = 1.939
Prob > |z| = 0.0526
Exact prob = 0.0592 (100,000 Monte Carlo permutations)
```

Test of departure from trend:

```
chi2(2) = 5.45
Prob > chi2 = 0.0656
```

The reported exact  $p$ -value from this specification is 0.0592, and we see from the table reported by `permut` that the Monte Carlo 95% confidence interval for it is [0.0577, 0.0606]. Clearly, the asymptotic  $p$ -value 0.0526 is a bit anticonservative. If we were going to publish the result, we might want to run the command again with even more permutations, perhaps 1,000,000 or more, to narrow the width of the confidence level to less than 0.001. With only 800 observations in these data, the Monte Carlo permutations are computed quickly.

## ▷ Example 2

We continue with the [previous example](#) to illustrate the use of the `scoregroup()` option. When we tested the linear trend of dose, we got a  $p$ -value of 0.0656 for the departure from linearity. So maybe the trend is not linear. Let's test a quadratic trend.

To use the `scoregroup()` option, the variable in `group()` must be 1, 2, ... The variable dose is 10, 20, 30, 40. We can convert it to 1, 2, 3, 4 in several ways. Here we use the `egen group()` function because this works in general.

```
. egen idose = group(dose)
. tabulate idose
```

| group(dose) | Freq. | Percent | Cum.   |
|-------------|-------|---------|--------|
| 1           | 200   | 25.00   | 25.00  |
| 2           | 200   | 25.00   | 50.00  |
| 3           | 200   | 25.00   | 75.00  |
| 4           | 200   | 25.00   | 100.00 |
| Total       | 800   | 100.00  |        |

Now, we specify `scoregroup(1 4 9 16)` to test a quadratic trend.

```
. nptrend relief, group(idose) carmitage scoregroup(1 4 9 16)
Cochran-Armitage test for trend
 Number of observations = 800
 Number of groups = 4
Number of response levels = 2
```

| Group | Group score | Mean<br>response<br>score | Number<br>of obs |
|-------|-------------|---------------------------|------------------|
| idose |             |                           |                  |
| 1     | 1           | .6                        | 200              |
| 2     | 4           | .54                       | 200              |
| 3     | 9           | .585                      | 200              |
| 4     | 16          | .685                      | 200              |

```
Statistic = .0070543
Std. err. = .0030468
 z = 2.315
Prob > |z| = 0.0206
```

```
Test of departure from trend:
 chi2(2) = 3.85
Prob > chi2 = 0.1462
```

Of course, we could have just typed `generate dose2 = dose^2` and used this variable for `group()` to test the quadratic trend.

The  $p$ -value for the quadratic trend is 0.0206, and the departure  $p$ -value is 0.1462. The  $p$ -value for the linear trend was 0.0526. So it appears the relationship between dose and relief is closer to quadratic than linear. But should we be using `nptrend` to search for the trend with the smallest  $p$ -value? Surely, `logit` is the tool for that!

```

. generate dose2 = dose^2
. logit relief dose dose2
Iteration 0: Log likelihood = -537.58798
Iteration 1: Log likelihood = -532.96973
Iteration 2: Log likelihood = -532.96346
Iteration 3: Log likelihood = -532.96346

Logistic regression Number of obs = 800
LR chi2(2) = 9.25
Prob > chi2 = 0.0098
Pseudo R2 = 0.0086

Log likelihood = -532.96346

```

| relief | Coefficient | Std. err. | z     | P> z  | [95% conf. interval] |           |
|--------|-------------|-----------|-------|-------|----------------------|-----------|
| dose   | -.0720094   | .0367396  | -1.96 | 0.050 | -.1440177            | -1.19e-06 |
| dose2  | .0017005    | .0007276  | 2.34  | 0.019 | .0002744             | .0031266  |
| _cons  | .946503     | .4021702  | 2.35  | 0.019 | .1582638             | 1.734742  |

To be clear, we are not recommending a model such as this for these data. There are only four doses, and this logit model fits three of the four degrees of freedom. The purpose of the Cochran–Armitage test is to test a single hypothesized trend and report an honest  $p$ -value for it. If we want to test for a trend but do not have any idea what the trend might be, we may be better off using the Jonckheere–Terpstra test.

◀

## Jonckheere–Terpstra test

The Jonckheere–Terpstra test is useful when it is not clear what the trend might be and we simply want to test for any trend. That is, it tests whether the ordering of the groups is associated with the ordering of the responses. The test is typically used when there are many response levels and any number of groups.

Suppose there are  $J \geq 2$  ordered groups. Let  $y_{jk}$  be the  $k$ th response in the  $j$ th group, where  $k = 1, 2, \dots, n_j$ . The responses  $y_{jk}$  are given by *varname* (the variable specified immediately after `nptrend`) or by *varname* mapped to the values of `scoreresponse()`.

For groups  $j$  and  $j'$ , where  $j < j'$ , consider the  $n_j n_{j'}$  pairs

$$(y_{jk}, y_{j'k'})$$

Let  $C_{jj'}$  be the number of pairs such that  $y_{jk} < y_{j'k'}$  and  $D_{jj'}$  be the number of pairs such that  $y_{jk} > y_{j'k'}$ . The Jonckheere–Terpstra statistic is

$$T = \sum_{j < j'} (C_{jj'} - D_{jj'})$$

In other words, count the number of response pairs,  $C_{jj'}$ , where the group  $j$  response is less than the group  $j'$  response. That is, pairs in which the ordering of the responses is concordant with the ordering of the groups. Subtract from this the number of discordant pairs,  $D_{jj'}$ . Then, sum over the  $J(J-1)/2$  combinations of selecting two of the  $J$  groups, where group  $j$  is ordered before group  $j'$ .

Clearly, only the ordering of responses matters relative to the ordering of the groups. There is no need to hypothesize what the trend is.

Kendall's  $\tau$  (see [R] [spearman](#)) also uses only relative differences, and the Jonckheere–Terpstra test can be viewed as a generalization of Kendall's  $\tau$  for groups of unequal sizes. See [Jonckheere–Terpstra test for trend](#) in *Methods and formulas* below.

► Example 3

The following data (Altman 1991, 217) show ocular exposure to ultraviolet radiation for 32 pairs of sunglasses classified into 3 groups according to the amount of visible light transmitted.

| Group | Transmission of visible light | Ocular exposure to ultraviolet radiation    |
|-------|-------------------------------|---------------------------------------------|
| 1     | < 25%                         | 1.4 1.4 1.4 1.6 2.3 2.5                     |

Entering these data into Stata, we have

```
. use https://www.stata-press.com/data/r19/sg, clear
(Ultraviolet radiation exposure with sunglasses)
. list, separator(6)
```

|                         | group      | exposure |
|-------------------------|------------|----------|
| 1.                      | < 25%      | 1.4      |
| 2.                      | < 25%      | 1.4      |
| 3.                      | < 25%      | 1.4      |
| 4.                      | < 25%      | 1.6      |
| 5.                      | < 25%      | 2.3      |
| 6.                      | < 25%      | 2.5      |
| 7.                      | 25% to 35% | .9       |
| 8.                      | 25% to 35% | 1        |
| <i>(output omitted)</i> |            |          |
| 31.                     | > 35%      | 8.9      |
| 32.                     | > 35%      | 13.5     |

We can now use np trend to report the Jonckheere–Terpstra test results.

```
. np trend exposure, group(group) jterpstra
Jonckheere–Terpstra test for trend
Number of observations = 32
Number of groups = 3
Number of response levels = 23
```

| Group       | Group score | Mean response score | Number of obs |
|-------------|-------------|---------------------|---------------|
| group < 25% | 1           | 1.766667            | 6             |
| 25% to 35%  | 2           | 2.311111            | 18            |
| > 35%       | 3           | 4.85                | 8             |

```
Statistic = 82
Std. err. = 54.80056
z = 1.496
Prob > |z| = 0.1346
```

The approximate  $p$ -value is 0.1346. This  $p$ -value is an approximation to the permutation test  $p$ -value. That is, it comes from a  $z$  statistic that uses the exact variance of the permutation distribution. With only 32 observations, it seems better to simply compute the exact  $p$ -value using Monte Carlo permutations.

```
. set seed 1234
. nptrend exposure, group(group) jterpstra exact
Permutations (10,000):1,000.....2,000.....3,000.....4,000
>5,000.....6,000.....7,000.....8,000.....9,000.....
> ..10,000 done
Jonckheere-Terpstra test for trend
 Number of observations = 32
 Number of groups = 3
Number of response levels = 23
```

| Group       | Group score | Mean response score | Number of obs |
|-------------|-------------|---------------------|---------------|
| group < 25% | 1           | 1.766667            | 6             |
| 25% to 35%  | 2           | 2.311111            | 18            |
| > 35%       | 3           | 4.85                | 8             |

```
Statistic = 82
Std. err. = 54.80056
 z = 1.496
Prob > |z| = 0.1346
Exact prob = 0.1378 (10,000 Monte Carlo permutations)
```

Despite the small number of observations, the Monte Carlo exact  $p$ -value 0.1378 is close to the approximate  $p$ -value 0.1346. Because of the small number of observations, we might be tempted to try the `exact(enumerate)` option. We do so.

```
. nptrend exposure, group(group) jterpstra exact(enumerate, dots(1000))
(enumerating all 1.42e+12 possible permutations)
Permutations (1,415,721,106,800):10,000.....—Break—
r(1);
```

`nptrend` calls `permute` to do the enumeration, and `permute` tells us there are  $1.42 \times 10^{12}$  possible permutations. Because we do not want to wait years for the result, we pressed `Break`.

Let's randomly cut the dataset in half, from 32 observations to 16.

```
. set seed 25
. generate r = runiform()
. sort r
. keep in 1/16
(16 observations deleted)
. tabulate group
```

| Transmission of visible light | Freq. | Percent | Cum.   |
|-------------------------------|-------|---------|--------|
| < 25%                         | 2     | 12.50   | 12.50  |
| 25% to 35%                    | 9     | 56.25   | 68.75  |
| > 35%                         | 5     | 31.25   | 100.00 |
| Total                         | 16    | 100.00  |        |

Then, let's do the enumeration for these data:

```
. nptrend exposure, group(group) jterpstra exact(enumerate, dots(1000))
(enumerating all 240,240 possible permutations)
Permutations (240,240):10,000.....20,000.....30,000.....4
> 0,000.....50,000.....60,000.....70,000.....80,000.....90,
> 000.....100,000.....110,000.....120,000.....130,000.....1
> 40,000.....150,000.....160,000.....170,000.....180,000.....
> ..190,000.....200,000.....210,000.....220,000.....230,000....
>240,000. done
```

```
Jonckheere–Terpstra test for trend
Number of observations = 16
Number of groups = 3
Number of response levels = 15
```

| Group       | Group score | Mean response score | Number of obs |
|-------------|-------------|---------------------|---------------|
| group < 25% | 1           | 1.5                 | 2             |
| 25% to 35%  | 2           | 2.377778            | 9             |
| > 35%       | 3           | 6.92                | 5             |

```
Statistic = 49
Std. err. = 19.57188
z = 2.504
Prob > |z| = 0.0123
Exact prob = 0.0103 (enumerated all 240,240 permutations)
```

There are only 240,240 possible permutations now, and the computation takes little time. Despite there being only 16 observations, the exact *p*-value (without any error) 0.0103 is close to the approximate *p*-value 0.0123. Enumeration works quite well for tiny datasets such as this.

### Linear-by-linear trend test

The linear-by-linear trend test is an alternative to the Jonckheere–Terpstra test. The difference is that the linear-by-linear trend test uses response scores to specify the trend being tested. How the trend is hypothesized to vary across groups is specified by the group scores. The linear-by-linear trend test could be described as a parametric specification for trend that is tested nonparametrically!

If scores are not specified in the options, then the values of the response *varname* are used as response scores, and the values of *groupvar* are used as group scores.

The linear-by-linear statistic is

$$T = \frac{1}{N} \sum_{i=1}^I \sum_{j=1}^J n_{ij} (g_j - \bar{g})(r_i - \bar{r})$$

where  $N$  is the total number of observations,  $g_j$  is the group score for the  $j$ th group,  $\bar{g}$  is the mean group score over all observations,  $r_i$  is the response score for the  $i$ th ordered response, and  $\bar{r}$  is the mean response score over all observations.

The linear-by-linear statistic is equivalent to the Pearson correlation coefficient (see [R] [correlate](#)), the difference being that the Pearson correlation coefficient is standardized by the standard deviations of the scores. The  $p$ -values are slightly different because the  $p$ -value for the linear-by-linear test is based on its permutation distribution while the  $p$ -value for the Pearson correlation coefficient assumes normality.

Clearly, the statistic depends on the numerical values of both the response scores and the group scores. Different scores, even ones that give the same ordering, will produce different values of the statistic.

#### ▷ Example 4

We again use the sunglasses data from [example 3](#), where we did the Jonckheere–Terpstra test.

```
. use https://www.stata-press.com/data/r19/sg, clear
(Ultraviolet radiation exposure with sunglasses)
```

We calculate the linear-by-linear trend test for these data.

```
. nptrend exposure, group(group) linear
```

```
Linear-by-linear test for trend
```

```
Number of observations = 32
Number of groups = 3
Number of response levels = 23
```

| Group       | Group score | Mean response score | Number of obs |
|-------------|-------------|---------------------|---------------|
| group < 25% | 1           | 1.766667            | 6             |
| 25% to 35%  | 2           | 2.311111            | 18            |
| > 35%       | 3           | 4.85                | 8             |

```
Statistic = .7035156
Std. err. = .3063377
z = 2.297
Prob > |z| = 0.0216
```

The approximate  $p$ -value is 0.0216, which is much smaller than the Jonckheere–Terpstra test approximate  $p$ -value 0.1346. Such a difference is not surprising. The linear-by-linear trend test uses the actual values of the response in the statistic. The values of the response seem to follow a linear trend by group, and when this is true, one generally expects the  $p$ -value from the linear-by-linear trend test to be smaller than the  $p$ -value from the Jonckheere–Terpstra test.

Again, we might want to compute the exact  $p$ -value using Monte Carlo permutations.

```
. nptrend exposure, group(group) linear
> exact(montecarlo, reps(100000) dots(1000) rseed(1234))
Permutations (100,000):10,000.....20,000.....30,000.....4
> 0,000.....50,000.....60,000.....70,000.....80,000.....90,
> 000.....100,000 done
Linear-by-linear test for trend
 Number of observations = 32
 Number of groups = 3
Number of response levels = 23
```

| Group       | Group score | Mean response score | Number of obs |
|-------------|-------------|---------------------|---------------|
| group < 25% | 1           | 1.766667            | 6             |
| 25% to 35%  | 2           | 2.311111            | 18            |
| > 35%       | 3           | 4.85                | 8             |

```
Statistic = .7035156
Std. err. = .3063377
z = 2.297
Prob > |z| = 0.0216
Exact prob = 0.0146 (100,000 Monte Carlo permutations)
```

In this case, the exact  $p$ -value 0.0146 is smaller than the approximate  $p$ -value 0.0216.

◀

## Cuzick's test

Cuzick's test (Cuzick 1985) is an extension of the Kruskal–Wallis test (see [R] [kwallis](#)) for ordered groups. The response scores are ranked, the sum of the ranks is calculated for each group, and then these sums of ranks are weighted by the deviation of the group scores from their mean.

The statistic for Cuzick's test is

$$T = \frac{1}{N} \sum_{j=1}^J (g_j - \bar{g}) R_j$$

where  $N$  is the total number of observations,  $g_j$  is the group score for the  $j$ th group,  $\bar{g}$  is the mean group score over all observations, and  $R_j$  is the sum of the ranks of the response scores in the  $j$ th group.

The form of the statistic is similar to that of the statistic for the linear-by-linear test, but instead of using response scores being used directly, the ranks of the response scores are used. So only the ordering of the response scores matters. The numerical values of the group scores, however, are used in the calculation, so different group scores will give different values of the statistic.

## ▶ Example 5

We continue with the sunglasses data from [example 4](#). We now calculate Cuzick's test, calculating the exact  $p$ -value as well.

```
. nptrend exposure, group(group) cuzick
> exact(montecarlo, reps(10000) dots(1000) rseed(1234))
Permutations (100,000):10,000.....20,000.....30,000.....4
> 0,000.....50,000.....60,000.....70,000.....80,000.....90,
> 000.....100,000 done
```

Cuzick's test with rank scores

```
Number of observations = 32
Number of groups = 3
Number of response levels = 23
```

| Group          | Group score | Mean<br>response<br>score | Number<br>of obs |
|----------------|-------------|---------------------------|------------------|
| group<br>< 25% | 1           | 1.766667                  | 6                |
| 25% to 35%     | 2           | 2.311111                  | 18               |
| > 35%          | 3           | 4.85                      | 8                |

```
Statistic = 1.65625
Std. err. = 1.090461
z = 1.519
Prob > |z| = 0.1288
Exact prob = 0.1322 (100,000 Monte Carlo permutations)
```

The approximate  $p$ -value 0.1288 is close to the exact  $p$ -value 0.1322. These results are also close to the results from the Jonckheere–Terpstra test, where the approximate  $p$ -value was 0.1346. This is not surprising because using ranks of the responses in Cuzick's test is likely to be similar to the comparisons of orderings in the Jonckheere–Terpstra test. The latter test is better known than Cuzick's test, so for this reason alone, it may be preferable to use the Jonckheere–Terpstra test when reporting results.

◀

## Stored results

nptrend stores the following in `r()`:

### Scalars

```
r(N) number of observations
r(n_groups) number of groups
r(n_rsp_levels) number of response levels
r(beta) slope from Cochran–Armitage linear probability model
r(T) statistic
r(se) standard error of the statistic
r(z) z statistic
r(p) two-sided p -value from z statistic
r(p_l) lower one-sided p -value from z statistic
r(p_u) upper one-sided p -value from z statistic
r(chi2_depart) χ^2 for departure from Cochran–Armitage linear probability model
r(df_depart) degrees of freedom for departure χ^2
r(p_depart) p -value for departure χ^2
r(p_exact) two-sided exact p -value
r(p_l_exact) lower one-sided exact p -value
```

|                           |                                                       |

| <code>r(exact)</code>     | "montecarlo" or "enumerate"                           |
| <code>r(rngstate)</code>  | random-number state used for Monte Carlo permutations |
| Matrices                  |                                                       |
| <code>r(table)</code>     | table of mean response scores by group                |

If `exact(..., show)` is specified, the stored results from `permute` are returned as well; see [Stored results](#) in [\[R\] permute](#).

## Methods and formulas

Methods and formulas are presented under the following headings:

[Overview](#)  
[Cochran–Armitage test for trend](#)  
[Jonckheere–Terpstra test for trend](#)  
[Linear-by-linear test for trend](#)  
[Cuzick’s test with rank scores](#)

## Overview

We will use the same notation for all the tests. Let the set of distinct responses be indexed by  $i = 1, 2, \dots, I$ . Let the groups be indexed by  $j = 1, 2, \dots, J$ .

We call the scores for the responses “response scores” and denote them by  $r_i$ .

For the Cochran–Armitage test (when the response is 0/1), linear-by-linear trend test, and Cuzick’s test the groups have scores as well. We call these scores “group scores”, and denote them by  $g_j$ .

All the tests for trend reported by `nptrend` are based on tests of independence between the ordering of the responses (or their scores) and the ordering of the groups (or their scores). Because these are tests of independence, there is no need to hypothesize a direction of causal inference. Responses could be outcomes predicted by group membership, or “groups” could be outcomes predicted by what we are calling “responses”.

Let  $n_{ij}$  be the number of observations in the  $i$ th response category and  $j$ th group. Let  $N = \sum_{ij} n_{ij}$  be the total number of observations. Let  $n_{i+} = \sum_j n_{ij}$  be the row margins, and let  $n_{+j} = \sum_i n_{ij}$  be the column margins.

## Cochran–Armitage test for trend

When `carmitage` is specified, the Cochran–Armitage test is performed ([Cochran 1954](#); [Armitage 1955](#); [Agresti 2013](#)). It assesses whether the probability of a positive response is associated with a trend based on ordered groups. Or the specification can be flipped. It can be used to assess whether a trend based on ordered responses is associated with membership in one of two groups.

In these methods, we assume that the response is 0/1—that is, the response is indexed by  $i = 0, 1$ —and that there are  $J$  ordered groups with scores  $g_j$ . When the specification is flipped, response and group are interchanged in the equations below.

The Cochran–Armitage test is based on a linear probability model for  $\theta_j$ , the probability of having response  $i = 1$  for the subjects in the  $j$ th group,

$$\theta_j = \alpha + \beta(g_j - \bar{g})$$

where  $\alpha$  is the intercept,  $\beta$  is the slope,  $g_j$  are the group scores, and  $\bar{g}$  is the mean of the group scores.

The equation is solved using OLS,

$$\hat{\theta}_j = p + \hat{\beta}(g_j - \bar{g})$$

where  $p = (\sum_j n_{1j})/N$  and  $\bar{g} = (\sum_j n_{+j}g_j)/N$ .

The OLS solution for  $\hat{\beta}$  is

$$\hat{\beta} = \frac{\sum_j n_{+j}(p_j - p)(g_j - \bar{g})}{\sum_j n_{+j}(g_j - \bar{g})^2}$$

where  $p_j = n_{1j}/n_{+j}$ .

The test for independence between groups and responses can be separated into a test for the linear trend and a test for departure from the linear trend. The Pearson statistic for independence

$$X_{\text{Ind}}^2 = \frac{1}{p(1-p)} \sum_{j=1}^J n_{+j}(p_j - p)^2$$

is decomposed as

$$X_{\text{Ind}}^2 = z^2 + X_{\text{DL}}^2$$

where

$$z^2 = \frac{\hat{\beta}^2}{p(1-p)} \sum_{j=1}^J n_{+j}(g_j - \bar{g})^2$$

and

$$X_{\text{DL}}^2 = \frac{1}{p(1-p)} \sum_{j=1}^J n_{+j}(p_j - \hat{\theta}_j)^2$$

$z$  is the  $z$  statistic for the linear trend, and  $X_{\text{DL}}^2$  is the statistic for departure from a linear trend. Asymptotically,  $z$  has a standard normal distribution, and  $X_{\text{DL}}^2$  has a  $\chi^2$  distribution with  $J - 2$  degrees of freedom.

## Jonckheere–Terpstra test for trend

When `jterpstra` is specified, the Jonckheere–Terpstra test is performed (Terpstra 1952; Jonckheere 1954). The Jonckheere–Terpstra test is a test of whether the hypothesized ordering of the responses is associated with the hypothesized ordering of the groups. Typically, this test is used when there are only a few groups but many response categories or even continuous responses.

Only the ordering of the responses and groups matter. The numerical values of the scores do not matter, but scores can be specified to change the ordering.

Let  $y_{jk}$  be the  $k$ th response in the  $j$ th group, where  $k = 1, 2, \dots, n_{+j}$ . If the response falls in the  $i$ th response category, then  $y_{jk} = r_i$ , the response score for the  $i$ th category.

For groups  $j$  and  $j'$ , where  $j < j'$ , consider the pairs

$$(y_{jk}, y_{j'k'})$$

where  $k = 1, 2, \dots, n_{+j}$  and  $k' = 1, 2, \dots, n_{+j'}$ . A total of  $n_{+j}n_{+j'}$  pairs are formed for these two groups.

Let  $C_{jj'}$  be the number of pairs such that  $y_{jk} < y_{j'k'}$ , that is, pairs in which the response ordering is concordant with the group ordering. Let  $D_{jj'}$  be the number of discordant pairs with  $y_{jk} > y_{j'k'}$ . The Jonckheere–Terpstra statistic is

$$T = \sum_{j=1}^{J-1} \sum_{j'=j+1}^J (C_{jj'} - D_{jj'})$$

The Jonckheere–Terpstra statistic is sometimes expressed as sums over  $C_{jj'} + E_{jj'}/2$ , where  $E_{jj'}$  is the number of tied pairs with  $y_{jk} = y_{j'k'}$ . Because  $C_{jj'} + D_{jj'} + E_{jj'} = n_{+j}n_{+j'}$ , the statistic  $T$  is twice the statistic based on  $C_{jj'} + E_{jj'}/2$  minus a constant. The advantage of the formulation using  $C_{jj'} - D_{jj'}$  is that under the null hypothesis of independence between groups and responses, its expectation is zero. When  $T$  is positive, the observed trend is a positive trend between the group ordering and the response ordering, and when  $T$  is negative, it is a negative trend.

The variance of  $T$  can be computed exactly based on the permutation distribution of responses where the table margins  $n_{i+}$  and  $n_{+j}$  are fixed and each permutation is considered equally likely under the null hypothesis. The formula, however, is complicated when there are ties.

Let  $M$  be the number of distinct values in the responses. Let  $e_m$  be the multiplicity of the  $m$ th distinct response value. That is, the  $N$  observations  $y_{jk}$  consist of  $e_1$  observations with value  $z_1$ ,  $e_2$  observations with value  $z_2$ , etc., with  $\sum_m e_m = N$ . The variance of  $T$  under the null permutation distribution is exactly

$$\begin{aligned} \text{Var}(T) = & \frac{1}{18} \left[ N(N-1)(2N+5) - \sum_{j=1}^J n_{+j}(n_{+j}-1)(2n_{+j}+5) \right. \\ & \left. - \sum_{m=1}^M e_m(e_m-1)(2e_m+5) \right] \\ & + \frac{1}{2N(N-1)} \left\{ \sum_{j=1}^J n_{+j}(n_{+j}-1) \right\} \left\{ \sum_{m=1}^M e_m(e_m-1) \right\} \\ & + \frac{1}{9N(N-1)(N-2)} \left\{ \sum_{j=1}^J n_{+j}(n_{+j}-1)(n_{+j}-2) \right\} \\ & \quad \times \left\{ \sum_{m=1}^M e_m(e_m-1)(e_m-2) \right\} \end{aligned}$$

The approximate  $p$ -value is based on a normal approximation using the exact variance of  $T$ .

## Linear-by-linear test for trend

When `linear` is specified, the linear-by-linear trend test is calculated based on the statistic

$$T = \frac{1}{N} \sum_{i=1}^I \sum_{j=1}^J n_{ij} (g_j - \bar{g}) (r_i - \bar{r})$$

where  $g_j$  is the group score for the  $j$ th group,  $\bar{g} = (\sum_j n_{+j} g_j) / N$  is the mean group score over all observations,  $r_i$  is the response score for the  $i$ th ordered response, and  $\bar{r} = (\sum_i n_{i+} r_i) / N$  is the mean response score over all observations.

Under the null hypothesis of independence between groups and responses, the expectation of  $T$  is zero. The variance of  $T$  is based on the permutation distribution of responses where the table margins  $n_{i+}$  and  $n_{+j}$  are fixed and each permutation is considered equally likely under the null hypothesis. The variance of  $T$  is exactly

$$\text{Var}(T) = \frac{1}{N^2(N-1)} \left\{ \sum_{j=1}^J n_{+j} (g_j - \bar{g})^2 \right\} \left\{ \sum_{i=1}^I n_{i+} (r_i - \bar{r})^2 \right\}$$

The approximate  $p$ -value is based on a normal approximation using the exact variance of  $T$ .

Note the symmetry between the group and response scores in these equations. In the linear-by-linear test for trend, it is arbitrary as to what is a group with a group score and what is a response with a response score. The two are interchangeable.

## Cuzick's test with rank scores

When `cuzick` is specified, the test for trend is based on a method in [Cuzick \(1985\)](#), which is described in [Altman \(1991, 215–217\)](#).

Rank all  $N$  responses, using average ranks for ties. Let  $R_j$  be the sum of the ranks in the  $j$ th group. The statistic for Cuzick's test  $T$  is

$$T = \frac{1}{N} \sum_{j=1}^J (g_j - \bar{g}) R_j$$

where  $g_j$  is the group score for the  $j$ th group and  $\bar{g} = (\sum_j n_{+j} g_j) / N$ .

Under the null hypothesis of independence between groups and responses, the expectation of  $T$  is zero. When there are no ties, the variance of  $T$  is

$$\text{Var}(T) = \frac{N+1}{12N} \sum_{j=1}^J n_{+j} (g_j - \bar{g})^2$$

When there are ties, we again let  $e_m$  be the multiplicity of the  $m$ th distinct response value,  $m = 1, 2, \dots, M$ . Define

$$a = \frac{1}{N(N^2-1)} \sum_{m=1}^M e_m (e_m^2 - 1)$$

The corrected variance of  $T$  when there are ties is

$$\widetilde{\text{Var}}(T) = (1-a) \text{Var}(T)$$

## Exact p-values

Exact  $p$ -values are computed by `permut.e`. The variable permuted is that specified by `group()`, except for `carmitage` when the response variable is 0/1; in this case, the response variable is permuted. For details on the permutation computation, see [R] [permut.e](#).

## Acknowledgments

The original version of `nptrend` was written by K. A. Stepniewska, Worldwide Antimalarial Resistance Network, University of Oxford, UK, and D. G. Altman (1948–2018).

## Description

`ologit` fits ordered logit models of ordinal variable *depvar* on the independent variables *indepvars*. The actual values taken on by the dependent variable are irrelevant, except that larger values are assumed to correspond to “higher” outcomes.

## Quick start

Ordinal logit model of *y* on *x1* and categorical variables *a* and *b*

```
ologit y x1 i.a i.b
```

Same as above, and include interaction between *a* and *b* and report results as odds ratios

```
ologit y x1 a##b, or
```

With bootstrap standard errors

```
ologit y x1 i.a i.b, vce(bootstrap)
```

Analysis restricted to cases where `catvar = 0` using `svyset` data with replicate weights

```
svy bootstrap, subpop(if catvar==0): ologit y x1 i.a i.b
```

## Menu

Statistics > Ordinal outcomes > Ordered logistic regression

## Syntax

```
ologit depvar [indepvars] [if] [in] [weight] [, options]
```

*indepvars* may contain factor variables; see [U] 11.4.3 **Factor variables**.

*depvar* and *indepvars* may contain time-series operators; see [U] 11.4.4 **Time-series varlists**.

`bayes`, `bayesboot`, `bootstrap`, `by`, `fmm`, `fp`, `jackknife`, `mfp`, `mi estimate`, `nestreg`, `rolling`, `statsby`, `stepwise`, and `svy` are allowed; see [U] 11.1.10 **Prefix commands**. For more details, see [BAYES] **bayes: ologit** and [FMM] **fmm: ologit**.

`vce(bootstrap)` and `vce(jackknife)` are not allowed with the `mi estimate` prefix; see [MI] **mi estimate**.

Weights are not allowed with the `bootstrap` prefix; see [R] **bootstrap**.

`vce()` and weights are not allowed with the `svy` prefix; see [SVY] **svy**.

`fweights`, `iwweights`, and `pweights` are allowed; see [U] 11.1.6 **weight**.

`collinear` and `coeflegend` do not appear in the dialog box.

See [U] 20 **Estimation and postestimation commands** for more capabilities of estimation commands.

## Options

### Model

`offset(varname)`, `constraints(constraints)`; see [R] **Estimation options**.

### SE/Robust

`vce(vcetype)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory (`oim`, `opg`), that are robust to some kinds of misspecification (`robust`), that allow for intragroup correlation (`cluster clustvar`), and that use bootstrap or jackknife methods (`bootstrap`, `jackknife`); see [R] **vce\_option**.

## Reporting

`level(#)`; see [R] [Estimation options](#).

or reports the estimated coefficients transformed to odds ratios, that is,  $e^b$  rather than  $b$ . Standard errors and confidence intervals are similarly transformed. This option affects how results are displayed, not how they are estimated. or may be specified at estimation or when replaying previously estimated results.

`nocnsreport`; see [R] [Estimation options](#).

`display_options`: `nocl`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `nolstretch`; see [R] [Estimation options](#).

## Maximization

`maximize_options`: `difficult`, `technique(algorithm_spec)`, `iterate(#)`, `[no]log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `ltolerance(#)`, `nrtolerance(#)`, `nonrtolerance`, and `from(init_specs)`; see [R] [Maximize](#). These options are seldom used.

The following options are available with `ologit` but are not shown in the dialog box:

`collinear`, `coeflegend`; see [R] [Estimation options](#).

## Remarks and examples

Ordered logit models are used to estimate relationships between an ordinal dependent variable and a set of independent variables. An *ordinal* variable is a variable that is categorical and ordered, for instance, “poor”, “good”, and “excellent”, which might indicate a person’s current health status or the repair record of a car. If there are only two outcomes, see [R] [logistic](#), [R] [logit](#), and [R] [probit](#). This entry is concerned only with more than two outcomes. If the outcomes cannot be ordered (for example, residency in the north, east, south, or west), see [R] [mlogit](#). This entry is concerned only with models in which the outcomes can be ordered.

In ordered logit, an underlying score is estimated as a linear function of the independent variables and a set of cutpoints. The probability of observing outcome  $i$  corresponds to the probability that the estimated linear function, plus random error, is within the range of the cutpoints estimated for the outcome:

$$\Pr(\text{outcome}_j = i) = \Pr(\kappa_{i-1} < \beta_1 x_{1j} + \beta_2 x_{2j} + \cdots + \beta_k x_{kj} + u_j \leq \kappa_i)$$

$u_j$  is assumed to be logistically distributed in ordered logit. In either case, we estimate the coefficients  $\beta_1, \beta_2, \dots, \beta_k$  together with the cutpoints  $\kappa_1, \kappa_2, \dots, \kappa_{k-1}$ , where  $k$  is the number of possible outcomes.  $\kappa_0$  is taken as  $-\infty$ , and  $\kappa_k$  is taken as  $+\infty$ . All of this is a direct generalization of the ordinary two-outcome logit model.

► Example 1

We wish to analyze the 1977 repair records of 66 foreign and domestic cars. The data are a variation of the automobile dataset described in [U] 1.2.2 Example datasets. The 1977 repair records, like those in 1978, take on values “Poor”, “Fair”, “Average”, “Good”, and “Excellent”. Here is a cross-tabulation of the data:

```
. use https://www.stata-press.com/data/r19/fullauto
(Automobile models)
. tabulate rep77 foreign, chi2
```

| Repair record<br>1977 | Foreign  |         | Total |
|-----------------------|----------|---------|-------|
|                       | Domestic | Foreign |       |
| Poor                  | 2        | 1       | 3     |
| Fair                  | 10       | 1       | 11    |
| Average               | 20       | 7       | 27    |
| Good                  | 13       | 7       | 20    |
| Excellent             | 0        | 5       | 5     |
| Total                 | 45       | 21      | 66    |

Pearson chi2(4) = 13.8619 Pr = 0.008

Although it appears that foreign takes on the values Domestic and Foreign, it is actually a numeric variable taking on the values 0 and 1. Similarly, rep77 takes on the values 1, 2, 3, 4, and 5, corresponding to Poor, Fair, and so on. The more meaningful words appear because we have attached value labels to the data; see [U] 12.6.3 Value labels.

Because the  $\chi^2$  value is significant, we could claim that there is a relationship between foreign and rep77. Literally, however, we can only claim that the distributions are different; the  $\chi^2$  test is not directional. One way to model these data is to model the categorization that took place when the data were created. Cars have a true frequency of repair, which we will assume is given by  $S_j = \beta \text{foreign}_j + u_j$ , and a car is categorized as “poor” if  $S_j \leq \kappa_0$ , as “fair” if  $\kappa_0 < S_j \leq \kappa_1$ , and so on:

```
. ologit rep77 foreign
Iteration 0: Log likelihood = -89.895098
Iteration 1: Log likelihood = -85.951765
Iteration 2: Log likelihood = -85.908227
Iteration 3: Log likelihood = -85.908161
Iteration 4: Log likelihood = -85.908161
Ordered logistic regression
Log likelihood = -85.908161
Number of obs = 66
LR chi2(1) = 7.97
Prob > chi2 = 0.0047
Pseudo R2 = 0.0444
```

| rep77   | Coefficient | Std. err. | z    | P> z  | [95% conf. interval] |           |
|---------|-------------|-----------|------|-------|----------------------|-----------|
| foreign | 1.455878    | .5308951  | 2.74 | 0.006 | .4153425             | 2.496413  |
| /cut1   | -2.765562   | .5988208  |      |       | -3.939229            | -1.591895 |
| /cut2   | -.9963603   | .3217706  |      |       | -1.627019            | -.3657016 |
| /cut3   | .9426153    | .3136398  |      |       | .3278925             | 1.557338  |
| /cut4   | 3.123351    | .5423257  |      |       | 2.060412             | 4.18629   |

Our model is  $S_j = 1.46 \text{foreign}_j + u_j$ ; the expected value for foreign cars is 1.46 and, for domestic cars, 0; foreign cars have better repair records.

The estimated cutpoints tell us how to interpret the score. For a foreign car, the probability of a poor record is the probability that  $1.46 + u_j \leq -2.77$ , or equivalently,  $u_j \leq -4.23$ . Making this calculation requires familiarity with the logistic distribution: the probability is  $1/(1 + e^{4.23}) = 0.014$ . On the other hand, for domestic cars, the probability of a poor record is the probability  $u_j \leq -2.77$ , which is 0.059.

This, it seems to us, is a far more reasonable prediction than we would have made based on the table alone. The table showed that 2 of 45 domestic cars had poor records, whereas 1 of 21 foreign cars had poor records—corresponding to probabilities  $2/45 = 0.044$  and  $1/21 = 0.048$ . The predictions from our model imposed a smoothness assumption—foreign cars should not, overall, have better repair records without the difference revealing itself in each category. In our data, the fractions of foreign and domestic cars in the poor category are virtually identical only because of the randomness associated with small samples.

Thus if we were asked to predict the true fractions of foreign and domestic cars that would be classified in the various categories, we would choose the numbers implied by the ordered logit model:

|           | tabulate |         | logit    |         |
|-----------|----------|---------|----------|---------|
|           | Domestic | Foreign | Domestic | Foreign |
| Poor      | 0.044    | 0.048   | 0.059    | 0.014   |
| Fair      | 0.222    | 0.048   | 0.210    | 0.065   |
| Average   | 0.444    | 0.333   | 0.450    | 0.295   |
| Good      | 0.289    | 0.333   | 0.238    | 0.467   |
| Excellent | 0.000    | 0.238   | 0.043    | 0.159   |

See [R] [ologit postestimation](#) for a more complete explanation of how to generate predictions from an ordered logit model.

### □ Technical note

Here ordered logit provides an alternative to ordinary two-outcome logistic models with an arbitrary dichotomization, which might otherwise have been tempting. We could, for instance, have summarized these data by converting the five-outcome `rep77` variable to a two-outcome variable, combining cars in the average, fair, and poor categories to make one outcome and combining cars in the good and excellent categories to make the second.

Another even less appealing alternative would have been to use ordinary regression, arbitrarily labeling “excellent” as 5, “good” as 4, and so on. The problem is that with different but equally valid labelings (say, 10 for “excellent”), we would obtain different estimates. We would have no way of choosing one metric over another. That assertion is not, however, true of `ologit`. The actual values used to label the categories make no difference other than through the order they imply.

In fact, our labeling was 5 for “excellent”, 4 for “good”, and so on. The words “excellent” and “good” appear in our output because we attached a value label to the variables; see [U] [12.6.3 Value labels](#). If we were to now go back and type `replace rep77=10 if rep77==5`, changing all the 5s to 10s, we would still obtain the same results when we refit our model.

## ▷ Example 2

In the [example](#) above, we used ordered logit as a way to model a table. We are not, however, limited to including only one explanatory variable or to including only categorical variables. We can explore the relationship of `rep77` with any of the variables in our data. We might, for instance, model `rep77` not only in terms of the origin of manufacture, but also including `length` (a proxy for size) and `mpg`:

```
. ologit rep77 foreign length mpg
Iteration 0: Log likelihood = -89.895098
Iteration 1: Log likelihood = -78.775147
Iteration 2: Log likelihood = -78.254294
Iteration 3: Log likelihood = -78.250719
Iteration 4: Log likelihood = -78.250719

Ordered logistic regression Number of obs = 66
LR chi2(3) = 23.29
Prob > chi2 = 0.0000
Pseudo R2 = 0.1295

Log likelihood = -78.250719
```

| rep77   | Coefficient | Std. err. | z    | P> z  | [95% conf. interval] |          |
|---------|-------------|-----------|------|-------|----------------------|----------|
| foreign | 2.896807    | .7906411  | 3.66 | 0.000 | 1.347179             | 4.446435 |
| length  | .0828275    | .02272    | 3.65 | 0.000 | .0382972             | .1273579 |
| mpg     | .2307677    | .0704548  | 3.28 | 0.001 | .0926788             | .3688566 |
| /cut1   | 17.92748    | 5.551191  |      |       | 7.047344             | 28.80761 |
| /cut2   | 19.86506    | 5.59648   |      |       | 8.896161             | 30.83396 |
| /cut3   | 22.10331    | 5.708936  |      |       | 10.914               | 33.29262 |
| /cut4   | 24.69213    | 5.890754  |      |       | 13.14647             | 36.2378  |

`foreign` still plays a role—and an even larger role than previously. We find that larger cars tend to have better repair records, as do cars with better mileage ratings.

## Stored results

`ologit` stores the following in `e()`:

### Scalars

|                            |                                              |
|----------------------------|----------------------------------------------|

## Matrices

|                              |                                              |
|------------------------------|----------------------------------------------|
| <code>e(b)</code>            | coefficient vector                           |
| <code>e(Cns)</code>          | constraints matrix                           |
| <code>e(ilog)</code>         | iteration log (up to 20 iterations)          |
| <code>e(gradient)</code>     | gradient vector                              |
| <code>e(cat)</code>          | category values                              |
| <code>e(V)</code>            | variance–covariance matrix of the estimators |
| <code>e(V_modelbased)</code> | model-based variance                         |

## Functions

|                        |                         |
|------------------------|-------------------------|
| <code>e(sample)</code> | marks estimation sample |
|------------------------|-------------------------|

In addition to the above, the following is stored in `r()`:

## Matrices

|                       |                                                                                                                            |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------|
| <code>r(table)</code> | matrix containing the coefficients with their standard errors, test statistics, <i>p</i> -values, and confidence intervals |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------|

Note that results stored in `r()` are updated when the command is replayed and will be replaced when any *r*-class command is run after the estimation command.

## Methods and formulas

See [Long and Freese \(2014, chap. 7\)](#) for a discussion of models for ordinal outcomes and examples that use Stata. [Cameron and Trivedi \(2005, chap. 15\)](#) describe multinomial models, including the model fit by `ologit`. When you have a qualitative dependent variable, several estimation procedures are available. A popular choice is multinomial logistic regression (see [\[R\] `mlogit`](#)), but if you use this procedure when the response variable is ordinal, you are discarding information because multinomial logit ignores the ordered aspect of the outcome. Ordered logit and probit models provide a means to exploit the ordering information.

There is more than one “ordered logit” model. The model fit by `ologit`, which we will call the ordered logit model, is also known as the proportional odds model. Another popular choice, not fit by `ologit`, is known as the stereotype model; see [\[R\] `slogit`](#). All ordered logit models have been derived by starting with a binary logit/probit model and generalizing it to allow for more than two outcomes.

The proportional-odds ordered logit model is so called because, if we consider the odds  $\text{odds}(k) = P(Y \leq k)/P(Y > k)$ , then  $\text{odds}(k_1)$  and  $\text{odds}(k_2)$  have the same ratio for all independent variable combinations. The model is based on the principle that the only effect of combining adjoining categories in ordered categorical regression problems should be a loss of efficiency in estimating the regression parameters (McCullagh 1980). This model was also described by McKelvey and Zavoina (1975) and, previously, by Aitchison and Silvey (1957) in a different algebraic form. Brant (1990) offers a set of diagnostics for the model.

Peterson and Harrell (1990) suggest a model that allows nonproportional odds for a subset of the explanatory variables. `ologit` does not allow this, but a model similar to this was implemented by Fu (1998).

The stereotype model rejects the principle on which the ordered logit model is based. Anderson (1984) argues that there are two distinct types of ordered categorical variables: “grouped continuous”, such as income, where the “type a” model applies; and “assessed”, such as extent of pain relief, where the stereotype model applies. Greenland (1985) independently developed the same model. The stereotype model starts with a multinomial logistic regression model and imposes constraints on this model.

Goodness of fit for `ologit` can be evaluated by comparing the likelihood value with that obtained by fitting the model with `mlogit`. Let  $\ln L_1$  be the log-likelihood value reported by `ologit`, and let  $\ln L_0$  be the log-likelihood value reported by `mlogit`. If there are  $p$  independent variables (excluding the constant) and  $k$  categories, `mlogit` will estimate  $p(k - 1)$  additional parameters. We can then perform a “likelihood-ratio test”, that is, calculate  $-2(\ln L_1 - \ln L_0)$ , and compare it with  $\chi^2\{p(k - 2)\}$ . This test is suggestive only because the ordered logit model is not nested within the multinomial logit model. A large value of  $-2(\ln L_1 - \ln L_0)$  should, however, be taken as evidence of poorness of fit. Marginally large values, on the other hand, should not be taken too seriously.

The coefficients and cutpoints are estimated using maximum likelihood as described in [R] **Maximize**. In our parameterization, no constant appears, because the effect is absorbed into the cutpoints.

`ologit` and `oprobit` begin by tabulating the dependent variable. Category  $i = 1$  is defined as the minimum value of the variable,  $i = 2$  as the next ordered value, and so on, for the empirically determined  $k$  categories.

The probability of a given observation for ordered logit is

$$\begin{aligned}
 p_{ij} &= \Pr(y_j = i) = \Pr(\kappa_{i-1} < \mathbf{x}_j\boldsymbol{\beta} + u \leq \kappa_i) \\
 &= \frac{1}{1 + \exp(-\kappa_i + \mathbf{x}_j\boldsymbol{\beta})} - \frac{1}{1 + \exp(-\kappa_{i-1} + \mathbf{x}_j\boldsymbol{\beta})}
 \end{aligned}$$

$\kappa_0$  is defined as  $-\infty$  and  $\kappa_k$  as  $+\infty$ .

For ordered probit, the probability of a given observation is

$$\begin{aligned}
 p_{ij} &= \Pr(y_j = i) = \Pr(\kappa_{i-1} < \mathbf{x}_j\boldsymbol{\beta} + u \leq \kappa_i) \\
 &= \Phi(\kappa_i - \mathbf{x}_j\boldsymbol{\beta}) - \Phi(\kappa_{i-1} - \mathbf{x}_j\boldsymbol{\beta})
 \end{aligned}$$

where  $\Phi(\cdot)$  is the standard normal cumulative distribution function.

The log likelihood is

$$\ln L = \sum_{j=1}^N w_j \sum_{i=1}^k I_i(y_j) \ln p_{ij}$$

where  $w_j$  is an optional weight and

$$I_i(y_j) = \begin{cases} 1, & \text{if } y_j = i \\ 0, & \text{otherwise} \end{cases}$$

ologit and oprobit support the Huber/White/sandwich estimator of the variance and its clustered version using `vce(robust)` and `vce(cluster clustvar)`, respectively. See [P] `_robust`, particularly *Maximum likelihood estimators* and *Methods and formulas*.

These commands also support estimation with survey data. For details on VCEs with survey data, see [SVY] *Variance estimation*.

## Postestimation commands

The following postestimation commands are available after `ologit`:

| Command                      | Description                                                                                                                             |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <code>contrast</code>        | contrasts and ANOVA-style joint tests of parameters                                                                                     |
| <code>estat ic</code>        | Akaike's, consistent Akaike's, corrected Akaike's, and Schwarz's Bayesian information criteria (AIC, CAIC, AICc, and BIC, respectively) |
| <code>estat summarize</code> | summary statistics for the estimation sample                                                                                            |
| <code>estat vce</code>       | variance–covariance matrix of the estimators (VCE)                                                                                      |
| <code>estat (svy)</code>     | postestimation statistics for survey data                                                                                               |
| <code>estimates</code>       | cataloging estimation results                                                                                                           |
| <code>etable</code>          | table of estimation results                                                                                                             |
| * <code>forecast</code>      | dynamic forecasts and simulations                                                                                                       |
| * <code>hausman</code>       | Hausman's specification test                                                                                                            |
| <code>lincom</code>          | point estimates, standard errors, testing, and inference for linear combinations of parameters                                          |
| <code>linktest</code>        | link test for model specification                                                                                                       |
| * <code>lrtest</code>        | likelihood-ratio test                                                                                                                   |
| <code>margins</code>         | marginal means, predictive margins, marginal effects, and average marginal effects                                                      |
| <code>marginsplot</code>     | graph the results from margins (profile plots, interaction plots, etc.)                                                                 |
| <code>nlcom</code>           | point estimates, standard errors, testing, and inference for nonlinear combinations of parameters                                       |
| <code>predict</code>         | probabilities, linear predictions and their SEs, etc.                                                                                   |
| <code>predictnl</code>       | point estimates, standard errors, testing, and inference for generalized predictions                                                    |
| <code>pwcompare</code>       | pairwise comparisons of parameters                                                                                                      |
| <code>suest</code>           | seemingly unrelated estimation                                                                                                          |
| <code>test</code>            | Wald tests of simple and composite linear hypotheses                                                                                    |
| <code>testnl</code>          | Wald tests of nonlinear hypotheses                                                                                                      |

\* `forecast`, `hausman`, and `lrtest` are not appropriate with `svy` estimation results. `forecast` is also not appropriate with `mi` estimation results.

# predict

## Description for predict

`predict` creates a new variable containing predictions such as probabilities, linear predictions, and standard errors.

## Menu for predict

Statistics > Postestimation

## Syntax for predict

```
predict [type] { stub* | newvar | newvarlist } [if] [in] [, statistic
 outcome(outcome) nooffset]
```

```
predict [type] stub* [if] [in] , scores
```

| <i>statistic</i>  | Description                             |
|-------------------|-----------------------------------------|
| Main              |                                         |
| <code>pr</code>   | predicted probabilities; the default    |
| <code>xb</code>   | linear prediction                       |
| <code>stdp</code> | standard error of the linear prediction |

You specify one or  $k$  new variables with `pr`, where  $k$  is the number of outcomes. If you specify one new variable and you do not specify `outcome()`, then `outcome(#1)` is assumed.

You specify one new variable with `xb` and `stdp`.

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

## Options for predict

### Main

`pr`, the default, computes the predicted probabilities for all outcomes or for a specific outcome. To compute probabilities for all outcomes, you specify  $k$  new variables, where  $k$  is the number of categories of the dependent variable. Alternatively, you can specify `stub*`; in which case, `pr` will store predicted probabilities in variables `stub1`, `stub2`, ..., `stubk`. To compute the probability for a specific outcome, you specify one new variable and, optionally, the outcome value in option `outcome()`; if you omit `outcome()`, the first outcome value, `outcome(#1)`, is assumed.

Say that you fit a model by typing `estimation_cmd y x1 x2`, and `y` takes on four values. Then, you could type `predict p1 p2 p3 p4` to obtain all four predicted probabilities; alternatively, you could type `predict p*` to generate the four predicted probabilities. To compute specific probabilities one at a time, you can type `predict p1, outcome(#1)` (or simply `predict p1`), `predict p2, outcome(#2)`, and so on. See option `outcome()` for other ways to refer to outcome values.

`xb` calculates the linear prediction. You specify one new variable, for example, `predict linear, xb`. The linear prediction is defined, ignoring the contribution of the estimated cutpoints.

`stdp` calculates the standard error of the linear prediction. You specify one new variable, for example, `predict se, stdp`.

`outcome(outcome)` specifies for which outcome the predicted probabilities are to be calculated. `outcome()` should contain either one value of the dependent variable or one of #1, #2, ..., with #1 meaning the first category of the dependent variable, #2 meaning the second category, etc. `outcome()` is available only with the default `pr` option.

`nooffset` is relevant only if you specified `offset(varname)` for `ologit`. It modifies the calculations made by `predict` so that they ignore the offset variable; the linear prediction is treated as  $\mathbf{x}_j\mathbf{b}$  rather than as  $\mathbf{x}_j\mathbf{b} + \text{offset}_j$ . `nooffset` is not allowed with `scores`.

`scores` calculates equation-level score variables. The number of score variables created will equal the number of outcomes in the model. If the number of outcomes in the model was  $k$ , then

the first new variable will contain  $\partial \ln L / \partial (\mathbf{x}_j\mathbf{b})$ ;

the second new variable will contain  $\partial \ln L / \partial \kappa_1$ ;

the third new variable will contain  $\partial \ln L / \partial \kappa_2$ ;

...

and the  $k$ th new variable will contain  $\partial \ln L / \partial \kappa_{k-1}$ , where  $\kappa_i$  refers to the  $i$ th cutpoint.

## margins

### Description for margins

`margins` estimates margins of response for probabilities and linear predictions.

### Menu for margins

Statistics > Postestimation

### Syntax for margins

`margins [marginlist] [ , options ]`

`margins [marginlist] , predict(statistic ...) [predict(statistic ...) ...] [options]`

| <i>statistic</i>  | Description                           |
|-------------------|---------------------------------------|
| default           | probabilities for each outcome        |
| <code>pr</code>   | probability for a specified outcome   |
| <code>xb</code>   | linear prediction                     |
| <code>stdp</code> | not allowed with <code>margins</code> |

`pr` defaults to the first outcome.

Statistics not allowed with `margins` are functions of stochastic quantities other than `e(b)`.

For the full syntax, see [R] [margins](#).

## Remarks and examples

See [U] 20 Estimation and postestimation commands for instructions on obtaining the variance–covariance matrix of the estimators, predicted values, and hypothesis tests. Also see [R] lrtest for performing likelihood-ratio tests.

### ▷ Example 1

In example 2 of [R] ologit, we fit the model `ologit rep77 foreign length mpg`. The `predict` command can be used to obtain the predicted probabilities.

We type `predict` followed by the names of the new variables to hold the predicted probabilities, ordering the names from low to high. In our data, the lowest outcome is “poor”, and the highest is “excellent”. We have five categories, so we must type five names following `predict`; the choice of names is up to us:

```
. use https://www.stata-press.com/data/r19/fullauto
(Automobile models)
. ologit rep77 foreign length mpg
(output omitted)
. predict poor fair avg good exc
(option pr assumed; predicted probabilities)
. list exc good make model rep78 if rep77>=., sep(4) divider
```

|     | exc      | good     | make    | model   | rep78   |
|-----|----------|----------|---------|---------|---------|
| 3.  | .0033341 | .0393056 | AMC     | Spirit  | .       |
| 10. | .0098392 | .1070041 | Buick   | Opel    | .       |
| 32. | .0023406 | .0279497 | Ford    | Fiesta  | Good    |
| 44. | .015697  | .1594413 | Merc.   | Monarch | Average |
| 53. | .065272  | .4165188 | Peugeot | 604     | .       |
| 56. | .005187  | .059727  | Plym.   | Horizon | Average |
| 57. | .0261461 | .2371826 | Plym.   | Sapporo | .       |
| 63. | .0294961 | .2585825 | Pont.   | Phoenix | .       |

The eight cars listed were introduced after 1977, so they do not have 1977 repair records in our data. We predicted what their 1977 repair records might have been using the fitted model. We see that, based on its characteristics, the Peugeot 604 had about a  $41.65 + 6.53 \approx 48.2\%$  chance of a good or excellent repair record. The Ford Fiesta, which had only a 3% chance of a good or excellent repair record, in fact, had a good record when it was introduced in the following year.

□ Technical note

For ordered logit, `predict, xb` produces  $S_j = x_{1j}\beta_1 + x_{2j}\beta_2 + \dots + x_{kj}\beta_k$ . The ordered-logit predictions are then the probability that  $S_j + u_j$  lies between a pair of cutpoints,  $\kappa_{i-1}$  and  $\kappa_i$ . Some handy formulas are

$$\begin{aligned} \Pr(S_j + u_j < \kappa) &= 1/(1 + e^{S_j - \kappa}) \\ \Pr(S_j + u_j > \kappa) &= 1 - 1/(1 + e^{S_j - \kappa}) \\ \Pr(\kappa_1 < S_j + u_j < \kappa_2) &= 1/(1 + e^{S_j - \kappa_2}) - 1/(1 + e^{S_j - \kappa_1}) \end{aligned}$$

Rather than using `predict` directly, we could calculate the predicted probabilities by hand. If we wished to obtain the predicted probability that the repair record is excellent and the probability that it is good, we look back at `ologit`'s output to obtain the cutpoints. We find that “good” corresponds to the interval `/cut3 < S_j + u < /cut4` and “excellent” to the interval  $S_j + u > /cut4$ :

```
. predict score, xb
. generate probgood = 1/(1+exp(score-_b[/cut4])) - 1/(1+exp(score-_b[/cut3]))
. generate probexc = 1 - 1/(1+exp(score-_b[/cut4]))
```

The results of our calculation will be the same as those produced in the previous example. We refer to the estimated cutpoints just as we would any coefficient, so `_b[/cut3]` refers to the value of the `/cut3` coefficient; see [U] 13.5 Accessing coefficients and standard errors.

## Description

The `oneway` command reports one-way analysis-of-variance (ANOVA) models and performs multiple-comparison tests.

If you wish to fit more complicated ANOVA layouts or wish to fit analysis-of-covariance (ANCOVA) models, see [\[R\] anova](#).

See [\[D\] encode](#) for examples of fitting ANOVA models on string variables.

See [\[R\] loneway](#) for an alternative `oneway` command with slightly different features.

## Quick start

One-way ANOVA model of  $y$  for factor  $a$

```
oneway y a
```

Report the mean and std. dev. of  $y$  and number of observations for each level of  $a$

```
oneway y a, tabulate
```

Report all pairwise comparisons of the means of  $y$  across levels of  $a$  with  $p$ -values adjusted using Bonferroni's procedure

```
oneway y a, bonferroni
```

Same as above, but adjust  $p$ -values for multiple comparisons using Scheffé's method

```
oneway y a, scheffe
```

## Menu

Statistics > Linear models and related > ANOVA/MANOVA > One-way ANOVA

## Syntax

```
oneway response_var factor_var [if] [in] [weight] [, options]
```

| <code>wrap</code>         | do not break wide tables                                               |
| <code>missing</code>      | treat missing values as categories                                     |

`by` and `collect` are allowed; see [U] 11.1.10 Prefix commands.

`awweights` and `fweights` are allowed; see [U] 11.1.6 weight.

## Options

Main

`bonferroni` reports the results of a Bonferroni multiple-comparison test.

`scheffe` reports the results of a Scheffé multiple-comparison test.

`sidak` reports the results of a Šidák multiple-comparison test.

`tabulate` produces a table of summary statistics of the *response\_var* by levels of the *factor\_var*. The table includes the mean, standard deviation, frequency, and, if the data are weighted, the number of observations. Individual elements of the table may be included or suppressed by using the `[no]means`, `[no]standard`, `[no]freq`, and `[no]obs` options. For example, typing

```
oneway response factor, tabulate means standard
```

produces a summary table that contains only the means and standard deviations. You could achieve the same result by typing

```
oneway response factor, tabulate nofreq
```

`[no]means` includes or suppresses only the means from the table produced by the `tabulate` option. See `tabulate` above.

`[no]standard` includes or suppresses only the standard deviations from the table produced by the `tabulate` option. See `tabulate` above.

`[no]freq` includes or suppresses only the frequencies from the table produced by the `tabulate` option. See `tabulate` above.

[no]obs includes or suppresses only the reported number of observations from the table produced by the `tabulate` option. If the data are not weighted, only the frequency is reported. If the data are weighted, the frequency refers to the sum of the weights. See `tabulate` above.

`noanova` suppresses the display of the ANOVA table.

`no-label` causes the numeric codes to be displayed rather than the value labels in the ANOVA and multiple-comparison test tables.

`wrap` requests that Stata not break up wide tables to make them more readable.

`missing` requests that missing values of *factor\_var* be treated as a category rather than as observations to be omitted from the analysis.

## Remarks and examples

Remarks are presented under the following headings:

[Introduction](#)  
[Obtaining observed means](#)  
[Multiple-comparison tests](#)  
[Weighted data](#)  
[Video example](#)

### Introduction

The `oneway` command reports one-way ANOVA models. To perform a one-way layout of a variable called `endog` on `exog`, type `oneway endog exog`.

#### ▷ Example 1

We run an experiment varying the amount of fertilizer used in growing apple trees. We test four concentrations, using each concentration in three groves of 12 trees each. Later in the year, we measure the average weight of the fruit.

If all had gone well, we would have had 3 observations on the average weight for each of the four concentrations. Instead, two of the groves were mistakenly leveled by a confused man on a large bulldozer. We are left with the following dataset:

```
. use https://www.stata-press.com/data/r19/apple
(Apple trees)
. describe
Contains data from https://www.stata-press.com/data/r19/apple.dta
Observations: 10 Apple trees
Variables: 2 16 Jan 2024 11:23
```

| Variable name | Storage type | Display format | Value label | Variable label          |
|---------------|--------------|----------------|-------------|-------------------------|
| treatment     | int          | %8.0g          |             | Fertilizer              |
| weight        | double       | %10.0g         |             | Average weight in grams |

Sorted by:

```
. list, abbreviate(10)
```

|     | treatment | weight |
|-----|-----------|--------|
| 1.  | 1         | 117.5  |
| 2.  | 1         | 113.8  |
| 3.  | 1         | 104.4  |
| 4.  | 2         | 48.9   |
| 5.  | 2         | 50.4   |
| 6.  | 2         | 58.9   |
| 7.  | 3         | 70.4   |
| 8.  | 3         | 86.9   |
| 9.  | 4         | 87.7   |
| 10. | 4         | 67.3   |

To obtain the one-way ANOVA results, we type

```
. oneway weight treatment
```

| Source         | Analysis of variance |    |            | F     | Prob > F |

|                | SS                   | df | MS         |       |          |
| Between groups | 5295.54433           | 3  | 1765.18144 | 21.46 | 0.0013   |
| Within groups  | 493.591667           | 6  | 82.2652778 |       |          |
| Total          | 5789.136             | 9  | 643.237333 |       |          |

Bartlett's equal-variances test:  $\chi^2(3) = 1.3900$      $\text{Prob} > \chi^2 = 0.708$

We find significant (at better than the 1% level) differences among the four concentrations.

### □ Technical note

Rather than using the oneway command, we could have performed this analysis by using anova. [Example 1](#) in [\[R\] anova](#) repeats this same analysis. You may wish to compare the output.

You will find the oneway command quicker than the anova command, and, as you will learn, oneway allows you to perform multiple-comparison tests. On the other hand, anova will let you generate predictions, examine the covariance matrix of the estimators, and perform more general hypothesis tests.

### □ Technical note

Although the output is a usual ANOVA table, let's run through it anyway. The between-group sum of squares for the model is 5295.5 with 3 degrees of freedom, resulting in a mean square of  $5295.5/3 \approx 1765.2$ . The corresponding  $F$  statistic is 21.46 and has a significance level of 0.0013. Thus, the model appears to be significant at the 0.13% level.

The second line summarizes the within-group (residual) variation. The within-group sum of squares is 493.59 with 6 degrees of freedom, resulting in a mean squared error of 82.27.

The between- and residual-group variations sum to the total sum of squares (TSS), which is reported as 5789.1 in the last line of the table. This is the TSS of `weight` after removal of the mean. Similarly, the between plus residual degrees of freedom sum to the total degrees of freedom, 9. Remember that there are 10 observations. Subtracting 1 for the mean, we are left with 9 total degrees of freedom.

At the bottom of the table, Bartlett's test for equal variances is reported. The value of the statistic is 1.39. The corresponding significance level ( $\chi^2$  with 3 degrees of freedom) is 0.708, so we cannot reject the assumption that the variances are homogeneous.

## Obtaining observed means

### ► Example 2

We typed oneway weight treatment to obtain an ANOVA table of weight of fruit by fertilizer concentration. Although we obtained the table, we obtained no information on which fertilizer seems to work the best. If we add the tabulate option, we obtain that additional information:

```
. oneway weight treatment, tabulate
```

| Fertilizer | Summary of Average weight in grams |           |       |
|------------|------------------------------------|-----------|-------|
|            | Mean                               | Std. dev. | Freq. |
| 1          | 111.9                              | 6.7535176 | 3     |
| 2          | 52.733333                          | 5.3928966 | 3     |
| 3          | 78.65                              | 11.667262 | 2     |
| 4          | 77.5                               | 14.424978 | 2     |
| Total      | 80.62                              | 25.362124 | 10    |

| Source         | Analysis of variance |    |            | F     | Prob > F |
|----------------|----------------------|----|------------|-------|----------|
|                | SS                   | df | MS         |       |          |
| Between groups | 5295.54433           | 3  | 1765.18144 | 21.46 | 0.0013   |
| Within groups  | 493.591667           | 6  | 82.2652778 |       |          |
| Total          | 5789.136             | 9  | 643.237333 |       |          |

```
Bartlett's equal-variances test: chi2(3) = 1.3900 Prob>chi2 = 0.708
```

We find that the average weight was largest when we used fertilizer concentration 1.

## Multiple-comparison tests

### ▷ Example 3: Bonferroni multiple-comparison test

oneway can also perform multiple-comparison tests using either Bonferroni, Scheffé, or Šidák normalizations. For instance, to obtain the Bonferroni multiple-comparison test, we specify the `bonferroni` option:

```
. oneway weight treatment, bonferroni
```

| Source         | Analysis of variance |    |            | F     | Prob > F |
|----------------|----------------------|----|------------|-------|----------|
|                | SS                   | df | MS         |       |          |
| Between groups | 5295.54433           | 3  | 1765.18144 | 21.46 | 0.0013   |
| Within groups  | 493.591667           | 6  | 82.2652778 |       |          |
| Total          | 5789.136             | 9  | 643.237333 |       |          |

```
Bartlett's equal-variances test: chi2(3) = 1.3900 Prob>chi2 = 0.708
```

Comparison of Average weight in grams by Fertilizer  
(Bonferroni)

| Row Mean-<br>Col Mean | 1                 | 2                | 3              |
|-----------------------|-------------------|------------------|----------------|
| 2                     | -59.1667<br>0.001 |                  |                |
| 3                     | -33.25<br>0.042   | 25.9167<br>0.122 |                |
| 4                     | -34.4<br>0.036    | 24.7667<br>0.146 | -1.15<br>1.000 |

The results of the Bonferroni test are presented as a matrix. The first entry,  $-59.17$ , represents the difference between fertilizer concentrations 2 and 1 (labeled “Row Mean - Col Mean” in the upper stub of the table). Remember that in the [previous example](#) we requested the `tabulate` option. Looking back, we find that the means of concentrations 1 and 2 are 111.90 and 52.73, respectively. Thus,  $52.73 - 111.90 = -59.17$ .

Underneath that number is reported “0.001”. This is the Bonferroni-adjusted significance of the difference. The difference is significant at the 0.1% level. Looking down the column, we see that concentration 3 is also worse than concentration 1 (4.2% level), as is concentration 4 (3.6% level).

On the basis of this evidence, we would use concentration 1 if we grew apple trees.

### ▷ Example 4: Scheffé multiple-comparison test

We can just as easily obtain the Scheffé-adjusted significance levels. Rather than specifying the `bonferroni` option, we specify the `scheffe` option.

We will also add the `noanova` option to prevent Stata from redisplaying the ANOVA table:

```
. oneway weight treatment, noanova scheffe
 Comparison of Average weight in grams by Fertilizer
 (Scheffe)
```

| Row Mean-<br>Col Mean | 1                 | 2                | 3              |
|-----------------------|-------------------|------------------|----------------|
| 2                     | -59.1667<br>0.001 |                  |                |
| 3                     | -33.25<br>0.039   | 25.9167<br>0.101 |                |
| 4                     | -34.4<br>0.034    | 24.7667<br>0.118 | -1.15<br>0.999 |

The differences are the same as those we obtained in the Bonferroni output, but the significance levels are not. According to the Bonferroni-adjusted numbers, the significance of the difference between fertilizer concentrations 1 and 3 is 4.2%. The Scheffé-adjusted significance level is 3.9%.

We will leave it to you to decide which results are more accurate.

### ▷ Example 5: Šidák multiple-comparison test

Let's conclude this example by obtaining the Šidák-adjusted multiple-comparison tests. We do this to illustrate Stata's capabilities to calculate these results, because searching across adjustment methods until you find the results you want is not a valid technique for obtaining significance levels.

```
. oneway weight treatment, noanova sidak
 Comparison of Average weight in grams by Fertilizer
 (Sidak)
```

| Row Mean-<br>Col Mean | 1                 | 2                | 3              |
|-----------------------|-------------------|------------------|----------------|
| 2                     | -59.1667<br>0.001 |                  |                |
| 3                     | -33.25<br>0.041   | 25.9167<br>0.116 |                |
| 4                     | -34.4<br>0.035    | 24.7667<br>0.137 | -1.15<br>1.000 |

We find results that are similar to the Bonferroni-adjusted numbers.

Henry Scheffé (1907–1977) was born in New York. He studied mathematics at the University of Wisconsin, gaining a doctorate with a dissertation on differential equations. He taught mathematics at Wisconsin, Oregon State University, and Reed College, but his interests changed to statistics and he joined Wilks at Princeton. After periods at Syracuse, UCLA, and Columbia, Scheffé settled in Berkeley from 1953. His research increasingly focused on linear models and particularly ANOVA, on which he produced a celebrated monograph. His death was the result of a bicycle accident.

## Weighted data

### ▷ Example 6

`oneway` can work with both weighted and unweighted data. Let's assume that we wish to perform a one-way layout of the deathrate on the four census regions of the United States using state data. Our data contain three variables, `drate` (the deathrate), `region` (the region), and `pop` (the population of the state).

To fit the model, we type `oneway drate region [weight=pop]`, although we typically abbreviate `weight` as `w`. We will also add the `tabulate` option to demonstrate how the table of summary statistics differs for weighted data:

```
. use https://www.stata-press.com/data/r19/census8
(1980 Census data by state)
. oneway drate region [w=pop], tabulate
(analytic weights assumed)
```

| Census region                                                                        | Summary of Deathrate |           |            | Obs   |          |
|--------------------------------------------------------------------------------------|----------------------|-----------|------------|-------|----------|
|                                                                                      | Mean                 | Std. dev. | Freq.      |       |          |
| NE                                                                                   | 97.15                | 5.82      | 49135283   | 9     |          |
| N Cntrl                                                                              | 88.10                | 5.58      | 58865670   | 12    |          |
| South                                                                                | 87.05                | 10.40     | 74734029   | 16    |          |
| West                                                                                 | 75.65                | 8.23      | 43172490   | 13    |          |
| Total                                                                                | 87.34                | 10.43     | 225907472  | 50    |          |
| Analysis of variance                                                                 |                      |           |            |       |          |
| Source                                                                               | SS                   | df        | MS         | F     | Prob > F |
| Between groups                                                                       | 2360.92281           | 3         | 786.974272 | 12.17 | 0.0000   |
| Within groups                                                                        | 2974.09635           | 46        | 64.6542685 |       |          |
| Total                                                                                | 5335.01916           | 49        | 108.877942 |       |          |
| Bartlett's equal-variances test: $\chi^2(3) = 5.4971$ $\text{Prob} > \chi^2 = 0.139$ |                      |           |            |       |          |

When the data are weighted, the summary table has four columns rather than three. The column labeled “Freq.” reports the sum of the weights. The overall frequency tells us that there are approximately 226 million people in the United States, or at least there were in 1980.

The ANOVA table is appropriately weighted. Also see [U] 11.1.6 [weight](#).

## Methods and formulas

Methods and formulas are presented under the following headings:

[One-way analysis of variance](#)

[Bartlett's test](#)

[Multiple-comparison tests](#)

## One-way analysis of variance

The model of one-way ANOVA is

$$y_{ij} = \mu + \alpha_i + \epsilon_{ij}$$

for levels  $i = 1, \dots, k$  and observations  $j = 1, \dots, n_i$ . Define  $\bar{y}_i$  as the (weighted) mean of  $y_{ij}$  over  $j$  and  $\bar{y}$  as the overall (weighted) mean of  $y_{ij}$ . Define  $w_{ij}$  as the weight associated with  $y_{ij}$ , which is 1 if the data are unweighted.  $w_{ij}$  is normalized to sum to  $n = \sum_i n_i$  if `aweights` are used and is otherwise not normalized.  $w_i$  refers to  $\sum_j w_{ij}$ , and  $w$  refers to  $\sum_i w_i$ .

The between-group sum of squares is then

$$S_1 = \sum_i w_i (\bar{y}_i - \bar{y})^2$$

The TSS is

$$S = \sum_i \sum_j w_{ij} (y_{ij} - \bar{y})^2$$

The within-group sum of squares is given by  $S_e = S - S_1$ .

The between-group mean square is  $s_1^2 = S_1/(k - 1)$ , and the within-group mean square is  $s_e^2 = S_e/(w - k)$ . The test statistic is  $F = s_1^2/s_e^2$ . See, for instance, [Snedecor and Cochran \(1989\)](#).

## Bartlett's test

Bartlett's test assumes that you have  $m$  independent, normal, random samples and tests the hypothesis  $\sigma_1^2 = \sigma_2^2 = \dots = \sigma_m^2$ . The test statistic,  $M$ , is defined as

$$M = \frac{(T - m) \ln \hat{\sigma}^2 - \sum (T_i - 1) \ln \hat{\sigma}_i^2}{1 + \frac{1}{3(m-1)} \left\{ \left( \sum \frac{1}{T_i - 1} \right) - \frac{1}{T - m} \right\}}$$

where there are  $T$  overall observations,  $T_i$  observations in the  $i$ th group, and

$$(T_i - 1) \hat{\sigma}_i^2 = \sum_{j=1}^{T_i} (y_{ij} - \bar{y}_i)^2$$

$$(T - m) \hat{\sigma}^2 = \sum_{i=1}^m (T_i - 1) \hat{\sigma}_i^2$$

An approximate test of the homogeneity of variance is based on the statistic  $M$  with critical values obtained from the  $\chi^2$  distribution of  $m - 1$  degrees of freedom. See [Bartlett \(1937\)](#) or [Draper and Smith \(1998, 56–57\)](#).

## Multiple-comparison tests

Let's begin by reviewing the logic behind these adjustments. The “standard”  $t$  statistic for the comparison of two means is

$$t = \frac{\bar{y}_i - \bar{y}_j}{s \sqrt{\frac{1}{n_i} + \frac{1}{n_j}}}$$

where  $s$  is the overall standard deviation,  $\bar{y}_i$  is the measured average of  $y$  in group  $i$ , and  $n_i$  is the number of observations in the group. We perform hypothesis tests by calculating this  $t$  statistic. We simultaneously choose a critical level,  $\alpha$ , and look up the  $t$  statistic corresponding to that level in a table. We reject the hypothesis if our calculated  $t$  exceeds the value we looked up. Alternatively, because we have a computer at our disposal, we calculate the significance level  $e$  corresponding to our calculated  $t$  statistic, and if  $e < \alpha$ , we reject the hypothesis.

This logic works well when we are performing one test. Now consider what happens when we perform several separate tests, say,  $n$  of them. Let's assume, just for discussion, that we set  $\alpha$  equal to 0.05 and that we will perform six tests. For each test, we have a 0.05 probability of falsely rejecting the equality-of-means hypothesis. Overall, then, our chances of falsely rejecting at *least one* of the hypotheses is  $1 - (1 - 0.05)^6 \approx 0.26$  if the tests are independent.

The idea behind multiple-comparison tests is to control for the fact that we will perform multiple tests and to reduce our overall chances of falsely rejecting each hypothesis to  $\alpha$  rather than letting our chances increase with each additional test. (See [Miller \[1981\]](#) and [Hochberg and Tamhane \[1987\]](#) for rather advanced texts on multiple-comparison procedures.)

The Bonferroni adjustment (see [Miller \[1981\]](#); also see [van Belle et al. \[2004, 534–537\]](#)) does this by (falsely but approximately) asserting that the critical level we should use,  $a$ , is the true critical level,  $\alpha$ , divided by the number of tests,  $n$ ; that is,  $a = \alpha/n$ . For instance, if we are going to perform six tests, each at the 0.05 significance level, we want to adopt a critical level of  $0.05/6 \approx 0.00833$ .

We can just as easily apply this logic to  $e$ , the significance level associated with our  $t$  statistic, as to our critical level  $\alpha$ . If a comparison has a calculated significance of  $e$ , then its “real” significance, adjusted for the fact of  $n$  comparisons, is  $n \times e$ . If a comparison has a significance level of, say, 0.012, and we perform six tests, then its “real” significance is 0.072. If we adopt a critical level of 0.05, we cannot reject the hypothesis. If we adopt a critical level of 0.10, we can reject it.

Of course, this calculation can go above 1, but that just means that there is no  $\alpha < 1$  for which we could reject the hypothesis. (This situation arises because of the crude nature of the Bonferroni adjustment.) Stata handles this case by simply calling the significance level 1. Thus, the formula for the Bonferroni significance level is

$$e_b = \min(1, en)$$

where  $n = k(k - 1)/2$  is the number of comparisons.

The Šidák adjustment (Šidák [1967]; also see Winer, Brown, and Michels [1991, 165–166]) is slightly different and provides a tighter bound. It starts with the assertion that

$$a = 1 - (1 - \alpha)^{1/n}$$

Turning this formula around and substituting calculated significance levels, we obtain

$$e_s = \min\left\{1, 1 - (1 - e)^n\right\}$$

For example, if the calculated significance is 0.012 and we perform six tests, the “real” significance is approximately 0.07.

The Scheffé test (Scheffé [1953, 1959]; also see Kuehl [2000, 97–98]) differs in derivation, but it attacks the same problem. Let there be  $k$  means for which we want to make all the pairwise tests. Two means are declared significantly different if

$$t \geq \sqrt{(k - 1)F(\alpha; k - 1, \nu)}$$

where  $F(\alpha; k - 1, \nu)$  is the  $\alpha$ -critical value of the  $F$  distribution with  $k - 1$  numerator and  $\nu$  denominator degrees of freedom. Scheffé’s test has the nicety that it never declares a contrast significant if the overall  $F$  test is not significant.

Turning the test around, Stata calculates a significance level

$$\hat{e} = F\left(\frac{t^2}{k - 1}, k - 1, \nu\right)$$

For instance, you have a calculated  $t$  statistic of 4.0 with 50 degrees of freedom. The simple  $t$  test says that the significance level is 0.00021. The  $F$  test equivalent, 16 with 1 and 50 degrees of freedom, says the same. If you are comparing three means, however, you calculate an  $F$  test of 8.0 with 2 and 50 degrees of freedom, which says that the significance level is 0.0010.

## Description

`oprobit` fits ordered probit models of ordinal variable *depvar* on the independent variables *indepvars*. The actual values taken on by the dependent variable are irrelevant, except that larger values are assumed to correspond to “higher” outcomes.

## Quick start

Ordinal probit model of *y* on *x1* and categorical variables *a* and *b*

```
oprobit y x1 i.a i.b
```

Model of *y* on *x1* and a one-period lagged value of *x1* using `tsset` data

```
oprobit y x1 L.x1
```

Same as above, but calculate results for each level of *catvar* and save statistics to *myfile.dta*

```
statsby, by(catvar) saving(myfile): oprobit y x1 L.x1
```

## Menu

Statistics > Ordinal outcomes > Ordered probit regression

## Syntax

```
oprobit depvar [indepvars] [if] [in] [weight] [, options]
```

*indepvars* may contain factor variables; see [U] 11.4.3 **Factor variables**.

*depvar* and *indepvars* may contain time-series operators; see [U] 11.4.4 **Time-series varlists**.

`bayes`, `bayesboot`, `bootstrap`, `by`, `collect`, `fmm`, `fp`, `jackknife`, `mfp`, `mi estimate`, `nestreg`, `rolling`, `statsby`, `stepwise`, and `svy` are allowed; see [U] 11.1.10 **Prefix commands**. For more details, see [BAYES] **bayes: oprobit** and [FMM] **fmm: oprobit**.

`vce(bootstrap)` and `vce(jackknife)` are not allowed with the `mi estimate` prefix; see [MI] **mi estimate**.

Weights are not allowed with the `bootstrap` prefix; see [R] **bootstrap**.

`vce()` and weights are not allowed with the `svy` prefix; see [SVY] **svy**.

`fweights`, `iwweights`, and `pweights` are allowed; see [U] 11.1.6 **weight**.

`collinear` and `coeflegend` do not appear in the dialog box.

See [U] 20 **Estimation and postestimation commands** for more capabilities of estimation commands.

## Options

### Model

`offset(varname)`, `constraints(constraints)`; see [R] **Estimation options**.

### SE/Robust

`vce(vcetype)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory (`oim`, `opg`), that are robust to some kinds of misspecification (`robust`), that allow for intragroup correlation (`cluster clustvar`), and that use bootstrap or jackknife methods (`bootstrap`, `jackknife`); see [R] **vce\_option**.

## Reporting

`level(#)`; see [R] [Estimation options](#).

`nocnsreport`; see [R] [Estimation options](#).

*display\_options*: `nocl`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `nolstretch`; see [R] [Estimation options](#).

## Maximization

*maximize\_options*: `difficult`, `technique(algorithm_spec)`, `iterate(#)`, `[no]log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `ltolerance(#)`, `nrtolerance(#)`, `nonrtolerance`, and `from(init_specs)`; see [R] [Maximize](#). These options are seldom used.

The following options are available with `oprobit` but is not shown in the dialog box:

`collinear`, `coeflegend`; see [R] [Estimation options](#).

## Remarks and examples

An ordered probit model is used to estimate relationships between an ordinal dependent variable and a set of independent variables. An *ordinal* variable is a variable that is categorical and ordered, for instance, “poor”, “good”, and “excellent”, which might indicate a person’s current health status or the repair record of a car. If there are only two outcomes, see [R] [logistic](#), [R] [logit](#), and [R] [probit](#). This entry is concerned only with more than two outcomes. If the outcomes cannot be ordered (for example, residency in the north, east, south, or west), see [R] [mlogit](#). This entry is concerned only with models in which the outcomes can be ordered. See [R] [logistic](#) for a list of related estimation commands.

In ordered probit, an underlying score is estimated as a linear function of the independent variables and a set of cutpoints. The probability of observing outcome  $i$  corresponds to the probability that the estimated linear function, plus random error, is within the range of the cutpoints estimated for the outcome:

$$\Pr(\text{outcome}_j = i) = \Pr(\kappa_{i-1} < \beta_1 x_{1j} + \beta_2 x_{2j} + \cdots + \beta_k x_{kj} + u_j \leq \kappa_i)$$

$u_j$  is assumed to be normally distributed. In either case, we estimate the coefficients  $\beta_1, \beta_2, \dots, \beta_k$  together with the cutpoints  $\kappa_1, \kappa_2, \dots, \kappa_{I-1}$ , where  $I$  is the number of possible outcomes.  $\kappa_0$  is taken as  $-\infty$ , and  $\kappa_I$  is taken as  $+\infty$ . All of this is a direct generalization of the ordinary two-outcome probit model.

### ► Example 1

In [example 2](#) of [R] [ologit](#), we use a variation of the automobile dataset (see [U] [1.2.2 Example datasets](#)) to analyze the 1977 repair records of 66 foreign and domestic cars. We use ordered logit to explore the relationship of `rep77` in terms of `foreign` (origin of manufacture), `length` (a proxy for size), and `mpg`. Here we fit the same model using ordered probit rather than ordered logit:

```

. use https://www.stata-press.com/data/r19/fullauto
(Automobile models)
. oprobit rep77 foreign length mpg
Iteration 0: Log likelihood = -89.895098
Iteration 1: Log likelihood = -78.106316
Iteration 2: Log likelihood = -78.020086
Iteration 3: Log likelihood = -78.020025
Iteration 4: Log likelihood = -78.020025
Ordered probit regression
Log likelihood = -78.020025
Number of obs = 66
LR chi2(3) = 23.75
Prob > chi2 = 0.0000
Pseudo R2 = 0.1321

```

| rep77   | Coefficient | Std. err. | z    | P> z  | [95% conf. interval] |          |
|---------|-------------|-----------|------|-------|----------------------|----------|
| foreign | 1.704861    | .4246796  | 4.01 | 0.000 | .8725037             | 2.537217 |
| length  | .0468675    | .012648   | 3.71 | 0.000 | .022078              | .0716571 |
| mpg     | .1304559    | .0378628  | 3.45 | 0.001 | .0562463             | .2046656 |
| /cut1   | 10.1589     | 3.076754  |      |       | 4.128577             | 16.18923 |
| /cut2   | 11.21003    | 3.107527  |      |       | 5.119389             | 17.30067 |
| /cut3   | 12.54561    | 3.155233  |      |       | 6.361467             | 18.72975 |
| /cut4   | 13.98059    | 3.218793  |      |       | 7.671874             | 20.28931 |

We find that foreign cars have better repair records, as do larger cars and cars with better mileage ratings.

◀

## Stored results

oprobit stores the following in `e()`:

### Scalars

|                            |                                              |

| <code>e(ml_method)</code>      | type of ml method                                                        |
| <code>e(user)</code>           | name of likelihood-evaluator program                                     |
| <code>e(technique)</code>      | maximization technique                                                   |
| <code>e(properties)</code>     | b V                                                                      |
| <code>e(predict)</code>        | program used to implement <code>predict</code>                           |
| <code>e(marginsdefault)</code> | default <code>predict()</code> specification for <code>margins</code>    |
| <code>e(asbalanced)</code>     | factor variables <code>fvset</code> as <code>asbalanced</code>           |
| <code>e(asobserved)</code>     | factor variables <code>fvset</code> as <code>asobserved</code>           |
| Matrices                       |                                                                          |
| <code>e(b)</code>              | coefficient vector                                                       |
| <code>e(Cns)</code>            | constraints matrix                                                       |
| <code>e(ilog)</code>           | iteration log (up to 20 iterations)                                      |
| <code>e(gradient)</code>       | gradient vector                                                          |
| <code>e(cat)</code>            | category values                                                          |
| <code>e(V)</code>              | variance–covariance matrix of the estimators                             |
| <code>e(V_modelbased)</code>   | model-based variance                                                     |
| Functions                      |                                                                          |
| <code>e(sample)</code>         | marks estimation sample                                                  |

In addition to the above, the following is stored in `r()`:

|                       |                                                                                                                            |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------|
| Matrices              |                                                                                                                            |
| <code>r(table)</code> | matrix containing the coefficients with their standard errors, test statistics, <i>p</i> -values, and confidence intervals |

Note that results stored in `r()` are updated when the command is replayed and will be replaced when any *r*-class command is run after the estimation command.

## Postestimation commands

The following postestimation commands are available after `oprobit`:

| Command                      | Description                                                                                                                             |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <code>contrast</code>        | contrasts and ANOVA-style joint tests of parameters                                                                                     |
| <code>estat ic</code>        | Akaike's, consistent Akaike's, corrected Akaike's, and Schwarz's Bayesian information criteria (AIC, CAIC, AICc, and BIC, respectively) |
| <code>estat summarize</code> | summary statistics for the estimation sample                                                                                            |
| <code>estat vce</code>       | variance–covariance matrix of the estimators (VCE)                                                                                      |
| <code>estat (svy)</code>     | postestimation statistics for survey data                                                                                               |
| <code>estimates</code>       | cataloging estimation results                                                                                                           |
| <code>etable</code>          | table of estimation results                                                                                                             |
| * <code>forecast</code>      | dynamic forecasts and simulations                                                                                                       |
| * <code>hausman</code>       | Hausman's specification test                                                                                                            |
| <code>lincom</code>          | point estimates, standard errors, testing, and inference for linear combinations of parameters                                          |
| <code>linktest</code>        | link test for model specification                                                                                                       |
| * <code>lrtest</code>        | likelihood-ratio test                                                                                                                   |
| <code>margins</code>         | marginal means, predictive margins, marginal effects, and average marginal effects                                                      |
| <code>marginsplot</code>     | graph the results from margins (profile plots, interaction plots, etc.)                                                                 |
| <code>nlcom</code>           | point estimates, standard errors, testing, and inference for nonlinear combinations of parameters                                       |
| <code>predict</code>         | probabilities, linear predictions and their SEs, etc.                                                                                   |
| <code>predictnl</code>       | point estimates, standard errors, testing, and inference for generalized predictions                                                    |
| <code>pwcompare</code>       | pairwise comparisons of parameters                                                                                                      |
| <code>suest</code>           | seemingly unrelated estimation                                                                                                          |
| <code>test</code>            | Wald tests of simple and composite linear hypotheses                                                                                    |
| <code>testnl</code>          | Wald tests of nonlinear hypotheses                                                                                                      |

\*`forecast`, `hausman`, and `lrtest` are not appropriate with `svy` estimation results. `forecast` is also not appropriate with `mi` estimation results.

## predict

### Description for predict

`predict` creates a new variable containing predictions such as probabilities, linear predictions, and standard errors.

### Menu for predict

Statistics > Postestimation

### Syntax for predict

```
predict [type] { stub* | newvar | newvarlist } [if] [in] [, statistic
 outcome(outcome) nooffset]
```

```
predict [type] stub* [if] [in] , scores
```

| <i>statistic</i>  | Description                             |
|-------------------|-----------------------------------------|
| Main              |                                         |
| <code>pr</code>   | predicted probabilities; the default    |
| <code>xb</code>   | linear prediction                       |
| <code>stdp</code> | standard error of the linear prediction |

You specify one or  $k$  new variables with `pr`, where  $k$  is the number of outcomes. If you specify one new variable and you do not specify `outcome()`, then `outcome(#1)` is assumed.

You specify one new variable with `xb` and `stdp`.

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

### Options for predict

#### Main

`pr`, the default, computes the predicted probabilities for all outcomes or for a specific outcome. To compute probabilities for all outcomes, you specify  $k$  new variables, where  $k$  is the number of categories of the dependent variable. Alternatively, you can specify `stub*`; in which case, `pr` will store predicted probabilities in variables `stub1`, `stub2`, ..., `stubk`. To compute the probability for a specific outcome, you specify one new variable and, optionally, the outcome value in option `outcome()`; if you omit `outcome()`, the first outcome value, `outcome(#1)`, is assumed.

Say that you fit a model by typing `estimation_cmd y x1 x2`, and `y` takes on four values. Then, you could type `predict p1 p2 p3 p4` to obtain all four predicted probabilities; alternatively, you could type `predict p*` to generate the four predicted probabilities. To compute specific probabilities one at a time, you can type `predict p1, outcome(#1)` (or simply `predict p1`), `predict p2, outcome(#2)`, and so on. See option `outcome()` for other ways to refer to outcome values.

`xb` calculates the linear prediction. You specify one new variable, for example, `predict linear, xb`. The linear prediction is defined, ignoring the contribution of the estimated cutpoints.

`stdp` calculates the standard error of the linear prediction. You specify one new variable, for example, `predict se, stdp`.

`outcome(outcome)` specifies for which outcome the predicted probabilities are to be calculated. `outcome()` should contain either one value of the dependent variable or one of #1, #2, ..., with #1 meaning the first category of the dependent variable, #2 meaning the second category, etc. `outcome()` is available only with the default `pr` option.

`nooffset` is relevant only if you specified `offset(varname)` for `oprobit`. It modifies the calculations made by `predict` so that they ignore the offset variable; the linear prediction is treated as  $\mathbf{x}_j\mathbf{b}$  rather than as  $\mathbf{x}_j\mathbf{b} + \text{offset}_j$ . `nooffset` is not allowed with `scores`.

`scores` calculates equation-level score variables. The number of score variables created will equal the number of outcomes in the model. If the number of outcomes in the model was  $k$ , then

the first new variable will contain  $\partial \ln L / \partial (\mathbf{x}_j\mathbf{b})$ ;

the second new variable will contain  $\partial \ln L / \partial \kappa_1$ ;

the third new variable will contain  $\partial \ln L / \partial \kappa_2$ ;

...

and the  $k$ th new variable will contain  $\partial \ln L / \partial \kappa_{k-1}$ , where  $\kappa_i$  refers to the  $i$ th cutpoint.

## margins

### Description for margins

`margins` estimates margins of response for probabilities and linear predictions.

### Menu for margins

Statistics > Postestimation

### Syntax for margins

```
margins [marginlist] [, options]
```

```
margins [marginlist] , predict(statistic ...) [predict(statistic ...) ...] [options]
```

| <i>statistic</i>  | Description                           |
|-------------------|---------------------------------------|
| default           | probabilities for each outcome        |
| <code>pr</code>   | probability for a specified outcome   |
| <code>xb</code>   | linear prediction                     |
| <code>stdp</code> | not allowed with <code>margins</code> |

`pr` defaults to the first outcome.

Statistics not allowed with `margins` are functions of stochastic quantities other than  $e(b)$ .

For the full syntax, see [R] [margins](#).

## Remarks and examples

See [U] 20 [Estimation and postestimation commands](#) for instructions on obtaining the variance–covariance matrix of the estimators, predicted values, and hypothesis tests. Also see [R] [lrttest](#) for performing likelihood-ratio tests.

### ▷ Example 1

In [example 1](#) of [R] [oprobit](#), we fit the model `oprobit rep77 foreign length mpg`. The `predict` command can be used to obtain the predicted probabilities. We type `predict` followed by the names of the new variables to hold the predicted probabilities, ordering the names from low to high. In our data, the lowest outcome is “poor” and the highest is “excellent”. We have five categories, so we must type five names following `predict`; the choice of names is up to us:

```
. use https://www.stata-press.com/data/r19/fullauto
(Automobile models)
. oprobit rep77 foreign length mpg
(output omitted)
. predict poor fair avg good exc
(option pr assumed; predicted probabilities)
. list make model exc good if rep77>=., sep(4) divider
```

|     | make    | model   | exc      | good     |
|-----|---------|---------|----------|----------|
| 3.  | AMC     | Spirit  | .0006044 | .0351813 |
| 10. | Buick   | Opel    | .0043803 | .1133763 |
| 32. | Ford    | Fiesta  | .0002927 | .0222789 |
| 44. | Merc.   | Monarch | .0093209 | .1700846 |
| 53. | Peugeot | 604     | .0734199 | .4202766 |
| 56. | Plym.   | Horizon | .001413  | .0590294 |
| 57. | Plym.   | Sapporo | .0197543 | .2466034 |
| 63. | Pont.   | Phoenix | .0234156 | .266771  |

### □ Technical note

For ordered probit, `predict, xb` produces  $S_j = x_{1j}\beta_1 + x_{2j}\beta_2 + \dots + x_{kj}\beta_k$ . Ordered probit is identical to ordered logit, except that we use different distribution functions for calculating probabilities. The ordered-probit predictions are then the probability that  $S_j + u_j$  lies between a pair of cutpoints  $\kappa_{i-1}$  and  $\kappa_i$ . The formulas for ordered probit are

$$\Pr(S_j + u < \kappa) = \Phi(\kappa - S_j)$$

$$\Pr(S_j + u > \kappa) = 1 - \Phi(\kappa - S_j) = \Phi(S_j - \kappa)$$

$$\Pr(\kappa_1 < S_j + u < \kappa_2) = \Phi(\kappa_2 - S_j) - \Phi(\kappa_1 - S_j)$$

Rather than using `predict` directly, we could calculate the predicted probabilities by hand.

```
. predict pscore, xb
. generate probexc = normal(pscore-_b[/cut4])
. generate probgood = normal(_b[/cut4]-pscore) - normal(_b[/cut3]-pscore)
```

[U] [20 Estimation and postestimation commands](#)

[Description](#)[Options for orthog](#)[References](#)[Quick start](#)[Options for orthpoly](#)[Also see](#)[Menu](#)[Remarks and examples](#)[Syntax](#)[Methods and formulas](#)

## Description

`orthog` orthogonalizes a set of variables, creating a new set of orthogonal variables (all of type `double`), using a modified Gram–Schmidt procedure (Golub and Van Loan 2013). The order of the variables determines the orthogonalization; hence, the “most important” variables should be listed first.

Execution time is proportional to the square of the number of variables. With many ( $>10$ ) variables, `orthog` will be fairly slow.

`orthpoly` computes orthogonal polynomials for one variable.

## Quick start

Generate `ox1`, `ox2`, and `ox3` containing orthogonalized versions of `x1`, `x2`, and `x3`

```
orthog x1 x2 x3, generate(ox1 ox2 ox3)
```

Same as above

```
orthog x1 x2 x3, generate(ox*)
```

Generate `op1`, `op2`, and `op3` containing degree 1, 2, and 3 orthogonal polynomials for `x1`

```
orthpoly x1, generate(op1 op2 op3) degree(3)
```

Same as above

```
orthpoly x1, generate(op1-op3) degree(3)
```

Same as above, and generate matrix `op` containing coefficients of the orthogonal polynomials

```
orthpoly x1, generate(op1-op3) degree(3) poly(op)
```

## Menu

### **orthog**

Data > Create or change data > Other variable-creation commands > Orthogonalize variables

### **orthpoly**

Data > Create or change data > Other variable-creation commands > Orthogonal polynomials

## Syntax

### Orthogonalize variables

```
orthog [varlist] [if] [in] [weight], generate(newvarlist) [matrix(matname)]
```

### Compute orthogonal polynomial

```
orthpoly varname [if] [in] [weight],
{ generate(newvarlist) | poly(matname) } [degree(#)]
```

orthpoly requires that generate(*newvarlist*) or poly(*matname*), or both, be specified.

*varlist* may contain time-series operators; see [U] 11.4.4 Time-series varlists.

iweights, aweights, fweights, and pweights are allowed, see [U] 11.1.6 weight.

## Options for orthog

Main

generate(*newvarlist*) is required. generate() creates new orthogonal variables of type double. For orthog, *newvarlist* will contain the orthogonalized *varlist*. If *varlist* contains  $d$  variables, then so will *newvarlist*. *newvarlist* can be specified by giving a list of exactly  $d$  new variable names, or it can be abbreviated using the styles *newvar1–newvard* or *newvar\**. For these two styles of abbreviation, new variables *newvar1*, *newvar2*, ..., *newvard* are generated.

matrix(*matname*) creates a  $(d + 1) \times (d + 1)$  matrix containing the matrix  $R$  defined by  $X = QR$ , where  $X$  is the  $N \times (d + 1)$  matrix representation of *varlist* plus a column of ones and  $Q$  is the  $N \times (d + 1)$  matrix representation of *newvarlist* plus a column of ones ( $d$  = number of variables in *varlist*, and  $N$  = number of observations).

## Options for orthpoly

Main

generate(*newvarlist*) or poly(), or both, must be specified. generate() creates new orthogonal variables of type double. *newvarlist* will contain orthogonal polynomials of degree 1, 2, ...,  $d$  evaluated at *varname*, where  $d$  is as specified by degree( $d$ ). *newvarlist* can be specified by giving a list of exactly  $d$  new variable names, or it can be abbreviated using the styles *newvar1–newvard* or *newvar\**. For these two styles of abbreviation, new variables *newvar1*, *newvar2*, ..., *newvard* are generated.

poly(*matname*) creates a  $(d + 1) \times (d + 1)$  matrix called *matname* containing the coefficients of the orthogonal polynomials. The orthogonal polynomial of degree  $i \leq d$  is

$$\text{matname}[i, d + 1] + \text{matname}[i, 1] * \text{varname} + \text{matname}[i, 2] * \text{varname}^2 \\ + \dots + \text{matname}[i, i] * \text{varname}^i$$

The coefficients corresponding to the constant term are placed in the last column of the matrix. The last row of the matrix is all zeros, except for the last column, which corresponds to the constant term.

degree(#) specifies the highest-degree polynomial to include. Orthogonal polynomials of degree 1, 2, ...,  $d = \#$  are computed. The default is  $d = 1$ .

## Remarks and examples

Orthogonal variables are useful for two reasons. The first is numerical accuracy for highly collinear variables. Stata’s `regress` and other estimation commands can face much collinearity and still produce accurate results. But, at some point, these commands will drop variables because of collinearity. If you know with certainty that the variables are not perfectly collinear, you may want to retain all their effects in the model. If you use `orthog` or `orthpoly` to produce a set of orthogonal variables, all variables will be present in the estimation results.

Users are more likely to find orthogonal variables useful for the second reason: ease of interpreting results. `orthog` and `orthpoly` create a set of variables such that the “effects” of all the preceding variables have been removed from each variable. For example, if we issue the command

```
. orthog x1 x2 x3, generate(q1 q2 q3)
```

the effect of the constant is removed from `x1` to produce `q1`; the constant and `x1` are removed from `x2` to produce `q2`; and finally the constant, `x1`, and `x2` are removed from `x3` to produce `q3`. Hence,

$$\begin{aligned}q1 &= r_{01} + r_{11} x1 \\q2 &= r_{02} + r_{12} x1 + r_{22} x2 \\q3 &= r_{03} + r_{13} x1 + r_{23} x2 + r_{33} x3\end{aligned}$$

This effect can be generalized and written in matrix notation as

$$X = QR$$

where  $X$  is the  $N \times (d+1)$  matrix representation of *varlist* plus a column of ones, and  $Q$  is the  $N \times (d+1)$  matrix representation of *newvarlist* plus a column of ones ( $d$  = number of variables in *varlist* and  $N$  = number of observations). The  $(d+1) \times (d+1)$  matrix  $R$  is a permuted upper-triangular matrix, that is,  $R$  would be upper triangular if the constant were first, but the constant is last, so the first row/column has been permuted with the last row/column. Because Stata’s estimation commands list the constant term last, this allows  $R$ , obtained via the `matrix()` option, to be used to transform estimation results.

### ► Example 1: orthog

Consider Stata’s `auto.dta` dataset. Suppose that we postulate a model in which price depends on the car’s length, weight, headroom, and trunk size (`trunk`). These predictors are collinear, but not extremely so—the correlations are not that close to 1:

```
. use https://www.stata-press.com/data/r19/auto
(1978 automobile data)
. correlate length weight headroom trunk
(obs=74)
```

|          | length | weight | headroom | trunk  |
|----------|--------|--------|----------|--------|
| length   | 1.0000 |        |          |        |
| weight   | 0.9460 | 1.0000 |          |        |
| headroom | 0.5163 | 0.4835 | 1.0000   |        |
| trunk    | 0.7266 | 0.6722 | 0.6620   | 1.0000 |

regress certainly has no trouble fitting this model:

```
. regress price length weight headroom trunk
```

| Source   | SS        | df | MS         | Number of obs | = | 74     |
|----------|-----------|----|------------|---------------|---|--------|
| Model    | 236016580 | 4  | 59004145   | F(4, 69)      | = | 10.20  |
| Residual | 399048816 | 69 | 5783316.17 | Prob > F      | = | 0.0000 |
|          |           |    |            | R-squared     | = | 0.3716 |
|          |           |    |            | Adj R-squared | = | 0.3352 |
| Total    | 635065396 | 73 | 8699525.97 | Root MSE      | = | 2404.9 |

| price    | Coefficient | Std. err. | t     | P> t  | [95% conf. interval] |           |
|----------|-------------|-----------|-------|-------|----------------------|-----------|
| length   | -101.7092   | 42.12534  | -2.41 | 0.018 | -185.747             | -17.67147 |
| weight   | 4.753066    | 1.120054  | 4.24  | 0.000 | 2.518619             | 6.987512  |
| headroom | -711.5679   | 445.0204  | -1.60 | 0.114 | -1599.359            | 176.2236  |
| trunk    | 114.0859    | 109.9488  | 1.04  | 0.303 | -105.2559            | 333.4277  |
| _cons    | 11488.47    | 4543.902  | 2.53  | 0.014 | 2423.638             | 20553.31  |

However, we may believe a priori that length is the most important predictor, followed by weight, headroom, and trunk. We would like to remove the “effect” of length from all the other predictors, remove weight from headroom and trunk, and remove headroom from trunk. We can do this by running orthog, and then we fit the model again using the orthogonal variables:

```
. orthog length weight headroom trunk, gen(olength oweight oheadroom otrunk)
> matrix(R)
```

```
. regress price olength oweight oheadroom otrunk
```

| Source   | SS        | df | MS         | Number of obs | = | 74     |
|----------|-----------|----|------------|---------------|---|--------|
| Model    | 236016580 | 4  | 59004145   | F(4, 69)      | = | 10.20  |
| Residual | 399048816 | 69 | 5783316.17 | Prob > F      | = | 0.0000 |
|          |           |    |            | R-squared     | = | 0.3716 |
|          |           |    |            | Adj R-squared | = | 0.3352 |
| Total    | 635065396 | 73 | 8699525.97 | Root MSE      | = | 2404.9 |

| price     | Coefficient | Std. err. | t     | P> t  | [95% conf. interval] |          |
|-----------|-------------|-----------|-------|-------|----------------------|----------|
| olength   | 1265.049    | 279.5584  | 4.53  | 0.000 | 707.3454             | 1822.753 |
| oweight   | 1175.765    | 279.5584  | 4.21  | 0.000 | 618.0617             | 1733.469 |
| oheadroom | -349.9916   | 279.5584  | -1.25 | 0.215 | -907.6955            | 207.7122 |
| otrunk    | 290.0776    | 279.5584  | 1.04  | 0.303 | -267.6262            | 847.7815 |
| _cons     | 6165.257    | 279.5584  | 22.05 | 0.000 | 5607.553             | 6722.961 |

Using the matrix R, we can transform the results obtained using the orthogonal predictors back to the metric of original predictors:

```
. matrix b = e(b)*inv(R)
. matrix list b
```

```
b[1,5]
```

|    | length     | weight    | headroom   | trunk     | _cons     |
|----|------------|-----------|------------|-----------|-----------|
| y1 | -101.70924 | 4.7530659 | -711.56789 | 114.08591 | 11488.475 |

## □ Technical note

The matrix  $R$  obtained using the `matrix()` option with `orthog` can also be used to recover  $X$  (the original *varlist*) from  $Q$  (the orthogonalized *newvarlist*), one variable at a time. Continuing with the previous example, we illustrate how to recover the `trunk` variable:

```
. matrix C = R[1..., "trunk"]'
. matrix score double rtrunk = C
. compare rtrunk trunk
```

|                 | Count | Difference |          |          |
|-----------------|-------|------------|----------|----------|
|                 |       | Minimum    | Average  | Maximum  |
| rtrunk>trunk    | 74    | 8.88e-15   | 1.91e-14 | 3.55e-14 |
| Jointly defined | 74    | 8.88e-15   | 1.91e-14 | 3.55e-14 |
| Total           | 74    |            |          |          |

Here the recovered variable `rtrunk` is almost exactly the same as the original `trunk` variable. When you are orthogonalizing many variables, this procedure can be performed to check the numerical soundness of the orthogonalization. Because of the ordering of the orthogonalization procedure, the last variable and the variables near the end of the *varlist* are the most important ones to check. □

The `orthpoly` command effectively does for polynomial terms what the `orthog` command does for an arbitrary set of variables.

## ▷ Example 2: orthpoly

Again consider the `auto.dta` dataset. Suppose that we wish to fit the model

$$\text{mpg} = \beta_0 + \beta_1 \text{weight} + \beta_2 \text{weight}^2 + \beta_3 \text{weight}^3 + \beta_4 \text{weight}^4 + \epsilon$$

We will first compute the regression with natural polynomials:

```
. generate double w1 = weight
. generate double w2 = w1*w1
. generate double w3 = w2*w1
. generate double w4 = w3*w1
. correlate w1-w4
(obs=74)
```

|    | w1     | w2     | w3     | w4     |
|----|--------|--------|--------|--------|
| w1 | 1.0000 |        |        |        |
| w2 | 0.9915 | 1.0000 |        |        |
| w3 | 0.9665 | 0.9916 | 1.0000 |        |
| w4 | 0.9279 | 0.9679 | 0.9922 | 1.0000 |

```
. regress mpg w1-w4
```

| Source   | SS         | df | MS         | Number of obs | = | 74     |
|----------|------------|----|------------|---------------|---|--------|
| Model    | 1652.73666 | 4  | 413.184164 | F(4, 69)      | = | 36.06  |
| Residual | 790.722803 | 69 | 11.4597508 | Prob > F      | = | 0.0000 |
|          |            |    |            | R-squared     | = | 0.6764 |
|          |            |    |            | Adj R-squared | = | 0.6576 |
| Total    | 2443.45946 | 73 | 33.4720474 | Root MSE      | = | 3.3852 |

| mpg   | Coefficient | Std. err. | t     | P> t  | [95% conf. interval] |          |
|-------|-------------|-----------|-------|-------|----------------------|----------|
| w1    | .0289302    | .1161939  | 0.25  | 0.804 | -.2028704            | .2607307 |
| w2    | -.0000229   | .0000566  | -0.40 | 0.687 | -.0001359            | .0000901 |
| w3    | 5.74e-09    | 1.19e-08  | 0.48  | 0.631 | -1.80e-08            | 2.95e-08 |
| w4    | -4.86e-13   | 9.14e-13  | -0.53 | 0.596 | -2.31e-12            | 1.34e-12 |
| _cons | 23.94421    | 86.60667  | 0.28  | 0.783 | -148.8314            | 196.7198 |

Some of the correlations among the powers of weight are very large, but this does not create any problems for regress. However, we may wish to look at the quadratic trend with the constant removed, the cubic trend with the quadratic and constant removed, etc. orthpoly will generate polynomial terms with this property:

```
. orthpoly weight, generate(pw*) deg(4) poly(P)
```

```
. regress mpg pw1-pw4
```

| Source   | SS         | df | MS         | Number of obs | = | 74     |
|----------|------------|----|------------|---------------|---|--------|
| Model    | 1652.73666 | 4  | 413.184164 | F(4, 69)      | = | 36.06  |
| Residual | 790.722803 | 69 | 11.4597508 | Prob > F      | = | 0.0000 |
|          |            |    |            | R-squared     | = | 0.6764 |
|          |            |    |            | Adj R-squared | = | 0.6576 |
| Total    | 2443.45946 | 73 | 33.4720474 | Root MSE      | = | 3.3852 |

| mpg   | Coefficient | Std. err. | t      | P> t  | [95% conf. interval] |           |
|-------|-------------|-----------|--------|-------|----------------------|-----------|
| pw1   | -4.638252   | .3935245  | -11.79 | 0.000 | -5.423312            | -3.853192 |
| pw2   | .8263545    | .3935245  | 2.10   | 0.039 | .0412947             | 1.611414  |
| pw3   | -.3068616   | .3935245  | -0.78  | 0.438 | -1.091921            | .4781982  |
| pw4   | -.209457    | .3935245  | -0.53  | 0.596 | -.9945168            | .5756028  |
| _cons | 21.2973     | .3935245  | 54.12  | 0.000 | 20.51224             | 22.08236  |

Compare the *p*-values of the terms in the natural polynomial regression with those in the orthogonal polynomial regression. With orthogonal polynomials, it is easy to see that the pure cubic and quartic trends are not significant and that the constant, linear, and quadratic terms each have  $p < 0.05$ .

The matrix P obtained with the poly() option can be used to transform coefficients for orthogonal polynomials to coefficients for natural polynomials:

```
. orthpoly weight, poly(P) deg(4)
```

```
. matrix b = e(b)*P
```

```
. matrix list b
```

```
b[1,5]
```

|    | deg1      | deg2       | deg3      | deg4       | _cons     |
|----|-----------|------------|-----------|------------|-----------|
| y1 | .02893016 | -.00002291 | 5.745e-09 | -4.862e-13 | 23.944212 |

## Methods and formulas

orthog's orthogonalization can be written in matrix notation as

$$X = QR$$

where  $X$  is the  $N \times (d+1)$  matrix representation of *varlist* plus a column of ones and  $Q$  is the  $N \times (d+1)$  matrix representation of *newvarlist* plus a column of ones ( $d$  = number of variables in *varlist*, and  $N$  = number of observations). The  $(d+1) \times (d+1)$  matrix  $R$  is a permuted upper-triangular matrix; that is,  $R$  would be upper triangular if the constant were first, but the constant is last, so the first row/column has been permuted with the last row/column.

$Q$  and  $R$  are obtained using a modified Gram–Schmidt procedure; see [Golub and Van Loan \(2013, 254–255\)](#) for details. The traditional Gram–Schmidt procedure is notoriously unsound, but the modified procedure is good. orthog performs two passes of this procedure.

orthpoly uses the Christoffel–Darboux recurrence formula ([Abramowitz and Stegun 1964](#)).

Both orthog and orthpoly normalize the orthogonal variables such that

$$Q'WQ = MI$$

where  $W = \text{diag}(w_1, w_2, \dots, w_N)$  with weights  $w_1, w_2, \dots, w_N$  (all 1 if weights are not specified), and  $M$  is the sum of the weights (the number of observations if weights are not specified).

## Description

`pcorr` displays the partial and semipartial correlation coefficients of a specified variable with each variable in a varlist after removing the effects of all other variables in the varlist. The squared correlations and corresponding significance are also reported.

## Quick start

Partial and semipartial correlations of `v1` with `v2`, `v3`, and `v4`

```
pcorr v1 v2 v3 v4
```

Same as above, but for each level of categorical variable `catvar`

```
by catvar: pcorr v1 v2 v3 v4
```

Partial and semipartial correlations of `v5` with `v6`, `v7`, and `v8`, and a one-period lag of `v5` using `tsset` data

```
pcorr v5 L.v5 v6 v7 v8
```

## Menu

Statistics > Summaries, tables, and tests > Summary and descriptive statistics > Partial correlations

## Syntax

```
pcorr varname varlist [if] [in] [weight]
```

*varlist* may contain factor variables; see [U] 11.4.3 Factor variables.

*varname* and *varlist* may contain time-series operators; see [U] 11.4.4 Time-series varlists.

`by` and `collect` are allowed; see [U] 11.1.10 Prefix commands.

`aweight`s and `fweight`s are allowed; see [U] 11.1.6 weight.

## Remarks and examples

Assume that  $y$  is determined by  $x_1, x_2, \dots, x_k$ . The partial correlation between  $y$  and  $x_1$  is an attempt to estimate the correlation that would be observed between  $y$  and  $x_1$  if the other  $x$ 's did not vary. The semipartial correlation, also called part correlation, between  $y$  and  $x_1$  is an attempt to estimate the correlation that would be observed between  $y$  and  $x_1$  after the effects of all other  $x$ 's are removed from  $x_1$  but not from  $y$ .

Both squared correlations estimate the proportion of the variance of  $y$  that is explained by each predictor. The squared semipartial correlation between  $y$  and  $x_1$  represents the proportion of variance in  $y$  that is explained by  $x_1$  only. This squared correlation can also be interpreted as the decrease in the model's  $R^2$  value that results from removing  $x_1$  from the full model. Thus, one could use the squared semipartial correlations as criteria for model selection. The squared partial correlation between  $y$  and  $x_1$  represents the proportion of variance in  $y$  not associated with any other  $x$ 's that is explained by  $x_1$ . Thus, the squared partial correlation gives an estimate of how much of the variance of  $y$  not explained by the other  $x$ 's is explained by  $x_1$ .

### ▷ Example 1

Using our automobile dataset (described in [U] 1.2.2 Example datasets), we can obtain the simple correlations between price, mpg, weight, and foreign from `correlate` (see [R] `correlate`):

```
. use https://www.stata-press.com/data/r19/auto
(1978 automobile data)
. correlate price mpg weight foreign
(obs=74)
```

|         | price   | mpg     | weight  | foreign |
|---------|---------|---------|---------|---------|
| price   | 1.0000  |         |         |         |
| mpg     | -0.4686 | 1.0000  |         |         |
| weight  | 0.5386  | -0.8072 | 1.0000  |         |
| foreign | 0.0487  | 0.3934  | -0.5928 | 1.0000  |

Although `correlate` gave us the full correlation matrix, our interest is in just the first column. We find, for instance, that the higher the mpg, the lower the price. We obtain the partial and semipartial correlation coefficients by using `pcorr`:

```
. pcorr price mpg weight foreign
(obs=74)
```

Partial and semipartial correlations of price with

| Variable | Partial corr. | Semipartial corr. | Partial corr. <sup>2</sup> | Semipartial corr. <sup>2</sup> | Significance value |
|----------|---------------|-------------------|----------------------------|--------------------------------|--------------------|
| mpg      | 0.0352        | 0.0249            | 0.0012                     | 0.0006                         | 0.7693             |
| weight   | 0.5488        | 0.4644            | 0.3012                     | 0.2157                         | 0.0000             |
| foreign  | 0.5402        | 0.4541            | 0.2918                     | 0.2062                         | 0.0000             |

We now find that the partial and semipartial correlations of price with mpg are near 0. In the simple correlations, we found that price and foreign were virtually uncorrelated. In the partial and semipartial correlations, we find that price and foreign are positively correlated. The nonsignificance of mpg tells us that the amount in which  $R^2$  decreases by removing mpg from the model is not significant. We find that removing either weight or foreign results in a significant drop in the  $R^2$  of the model.

◀

### □ Technical note

Use caution when interpreting the above results. As we said at the outset, the partial and semipartial correlation coefficients are an *attempt* to estimate the correlation that would be observed if the effects of all other variables were taken out of both  $y$  and  $x$  or only  $x$ . `pcorr` makes it too easy to ignore the fact that we are fitting a model. In the example above, the model is

$$\text{price} = \beta_0 + \beta_1 \text{mpg} + \beta_2 \text{weight} + \beta_3 \text{foreign} + \epsilon$$

which is, in all honesty, a rather silly model. Even if we accept the implied economic assumptions of the model—that consumers value mpg, weight, and foreign—do we really believe that consumers place equal value on every extra 1,000 pounds of weight? That is, have we correctly parameterized the model? If we have not, then the estimated partial and semipartial correlation coefficients may not represent what they claim to represent. Partial and semipartial correlation coefficients are a reasonable way to summarize data if we are convinced that the underlying model is reasonable. We should not, however, pretend that there is no underlying model and that these correlation coefficients are unaffected by the assumptions and parameterization. □

## Stored results

pcorr stores the following in `r()`:

### Scalars

`r(N)`            number of observations  
`r(df)`            degrees of freedom

### Matrices

`r(p_corr)`        partial correlation coefficient vector  
`r(sp_corr)`        semipartial correlation coefficient vector

## Methods and formulas

Results are obtained by fitting a linear regression of *varname* on *varlist*; see [R] [regress](#). The partial correlation coefficient between *varname* and each variable in *varlist* is then calculated as

$$\frac{t}{\sqrt{t^2 + n - k}}$$

(Greene 2018, 39), where  $t$  is the  $t$  statistic,  $n$  is the number of observations, and  $k$  is the number of independent variables, including the constant but excluding any dropped variables.

The semipartial correlation coefficient between *varname* and each variable in *varlist* is calculated as

$$\text{sign}(t) \sqrt{\frac{t^2(1 - R^2)}{n - k}}$$

(Cohen et al. 2003, 89), where  $R^2$  is the model  $R^2$  value, and  $t$ ,  $n$ , and  $k$  are as described above.

The significance is given by  $2\Pr(t_{n-k} > |t|)$ , where  $t_{n-k}$  follows a Student's  $t$  distribution with  $n - k$  degrees of freedom.

## Acknowledgment

The addition of semipartial correlation coefficients to pcorr is based on the pcorr2 command by Richard Williams of the Department of Sociology at the University of Notre Dame.

## Description

`permute` performs permutation tests using Monte Carlo permutations or by enumeration of all possible distinct permutations. A single variable is chosen to be permuted, and the permutation distribution is estimated (or in the case of enumeration, fully determined) for specified statistics returned by a Stata command or a user-written program.

## Quick start

Estimate  $p$ -values for a permutation test of the coefficient of  $x$  in a linear regression, permuting values of the outcome  $y$

```
permute y _b[x] : regress y x
```

Test for  $r(\text{mystat})$  returned by program `myprog`, permuting values of  $y$

```
permute y r(mystat) : myprog
```

Same as above, but increase the number of permutations from the default of 100 to 10,000

```
permute y r(mystat), reps(10000) : myprog
```

Same as above, but display a dot for every 100 permutations instead of every permutation

```
permute y r(mystat), reps(10000) dots(100) : myprog
```

Same as above, but set the random-number seed for reproducibility, and save the permuted statistics in `myfile.dta`

```
permute y r(mystat), reps(10000) dots(100) rseed(1) saving(myfile) : ///
myprog
```

Test for  $r(\text{mystat1})$  and  $r(\text{mystat2})$ , naming the statistics `stat1` and `stat2`, respectively

```
permute y stat1=r(mystat1) stat2=r(mystat2), reps(10000) rseed(1) : ///
myprog
```

Perform permutations within strata defined by `svar`

```
permute y stat=r(mystat), reps(10000) rseed(1) strata(svar) : myprog
```

Enumerate the full permutation distribution and display a dot for every 1,000 permutations

```
permute y stat=r(mystat), enumerate dots(1000) : myprog
```

## Menu

Statistics > Resampling > Permutation tests

## Syntax

Perform permutation test

```
permute permvar exp_list [, options] : command
```

Report saved results

```
permute [varlist] [using filename] [, display_options]
```

## Options

Main

`reps(#)` specifies the number of Monte Carlo permutations to perform. The default is `reps(100)`.

The default of 100 permutations is chosen for convenience. In real-world applications, you will most likely need to use more permutations. `permute` reports the Monte Carlo error, which you can use to evaluate whether the specified number of permutations provides sufficient precision for the reported *p*-value estimates.

`enumerate` specifies that all possible distinct permutations be computed. This gives the full permutation distribution and *p*-values with no error. `reps()` and `rseed()` cannot be specified with `enumerate`.

The number of all possible distinct permutations is typically extremely large. Only for some small problems will it be practical to fully enumerate the permutation distribution. If all the values of *permvar* are unique, the number of possible permutations is  $N!$ , where  $N$  is the number of observations. When *permvar* has a lot of repeated values (when, for example, it is a 0/1 variable), the number of possible distinct permutations can be considerably less than  $N!$  and may make enumeration feasible.

Before beginning the enumeration, `permute` will calculate and display the number of distinct permutations, allowing you to press *Break* when you see that the number of permutations is so large as to make computation time impossibly long.

## Options

`rseed(#)` sets the random-number seed. Specifying this option is equivalent to typing the following command prior to calling `permute`:

```
. set seed #
```

`strata(varlist)` specifies that the permutations be performed within each stratum defined by the values of `varlist`.

`saving(filename[ , double every(#) replace ])` creates a Stata data file (.dta file) consisting of variables for each statistic in `exp_list` containing the results for each permutation.

`double` specifies that the results for each permutation be saved as doubles, meaning 8-byte reals. By default, they are saved as floats, meaning 4-byte reals.

`every(#)` specifies that results be written to disk every `#`th permutation. `every()` should be specified only in conjunction with `saving()` when `command` takes a long time for each permutation. This will allow recovery of partial results should some other software crash your computer. See [P] [postfile](#).

`replace` specifies that `filename` be overwritten if it exists.

## Reporting

`standardize` specifies that the observed value of each test statistic be standardized. That is, the observed test statistic  $T_{\text{obs}}$  is standardized by calculating  $[T_{\text{obs}} - \text{mean}(T)]/\sqrt{\text{Var}(T)}$ , where  $\text{mean}(T)$  and  $\text{Var}(T)$  are the mean and variance of the permutation distribution of  $T$ . Standardized test statistics are useful for seeing roughly how extreme (and in what direction) the observed test statistic is.

`level(#)` specifies the confidence level, as a percentage, for confidence intervals. The default is `level(95)` or as set by `set level`; see [R] [level](#).

`title(text)` specifies a title to be displayed above the table of permutation results.

`dots(#)` and `nodots` specify whether to display permutation dots. By default, one dot character is displayed for each successful permutation. An “x” is displayed if `command` returns an error or if any value in `exp_list` is missing. You can also control whether dots are displayed using `set dots`; see [R] [set](#).

`dots(#)` displays dots every `#` permutations. `dots(0)` is a synonym for `nodots`.

`nodots` suppresses display of the permutation dots.

`nowarning` suppresses the printing of a warning message when `command` does not set `e(sample)`.

`noisily` requests that any output from `command` be displayed. This option implies the `nodots` option.

`trace` causes a trace of the execution of `command` to be displayed. This option implies the `noisily` option.

`verbose` requests that the full table legend be displayed when multiple coefficients or standard errors are specified using the `_b` or `_se` notation.

`noheader` suppresses display of the table header. This option implies the `nolegend` option.

`nolegend` suppresses display of the table legend. The table legend identifies the rows of the table with the expressions they represent.

Advanced

`nodrop` prevents `permute` from dropping observations outside the `if` and `in` qualifiers. `nodrop` will also cause `permute` to ignore the contents of `e(sample)` if it exists as a result of running *command*. By default, `permute` temporarily drops out-of-sample observations.

`reject(exp)` specifies an expression that indicates when results should be rejected. When *exp* is true, the resulting values are reset to missing values.

`eps(#)` specifies the numerical tolerance for testing  $T \leq T_{\text{obs}}$  and  $T \geq T_{\text{obs}}$ , where  $T$  is the test statistic and  $T_{\text{obs}}$  is its observed value. These are considered true if, respectively,  $T \leq T_{\text{obs}} + \#$  or  $T \geq T_{\text{obs}} - \#$ . The default is `eps(1e-7)`. You will not have to specify `eps()` under normal circumstances.

*Efficiency considerations for Monte Carlo permutations*

*Efficiency considerations for enumeration*

## Introduction

Permutation tests are based on the idea of scrambling—that is, permuting—the order of a variable in all possible ways, calculating the value of a test statistic for each permutation, and taking this set of values of the statistic as its distribution.

For instance, consider the correlation of two variables,  $\text{corr}(\mathbf{x}, \mathbf{y})$ , where  $\mathbf{x} = (x_1, \dots, x_n)$  and  $\mathbf{y} = (y_1, \dots, y_n)$ . We hold the order of  $\mathbf{x}$  fixed and permute the order of  $\mathbf{y}$  in all possible ways. For each permutation  $\mathbf{y}^*$ , we calculate  $T^* = \text{corr}(\mathbf{x}, \mathbf{y}^*)$ . The set of  $T^*$  gives the permutation distribution for the correlation. This permutation distribution is the distribution of the correlation under the null hypothesis that the ordering of the elements of  $\mathbf{y}$  are independent of the ordering of the elements of  $\mathbf{x}$ , conditional on the observed values of  $\mathbf{x}$  and  $\mathbf{y}$ .

Aside: Actually, the null hypothesis does not require independence. A weaker assumption of exchangeability is sufficient. If  $\mathbf{x}$  and  $\mathbf{y}$  are observed values of the random variates  $\mathbf{X} = (X_1, \dots, X_n)$  and  $\mathbf{Y} = (Y_1, \dots, Y_n)$ , then the joint distribution  $f(\mathbf{X}, \mathbf{Y})$  is called exchangeable when it is invariant to the orderings of  $X_1, \dots, X_n$  and  $Y_1, \dots, Y_n$ .

The  $p$ -value for the permutation test is the proportion of permutations that produce a test statistic  $T^*$  as extreme or more extreme than the test statistic  $T_{\text{obs}}$  computed using the observed data.

`permute` estimates  $p$ -values for permutation tests using Monte Carlo permutations or by enumerating all possible permutations when the `enumerate` option is specified. To do Monte Carlo permutations, you type

```
. permute permvar exp_list, reps(#): command
```

The values in the variable *permvar* are randomly permuted *#* times, each time executing *command* and collecting the associated values from the expressions in *exp\_list*.

*command* defines the statistical command to be executed. Most Stata commands and user-written programs can be used with `permute`, as long as they follow standard Stata syntax; see [U] 11 Language syntax. *exp\_list* specifies the statistics to be collected from the execution of *command*. Despite the fact that `permute` works with most Stata commands, that does not mean the resulting permutation test is a sensible test. See, for example, Good (2006).

To enumerate all possible distinct permutations, you type

```
. permute permvar exp_list, enumerate: command
```

`permute` may be used for replaying results, but this feature is appropriate only when a dataset generated by `permute` is currently in memory or is identified by the `using` specification.

## Monte Carlo permutation tests

We first demonstrate how to apply the `permute` prefix by testing for a difference in the distribution of a variable across two groups. Here we perform the test using Monte Carlo permutations. In [example 3](#), we do the same test using complete enumeration.

### ► Example 1: Wilcoxon rank-sum test

Let's consider calculating the  $p$ -value for the Wilcoxon rank-sum test performed by `ranksum`. Suppose that we collected data from some experiment:  $y$  is some measure we took on 17 individuals, and `group` identifies the group to which an individual belongs.

```
. use https://www.stata-press.com/data/r19/permute2
. list, sepby(group)
```

|     | group | y  |
|-----|-------|----|
| 1.  | 1     | 6  |
| 2.  | 1     | 11 |
| 3.  | 1     | 20 |
| 4.  | 1     | 2  |
| 5.  | 1     | 9  |
| 6.  | 1     | 5  |
| 7.  | 0     | 2  |
| 8.  | 0     | 1  |
| 9.  | 0     | 6  |
| 10. | 0     | 0  |
| 11. | 0     | 2  |
| 12. | 0     | 3  |
| 13. | 0     | 3  |
| 14. | 0     | 12 |
| 15. | 0     | 4  |
| 16. | 0     | 1  |
| 17. | 0     | 5  |

We analyze the data using ranksum:

```
. ranksum y, by(group)
Two-sample Wilcoxon rank-sum (Mann-Whitney) test
```

| group    | Obs | Rank sum | Expected |
|----------|-----|----------|----------|
| 0        | 11  | 79       | 99       |
| 1        | 6   | 74       | 54       |
| Combined | 17  | 153      | 153      |

```
Unadjusted variance 99.00
Adjustment for ties -0.97

Adjusted variance 98.03
H0: y(group==0) = y(group==1)
 z = -2.020
Prob > |z| = 0.0434
Exact prob = 0.0436
```

The test gives an approximate *p*-value of 0.0434 and an exact *p*-value of 0.0436.

Let's try to reproduce these results using permute. The test statistic *T* for the Wilcoxon rank-sum test is the sum of the ranks for the first group, which is 79, and is stored as `r(sum_obs)`. We specify `reps(10000)` to do 10,000 Monte Carlo permutations and `dots(100)` to display a dot every 100th permutation. We set the random-number seed so that we can duplicate our results.

```
. set seed 1234
. permute group r(sum_obs), reps(10000) dots(100): ranksum y, by(group)
(running ranksum on estimation sample)
warning: ranksum does not set e(sample), so no observations will be excluded
from the permutations because of missing values or other reasons. To
exclude observations, press Break, save the data, drop any
observations that are to be excluded, and rerun permute.
Permutations (10,000):1,000.....2,000.....3,000.....4,000
>5,000.....6,000.....7,000.....8,000.....9,000.....
> ..10,000 done
Monte Carlo permutation results Number of observations = 17
Permutation variable: group Number of permutations = 10,000
Command: ranksum y, by(group)
 _pm_1: r(sum_obs)
```

| T     | T(obs) | Test      | c    | n     | p     | Monte Carlo error |             |       |
|-------|--------|-----------|------|-------|-------|-------------------|-------------|-------|
|       |        |           |      |       |       | SE(p)             | [95% CI(p)] |       |
| _pm_1 | 79     | lower     | 223  | 10000 | .0223 | .0015             | .0195       | .0254 |
|       |        | upper     | 9817 | 10000 | .9817 | .0013             | .9789       | .9842 |
|       |        | two-sided |      |       |       | .0446             | .0021       | .0406 |

Notes: For lower one-sided test,  $c = \#\{T \leq T(\text{obs})\}$  and  $p = p_{\text{lower}} = c/n$ .  
 For upper one-sided test,  $c = \#\{T \geq T(\text{obs})\}$  and  $p = p_{\text{upper}} = c/n$ .  
 For two-sided test,  $p = 2 \cdot \min(p_{\text{lower}}, p_{\text{upper}})$ ; SE and CI approximate.

The lengthy message about `e(sample)` is worth noting. If there were missing values in the data, we might want to drop those observations before running `permute`. To suppress the message in future runs, use the `nowarning` option.

The two-sided  $p$ -value obtained by this Monte Carlo procedure is 0.0446, which is close to the exact  $p$ -value of 0.0436 computed by `ranksum`. See the [next section](#) for a description of how two-sided  $p$ -values are calculated when performing permutation tests. See [example 2](#) for a test that requires a one-sided  $p$ -value.

Note that we typed

```
. permute group ...
```

rather than

```
. permute y ...
```

We permuted the 0/1 variable `group`, which defines the groups, rather than the outcome variable `y`. For a statistic dependent on only two variables, it obviously does not matter which one we permute in terms of the theory of the test, but it does matter in terms of the efficiency of how `permute` does the computation. `permute` uses a different random shuffling algorithm for 0/1 (or dichotomous) variables than it does with other variables. See [Efficiency considerations for Monte Carlo permutations](#) below for details.

`permute` reports standard errors and confidence intervals for  $p$ -values because, as with any other Monte Carlo procedure, they are approximations to the true exact  $p$ -values. These statistics are useful to assess the precision of the computed  $p$ -values. If you need more precision, specify more permutations in the `reps()` option. See [Methods and formulas](#) for a description of how the standard errors and confidence intervals are calculated.

The confidence interval for the Monte Carlo two-sided  $p$ -value in this example is [0.0406, 0.0486]. If we want to increase the precision of the  $p$ -value, we could run `permute` again with more random permutations to narrow the confidence interval. The total number of possible distinct permutations of `group`, however, is not extremely large, and we can perform the permutation test using enumeration. See [example 3](#), where we do just that.

◀

## Two-sided $p$ -values from permutation tests

In the above example, we used the two-sided  $p$ -value for our hypothesis testing. For permutation distributions, two-sided  $p$ -values require some explanation about how they are calculated.

`permute` calculates the two-sided  $p$ -value as  $p = 2 \min(p_{\text{lower}}, p_{\text{upper}})$ , where  $p_{\text{lower}}$  is the lower one-sided  $p$ -value and  $p_{\text{upper}}$  the upper one-sided  $p$ -value. (More precisely,  $p = \min[1, 2 \min(p_{\text{lower}}, p_{\text{upper}})]$  is used because obviously  $p$ -values must be bounded by 1.)

In general, the  $p$ -value is defined as the probability under the null hypothesis of obtaining a value of the test statistic  $T$  equal to or more extreme than the value  $T_{\text{obs}}$  that was actually observed. For one-sided  $p$ -values, what is “more extreme” is clear. For lower one-sided  $p$ -values, it is the probability that  $T \leq T_{\text{obs}}$ , and for upper one-sided  $p$ -values, it is the probability that  $T \geq T_{\text{obs}}$ . When  $T$  has a symmetric distribution, the two-sided  $p$ -value is typically defined as the probability that  $|T| \geq |T_{\text{obs}}|$ . Permutation distributions, however, are not in general symmetric.

Under a permutation-based null hypothesis, the domain of  $T$  consists of all the possible permutations of the underlying data used to calculate  $T$ . The domain is discrete and finite, and hence the permutation distribution of  $T$  is discrete and finite. These finite distributions are symmetric only in certain cases. For instance, with our example of the [Wilcoxon rank-sum test](#), if the data consist of untied ranks, the distribution is symmetric. When there are ties in the ranks, however, the distribution is in most cases not symmetric.

When distributions are asymmetric, what values of  $T$  are “more extreme” than  $T_{\text{obs}}$ ? Suppose  $T_{\text{obs}}$  is below the mean of the distribution. Clearly, the lower-tail values  $T \leq T_{\text{obs}}$  are more extreme. But what values of  $T$  from the upper tail are more extreme?

For asymmetric distributions, the rationale for using  $p = 2 \min(p_{\text{lower}}, p_{\text{upper}})$  for two-sided tests is the following: It takes the smallest one-sided  $p$ -value and doubles it. Comparing this two-sided  $p$ -value against a significance level of, say, 0.05 is equivalent to comparing the smallest one-sided  $p$ -value against a level of 0.025. It essentially turns the two-sided test into a one-sided test with the significance level cut in half. So this definition conveniently sidesteps the need to define what values of  $T$  from the opposite tail from  $T_{\text{obs}}$  are more extreme! Also, it is appropriate for both symmetric and asymmetric distributions.

## One-sided permutation test

In some cases, we will want to perform a permutation test based on a one-sided  $p$ -value.

### ▷ Example 2: Permutation tests with ANOVA

Consider some fictional data from an experimental randomized complete-block design in which there are 5 subjects each receiving 10 different treatments. We want to test whether any of the treatments have an effect different from the effects of the other treatments.

Let’s load the data and list the data for the first two subjects:

```
. use https://www.stata-press.com/data/r19/permute1, clear
. sort subject treatment
. list subject treatment y in 1/20, abbrev(10)
```

|       | subject | treatment | y        |
|-------|---------|-----------|----------|
| 1.    | 1       | 1         | 4.407557 |
| 2.    | 1       | 2         | 4.280349 |
| 3.    | 1       | 3         | 4.418574 |
| 4.    | 1       | 4         | 4.075359 |
| 5.    | 1       | 5         | 3.899775 |
| <hr/> |         |           |          |
| 6.    | 1       | 6         | 5.533271 |
| 7.    | 1       | 7         | 5.142111 |
| 8.    | 1       | 8         | 5.791124 |
| 9.    | 1       | 9         | 4.504411 |
| 10.   | 1       | 10        | 4.896333 |
| <hr/> |         |           |          |
| 11.   | 2       | 1         | 5.693386 |
| 12.   | 2       | 2         | 4.508785 |
| 13.   | 2       | 3         | 5.10376  |
| 14.   | 2       | 4         | 5.753985 |
| 15.   | 2       | 5         | 5.092277 |
| <hr/> |         |           |          |
| 16.   | 2       | 6         | 4.496496 |
| 17.   | 2       | 7         | 6.339948 |
| 18.   | 2       | 8         | 4.820389 |
| 19.   | 2       | 9         | 5.686253 |
| 20.   | 2       | 10        | 6.951727 |

These data may be analyzed using anova.

```
. anova y treatment subject
```

|           | Number of obs = | 50      | R-squared =     | 0.3544 |        |
|-----------|-----------------|---------|-----------------|--------|--------|
|           | Root MSE =      | .914159 | Adj R-squared = | 0.1213 |        |
| Source    | Partial SS      | df      | MS              | F      | Prob>F |
| Model     | 16.518219       | 13      | 1.2706322       | 1.52   | 0.1574 |
| treatment | 13.022671       | 9       | 1.4469634       | 1.73   | 0.1174 |
| subject   | 3.4955481       | 4       | .87388703       | 1.05   | 0.3973 |
| Residual  | 30.08475        | 36      | .83568751       |        |        |
| Total     | 46.602969       | 49      | .951081         |        |        |

anova gives a  $p$ -value of 0.1174 for the treatment effect. This  $p$ -value is calculated with the assumption of normality for the distribution of the outcome conditional on the means of each treatment and subject effect.

Suppose we do not want to assume normality. The treatments were assigned in a random order to each of the subjects. A null hypothesis of no treatment effect means that the observed values of  $y$  and their order were determined by factors other than the treatments. The treatments were essentially labels that had nothing to do with the outcomes, and any other ordering of the labels would be a possible occurrence. That is, we imagine running the experiment multiple times, each with a different ordering of the treatments, but each time, we get the same observed values of  $y$ . This is the permutation-based formulation of the null hypothesis.

What about the subjects? Each subject gets each of the 10 treatments, so clearly we must permute the treatments within each subject independently of the permutations for the other subjects. We can do this using the `strata()` option with `permute`.

If we type `ereturn list` after `anova`, we see that the  $F$  statistic for treatment is stored in `e(F_1)`. This is our test statistic for our permutation test.

We save the dataset containing all the permutations of the test statistic using the `saving()` option. Specifying the test statistic as `F_treatment=e(F_1)` labels the test statistic as `F_treatment` in the output and is also the name of the variable containing the test statistic in `permanova.dta`, the dataset created by `saving()`. We set the seed for the random-number generator and also specify the `nodots` option to suppress the dots in the output.

```

. permute treatment F_treatment=e(F_1), reps(10000) strata(subject)
> saving(permanova) rseed(1234) nodots: anova y treatment subject

Monte Carlo permutation results Number of observations = 50
Permutation variable: treatment Number of strata = 5
 Number of permutations = 10,000

 Command: anova y treatment subject
 F_treatment: e(F_1)

```

| T           | T(obs)   | Test      | c    | n     | p     | Monte Carlo error |             |       |
|-------------|----------|-----------|------|-------|-------|-------------------|-------------|-------|
|             |          |           |      |       |       | SE(p)             | [95% CI(p)] |       |
| F_treatment | 1.731465 | lower     | 8788 | 10000 | .8788 | .0033             | .8722       | .8851 |
|             |          | upper     | 1212 | 10000 | .1212 | .0033             | .1149       | .1278 |
|             |          | two-sided |      |       |       | .2424             | .0043       | .2340 |

Notes: For lower one-sided test,  $c = \#\{T \leq T(\text{obs})\}$  and  $p = p_{\text{lower}} = c/n$ .  
 For upper one-sided test,  $c = \#\{T \geq T(\text{obs})\}$  and  $p = p_{\text{upper}} = c/n$ .  
 For two-sided test,  $p = 2 \cdot \min(p_{\text{lower}}, p_{\text{upper}})$ ; SE and CI approximate.

Our test statistic is an  $F$  statistic, so we are interested in the number of permutations that have a larger (more extreme) statistic than the 1.73 we obtained with our original data. Therefore, we want the upper one-sided  $p$ -value, which is 0.1212. This value is close to the  $p$ -value given by `anova` of 0.1174 for the treatment effect.

◀

For an additional example of a permutation test, with an application in epidemiology, see [Hayes and Moulton \(2017, 237–241\)](#).

## Enumeration

When the number of observations,  $N$ , in a dataset is small, it may be possible to enumerate all possible permutations and obtain  $p$ -values without the error involved in computing Monte Carlo  $p$ -values.

When `permute` does an enumeration, not only does  $N$  matter, but the number of distinct values of the permutation variable matters as well. `permute` does the enumeration by computing only permutations that give different arrangements of the permutation variable; that is, it does not compute any duplicate permutations. So the number of distinct values (and their multiplicity) of the permutation variable determines the number of permutations enumerated and so determines whether enumeration is feasible. See [Efficiency considerations for enumeration](#) below for details.

### ▷ Example 3: Wilcoxon rank-sum test using enumeration

Here we repeat [example 1](#), but this time we do it by enumerating all possible permutations. We load the data:

```
. use https://www.stata-press.com/data/r19/permute2
```

The data consist of an outcome  $y$  grouped by the variable `group`. If we tabulate `group`

```
. tabulate group
```

| Group | Freq. | Percent | Cum.   |
|-------|-------|---------|--------|
| 0     | 11    | 64.71   | 64.71  |
| 1     | 6     | 35.29   | 100.00 |
| Total | 17    | 100.00  |        |

we see that `group` consists of 11 zeros and 6 ones. Hence, there are only  $\binom{17}{6} = 12,376$  possible distinct permutations of `group`.

In [example 1](#), we used `ranksum` to compute the test statistic, but each time `ranksum` is called, it computes the ranks of  $y$ . It is unnecessary to recompute the ranks for each permutation. It is better to compute the ranks just once at the outset. We can do this using the `rank()` function of `egen`:

```
. egen r = rank(y)
```

The test statistic is the sum of the ranks for either one of the groups. The sum can be computed efficiently using `summarize` with an `if` restriction and the `meanonly` option.

```
. permute group r(sum), enumerate nodrop nowarning dots(100): summarize r
> if group == 1, meanonly
(running summarize on estimation sample)
(enumerating all 12,376 possible permutations)
Permutations (12,376):1,000.....2,000.....3,000.....4,000
>5,000.....6,000.....7,000.....8,000.....9,000.....
> ..10,000.....11,000.....12,000.... done

Enumeration permutation results
Number of observations = 17
Number of permutations = 12,376
Permutation variable: group

Command: summarize r if group == 1, meanonly
 _pm_1: r(sum)
```

| T     | T(obs) | Test      | c     | n     | p     |
|-------|--------|-----------|-------|-------|-------|
| _pm_1 | 74     | lower     | 12142 | 12376 | .9811 |
|       |        | upper     | 270   | 12376 | .0218 |
|       |        | two-sided |       |       | .0436 |

Notes: For lower one-sided test,  $c = \#\{T \leq T(\text{obs})\}$  and  $p = p_{\text{lower}} = c/n$ .  
 For upper one-sided test,  $c = \#\{T \geq T(\text{obs})\}$  and  $p = p_{\text{upper}} = c/n$ .  
 For two-sided test,  $p = 2 \cdot \min(p_{\text{lower}}, p_{\text{upper}})$ .

Note that it is necessary to specify the `nodrop` option. Otherwise, `permute` would drop all observations not satisfying `if group == 1` before doing the permutations, and that would not give us what we want.

`permute` with the `enumerate` option gave a two-sided  $p$ -value of 0.0436, which is the same as the exact  $p$ -value reported by `ranksum`, as it should be.

With `group` as the variable being permuted, the number of distinct permutations is quite small. If, however, we attempt to do the enumeration for all the distinct permutations of `r`:

```
. permute r r(sum), enumerate nodrop nowarning dots(100):
> summarize r if group == 1, meanonly
(running summarize on estimation sample)
(enumerating all 3.71e+12 possible permutations)
Permutations (3,705,077,376,000):1,000.....2,000.....3,000
>4,000.....—Break—
r(1);
```

Each permutation takes about 0.1 millisecond on our computer. Thus, the enumeration will take  $0.1 \times 3.71 \times 10^{12} / (365 \times 24 \times 60 \times 60 \times 1000) \approx 12$  years, so we pressed *Break*.

◀

## Efficiency considerations for Monte Carlo permutations

Suppose you want to perform a randomization two-sample *t* test, which is like the two-sample *t* test that assumes normality, only the randomization test is based on permuting the variable that defines the samples. It is the same as the Wilcoxon rank-sum test, except the observed values of the outcome, rather than their ranks, are used for the test statistic.

So say we have a variable `x` with continuous outcomes for two groups defined by the variable `group`, with values 0 or 1. The randomization two-sample *t* test could be done using Monte Carlo permutations by typing

```
. permute x r(mu_1), reps(10000): ttest x, by(group)
```

Or by typing

```
. permute group r(mu_1), reps(10000): ttest x, by(group)
```

In the first case, `x` was permuted, and in the second, `group`. Both are valid ways to do Monte Carlo permutations. `permute` is smart, however, and treats a 0/1 variable differently from how it treats a variable with lots of distinct values.

Suppose there are fewer 1s than 0s in `group`. Rather than randomly permuting all the 0s and 1s, `permute` randomly shuffles the 1s into the 0s. If there are only a few 1s relative to the number of 0s, this method is much faster than permuting all the values. Hence, if you are doing a permutation test that involves two variables, pick the one with the fewest distinct values to be the *permvar*.

When the `strata()` option is specified, `permute` uses special code for the case in which the *permvar* is dichotomous (with, say, values  $y_0$  and  $y_1$ ) and each stratum contains a single observation equal to  $y_1$  and all other observations in the stratum equal to  $y_0$  (and  $y_0$  and  $y_1$  do not flip or change in value across strata). If you are doing a stratified permutation test and you have such a variable whose permutations will give the test you want, be sure to make it the *permvar*.

For all types of data, Monte Carlo permutations of the *permvar* are computed quickly. If the command calculating the test statistic for each permutation is not fast, it is unlikely you will notice the greater speed of permuting a dichotomous variable. If, however, you are using a fast command such as `regress`, you likely will notice the greater speed.

## Efficiency considerations for enumeration

Doing an enumeration of all possible distinct permutations using the `enumerate` option, however, is a different story. Here the selection of the *permvar* is crucial and typically determines whether it is feasible to do the enumeration.

Consider performing the randomization *t* test we described earlier using enumeration:

```
. permute group r(mu_1), enumerate: tttest x, by(group)
```

Suppose there are 20 observations, 10 with `group = 0` and 10 with `group = 1`. Typing `permute group ...` will enumerate all  $\binom{20}{10} = 184,756$  possible distinct permutations of `group`. (When we say “distinct permutations”, we mean that duplicate permutations are not computed.)

If, however, we type

```
. permute x r(mu_1), enumerate: tttest x, by(group)
```

`permute x ...` will attempt to enumerate all possible permutations of `x`. If all the values of `x` are unique, there are  $20! \approx 2.4 \times 10^{18}$  possible permutations of `x`, which is much larger than 184,756.

Hence, a dichotomous variable or a variable with few distinct values should always be chosen as the *permvar* rather than another variable with many distinct values whenever possible. (To be precise, both the number of distinct values and their multiplicities determine the number of permutations. See [Methods and formulas](#).)

See [example 3](#) for an example using enumeration.

## Stored results

`permute` stores the following in `r()`:

### Scalars

|                          |                                                            |
|--------------------------|------------------------------------------------------------|
| <code>r(N)</code>        | number of observations for <i>command</i>                  |
| <code>r(n_reps)</code>   | number of permutations performed                           |
| <code>r(k_exp)</code>    | number of standard expressions                             |
| <code>r(k_eeexp)</code>  | number of <code>_b</code> and <code>_se</code> expressions |
| <code>r(n_strata)</code> | number of strata, if <code>strata()</code> specified       |
| <code>r(level)</code>    | confidence level                                           |

### Macros

|                           |                                                            |
|---------------------------|------------------------------------------------------------|
| <code>r(cmd)</code>       | <code>permute</code>                                       |
| <code>r(command)</code>   | <i>command</i> following colon                             |
| <code>r(permvar)</code>   | permutation variable                                       |
| <code>r(enumerate)</code> | "enumerate", if <code>enumerate</code> specified           |
| <code>r(title)</code>     | title in output                                            |
| <code>r(rngstate)</code>  | random-number state used for Monte Carlo permutations      |
| <code>r(exp#)</code>      | #th expression                                             |
| <code>r(strata)</code>    | strata variable, if <code>strata()</code> specified        |
| <code>r(missing)</code>   | "missing" when one or more expressions equal missing value |

### Matrices

|                            |                                                                         |
|----------------------------|-------------------------------------------------------------------------|
| <code>r(b)</code>          | observed statistics                                                     |
| <code>r(b_std)</code>      | standardized observed statistics, if <code>standardize</code> specified |
| <code>r(n)</code>          | number of nonmissing results                                            |
| <code>r(c_lower)</code>    | counts for lower one-sided <i>p</i> -values                             |
| <code>r(c_upper)</code>    | counts for upper one-sided <i>p</i> -values                             |
| <code>r(p_lower)</code>    | lower one-sided <i>p</i> -values                                        |
| <code>r(p_upper)</code>    | upper one-sided <i>p</i> -values                                        |
| <code>r(p_twosided)</code> | two-sided <i>p</i> -values                                              |

|                               |                                                                 |
|-------------------------------|-----------------------------------------------------------------|
| <code>r(se_p_lower)</code>    | Monte Carlo standard errors of lower one-sided $p$ -values      |
| <code>r(se_p_upper)</code>    | Monte Carlo standard errors of upper one-sided $p$ -values      |
| <code>r(se_p_twosided)</code> | Monte Carlo standard errors of two-sided $p$ -values            |
| <code>r(ci_p_lower)</code>    | Monte Carlo confidence intervals of lower one-sided $p$ -values |
| <code>r(ci_p_upper)</code>    | Monte Carlo confidence intervals of upper one-sided $p$ -values |
| <code>r(ci_p_twosided)</code> | Monte Carlo confidence intervals of two-sided $p$ -values       |

## Methods and formulas

One-sided  $p$ -values are based on counts of the test statistic  $T$  calculated for each permutation that are more extreme than the observed value  $T_{\text{obs}}$ . The lower one-sided  $p$ -value uses the count  $c = \#\{T \leq T_{\text{obs}}\}$ , and the upper one-sided  $p$ -value uses  $c = \#\{T \geq T_{\text{obs}}\}$ .

The counts from Monte Carlo permutations are assumed to have a binomial distribution. Standard errors and confidence intervals are computed using `cii proportions`  $n$   $c$ , where  $n$  is the number of permutations that yielded nonmissing results and  $c$  is the count. The confidence intervals are exact binomial confidence intervals. See *Methods and formulas* in [R] `ci`.

`permute` calculates the two-sided  $p$ -value as  $p = \min[1, 2 \min(p_{\text{lower}}, p_{\text{upper}})]$ , where  $p_{\text{lower}}$  is the lower one-sided  $p$ -value and  $p_{\text{upper}}$  the upper one-sided  $p$ -value. Because the definition of the two-sided  $p$ -value does not yield a simple formula for the standard error or confidence interval for Monte Carlo permutations, the following ad hoc procedure is used. If  $p_{\text{lower}}$  is the minimum one-sided  $p$ -value, its count  $c_{\text{lower}}$  is doubled. If  $p_{\text{upper}}$  is the minimum one-sided  $p$ -value, its count  $c_{\text{upper}}$  is doubled. More precisely, the value  $c_2 = \min[n, 2 \min(c_{\text{lower}}, c_{\text{upper}})]$  is used, and its distribution is assumed to be approximately binomial. Standard errors and confidence intervals are computed using `cii proportions`  $n$   $c_2$ , `wald`. The confidence intervals produced are asymptotic binomial confidence intervals.

When `enumerate` is specified, the  $p$ -values have no error.

Suppose there are  $N$  observations and the variable being permuted contains  $K$  distinct values, each with multiplicity  $n_k$ ,  $k = 1, \dots, K$ . The total number of distinct permutations is

$$\frac{N!}{n_1! n_2! \cdots n_K!}$$

This is the number of permutations computed when `enumerate` is specified.

When `standardize` is specified, instead of displaying the observed test statistic  $T_{\text{obs}}$ , the standardized statistic

$$\frac{T_{\text{obs}} - \text{mean}(T)}{\sqrt{\text{Var}(T)}}$$

is displayed where  $\text{mean}(T)$  and  $\text{Var}(T)$  are the mean and variance of the permutation distribution of  $T$ :

$$\text{mean}(T) = \frac{1}{n} \sum_{i=1}^n T_i$$

$$\text{Var}(T) = \frac{1}{n} \sum_{i=1}^n \{T_i - \text{mean}(T)\}^2$$

$n$  is the number of permutations, and  $T_i$  is the test statistic calculated for the  $i$ th permutation.

## Description

The term pk refers to pharmacokinetic data and the Stata commands, all of which begin with the letters pk, designed to do some of the analyses commonly performed in the pharmaceutical industry. The system is intended for the analysis of pharmacokinetic data, although some of the commands are for general use.

The pk commands are

|            |                       |                                              |
|------------|-----------------------|----------------------------------------------|
| pkexamine  | [R] <b>pkexamine</b>  | Calculate pharmacokinetic measures           |
| pksumm     | [R] <b>pksumm</b>     | Summarize pharmacokinetic data               |
| pkshape    | [R] <b>pkshape</b>    | Reshape (pharmacokinetic) Latin-square data  |
| pkcross    | [R] <b>pkcross</b>    | Analyze crossover experiments                |
| pkequiv    | [R] <b>pkequiv</b>    | Perform bioequivalence tests                 |
| pkcollapse | [R] <b>pkcollapse</b> | Generate pharmacokinetic measurement dataset |

Also see [ME] **menl** for fitting pharmacokinetic models using nonlinear mixed-effects models; for instance, see [example 15](#) in [ME] **menl**.

## Remarks and examples

Several types of clinical trials are commonly performed in the pharmaceutical industry. Examples include combination trials, multicenter trials, equivalence trials, and active control trials. For each type of trial, there is an optimal study design for estimating the effects of interest. The pk system can be used to analyze equivalence trials, which are usually conducted using a crossover design; however, it is possible to use a parallel design and still draw conclusions about equivalence.

Equivalence trials assess bioequivalence between two drugs. Although proving that two drugs behave the same is impossible, regulatory agencies believe that if the absorption properties of two drugs are similar, the two drugs will produce similar effects and have similar safety profiles. Generally, the goal of an equivalence trial is to assess the equivalence of a generic drug to an existing drug. This goal is commonly accomplished by comparing a confidence interval about the difference between a pharmacokinetic measurement of two drugs with an equivalence limit constructed from regulations. If the confidence interval is entirely within the equivalence limit, the drugs are declared bioequivalent. Another approach to assessing bioequivalence is to use the method of interval hypotheses testing. `pkequiv` is used to conduct these tests of bioequivalence.

Several pharmacokinetic measures can be used to ascertain how available a drug is for cellular absorption. The most common measure is the area under the concentration–time curve (AUC). Another common measure of drug availability is the maximum concentration ( $C_{\max}$ ) achieved by the drug during the follow-up period. Stata reports these and other less common measures of drug availability, including the time at which the maximum drug concentration was observed and the duration of the period during which the subject was being measured. Stata also reports the elimination rate, that is, the rate at which the drug is metabolized, and the drug’s half-life, that is, the time it takes for the drug concentration to fall to one-half of its maximum concentration.

pkexamine computes and reports all the pharmacokinetic measures that Stata produces, including four calculations of the AUC. The standard AUC from 0 to the maximum observed time ( $AUC_{0,t_{\max}}$ ) is computed using cubic splines or the trapezoidal rule. Additionally, pkexamine also computes the AUC from 0 to infinity by extending the standard concentration–time curve from the maximum observed time using three different methods. The first method simply extends the standard curve by using a least-squares linear fit through the last few data points. The second method extends the standard curve by fitting a decreasing exponential curve through the last few data points. The third method extends the curve by fitting a least-squares linear regression line on the log concentration. The mathematical details of these extensions are described in *Methods and formulas* of [R] [pkexamine](#).

Data from an equivalence trial may also be analyzed using methods appropriate to the particular study design. When you have a crossover design, pkcross can be used to fit an appropriate ANOVA model. A crossover design is simply a restricted Latin square; therefore, pkcross can also be used to analyze any Latin-square design.

Some practical concerns arise when dealing with data from equivalence trials. Primarily, the data must be organized in a manner that Stata can use. The pk commands include pkcollapse and pkshape, which are designed to help transform data from a common format to one that is suitable for analysis with Stata.

In the following examples, we illustrate several different data formats that are often encountered in pharmaceutical research and describe how these formats can be transformed to formats that can be analyzed with Stata.

### ▷ Example 1

Assume that we have one subject and are interested in determining the drug profile for that subject. A reasonable experiment would be to give the subject the drug and then measure the concentration of the drug in the subject's blood over a given period. For example, here is part of a dataset from [Chow and Liu \(2009, 13\)](#):

```
. use https://www.stata-press.com/data/r19/auc
(Primidone concentrations)
. list, abbrev(14)
```

|     | id | time | concentration |
|-----|----|------|---------------|
| 1.  | 1  | 0    | 0             |
| 2.  | 1  | .5   | 0             |
| 3.  | 1  | 1    | 2.8           |
| 4.  | 1  | 1.5  | 4.4           |
| 5.  | 1  | 2    | 4.4           |
| 6.  | 1  | 3    | 4.7           |
| 7.  | 1  | 4    | 4.1           |
| 8.  | 1  | 6    | 4             |
| 9.  | 1  | 8    | 3.6           |
| 10. | 1  | 12   | 3             |
| 11. | 1  | 16   | 2.5           |
| 12. | 1  | 24   | 2             |
| 13. | 1  | 32   | 1.6           |

Examining these data, we notice that the concentration quickly increases, plateaus for a short period, and then slowly decreases over time. `pkexamine` is used to calculate the pharmacokinetic measures of interest. `pkexamine` is explained in detail in [R] `pkexamine`. The output is

```
. pkexamine time concentration
 Maximum concentration = 4.7
 Time of maximum concentration = 3
 Time of last observation (Tmax) = 32
 Elimination rate = 0.0279
 Half life = 24.8503
```

Area under the curve

| AUC [0, Tmax] | AUC [0, inf.)<br>Linear of log conc. | AUC [0, inf.)<br>Linear fit | AUC [0, inf.)<br>Exponential fit |
|---------------|--------------------------------------|-----------------------------|----------------------------------|
| 85.24         | 142.603                              | 107.759                     | 142.603                          |

Fit based on last 3 points.

◀

## ▶ Example 2

Clinical trials require that data be collected on more than one subject. There are several ways to enter raw measured data collected on several subjects. It would be reasonable to enter for each subject the drug concentration value at specific points in time. Such data could be

| id | conc1 | conc2 | conc3 | conc4 | conc5 | conc6 | conc7 |
|----|-------|-------|-------|-------|-------|-------|-------|
| 1  | 0     | 1     | 4     | 7     | 5     | 3     | 1     |
| 2  | 0     | 2     | 6     | 5     | 4     | 3     | 2     |
| 3  | 0     | 1     | 2     | 3     | 5     | 4     | 1     |

where `conc1` is the concentration at the first measured time, `conc2` is the concentration at the second measured time, etc. This format requires that each drug concentration measurement be made at the same time on each subject. Another more flexible way to enter the data is to have an observation with three variables for each time measurement on a subject. Each observation would have a subject ID, the time at which the measurement was made, and the corresponding drug concentration at that time. The data would be as follows:

```
. use https://www.stata-press.com/data/r19/pkdata
(Fictional drug concentration data)
. list id conc1 time, sepby(id)
```

|                         | id | conc1    | time |
|-------------------------|----|----------|------|
| 1.                      | 1  | 0        | 0    |
| 2.                      | 1  | 3.073403 | .5   |
| 3.                      | 1  | 5.188444 | 1    |
| 4.                      | 1  | 5.898577 | 1.5  |
| 5.                      | 1  | 5.096378 | 2    |
| 6.                      | 1  | 6.094085 | 3    |
| 7.                      | 1  | 5.158772 | 4    |
| 8.                      | 1  | 5.7065   | 6    |
| 9.                      | 1  | 5.272467 | 8    |
| 10.                     | 1  | 4.4576   | 12   |
| 11.                     | 1  | 5.146423 | 16   |
| 12.                     | 1  | 4.947427 | 24   |
| 13.                     | 1  | 1.920421 | 32   |
| 14.                     | 2  | 0        | 0    |
| 15.                     | 2  | 2.48462  | .5   |
| 16.                     | 2  | 4.883569 | 1    |
| 17.                     | 2  | 7.253442 | 1.5  |
| 18.                     | 2  | 5.849345 | 2    |
| 19.                     | 2  | 6.761085 | 3    |
| 20.                     | 2  | 4.33839  | 4    |
| 21.                     | 2  | 5.04199  | 6    |
| 22.                     | 2  | 4.25128  | 8    |
| 23.                     | 2  | 6.205004 | 12   |
| 24.                     | 2  | 5.566165 | 16   |
| 25.                     | 2  | 3.689007 | 24   |
| 26.                     | 2  | 3.644063 | 32   |
| <i>(output omitted)</i> |    |          |      |
| 207.                    | 16 | 4.673281 | 24   |
| 208.                    | 16 | 3.487347 | 32   |

Stata expects the data to be organized in the second form, as shown in `pkdata.dta`. If your data are organized as described in the first format, you will need to reshape the data to the second form; see [D] [reshape](#). Because the data in the second (or long) format contain information for one drug on several subjects, `pksumm` can be used to produce summary statistics of the pharmacokinetic measurements. The output is

```
. pksumm id time conc1
.....
```

Summary statistics for the pharmacokinetic measures

| Measure | Mean   | Median | Variance  | Skewness | Kurtosis | Number of observations = 16 |
|---------|--------|--------|-----------|----------|----------|-----------------------------|
|         |        |        |           |          |          | p-value                     |
| auc     | 151.63 | 152.18 | 127.58    | -0.34    | 2.07     | 0.55                        |

Until now, we have been concerned with the profile of only one drug. We have characterized the profile of that drug by individual subjects by using `pkexamine` and by a group of subjects by using `pksumm`. The goal of an equivalence trial, however, is to compare two drugs, which we will do in the rest of this example.

For equivalence trials, the study design most often used is the crossover design. For a complete discussion of crossover designs, see [Ratkowsky, Evans, and Alldredge \(1993\)](#).

In brief, crossover designs require that each subject be given both treatments at two different times. The order in which the treatments are applied changes between groups. For example, if we had 16 subjects numbered 1–16, the first 8 would receive reference treatment “R” during the first period of the study, and then they would be given test treatment “T”. The second 8 subjects would be given treatment “T” during the first period of the study, and then they would be given treatment “R”. Each subject in the study will have four variables that describe the observation: a subject identifier, a sequence identifier that indicates the order of treatment, and two outcome variables, one for each treatment. The outcome variables for each subject are the pharmacokinetic measures. The data must be transformed from a series of measurements on individual subjects to data containing the pharmacokinetic measures for each subject. In Stata parlance, this is referred to as a collapse, which can be done with `pkcollapse`; see [\[R\] pkcollapse](#).

Here is part of our data:

```
. list, sepby(id)
```

|      | id | seq | time                    | conc1    | conc2    |
|------|----|-----|-------------------------|----------|----------|
| 1.   | 1  | 1   | 0                       | 0        | 0        |
| 2.   | 1  | 1   | .5                      | 3.073403 | 3.712592 |

| 27.  | 3  | 1   | 0                       | 0        | 0        |
|      |    |     | <i>(output omitted)</i> |          |          |
| 208. | 16 | 2   | 32                      | 3.487347 | 5.213639 |

This format is similar to the second format described above, except that now we have measurements for two drugs at each time for each subject. We transform these data with `pkcollapse`:

```
. pkcollapse time conc1 conc2, id(id) keep(seq) stat(auc)
.....
. list, sep(8) abbrev(10)
```

|     | id | seq | auc_conc1 | auc_conc2 |
|-----|----|-----|-----------|-----------|
| 1.  | 1  | 1   | 150.9643  | 218.5551  |
| 2.  | 2  | 1   | 146.7606  | 133.3201  |
| 3.  | 3  | 1   | 160.6548  | 126.0635  |
| 4.  | 4  | 1   | 157.8622  | 96.17461  |
| 5.  | 5  | 1   | 133.6957  | 188.9038  |
| 6.  | 6  | 1   | 160.639   | 223.6922  |
| 7.  | 7  | 1   | 131.2604  | 104.0139  |
| 8.  | 8  | 1   | 168.5186  | 237.8962  |
| 9.  | 9  | 2   | 137.0627  | 139.7382  |
| 10. | 10 | 2   | 153.4038  | 202.3942  |
| 11. | 11 | 2   | 163.4593  | 136.7848  |
| 12. | 12 | 2   | 146.0462  | 104.5191  |
| 13. | 13 | 2   | 158.1457  | 165.8654  |
| 14. | 14 | 2   | 147.1977  | 139.235   |
| 15. | 15 | 2   | 164.9988  | 166.2391  |
| 16. | 16 | 2   | 145.3823  | 158.5146  |

For this example, we chose to use the  $AUC_{0,t_{max}}$  for two drugs as our pharmacokinetic measure. We could have used any of the measures computed by `pkexamine`. In addition to the AUCs, the dataset also contains a sequence variable for each subject indicating when each treatment was administered.

The data produced by `pkcollapse` are in what Stata calls wide format; that is, there is one observation per subject containing two or more outcomes. To use `pkcross` and `pkequiv`, we need to transform these data to long format, which we can do using `pkshape`; see [R] [pkshape](#).

Consider the first subject in the dataset. This subject is in sequence 1, which means that treatment “R” was applied during the first period of the study and treatment “T” was applied in the second period of the study. We need to split the first observation into two observations so that the outcome measure is only in one variable. We also need two new variables, one indicating the treatment the subject received and another recording the period of the study when the subject received that treatment. We might expect the expansion of the first subject to be

| id | sequence | auc      | treat | period |
|----|----------|----------|-------|--------|
| 1  | 1        | 150.9643 | R     | 1      |
| 1  | 1        | 218.5551 | T     | 2      |

We see that subject number 1 was in sequence 1, had an  $AUC_{0,t_{max}}$  of 150.9643 when treatment “R” was applied in the first period of the study, and had an  $AUC_{0,t_{max}}$  of 218.5551 when treatment “T” was applied in the second period.

Similarly, the expansion of subject 9 (the first subject in sequence 2) would be

| id | sequence | auc      | treat | period |
|----|----------|----------|-------|--------|
| 9  | 2        | 137.0627 | T     | 1      |
| 9  | 2        | 139.7382 | R     | 2      |

Here treatment “T” was applied to the subject during the first period of the study, and treatment “R” was applied to the subject during the second period of the study.

An additional complication is common in crossover study designs. The treatment applied in the first period of the study might still have some effect on the outcome in the second period. In this example, each subject was given one treatment followed by another treatment. To get accurate estimates of treatment effects, it is necessary to account for the carryover effect, the effect that the first treatment has in the second period of the study. We must, therefore, have a variable that indicates which treatment was applied in the first treatment period. `pkshape` creates a variable that indicates the carryover effect. For treatments applied during the first treatment period, there will never be a carryover effect. The sequence, treatment, and carryover variables all receive value labels. Thus, the expanded data created by `pkshape` for subject 1 and subject 9 will be as shown in the results:

```
. pkshape id seq auc*, order(RT TR)
. sort id sequence period
. list, sep(16)
```

|     | id | sequence | outcome  | treat | carry | period |
|-----|----|----------|----------|-------|-------|--------|
| 1.  | 1  | RT       | 150.9643 | R     | 0     | 1      |
| 2.  | 1  | RT       | 218.5551 | T     | R     | 2      |
| 3.  | 2  | RT       | 146.7606 | R     | 0     | 1      |
| 4.  | 2  | RT       | 133.3201 | T     | R     | 2      |
| 5.  | 3  | RT       | 160.6548 | R     | 0     | 1      |
| 6.  | 3  | RT       | 126.0635 | T     | R     | 2      |
| 7.  | 4  | RT       | 157.8622 | R     | 0     | 1      |
| 8.  | 4  | RT       | 96.17461 | T     | R     | 2      |
| 9.  | 5  | RT       | 133.6957 | R     | 0     | 1      |
| 10. | 5  | RT       | 188.9038 | T     | R     | 2      |
| 11. | 6  | RT       | 160.639  | R     | 0     | 1      |
| 12. | 6  | RT       | 223.6922 | T     | R     | 2      |
| 13. | 7  | RT       | 131.2604 | R     | 0     | 1      |
| 14. | 7  | RT       | 104.0139 | T     | R     | 2      |
| 15. | 8  | RT       | 168.5186 | R     | 0     | 1      |
| 16. | 8  | RT       | 237.8962 | T     | R     | 2      |
| 17. | 9  | TR       | 137.0627 | T     | 0     | 1      |
| 18. | 9  | TR       | 139.7382 | R     | T     | 2      |
| 19. | 10 | TR       | 153.4038 | T     | 0     | 1      |
| 20. | 10 | TR       | 202.3942 | R     | T     | 2      |
| 21. | 11 | TR       | 163.4593 | T     | 0     | 1      |
| 22. | 11 | TR       | 136.7848 | R     | T     | 2      |
| 23. | 12 | TR       | 146.0462 | T     | 0     | 1      |
| 24. | 12 | TR       | 104.5191 | R     | T     | 2      |
| 25. | 13 | TR       | 158.1457 | T     | 0     | 1      |
| 26. | 13 | TR       | 165.8654 | R     | T     | 2      |
| 27. | 14 | TR       | 147.1977 | T     | 0     | 1      |
| 28. | 14 | TR       | 139.235  | R     | T     | 2      |
| 29. | 15 | TR       | 164.9988 | T     | 0     | 1      |
| 30. | 15 | TR       | 166.2391 | R     | T     | 2      |
| 31. | 16 | TR       | 145.3823 | T     | 0     | 1      |
| 32. | 16 | TR       | 158.5146 | R     | T     | 2      |

Crossover designs do not require that each subject receive each treatment, but if they do, the crossover design is referred to as a complete crossover design.

The dataset (`pkdata.dta`) in this example is organized in a manner that can be analyzed with Stata. To fit an ANOVA model to these data, we can use `anova` or `pkcross`. To conduct equivalence tests, we can use `pkequiv`.

## Description

pkcollapse generates new variables with the pharmacokinetic summary measures of interest.

pkcollapse is one of the pk commands. Please read [\[R\] pk](#) before reading this entry.

## Quick start

Single concentration, v1, measured over time, tvar, for patients identified by idvar

```
pkcollapse tvar v1, id(idvar)
```

Same as above, but add additional drug concentration data stored in v2

```
pkcollapse tvar v1 v2, id(idvar)
```

Same as above, but use trapezoidal rule for calculating area under the concentration–time curve ( $AUC_{0,t_{\max}}$ )

```
pkcollapse tvar v1 v2, id(idvar) trapezoid
```

Same as above, and increase the number of data points used to estimate  $AUC_{0,\infty}$  to 10

```
pkcollapse tvar v1 v2, id(idvar) trapezoid fit(10)
```

Retain variables v3 and v4 when collapsing dataset

```
pkcollapse tvar v1 v2, id(idvar) keep(v3 v4)
```

## Menu

Statistics > Epidemiology and related > Other > Generate pharmacokinetic measurement dataset

## Syntax

```
pkcollapse time concentration [concentration [...] [if], id(id_var) [options]
```

## Options

### Main

*id*(*id\_var*) is required and specifies the variable that contains the subject ID over which *pkcollapse* is to operate.

*stat*(*measures*) specifies the measures to be generated. The default is to generate all the measures.

*trapezoid* tells Stata to use the trapezoidal rule when calculating the  $AUC_{0,t_{\max}}$ . The default is to use cubic splines, which give better results for most functions. When the curve is irregular, *trapezoid* may give better results.

*fit*(#) specifies the number of points to use in estimating the  $AUC_{0,\infty}$ . The default is *fit*(3), the last three points. This number should be viewed as a minimum; the appropriate number of points will depend on your data.

*keep*(*varlist*) specifies the variables to be kept during the collapse. Variables not specified with the *keep*() option will be dropped. When *keep*() is specified, the kept variables are checked to ensure that all values of the variables are the same within *id\_var*.

*force* forces the collapse, even when values of the *keep*() variables differ within *id\_var*.

*nodots* suppresses the display of dots during calculation.

## Remarks and examples

pkcollapse generates all the summary pharmacokinetic measures.

### ▷ Example 1

We demonstrate the use of pkcollapse with pkdata.dta described in [example 2](#) of [R] [pk](#). We have drug concentration data on 16 subjects. Each subject is measured at 13 time points over a 32-hour period. Some of the records are as follows:

```
. use https://www.stata-press.com/data/r19/pkdata
(Fictional drug concentration data)
. list, sep(0)
```

|      | id | seq | time             | conc1    | conc2    |
|------|----|-----|------------------|----------|----------|
| 1.   | 1  | 1   | 0                | 0        | 0        |
| 2.   | 1  | 1   | .5               | 3.073403 | 3.712592 |
|      |    |     | (output omitted) |          |          |
| 14.  | 2  | 1   | 0                | 0        | 0        |
| 15.  | 2  | 1   | .5               | 2.48462  | .9209593 |
| 16.  | 2  | 1   | 1                | 4.883569 | 5.925818 |
| 17.  | 2  | 1   | 1.5              | 7.253442 | 8.710549 |
| 18.  | 2  | 1   | 2                | 5.849345 | 10.90552 |
| 19.  | 2  | 1   | 3                | 6.761085 | 8.429898 |
|      |    |     | (output omitted) |          |          |
| 207. | 16 | 2   | 24               | 4.673281 | 6.059818 |
| 208. | 16 | 2   | 32               | 3.487347 | 5.213639 |

Although pksumm allows us to view all the pharmacokinetic measures, we can create a dataset with the measures by using pkcollapse.

```
. pkcollapse time conc1 conc2, id(id) stat(auc) keep(seq)
.....
. list, sep(8) abbrev(10)
```

|     | id | seq | auc_conc1 | auc_conc2 |
|-----|----|-----|-----------|-----------|
| 1.  | 1  | 1   | 150.9643  | 218.5551  |
| 2.  | 2  | 1   | 146.7606  | 133.3201  |
| 3.  | 3  | 1   | 160.6548  | 126.0635  |
| 4.  | 4  | 1   | 157.8622  | 96.17461  |
| 5.  | 5  | 1   | 133.6957  | 188.9038  |
| 6.  | 6  | 1   | 160.639   | 223.6922  |
| 7.  | 7  | 1   | 131.2604  | 104.0139  |
| 8.  | 8  | 1   | 168.5186  | 237.8962  |
| 9.  | 9  | 2   | 137.0627  | 139.7382  |
| 10. | 10 | 2   | 153.4038  | 202.3942  |
| 11. | 11 | 2   | 163.4593  | 136.7848  |
| 12. | 12 | 2   | 146.0462  | 104.5191  |
| 13. | 13 | 2   | 158.1457  | 165.8654  |
| 14. | 14 | 2   | 147.1977  | 139.235   |
| 15. | 15 | 2   | 164.9988  | 166.2391  |
| 16. | 16 | 2   | 145.3823  | 158.5146  |

The resulting dataset contains one observation per subject and is in wide format. If we want to use [pkcross](#) or [pkequiv](#), we must transform these data to long format with the [pkshape](#) command, which we do in [example 2](#) of [\[R\] pk](#).

## Methods and formulas

The statistics generated by `pkcollapse` are described in [\[R\] pkexamine](#).

## Description

`pkcross` analyzes data from a crossover design experiment. When analyzing pharmaceutical trial data, if the treatment, carryover, and sequence variables are known, the omnibus test for separability of the treatment and carryover effects is calculated.

`pkcross` is one of the `pk` commands. Please read [\[R\] pk](#) before reading this entry.

## Quick start

For pharmacokinetic outcome `y` measured for subjects identified by `idvar` given treatments `treat` in sequences identified by `seq` in periods `period` with potential carryover effects from previous treatment `carry`:

Sequence, treatment, and period effects for a  $2 \times 2$  design

```
pkcross y, param(3) id(idvar) sequence(seq) treatment(treat) ///
 period(period)
```

Same as above, but estimate the carryover effect instead of the sequence effect

```
pkcross y, param(1) id(idvar) treatment(treat) period(period) ///
 carryover(carry)
```

Only estimate sequence, treatment, and period effects in higher-order designs

```
pkcross y, id(idvar) sequence(seq) treatment(treat) carryover(none)
```

Also estimate carryover effect and omnibus measure of separability of treatment and carryover effects

```
pkcross y, model(seq / idvar | seq treat carry period) ///
 treatment(treat) carryover(carry) sequence(seq)
```

## Menu

Statistics > Epidemiology and related > Other > Analyze crossover experiments

## Syntax

```
pkcross outcome [if] [in] [, options]
```

| <i>options</i>                         | Description                                                                                                                       |
|----------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------|
| Model                                  |                                                                                                                                   |
| <code>sequence(<i>varname</i>)</code>  | sequence variable; default is <code>sequence(sequence)</code>                                                                     |
| <code>treatment(<i>varname</i>)</code> | treatment variable; default is <code>treatment(treat)</code>                                                                      |
| <code>period(<i>varname</i>)</code>    | period variable; default is <code>period(period)</code>                                                                           |
| <code>id(<i>varname</i>)</code>        | ID variable; default is <code>id(id)</code>                                                                                       |
| <code>carryover(<i>varname</i>)</code> | carryover variable; default is <code>carryover(carry)</code>                                                                      |
| <code>carryover(none)</code>           | omit carryover effects from model; default is <code>carryover(carry)</code>                                                       |
| <code>model(<i>string</i>)</code>      | specify the model to fit                                                                                                          |
| <code>sequential</code>                | estimate sequential instead of partial sums of squares                                                                            |
| Parameterization                       |                                                                                                                                   |
| <code>param(3)</code>                  | estimate mean and the period, treatment, and sequence effects; assume no carryover effects exist; the default                     |
| <code>param(1)</code>                  | estimate mean and the period, treatment, and carryover effects; assume no sequence effects exist                                  |
| <code>param(2)</code>                  | estimate mean, period and treatment effects, and period-by-treatment interaction; assume no sequence or carryover effects exist   |
| <code>param(4)</code>                  | estimate mean, sequence and treatment effects, and sequence-by-treatment interaction; assume no period or carryover effects exist |

## Options

### Model

`sequence(varname)` specifies the variable that contains the sequence in which the treatment was administered. If this option is not specified, `sequence(sequence)` is assumed.

`treatment(varname)` specifies the variable that contains the treatment information. If this option is not specified, `treatment(treat)` is assumed.

`period(varname)` specifies the variable that contains the period information. If this option is not specified, `period(period)` is assumed.

`id(varname)` specifies the variable that contains the subject identifiers. If this option is not specified, `id(id)` is assumed.

`carryover(varname|none)` specifies the variable that contains the carryover information. If `carry(none)` is specified, the carryover effects are omitted from the model. If this option is not specified, `carryover(carry)` is assumed.

`model(string)` specifies the model to be fit. For higher-order crossover designs, this option can be useful if you want to fit a model other than the default. However, `anova` (see [R] [anova](#)) can also be used to fit a crossover model. The default model for higher-order crossover designs is outcome predicted by sequence, period, treatment, and carryover effects. By default, the model statement is `model(sequence period treat carry)`.

`sequential` specifies that sequential sums of squares be estimated.

## Parameterization

`param(#)` specifies which of the four parameterizations to use for the analysis of a  $2 \times 2$  crossover experiment. This option is ignored with higher-order crossover designs. The default is `param(3)`. See the [technical note](#) in this entry for  $2 \times 2$  crossover designs for more details.

`param(3)` estimates the overall mean, the period effects, the treatment effects, and the sequence effects, assuming that no carryover effects exist. This is the default parameterization.

`param(1)` estimates the overall mean, the period effects, the treatment effects, and the carryover effects, assuming that no sequence effects exist.

`param(2)` estimates the overall mean, the period effects, the treatment effects, and the period-by-treatment interaction, assuming that no sequence or carryover effects exist.

`param(4)` estimates the overall mean, the sequence effects, the treatment effects, and the sequence-by-treatment interaction, assuming that no period or carryover effects exist. When the sequence-by-treatment interaction is equivalent to the period effect, this reduces to the third parameterization.

## Remarks and examples

`pkcross` is designed to analyze crossover experiments. Use `pkshape` first to reshape your data; see [\[R\] pkshape](#). `pkcross` assumes that the data were reshaped by `pkshape` or are organized in the same manner as produced with `pkshape`. Washout periods are indicated by the number 0. See the technical note below for more information on analyzing  $2 \times 2$  crossover experiments.

### □ Technical note

The  $2 \times 2$  crossover design cannot be used to estimate more than four parameters because there are only four pieces of information (the four cell means) collected. `pkcross` uses ANOVA models to analyze the data, so one of the four parameters must be the overall mean of the model, leaving just 3 degrees of freedom to estimate the remaining effects (period, sequence, treatment, and carryover). Thus, the model is overparameterized. Estimation of treatment and carryover effects requires the assumption of either no period effects or no sequence effects. Some researchers maintain that estimating carryover effects at the expense of other effects is a bad idea. This is a limitation of this design. `pkcross` implements four parameterizations for this model. They are numbered sequentially from one to four and are described in [Options](#).

□

### ▷ Example 1

Consider the example data published in [Chow and Liu \(2009, 71\)](#). There are 24 patients, 12 in each sequence. Sequence 1 is the reference formulation followed by the test formulation; sequence 2 is the test formulation followed by the reference formulation. After reshaping the data with [pkshape](#), we have variables that identify the subjects, periods, treatments, sequence, and carryover treatment. The outcome variable contains the reported  $AUC_{0,t_{\max}}$ . To compute the ANOVA table, use `pkcross`:

```

. use https://www.stata-press.com/data/r19/chowliu
. pkshape id seq period1 period2, order(RT TR)
. pkcross outcome
 Sequence variable = sequence
 Period variable = period
 Treatment variable = treat
 Carryover variable = carry
 ID variable = id

```

Analysis of variance (ANOVA) for a 2x2 crossover study

| Source of variation  | Partial SS | df | MS     | F    | Prob > F |
|----------------------|------------|----|--------|------|----------|
| <b>Intersubjects</b> |            |    |        |      |          |
| Sequence effect      | 276.00     | 1  | 276.00 | 0.37 | 0.5468   |
| Residuals            | 16211.49   | 22 | 736.89 | 4.41 | 0.0005   |
| <b>Intrasubjects</b> |            |    |        |      |          |
| Treatment effect     | 62.79      | 1  | 62.79  | 0.38 | 0.5463   |
| Period effect        | 35.97      | 1  | 35.97  | 0.22 | 0.6474   |
| Residuals            | 3679.43    | 22 | 167.25 |      |          |
| Total                | 20265.68   | 47 |        |      |          |

Omnibus measure of separability of treatment and carryover = 29.2893%

There is evidence of intersubject variability, but there are no other significant effects. The omnibus test for separability is a measure reflecting the degree to which the study design allows the treatment effects to be estimated independently of the carryover effects. The measure of separability of the treatment and carryover effects indicates approximately 29% separability, which can be interpreted as the degree to which the treatment and carryover effects are orthogonal. This is a characteristic of the design of the study. For a complete discussion, see [Ratkowsky, Evans, and Alldredge \(1993\)](#). Compared with the output in [Chow and Liu \(2009\)](#), the sequence effect is mislabeled as a carryover effect. See [Ratkowsky, Evans, and Alldredge \(1993, sec. 3.2\)](#) for a complete discussion of the mislabeling.

By specifying `param(1)`, we obtain parameterization 1 for this model.

```

. pkcross outcome, param(1)
 Sequence variable = sequence
 Period variable = period
 Treatment variable = treat
 Carryover variable = carry
 ID variable = id

```

Analysis of variance (ANOVA) for a 2x2 crossover study

| Source of variation | Partial SS | df | MS     | F    | Prob > F |
|---------------------|------------|----|--------|------|----------|
| Treatment effect    | 301.04     | 1  | 301.04 | 0.67 | 0.4189   |
| Period effect       | 255.62     | 1  | 255.62 | 0.57 | 0.4561   |
| Carryover effect    | 276.00     | 1  | 276.00 | 0.61 | 0.4388   |
| Residuals           | 19890.92   | 44 | 452.07 |      |          |
| Total               | 20265.68   | 47 |        |      |          |

Omnibus measure of separability of treatment and carryover = 29.2893%

## ► Example 2

Consider the case of a two-treatment, four-sequence, two-period crossover design. This design is commonly referred to as Balaam's design (Balaam 1968). Ratkowsky, Evans, and Alldredge (1993, 140) published the following data from an amantadine trial, originally published by Taka and Armitage (1983):

```
. use https://www.stata-press.com/data/r19/balaam, clear
. list, sep(0)
```

|     | id | seq | period1 | period2 | period3 |
|-----|----|-----|---------|---------|---------|
| 1.  | 1  | -ab | 9       | 8.75    | 8.75    |
| 2.  | 2  | -ab | 12      | 10.5    | 9.75    |
| 3.  | 3  | -ab | 17      | 15      | 18.5    |
| 4.  | 4  | -ab | 21      | 21      | 21.5    |
| 5.  | 1  | -ba | 23      | 22      | 18      |
| 6.  | 2  | -ba | 15      | 15      | 13      |
| 7.  | 3  | -ba | 13      | 14      | 13.75   |
| 8.  | 4  | -ba | 24      | 22.75   | 21.5    |
| 9.  | 5  | -ba | 18      | 17.75   | 16.75   |
| 10. | 1  | -aa | 14      | 12.5    | 14      |
| 11. | 2  | -aa | 27      | 24.25   | 22.5    |
| 12. | 3  | -aa | 19      | 17.25   | 16.25   |
| 13. | 4  | -aa | 30      | 28.25   | 29.75   |
| 14. | 1  | -bb | 21      | 20      | 19.51   |
| 15. | 2  | -bb | 11      | 10.5    | 10      |
| 16. | 3  | -bb | 20      | 19.5    | 20.75   |
| 17. | 4  | -bb | 25      | 22.5    | 23.5    |

The sequence identifier must be a string with 0s to indicate washout or baseline periods, or a number. If the sequence identifier is numeric, the `order()` option must be specified with `pkshape`. If the sequence identifier is a string, `pkshape` will use the string values to create sequence, period, and treatment variables. In this example, the dash is used to indicate a baseline period, which is an invalid code for this purpose. Therefore, we use the `subinstr()` function to replace each dash with a 0. After doing so, we can use `pkshape` to format the data in a way that can be used with `pkcross`. We leave most `pkcross` options at their defaults, but we specify the `sequential` option to calculate sequential sums of squares instead of the default partial sums of squares.

```

. replace seq = substr(seq, "-", "0", .)
(17 real changes made)
. pkshape id seq period1 period2 period3
. pkcross outcome, sequential
 Sequence variable = sequence
 Period variable = period
 Treatment variable = treat
 Carryover variable = carry
 ID variable = id

```

Analysis of variance (ANOVA) for a crossover study

| Source of variation  | SS      | df | MS    | F     | Prob > F |
|----------------------|---------|----|-------|-------|----------|
| <b>Intersubjects</b> |         |    |       |       |          |
| Sequence effect      | 285.82  | 3  | 95.27 | 1.01  | 0.4180   |
| Residuals            | 1221.49 | 13 | 93.96 | 59.96 | 0.0000   |
| <b>Intrasubjects</b> |         |    |       |       |          |
| Period effect        | 15.13   | 2  | 7.56  | 6.34  | 0.0048   |
| Treatment effect     | 8.48    | 1  | 8.48  | 8.86  | 0.0056   |
| Carryover effect     | 0.11    | 1  | 0.11  | 0.12  | 0.7366   |
| Residuals            | 29.56   | 30 | 0.99  |       |          |
| Total                | 1560.59 | 50 |       |       |          |

Omnibus measure of separability of treatment and carryover = 64.6447%

◀

### ▶ Example 3

For this example, we return to `pkdata.dta` from [example 2](#) of [R] `pk` and use `pkcollapse` and `pkshape` on the data as discussed in that example.

```

. use https://www.stata-press.com/data/r19/pkdata, clear
(Fictional drug concentration data)
. pkcollapse time conc1 conc2, id(id) keep(seq) stat(auc)
.....
. pkshape id seq auc*, order(RT TR)

```

After sorting the data with `sort`, our data appear as follows:

```
. sort period id
. list, sep(8)
```

|     | id | sequence | outcome  | treat | carry | period |
|-----|----|----------|----------|-------|-------|--------|
| 1.  | 1  | RT       | 150.9643 | R     | 0     | 1      |

| 23. | 7  | RT       | 104.0139 | T     | R     | 2      |
| 24. | 8  | RT       | 237.8962 | T     | R     | 2      |
| 25. | 9  | TR       | 139.7382 | R     | T     | 2      |
| 26. | 10 | TR       | 202.3942 | R     | T     | 2      |
| 27. | 11 | TR       | 136.7848 | R     | T     | 2      |
| 28. | 12 | TR       | 104.5191 | R     | T     | 2      |
| 29. | 13 | TR       | 165.8654 | R     | T     | 2      |
| 30. | 14 | TR       | 139.235  | R     | T     | 2      |
| 31. | 15 | TR       | 166.2391 | R     | T     | 2      |
| 32. | 16 | TR       | 158.5146 | R     | T     | 2      |

We now fit an ANOVA model using pkcross:

```
. pkcross outcome
 Sequence variable = sequence
 Period variable = period
 Treatment variable = treat
 Carryover variable = carry
 ID variable = id
```

Analysis of variance (ANOVA) for a 2x2 crossover study

| Source of variation  | Partial SS      | df        | MS      | F    | Prob > F |
|----------------------|-----------------|-----------|---------|------|----------|
| <b>Intersubjects</b> |                 |           |         |      |          |
| Sequence effect      | 378.04          | 1         | 378.04  | 0.29 | 0.5961   |
| Residuals            | 17991.26        | 14        | 1285.09 | 1.40 | 0.2691   |
| <b>Intrasubjects</b> |                 |           |         |      |          |
| Treatment effect     | 455.04          | 1         | 455.04  | 0.50 | 0.4931   |
| Period effect        | 419.47          | 1         | 419.47  | 0.46 | 0.5102   |
| Residuals            | 12860.78        | 14        | 918.63  |      |          |
| <b>Total</b>         | <b>32104.59</b> | <b>31</b> |         |      |          |

Omnibus measure of separability of treatment and carryover = 29.2893%

◀

#### ▷ Example 4

Consider the case of a six-treatment crossover trial in which the squares are not variance balanced. The following dataset is from a partially balanced crossover trial published by [Patterson and Lucas \(1962\)](#) and reproduced in [Ratkowsky, Evans, and Alldredge \(1993, 231\)](#):

```
. use https://www.stata-press.com/data/r19/nobalance, clear
. list, sep(4)
```

|     | cow | seq  | period1 | period2 | period3 | period4 | block |
|-----|-----|------|---------|---------|---------|---------|-------|
| 1.  | 1   | adbe | 38.7    | 37.4    | 34.3    | 31.3    | 1     |
| 2.  | 2   | baed | 48.9    | 46.9    | 42      | 39.6    | 1     |
| 3.  | 3   | ebda | 34.6    | 32.3    | 28.5    | 27.1    | 1     |
| 4.  | 4   | deab | 35.2    | 33.5    | 28.4    | 25.1    | 1     |
| 5.  | 1   | dafc | 32.9    | 33.1    | 27.5    | 25.1    | 2     |
| 6.  | 2   | fdca | 30.4    | 29.5    | 26.7    | 23.1    | 2     |
| 7.  | 3   | cfad | 30.8    | 29.3    | 26.4    | 23.2    | 2     |
| 8.  | 4   | acdf | 25.7    | 26.1    | 23.4    | 18.7    | 2     |
| 9.  | 1   | efbc | 25.4    | 26      | 23.9    | 19.9    | 3     |
| 10. | 2   | becf | 21.8    | 23.9    | 21.7    | 17.6    | 3     |
| 11. | 3   | fceb | 21.4    | 22      | 19.4    | 16.6    | 3     |
| 12. | 4   | cbfe | 22.8    | 21      | 18.6    | 16.1    | 3     |

When there is no variance balance in the design, a square or blocking variable is needed to indicate in which treatment cell a sequence was observed, but the mechanical steps are the same.

```
. pkshape cow seq period1 period2 period3 period4
. pkcross outcome, model(block cow|block period|block treat carry) sequential
 Number of obs = 48 R-squared = 0.9965
 Root MSE = .740408 Adj R-squared = 0.9903
```

| Source       | Seq. SS    | df | MS         | F       | Prob > F |
|--------------|------------|----|------------|---------|----------|

| period block | 408.031253 | 9  | 45.3368059 | 82.70   | 0.0000   |
| treat        | 2.5000057  | 5  | .50000114  | 0.91    | 0.4964   |
| carry        | 3.88428906 | 5  | .776857812 | 1.42    | 0.2680   |
| Residual     | 9.31945887 | 17 | .548203463 |         |          |
| Total        | 2659.45256 | 47 | 56.584097  |         |          |

When the model statement is used and the omnibus measure of separability is desired, specify the variables in the `treatment()`, `carryover()`, and `sequence()` options to `pkcross`.

◀

## Methods and formulas

`pkcross` uses ANOVA to fit models for crossover experiments; see [R] [anova](#).

The omnibus measure of separability is

$$S = 100(1 - V)\%$$

where  $V$  is Cramér's  $V$  and is defined as

$$V = \left\{ \frac{\frac{\chi^2}{N}}{\min(r-1, c-1)} \right\}^{\frac{1}{2}}$$

$N$  is the sample size and  $\chi^2$  is calculated as

$$\chi^2 = \sum_i \sum_j \left\{ \frac{(O_{ij} - E_{ij})^2}{E_{ij}} \right\}$$

where  $O$  and  $E$  are the observed and expected counts in an  $r \times c$  table of the number of times each treatment is followed by the other treatments.

## Description

`pkequiv` tests for average bioequivalence between two drugs. By default, `pkequiv` computes a confidence interval (CI) for the ratio of treatment geometric means, calculated using log-scaled data. `pkequiv` can also calculate CIs using the original data, such as the classic shortest CI and a CI based on Fieller's theorem. Additionally, `pkequiv` performs interval hypothesis tests for bioequivalence, such as Schuirmann's two one-sided tests.

`pkequiv` is one of the `pk` commands. Please read [\[R\] pk](#) before reading this entry.

## Quick start

Log-scale CI for the geometric mean ratio of pharmacokinetic (PK) outcome `auc`—the area under the concentration-time curve (AUC)—between drugs identified by `treat`, given during period `period` in sequence `sequence`, with subjects identified by `id`

```
pkequiv auc treat period sequence id
```

Same as above, but use an equivalence limit of 0.1, do not perform Schuirmann's two one-sided tests, and do not perform a bootstrap analysis of the long-run probability of bioequivalence

```
pkequiv auc treat period sequence id, limit(0.1) notost noboot
```

Analyze data using the original scale, and calculate a CI for the ratio using Fieller's theorem

```
pkequiv auc treat period sequence id, fieller
```

Same as above, but specify that treatment 2 is the reference drug and treatment 1 is the test drug

```
pkequiv auc treat period sequence id, fieller compare(2 1)
```

## Menu

Statistics > Epidemiology and related > Other > Bioequivalence tests

## Syntax

```
pkequiv outcome treatment period sequence id [if] [in] [, options]
```

## Options

### Options

`compare(# #)` specifies the two treatments being compared, where the first value corresponds to the reference drug and the second value corresponds to the test drug. If there are more than two treatments, `compare()` is required; bioequivalence can be determined between any two treatments.

`limit(#)` specifies the equivalence limit. The default is `limit(0.2)`. Using the log scale, this yields equivalence limits of 80% to 125% for the ratio of geometric means. Using the original scale, this yields limits of 80% to 120% for the ratio of arithmetic means and limits of  $\pm 20\%$  for the difference between arithmetic means. See *Equivalence limits* in *Methods and formulas*.

`level(#)` specifies the confidence level, as a percentage, for CIs. The default is `level(90)`. This setting is not controlled by the `set level` command.

`log` specifies a CI for the ratio of treatment geometric means, calculated using the log-transformed outcome. This is the default CI, and its use is recommended by the [US Food and Drug Administration \(FDA\) \(2001, 2022\)](#) and the [European Medicines Agency \(2010\)](#). `log` may not be combined with `classic`, `fieller`, `symmetric`, or `anderson`.

`classic` specifies the classic shortest CI for the difference between treatment arithmetic means, calculated using the original scale of the data. This CI is also expressed as a CI for the ratio of arithmetic means. `classic` may not be combined with `log`, `fieller`, or `symmetric`.

`fieller` specifies a CI based on Fieller's theorem for the ratio of treatment arithmetic means, calculated using the original scale of the data. `fieller` may not be combined with `log`, `classic`, `symmetric`, `tost`, `notost`, `anderson`, `noboot`, or `reps()`.

`symmetric` specifies a CI for the difference between treatment arithmetic means that is symmetric around zero, calculated using the original scale of the data. Use of this CI for bioequivalence testing has been criticized by [Mantel \(1977\)](#), [Kirkwood \(1981\)](#), and others, so it is included mainly for historical purposes. `symmetric` may not be combined with `log`, `classic`, `fieller`, `tost`, `notost`, `anderson`, `noboot`, or `reps()`.

`tost` and `notost` perform or suppress the calculation of Schuirmann’s (1987) two one-sided tests (TOST) for bioequivalence. `tost` is the default whenever log-scale or classic CIs are computed. With a log-scale CI, the TOST will be performed on log-transformed outcome data; with a classic CI, the TOST will be performed on untransformed data. The TOST procedure may not be combined with CIs based on Fieller’s theorem or with symmetric CIs, so `tost` and `notost` may not be combined with `fieller` or `symmetric`.

`anderson` specifies that the [Anderson and Hauck \(1983\)](#) hypothesis test for bioequivalence be computed. Use of this test has been criticized by the US FDA (1988), [Schuirmann \(1987\)](#), and others, so it is included mainly for historical purposes. This test is supported only with `classic`.

`noboot` prevents the computation of the probability that the CI lies within the equivalence limits. By default, this probability is estimated via bootstrap resampling with 1,000 replications. This probability is not computed with CIs based on Fieller’s theorem or with symmetric CIs, so `noboot` may not be combined with `fieller` or `symmetric`, nor may it be combined with `reps()`.

`reps(#)` specifies the number of bootstrap replications to be performed when estimating the probability that the CI lies within the equivalence limits. The default is `reps(1000)`. `reps()` may not be combined with `fieller`, `symmetric`, or `noboot`.

## Remarks and examples

Remarks are presented under the following headings:

[Introduction](#)  
[Examples](#)

## Introduction

`pkequiv` is used to determine average bioequivalence based on data from a nonreplicated crossover study. A crossover study is a longitudinal study where each subject undergoes treatment with both reference (R) and test (T) drugs. In a nonreplicated crossover study, subjects receive each treatment only once, so the sequence of treatments is either R followed by T or T followed by R.

Two drugs are bioequivalent if their bioavailability profiles are sufficiently similar. The most common PK metrics used as measures of bioavailability are the AUC and the maximum concentration ( $C_{\max}$ ).

“Average bioequivalence” between two drugs is declared if the average PK metric of the test drug is close enough to the average PK metric of the reference drug. This is traditionally done by constructing a CI for a measure of disparity between the average PK metrics. If the CI is entirely contained within prespecified equivalence limits, the two drugs are said to demonstrate average bioequivalence.

Two measures of disparity can be used: the difference between treatment means ( $T - R$ ) and the ratio of treatment means ( $T/R$ ). Equivalence limits for the difference and for the ratio are controlled with the `limit()` option; see [Equivalence limits](#) in *Methods and formulas* for details.

By default, `pkequiv` analyzes PK data using the log scale and calculates a CI for the geometric mean ratio, which is the ratio of exponentiated means of the log-transformed outcome. This approach is recommended by the US FDA (2001, 2022) and the European Medicines Agency (2010) for the analysis of most PK metrics. One motivation for taking the log of PK metrics AUC and  $C_{\max}$  is that the biological model postulated for each of those metrics contains a multiplicative term that is a function of the subject; this term becomes additive on the log scale (US FDA 2001, 2022).

The `classic` option analyzes PK data using the original scale and calculates the classic shortest CI for the difference between treatment arithmetic means. This CI is transformed into an approximate CI for the ratio of treatment arithmetic means; see *Classic interval* in *Methods and formulas* for details. The CIs for the difference and for the ratio are compared with their respective equivalence limits, and if the CIs are within the equivalence limits, the two drugs are bioequivalent. The comparison of the difference is mathematically identical to the comparison of the ratio, so the two comparisons will always agree.

The `fieller` option calculates an exact CI for the ratio of treatment arithmetic means, computed using the untransformed data. This approach is most frequently used when the outcome variable is a clinical outcome instead of a PK metric. These trials, called comparative clinical endpoint studies, can have binary outcomes (such as success or failure) or continuous outcomes (such as percent improvement versus baseline), and are generally not analyzed using the log scale (US FDA 2022).

The `symmetric` option uses the original scale of the data to calculate a CI for the difference between treatment arithmetic means that is symmetric around zero. The symmetric CI has received considerable criticism since its proposal by Westlake (1976), so it is included chiefly for historical purposes. See, for example, the criticisms of Mantel (1977) and Kirkwood (1981). Although this CI is symmetric around zero, it is asymmetric with respect to the estimated difference between means. This shift away from the observed difference between means causes unequal tail probabilities. As the difference between means increases, the symmetric CI is shifted ever farther from the estimated difference, and the tail probability becomes dominated by one side.

In addition to calculating CIs, `pkequiv` can conduct interval hypothesis tests of bioequivalence. When a log-scale or classic CI is requested, `pkequiv` performs Schuirmann's (1987) TOST unless the `notost` option is specified. The TOST procedure consists of two hypothesis tests: one to determine whether the average PK metric of the test drug exceeds the upper equivalence limit and one to determine whether it is less than the lower equivalence limit. In both cases, the null hypothesis is that the two drugs are not bioequivalent, so rejecting both null hypotheses leads to a conclusion of bioequivalence. The formula for the TOST is an inversion of the formula for the CI; see *Schuirmann's two one-sided tests* in *Methods and formulas* for details. This ensures that the conclusion reached by the TOST with two  $\alpha$ -level tests will agree with the conclusion reached by comparing the  $(1 - 2\alpha)100\%$  CI against the equivalence limits.

The `anderson` option is used to perform Anderson and Hauck's (1983) test, where the null hypothesis is that the two drugs are not bioequivalent. This procedure offers the appeal of a single test of bioequivalence that is more powerful than Schuirmann's TOST for any nominal significance level  $\alpha$ . However, two serious criticisms of this test have prevented its widespread adoption (US FDA 1988), so it is included mainly for historical reasons. The actual size of Anderson and Hauck's test generally exceeds the nominal size of the test, meaning that the probability of committing a type I error and erroneously concluding bioequivalence is greater than desired (Frick 1987). Additionally, the rejection region of Anderson and Hauck's test is nonconvex and unbounded (Schuirmann 1987), meaning that  $H_0$  will be rejected for any arbitrarily large difference between means as long as the corresponding standard error is sufficiently large.

## Examples

pkequiv requires that the user specify the *outcome*, *treatment*, *period*, *sequence*, and *id* variables. The dataset must be in the same format as that produced by pkshape; see [R] [pkshape](#). The examples below assume the use of a  $2 \times 2 \times 2$  design: a crossover study with 2 treatments, 2 periods, and 2 sequences. If your dataset includes results for more than two treatments, you will need to use the `compare()` option to specify which two treatments are being compared.

### ► Example 1

We use `pkdata.dta` from [example 2](#) of [R] [pk](#). We use `pkcollapse` and `pkshape` on the data as discussed in that example. After we sort the data with the `sort` command, our data appear as follows:

```
. use https://www.stata-press.com/data/r19/pkdata
(Fictional drug concentration data)
. pkcollapse time conc1 conc2, id(id) keep(seq) stat(auc)
.....
. pkshape id seq auc*, order(RT TR)
. sort period id
. list, sep(4)
```

|                  | id | sequence | outcome  | treat | carry | period |
|------------------|----|----------|----------|-------|-------|--------|
| 1.               | 1  | RT       | 150.9643 | R     | 0     | 1      |
| 2.               | 2  | RT       | 146.7606 | R     | 0     | 1      |
| 3.               | 3  | RT       | 160.6548 | R     | 0     | 1      |
| 4.               | 4  | RT       | 157.8622 | R     | 0     | 1      |
| 5.               | 5  | RT       | 133.6957 | R     | 0     | 1      |
| 6.               | 6  | RT       | 160.639  | R     | 0     | 1      |
| 7.               | 7  | RT       | 131.2604 | R     | 0     | 1      |
| 8.               | 8  | RT       | 168.5186 | R     | 0     | 1      |
| 9.               | 9  | TR       | 137.0627 | T     | 0     | 1      |
| 10.              | 10 | TR       | 153.4038 | T     | 0     | 1      |
| 11.              | 11 | TR       | 163.4593 | T     | 0     | 1      |
| 12.              | 12 | TR       | 146.0462 | T     | 0     | 1      |
| (output omitted) |    |          |          |       |       |        |
| 25.              | 9  | TR       | 139.7382 | R     | T     | 2      |
| 26.              | 10 | TR       | 202.3942 | R     | T     | 2      |
| 27.              | 11 | TR       | 136.7848 | R     | T     | 2      |
| 28.              | 12 | TR       | 104.5191 | R     | T     | 2      |
| 29.              | 13 | TR       | 165.8654 | R     | T     | 2      |
| 30.              | 14 | TR       | 139.235  | R     | T     | 2      |
| 31.              | 15 | TR       | 166.2391 | R     | T     | 2      |
| 32.              | 16 | TR       | 158.5146 | R     | T     | 2      |

The outcome variable is the AUC, and we use `pkequiv` to conduct a bioequivalence test between reference drug “R” and test drug “T” using the log scale.

```
. set seed 123
. pkequiv outcome treat period sequence id
Log-transformed confidence interval for bioequivalence
Outcome: ln(outcome)
Treatment: treat = R (reference)
 treat = T (test)
Period: period
Sequence: sequence
Subject ID: id
```

|                          | [Equivalence limits] |     | [90% conf. interval] |         | Estimate |
|--------------------------|----------------------|-----|----------------------|---------|----------|
| Geometric mean ratio (%) | 80                   | 125 | 91.087               | 116.210 | 102.885  |

Bootstrap prob. that confidence interval is within equivalence limits = 0.901

Schuirmann’s two one-sided tests

```
t statistics: Upper = -2.816 p-value = 0.0069
 Lower = 3.638 p-value = 0.0013
```

The equivalence table for the log-transformed CI contains columns for the equivalence limits (which can be controlled by using the `limit()` option), the confidence interval (the width of which can be controlled by using the `level()` option), and the point estimate. The default value of `limit(0.2)` yields equivalence limits of [80%, 125%] for the ratio of geometric means. The default value of `level(90)` specifies a 90% CI.

The CI of [91.087%, 116.210%] is symmetric around the estimated geometric mean ratio of 102.885%. The interval is entirely contained within the equivalence limits, so we declare average bioequivalence between the test and reference drugs.

To determine the probability that the CI would lie within the equivalence limits if this experiment were to be repeated, `pkequiv` conducts a bootstrap with 1,000 replications. In this example, there is a 90.1% assurance that the observed CI would be within the equivalence limits in the long run. Because of the nature of the bootstrap, we expect the bootstrap probability calculation to vary slightly from run to run, so we specified the command `set seed 123` before executing `pkequiv` for you to match the bootstrap probability exactly when you run this example.

The output also displays Schuirmann’s two one-sided tests. The upper one-sided test is a formal statistical test of whether the geometric mean ratio exceeds the upper equivalence limit, and the lower one-sided test evaluates whether the geometric mean ratio is below the lower equivalence limit. The null hypothesis for both of Schuirmann’s two one-sided tests is that the two drugs are not bioequivalent, so rejecting both of these null hypotheses supports a conclusion of average bioequivalence.

Schuirmann’s two one-sided tests are constructed by inverting the formula for the CI (see *Schuirmann’s two one-sided tests* in *Methods and formulas*), so conducting the TOST at the  $\alpha$  level will always agree with the conclusion of bioequivalence or bioinequivalence reached by comparing the  $(1 - 2\alpha)100\%$  CI against the equivalence limits. The default of `level(90)` yields  $\alpha = 0.05$ , and because we have already demonstrated that the 90% CI is within its equivalence limits, it comes as no surprise that we can reject the null hypotheses of both one-sided tests at the 0.05 level.

We now repeat this same analysis using the classic shortest CI instead of the log-transformed CI. For speed, we specify the `noboot` option to omit the bootstrap.

```
. pkequiv outcome treat period sequence id, classic noboot
Classic confidence interval for bioequivalence
Outcome: outcome
Treatment: treat = R (reference)
 treat = T (test)
Period: period
Sequence: sequence
Subject ID: id
```

|                            | [Equivalence limits] |        | [90% conf. interval] |         | Estimate |
|----------------------------|----------------------|--------|----------------------|---------|----------|
| Arithmetic mean difference | -30.296              | 30.296 | -11.332              | 26.416  | 7.542    |
| ratio (%)                  | 80                   | 120    | 92.519               | 117.439 | 104.979  |

Schuirmann's two one-sided tests

```
t statistics: Upper = -2.123
 Lower = 3.531
```

p-value = 0.0260

p-value = 0.0017

The equivalence table for the classic CI has two rows: one for the difference between the arithmetic means of the test and reference groups and one for the ratio of arithmetic means. The default value of `limit(0.2)` indicates that bioequivalence is declared if the CI for the difference is within the range  $[-30.296, 30.296]$ , which corresponds to a CI for the ratio within  $[80\%, 120\%]$ . If the CI for the difference is within its equivalence limits, the CI for the ratio must be too, and vice versa.

The 90% CI for the ratio of arithmetic means,  $[92.519\%, 117.439\%]$ , is not exactly the same as the 90% CI for the ratio of geometric means, but it is entirely contained within its equivalence limits, so it yields the same conclusion of bioequivalence. However, now the upper equivalence limit for the ratio is only 120% (as opposed to 125% when conducting log-scale analysis), so here the upper endpoint of the CI comes closer to its equivalence limit. As expected, the 90% CI for the difference between means,  $[-11.332, 26.416]$ , is also contained within its equivalence limits, supporting a conclusion of bioequivalence.

When combined with the `classic` option, Schuirmann's two one-sided tests are performed on the untransformed outcomes, which is why the test statistics and  $p$ -values above differ slightly from those reported with the log-transformed CI in the first part of this example. But this ensures that the TOST with level  $\alpha$  tests will agree with the conclusion of bioequivalence or bioinequivalence reached by comparing the classic  $(1 - 2\alpha)100\%$  CI against the equivalence limits.

Schuirmann's upper one-sided test presents evidence that the difference between the average AUCs of the test and reference drugs does not exceed the upper equivalence limit ( $p = 0.026$ ), while Schuirmann's lower one-sided test presents evidence that the difference between the average AUCs of the test and reference drugs is not less than the lower equivalence limit ( $p = 0.0017$ ). Considering these two tests together, we reject the null hypothesis of bioinequivalence at the  $\alpha = 0.05$  level, which is the same conclusion that we reached when we compared the CIs with their equivalence limits.

## ► Example 2

We now use the data published in [Chow and Liu \(2009, 71\)](#), which we describe in [example 1](#) of [\[R\] pkshape](#). As before, the *outcome* variable is AUC, and we use `pkshape` to reshape the data. We use the same `pkequiv` specification as we did in [example 1](#) above to conduct a bioequivalence test.

```
. use https://www.stata-press.com/data/r19/chowliu, clear
. pkshape id seq period1 period2, order(RT TR)
. set seed 123
. pkequiv outcome treat period sequence id
Log-transformed confidence interval for bioequivalence
Outcome: ln(outcome)
Treatment: treat = R (reference)
 treat = T (test)
Period: period
Sequence: sequence
Subject ID: id
```

|                          | [Equivalence limits] |     | [90% conf. interval] |         | Estimate |
|--------------------------|----------------------|-----|----------------------|---------|----------|
| Geometric mean ratio (%) | 80                   | 125 | 88.313               | 106.928 | 97.175   |

Bootstrap prob. that confidence interval is within equivalence limits = 0.985

Schuirmann's two one-sided tests

```
t statistics: Upper = -4.521 p-value = 0.0001
 Lower = 3.492 p-value = 0.0010
```

For these data, the 90% CI for the ratio of treatment geometric means is well within the equivalence limits, supporting a conclusion of average bioequivalence. The bootstrap probability that the CI is within the equivalence limits is 98.5%, indicating that if this experiment were to be repeated many times, the vast majority of replications would support a conclusion of bioequivalence. Examining the TOST, we reject both null hypotheses at the 5% level, which agrees with the conclusion we reached by comparing the 90% CI against the equivalence limits.

If we want to conduct a test of average bioequivalence using the original scale of the data, we can employ Fieller's theorem to calculate an exact CI for the ratio of arithmetic means. Here we repeat the previous analysis, but we add the `fieller` option to calculate a CI based on Fieller's theorem.

```
. pkequiv outcome treat period sequence id, fieller
Confidence interval for bioequivalence based on Fieller's theorem
Outcome: outcome
Treatment: treat = R (reference)
 treat = T (test)
Period: period
Sequence: sequence
Subject ID: id
```

|                           | [Equivalence limits] |     | [90% conf. interval] |         | Estimate |
|---------------------------|----------------------|-----|----------------------|---------|----------|
| Arithmetic mean ratio (%) | 80                   | 120 | 89.787               | 105.193 | 97.229   |

The exact 90% CI for the ratio of treatment arithmetic means is quite similar to the CI for the ratio of geometric means. Because we performed this analysis using the original scale of the data, the upper equivalence limit for the ratio is 120%, not 125% (the value used for log-scale analysis). But the narrow CI for the ratio of arithmetic means is well contained within these narrower equivalence limits, supporting a conclusion of average bioequivalence.

## Stored results

pkequiv stores the following in `r()`:

### Scalars

|                               |                                                                                                                   |

## Methods and formulas

Methods and formulas are presented under the following headings:

- Data and model
- Equivalence limits
- Confidence intervals
  - Classic interval
  - Intervals using log-transformed data
  - Intervals symmetric around zero
  - Intervals using Fieller's theorem
- Interval hypothesis tests
  - Schuirmann's two one-sided tests
  - Schuirmann's two one-sided tests with a classic CI
  - Schuirmann's two one-sided tests with a log-scale CI
  - Anderson and Hauck's test

## Data and model

Let  $y_{ij}$  be the observed PK outcome for subject  $i = 1, \dots, n$  in period  $j = 1, 2$ . Let  $\mathcal{RT}$  be the set of subject IDs for subjects who received the reference drug before the test drug, which we will designate as sequence 1. Let  $\mathcal{TR}$  be the set of IDs for subjects who received the test drug before the reference drug, which we will call sequence 2. Let  $n_1$  and  $n_2$  represent the number of subjects in sequences 1 and 2, respectively, with  $n = n_1 + n_2$ .

Consider a model for the log-transformed outcome first:

$$\ln(y_{ij}) = \mu_{ij}^* + s_i^* + p_j^* + \epsilon_{ij}^* \quad (1)$$

$s_i^*$  is the random effect of subject  $i$ , where  $s_i^* \sim$  i.i.d.  $N(0, \sigma_s^{*2})$  and  $\sigma_s^{*2}$  controls between-subjects variability.  $p_j^*$  is the fixed effect of period  $j$ , subject to the constraint  $p_1^* + p_2^* = 0$ . Random error  $\epsilon_{ij}^*$  is independent of  $s_i^*$ , and  $\epsilon_{ij}^* \sim$  i.i.d.  $N(0, \sigma_e^{*2})$ . Fixed effect  $\mu_{ij}^*$  is defined as follows,

$$\mu_{ij}^* = \begin{cases} \mu_R^* & \text{if } (i \in \mathcal{RT} \text{ and } j = 1) \text{ or } (i \in \mathcal{TR} \text{ and } j = 2) \\ \mu_T^* & \text{if } (i \in \mathcal{RT} \text{ and } j = 2) \text{ or } (i \in \mathcal{TR} \text{ and } j = 1) \end{cases}$$

where  $\mu_R^*$  and  $\mu_T^*$  are the population means of the log-transformed PK outcomes for the reference and test drugs, respectively. The model above assumes there are no unequal carryover effects.

By default, `pkequiv` produces a CI for the geometric mean ratio of the PK outcome, defined as  $R_g = \exp(\mu_T^*) / \exp(\mu_R^*)$ . `pkequiv` also produces CIs for the difference  $D_a = \mu_T - \mu_R$  and ratio  $R_a = \mu_T / \mu_R$  of arithmetic means of the PK outcome. The arithmetic means  $\mu_T$  and  $\mu_R$  are estimated from (1) applied to the untransformed PK outcome,

$$y_{ij} = \mu_{ij} + s_i + p_j + \epsilon_{ij} \quad (2)$$

$$\mu_{ij} = \begin{cases} \mu_R & \text{if } (i \in \mathcal{RT} \text{ and } j = 1) \text{ or } (i \in \mathcal{TR} \text{ and } j = 2) \\ \mu_T & \text{if } (i \in \mathcal{RT} \text{ and } j = 2) \text{ or } (i \in \mathcal{TR} \text{ and } j = 1) \end{cases}$$

where  $\mu_R$  and  $\mu_T$  are the population means of the untransformed PK outcomes for the reference and test drugs, respectively. Subject-specific random effect  $s_i \sim$  i.i.d.  $N(0, \sigma_s^2)$  is independent of random error  $\epsilon_{ij} \sim$  i.i.d.  $N(0, \sigma_e^2)$ , where  $\sigma_s^2$  controls between-subjects variability and  $\sigma_e^2$  controls within-subjects variability. Period effect  $p_j$  is defined similarly to (1).

## Equivalence limits

Equivalence limits are controlled by using the `limit()` option. Depending on the type of CI requested, equivalence limits will be calculated for the ratio of treatment means, the difference between treatment means, or both.

The lower equivalence limit for the ratio of treatment means is  $l_R = \{1 - \text{limit}()\}100\%$ . The upper equivalence limit for the ratio is  $u_R = [1/\{1 - \text{limit}()\}]100\%$  when performing analysis on the log scale, and it is  $u_R = \{1 + \text{limit}()\}100\%$  when performing calculations on the original scale of the data. The default value of `limit()` is 0.2, which yields equivalence limits of 80% to 125% when using the log scale and equivalence limits of 80% to 120% when using the original scale.

The lower and upper equivalence limits for the difference between treatment arithmetic means are

$$l_D = -\text{limit}() \times \hat{\mu}_R \quad \text{and} \quad u_D = \text{limit}() \times \hat{\mu}_R \quad (3)$$

respectively. The estimated marginal mean  $\hat{\mu}_R$ , also known as the least-squares mean, is used for calculations because the true value of  $\mu_R$  in the population is unknown.

When we conduct inference using the ratio of treatment means, bioequivalence is declared when  $(l_R < L_R)$  and  $(U_R < u_R)$ , where  $L_R$  and  $U_R$  are the lower and upper endpoints, respectively, of the CI for the ratio. When we consider the difference between treatment means, average bioequivalence is declared when  $(l_D < L_D)$  and  $(U_D < u_D)$ , where  $L_D$  is the lower endpoint of the CI for the difference and  $U_D$  is the upper endpoint.

## Confidence intervals

`pkequiv` supports four types of CIs: a CI calculated using the log scale, the classic shortest CI, a CI symmetric around zero, and a CI based on Fieller's theorem. The width of the CI is controlled by the `level()` option, with a default of `level(90)` yielding a 90% CI. This option also sets the significance level  $\alpha$  of the bioequivalence test, with the default of  $\alpha = 0.05$  given by the relationship  $\alpha = \{100 - \text{level}()\}/200$ . The formula for the log-scale CI is based on the formula for the classic CI, which is presented first.

### Classic interval

The lower limit of the classic shortest CI for the difference between two treatment means is

$$L_{D,\text{classic}} = (\hat{\mu}_T - \hat{\mu}_R) - t_{(\alpha, n_1 + n_2 - 2)} \hat{\sigma}_d \sqrt{\frac{1}{n_1} + \frac{1}{n_2}} \quad (4)$$

and the upper limit is

$$U_{D,\text{classic}} = (\hat{\mu}_T - \hat{\mu}_R) + t_{(\alpha, n_1 + n_2 - 2)} \hat{\sigma}_d \sqrt{\frac{1}{n_1} + \frac{1}{n_2}} \quad (5)$$

Here  $\hat{\mu}_R$  and  $\hat{\mu}_T$  are the estimated marginal means of the reference and test drugs, respectively, estimated using (2). The term  $t_{(\alpha, n_1 + n_2 - 2)}$  represents the upper  $\alpha$  critical value of a central  $t$  distribution with  $n_1 + n_2 - 2$  degrees of freedom.  $\hat{\sigma}_d$  is the pooled sample standard deviation of the period differences from both sequences, defined as

$$\hat{\sigma}_d = \sqrt{\frac{1}{n_1 + n_2 - 2} \left\{ \sum_{i \in \mathcal{RT}} (d_i - \bar{d}_{RT})^2 + \sum_{i \in \mathcal{TR}} (d_i - \bar{d}_{TR})^2 \right\}} \quad (6)$$

The period difference for subject  $i$  is  $d_i = (y_{i2} - y_{i1})/2$ , the average period difference in sequence 1 is  $\bar{d}_{RT} = (1/n_1) \sum_{i \in \mathcal{RT}} d_i$ , and the average period difference in sequence 2 is  $\bar{d}_{TR} = (1/n_2) \sum_{i \in \mathcal{TR}} d_i$ .

The limits of the approximate CI for the ratio are

$$L_{R,\text{classic}} = \left( \frac{L_{D,\text{classic}}}{\hat{\mu}_R} + 1 \right) 100\%$$

and

$$U_{R,\text{classic}} = \left( \frac{U_{D,\text{classic}}}{\hat{\mu}_R} + 1 \right) 100\%$$

This CI for the ratio is approximate because the denominator  $\hat{\mu}_R$  is an estimate of the true population average  $\mu_R$ . The conclusion of average bioequivalence will be the same regardless of whether you compute the classic CI for the difference or for the ratio. If one CI is within its equivalence limits, the other one necessarily is too.

The finite sample performance of the classic CI is assessed via bootstrap simulation. Bootstrap samples are drawn with replacement using the patient IDs as clusters, and the default of `reps` (1000) calls for 1,000 bootstrap samples. For each sample, a classic CI is constructed and compared with the equivalence limits. The bootstrap probability is computed as the proportion of CIs that are within the equivalence limits.

## Intervals using log-transformed data

Calculation of the log-scale CI for the ratio of treatment geometric means,  $[L_{R,\log}, U_{R,\log}]$ , begins with taking the natural logarithm of the PK outcome and using (1) to calculate estimated marginal means  $\hat{\mu}_R^*$  and  $\hat{\mu}_T^*$ .

Next, the estimated standard deviation of log-scale period differences,  $\hat{\sigma}_d^*$ , is calculated by substituting  $\ln(y_{ij})$  for  $y_{ij}$  in (6). A classic CI for the difference between means of the log-PK metric is calculated, substituting  $\hat{\mu}_R^*$  for  $\hat{\mu}_R$  and  $\hat{\mu}_T^*$  for  $\hat{\mu}_T$  in (4) and (5).

The endpoints of this interval,  $L_{D,\log}$  and  $U_{D,\log}$ , are exponentiated to yield  $L_{R,\log} = \exp(L_{D,\log})$  and  $U_{R,\log} = \exp(U_{D,\log})$ . These are the endpoints of an exact CI for the geometric mean ratio:  $R_g = \exp(\mu_T^*) / \exp(\mu_R^*)$ .

Use of this approach is recommended by the US FDA (2001, 2022) and the European Medicines Agency (2010). PK metrics such as AUC and  $C_{\max}$  are often right-skewed, but the US FDA's rationale for requesting log-scale bioequivalence analysis is not based on the distribution of the data but instead on properties of the model of log-PK data. The US FDA has, since 1991, recommended that analysis of bioequivalence be conducted using the ratio of treatment geometric means (US FDA 2001). Additionally, the models postulated for PK parameters in bioequivalence studies contain a multiplicative subject effect when analyzed on the original scale, but this effect is additive on the logarithmic scale (US FDA 2022).

The finite sample performance of the log-transformed CI is assessed via bootstrap simulation. This is equivalent to the bootstrap procedure used to determine the long-run performance of the classic CI, where patient IDs are used as clusters during the resampling process.

### Intervals symmetric around zero

The lower and upper limits for the symmetric CI are, respectively,  $L_{D,\text{sym}} = \hat{\mu}_R - \Delta$  and  $U_{D,\text{sym}} = \hat{\mu}_R + \Delta$ . To calculate  $\Delta$ , we must solve a system of two equations,

$$\Delta = b_1 \hat{\sigma}_d \sqrt{\frac{1}{n_1} + \frac{1}{n_2}} - (\hat{\mu}_R - \hat{\mu}_T)$$

and (simultaneously)

$$\Delta = -b_2 \hat{\sigma}_d \sqrt{\frac{1}{n_1} + \frac{1}{n_2}} + (\hat{\mu}_R - \hat{\mu}_T)$$

Values  $b_1$  and  $b_2$  are computed iteratively to satisfy the above equalities and the condition

$$\int_{b_1}^{b_2} f(t) dt = 1 - 2\alpha$$

where  $f(t)$  is the probability density function of a central  $t$  distribution with  $n_1 + n_2 - 2$  degrees of freedom.

### Intervals using Fieller's theorem

To calculate an exact CI for the ratio of treatment means without using the log scale, [Locke \(1984\)](#) employed Fieller's theorem ([1954](#)) to obtain  $[L_{R,\text{Fieller}}, U_{R,\text{Fieller}}]$ . See [Locke \(1984\)](#) or [Chow and Liu \(2009, 88–92\)](#) for details about calculating the exact CI based on Fieller's theorem.

### Interval hypothesis tests

pkequiv offers two types of interval hypothesis tests of bioequivalence: Schuirmann's two one-sided tests ([1987](#)) and Anderson and Hauck's test ([1983](#)). The null hypothesis for both types of tests is that the two treatments are not bioequivalent, so bioequivalence is declared when the null hypotheses are rejected.

#### Schuirmann's two one-sided tests

The hypotheses for Schuirmann's lower one-sided test are  $H_{0L}: \mu_T - \mu_R \leq l_D$  and  $H_{aL}: \mu_T - \mu_R > l_D$ . For the upper one-sided test, the hypotheses are  $H_{0U}: \mu_T - \mu_R \geq u_D$  and  $H_{aU}: \mu_T - \mu_R < u_D$ . The test statistics for the TOST are

$$T_L = \frac{(\hat{\mu}_T - \hat{\mu}_R) - l_D}{\hat{\sigma}_d \sqrt{\frac{1}{n_1} + \frac{1}{n_2}}} \quad \text{and} \quad T_U = \frac{(\hat{\mu}_T - \hat{\mu}_R) - u_D}{\hat{\sigma}_d \sqrt{\frac{1}{n_1} + \frac{1}{n_2}}} \quad (7)$$

The  $p$ -values for the lower and upper one-sided tests are  $p_L = F_t(T_L)$  and  $p_U = 1 - F_t(T_U)$ , respectively, where  $F_t$  is the cumulative distribution function of the central  $t$  distribution with  $n_1 + n_2 - 2$  degrees of freedom.

### Schirmann's two one-sided tests with a classic CI

Schirmann's two one-sided tests are inversions of the formulas for the endpoints of the [classic CI](#) for the difference in treatment means. Thus, rejecting  $H_{0L}$  at the  $\alpha$  level is the same as concluding  $l_D < L_{D,\text{classic}}$  for a  $(1 - 2\alpha)100\%$  CI, and rejecting  $H_{0U}$  is the same as concluding  $U_{D,\text{classic}} < u_D$ . If both null hypotheses are rejected, the entire CI lies within the equivalence limits.

### Schirmann's two one-sided tests with a log-scale CI

The log-scale CI is calculated using the same formula as the classic CI, but the outcome is the natural log of the PK metric. Thus, the procedure for conducting the TOST on the log scale is the same as on the original scale, but the log-transformed PK outcome is used.

In (7), terms  $\hat{\mu}_R$ ,  $\hat{\mu}_T$ , and  $\hat{\sigma}_d$  are replaced with the values used in the calculation of the [log-scale CI](#):  $\hat{\mu}_R^*$ ,  $\hat{\mu}_T^*$ , and  $\hat{\sigma}_d^*$ . The terms  $l_D$  and  $u_D$  in (7) are likewise replaced with  $l_D^*$  and  $u_D^*$ , the equivalence limits for the difference between log-transformed treatment means, which are calculated by replacing  $\hat{\mu}_R$  with  $\hat{\mu}_R^*$  in (3).

Rejecting both null hypotheses of the TOST on the log scale is equivalent to concluding  $l_D^* < L_{D,\log}$  and  $U_{D,\log} < u_D^*$ , which, in turn, is equivalent to concluding  $l_R < L_{R,\log}$  and  $U_{R,\log} < u_R$ .

### Anderson and Hauck's test

Anderson and Hauck's test may be conducted only when calculating the classic shortest CI on the original scale of the data. The null hypothesis for Anderson and Hauck's test is  $H_0 : (\mu_T - \mu_R \leq l_D) \cup (\mu_T - \mu_R \geq u_D)$ . The alternative hypothesis for Anderson and Hauck's test is  $H_a : l_D < (\mu_T - \mu_R) < u_D$ . The test statistic is

$$T_{\text{AH}} = \frac{(\hat{\mu}_T - \hat{\mu}_R) - (l_D + u_D)/2}{\hat{\sigma}_d \sqrt{\frac{1}{n_1} + \frac{1}{n_2}}}$$

and the noncentrality parameter is estimated by

$$\hat{\delta} = \frac{u_D - l_D}{2\hat{\sigma}_d \sqrt{\frac{1}{n_1} + \frac{1}{n_2}}}$$

The  $p$ -value is calculated as

$$p = F_t(|T_{\text{AH}}| - \hat{\delta}) - F_t(-|T_{\text{AH}}| - \hat{\delta})$$

where  $F_t$  is the cumulative distribution function of the central  $t$  distribution with  $n_1 + n_2 - 2$  degrees of freedom.

## Description

`pkexamine` calculates pharmacokinetic measures from concentration-and-time subject-level data. `pkexamine` computes and displays the maximum measured concentration, the time at the maximum measured concentration, the time of the last measurement, the elimination time, the half-life, and the area under the concentration–time curve ( $AUC_{0,t_{\max}}$ ). Three estimates of the AUC from 0 to infinity ( $AUC_{0,\infty}$ ) are also calculated.

`pkexamine` is one of the `pk` commands. Please read [\[R\] pk](#) before reading this entry.

## Quick start

Pharmacokinetic measures for concentrations `y` at times `tvar` where `idvar = 4`

```
pkexamine tvar y if idvar==4
```

Same as above, but use trapezoidal rule to calculate  $AUC_{0,t_{\max}}$

```
pkexamine tvar y if idvar==4, trapezoid
```

Plot concentration–time curve where `idvar = 2`

```
pkexamine tvar y if idvar==2, graph
```

Same as above, and save graph as `mygraph`

```
pkexamine tvar y if idvar==2, graph saving(mygraph)
```

## Options

### Main

`fit(#)` specifies the number of points, counting back from the last measurement, to use in fitting the extension to estimate the  $AUC_{0,\infty}$ . The default is `fit(3)`, or the last three points. This value should be viewed as a minimum; the appropriate number of points will depend on your data.

`trapezoid` specifies that the trapezoidal rule be used to calculate the  $AUC_{0,t_{\max}}$ . The default is cubic splines, which give better results for most functions. When the curve is irregular, `trapezoid` may give better results.

`graph` tells pkexamine to graph the concentration–time curve.

`line` and `log` specify the estimates of the  $AUC_{0,\infty}$  to display when graphing the  $AUC_{0,\infty}$ . If the `graph` option is not also specified, then these options are ignored.

`exp(#)` specifies that the exponential fit for the  $AUC_{0,\infty}$  be plotted. You must specify the maximum time value to which you want to plot the curve, and this time value must be greater than the maximum time measurement in the data. If you specify 0, the curve will be plotted to the point at which the linear extension would cross the  $x$  axis. If the `graph` option is not also specified, then this option is ignored. This option is not valid with the `line` or `log` option.

## AUC plot

*cline\_options* affect the rendition of the plotted points connected by lines; see [G-3] *cline\_options*.

*marker\_options* specify the look of markers. This look includes the marker symbol, size, color, and outline; see [G-3] *marker\_options*.

*marker\_label\_options* specify if and how the markers are to be labeled; see [G-3] *marker\_label\_options*.

## Add plots

`addplot (plot)` provides a way to add other plots to the generated graph; see [G-3] *addplot\_option*.

## Y axis, X axis, Titles, Legend, Overall

*twoway\_options* are any of the options documented in [G-3] *twoway\_options*, excluding `by()`. These include options for titling the graph (see [G-3] *title\_options*) and for saving the graph to disk (see [G-3] *saving\_option*).

## Remarks and examples

`pkexamine` computes summary statistics for a given patient in a pharmacokinetic trial. If by *idvar*: is specified, statistics will be displayed for each subject in the data.

### ▷ Example 1

Chow and Liu (2009, 13) present data on a study examining primidone concentrations versus time over a 32-hour period after dosing a subject.

| 8.  | 1  | 6    | 4             |
| 9.  | 1  | 8    | 3.6           |
| 10. | 1  | 12   | 3             |
| 11. | 1  | 16   | 2.5           |
| 12. | 1  | 24   | 2             |
| 13. | 1  | 32   | 1.6           |

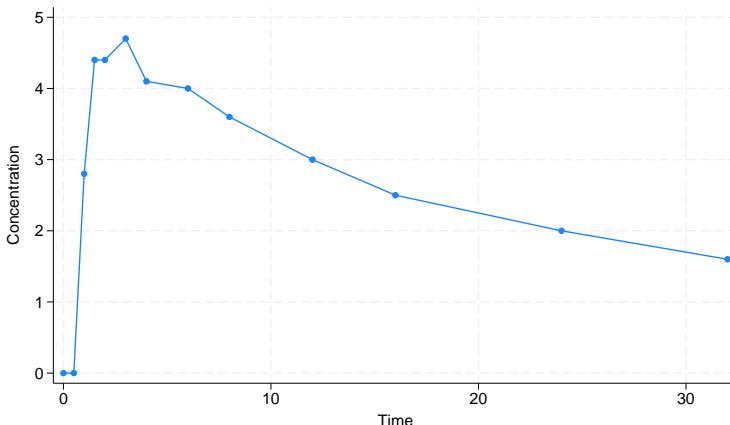

We use pkexamine to produce the summary statistics:

```
. pkexamine time concentration, graph
 Maximum concentration = 4.7
 Time of maximum concentration = 3
 Time of last observation (Tmax) = 32
 Elimination rate = 0.0279
 Half life = 24.8503
```

Area under the curve

| AUC [0, Tmax] | AUC [0, inf.)<br>Linear of log conc. | AUC [0, inf.)<br>Linear fit | AUC [0, inf.)<br>Exponential fit |
|---------------|--------------------------------------|-----------------------------|----------------------------------|
| 85.24         | 142.603                              | 107.759                     | 142.603                          |

Fit based on last 3 points.

The maximum concentration of 4.7 occurs at time 3, and the time of the last observation (Tmax) is 32. In addition to  $AUC_{0,t_{max}}$ , which is calculated from 0 to the maximum value of time, pkexamine also reports  $AUC_{0,\infty}$ , the AUC computed by extending the curve with each of three methods: a linear fit to the log of the concentration, a linear regression line, and a decreasing exponential regression line. See [Methods and formulas](#) for details on these three methods.

By default, all extensions to the AUC are based on the last three points. In looking at the graph for these data, it seems more appropriate to use the last seven points to estimate the  $AUC_{0,\infty}$ :

```
. pkexamine time concentration, fit(7)
 Maximum concentration = 4.7
 Time of maximum concentration = 3
 Time of last observation (Tmax) = 32
 Elimination rate = 0.0349
 Half life = 19.8354
```

Area under the curve

| AUC [0, Tmax] | AUC [0, inf.)<br>Linear of log conc. | AUC [0, inf.)<br>Linear fit | AUC [0, inf.)<br>Exponential fit |
|---------------|--------------------------------------|-----------------------------|----------------------------------|
| 85.24         | 131.027                              | 96.805                      | 129.181                          |

Fit based on last 7 points.

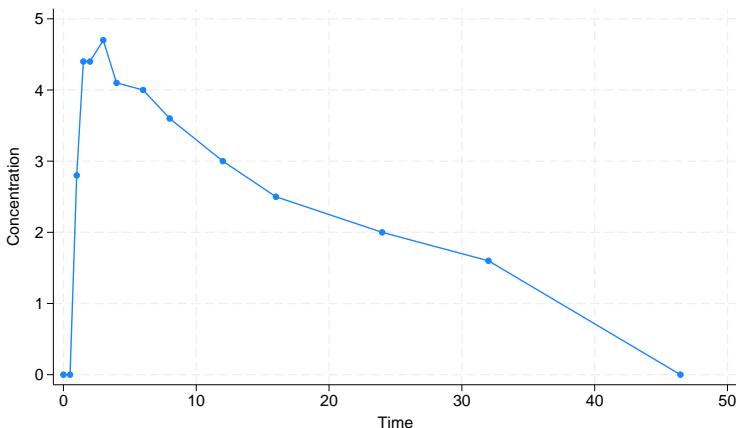

This approach decreased the estimate of the  $AUC_{0,\infty}$  for all extensions. To see a graph of the  $AUC_{0,\infty}$  using a linear extension, specify the graph and line options.

```
. pkexamine time concentration, fit(7) graph line
 Maximum concentration = 4.7
 Time of maximum concentration = 3
 Time of last observation (Tmax) = 32
 Elimination rate = 0.0349
 Half life = 19.8354
```

Area under the curve

| AUC [0, Tmax] | AUC [0, inf.)<br>Linear of log conc. | AUC [0, inf.)<br>Linear fit | AUC [0, inf.)<br>Exponential fit |
|---------------|--------------------------------------|-----------------------------|----------------------------------|
| 85.24         | 131.027                              | 96.805                      | 129.181                          |

Fit based on last 7 points.

◀

## Stored results

pkexamine stores the following in `r()`:

Scalars

```
r(auc) AUC
r(half) half-life of the drug
r(ke) elimination rate
r(tmax) time at last concentration measurement
r(cmax) maximum concentration
r(tomc) time of maximum concentration
r(auc_line) AUC0,∞ estimated with a linear fit
r(auc_exp) AUC0,∞ estimated with an exponential fit
r(auc_ln) AUC0,∞ estimated with a linear fit of the natural log
```

## Methods and formulas

Let  $i$  index the observations sorted by time, let  $k$  be the number of observations, and let  $f$  be the number of points specified in the `fit(#)` option.

The  $AUC_{0,t_{\max}}$  is defined as

$$AUC_{0,t_{\max}} = \int_0^{t_{\max}} C_t dt$$

where  $C_t$  is the concentration at time  $t$ . By default, the integral is calculated numerically using cubic splines. However, if the trapezoidal rule is used, the  $AUC_{0,t_{\max}}$  is given as

$$AUC_{0,t_{\max}} = \sum_{i=2}^k \frac{C_{i-1} + C_i}{2} (t_i - t_{i-1})$$

The  $AUC_{0,\infty}$  is the  $AUC_{0,t_{\max}} + AUC_{t_{\max},\infty}$ , or

$$AUC_{0,\infty} = \int_0^{t_{\max}} C_t dt + \int_{t_{\max}}^{\infty} C_t dt$$

When using the linear extension to the  $AUC_{0,t_{\max}}$ , the integration is cut off when the line crosses the  $x$  axis. The log extension is a linear extension on the log concentration scale. The area for the exponential extension is

$$AUC_{t_{\max},\infty} = \int_{t_{\max}}^{\infty} e^{\beta_0 + t\beta_1} dt = \frac{e^{\beta_0 + t_{\max}\beta_1}}{-\beta_1}$$

where  $\beta_0 > 0$  and  $\beta_1 < 0$  are the intercept and slope, respectively, of an exponential accelerated failure-time regression of concentration on time.

The elimination rate  $K_{\text{eq}}$  is the negative of the slope from a linear regression of log concentration on time fit to the number of points specified in the `fit(#)` option:

$$K_{\text{eq}} = - \frac{\sum_{i=k-f+1}^k (t_i - \bar{t}) (\ln C_i - \overline{\ln C})}{\sum_{i=k-f+1}^k (t_i - \bar{t})^2}$$

The half-life is

$$t_{\text{half}} = \frac{\ln 2}{K_{\text{eq}}}$$

## Description

`pkshape` reshapes data for use with `anova`, `pkcross`, and `pkequiv`; see [\[R\] anova](#), [\[R\] pkcross](#), and [\[R\] pkequiv](#). Latin-square and crossover data are often organized in a manner that cannot be analyzed easily with Stata. `pkshape` reorganizes the data in memory for use in Stata.

`pkshape` is one of the `pk` commands. Please read [\[R\] pk](#) before reading this entry.

## Quick start

Reshape data when string sequence variable `seq` = TR or RT for patients identified by `idvar` observed at `tvar1` and `tvar2`

```
pkshape idvar seq tvar1 tvar2
```

Same as above, but with numeric `seq` = 1 indicating TR and `seq` = 2 indicating RT

```
pkshape idvar seq tvar1 tvar2, order(TR RT)
```

Indicate that period 2 is a washout and the second treatment is administered in period 3

```
pkshape idvar seq tvar1 tvar2 tvar3, order(TOR ROT)
```

## Menu

Statistics > Epidemiology and related > Other > Reshape pharmacokinetic Latin-square data

## Syntax

```
pkshape id sequence period1 period2 [periodlist] [, options]
```

Variable *id* specifies unique subject identifiers. Variable *sequence* specifies the sequence (numeric or string) in which treatments were received. Variables *period1*, *period2*, and so on specify the pharmacokinetic measurements such as AUC in the corresponding periods.

| <i>options</i>                        | Description                                                                |
|---------------------------------------|----------------------------------------------------------------------------|
| <code>order(<i>string</i>)</code>     | apply treatments in specified order; required with numeric <i>sequence</i> |
| <code>outcome(<i>newvar</i>)</code>   | name for outcome variable; default is <code>outcome(outcome)</code>        |
| <code>treatment(<i>newvar</i>)</code> | name for treatment variable; default is <code>treatment(treat)</code>      |
| <code>carryover(<i>newvar</i>)</code> | name for carryover variable; default is <code>carryover(carry)</code>      |
| <code>sequence(<i>newvar</i>)</code>  | name for sequence variable; default is <code>sequence(sequence)</code>     |
| <code>period(<i>newvar</i>)</code>    | name for period variable; default is <code>period(period)</code>           |

## Options

`order(string)` specifies the order in which treatments were applied when generating the sequence, treatment, and carryover variables in the reorganized data. This option is required if the input sequence variable, *sequence*, is numeric. It is not allowed if *sequence* is a string variable. For crossover designs, any washout periods can be indicated with the number 0.

`outcome(newvar)` specifies the name for the outcome variable in the reorganized data. By default, `outcome(outcome)` is used.

`treatment(newvar)` specifies the name for the treatment variable in the reorganized data. By default, `treatment(treat)` is used.

`carryover(newvar)` specifies the name for the carryover variable in the reorganized data. By default, `carryover(carry)` is used.

`sequence(newvar)` specifies the name for the sequence variable in the reorganized data. By default, `sequence(sequence)` is used.

`period(newvar)` specifies the name for the period variable in the reorganized data. By default, `period(period)` is used.

## Remarks and examples

Often, data from a Latin-square experiment are naturally organized in a manner that Stata cannot manage easily. `pkshape` reorganizes Latin-square data so that they can be used with `anova` (see [R] [anova](#)) or any `pk` command. This includes the classic  $2 \times 2$  crossover design commonly used in pharmaceutical research, as well as many other Latin-square designs. When using `pkshape`, newly created variables will automatically be labeled and system value labels will be created. The value label `_treat1b1` will be attached to the treatment and carryover variables, to indicate which treatment is applied in a given period and which treatment is being carried over from the previous period. The value label `_seq1b1` will be attached to the sequence variable, indicating the sequence of treatments.

`pkshape` expects the data to be organized in the same format as that produced by [R] [pkcollapse](#)—with variables representing time periods of the study.

## ► Example 1

Consider the example data published in [Chow and Liu \(2009, 71\)](#). There are 24 patients, 12 in each sequence. Sequence 1 is the reference formulation followed by the test formulation; sequence 2 is the test formulation followed by the reference formulation. The measurements reported are the  $AUC_{0,t_{\max}}$  for each patient and for each period.

```

| 19. | 13 | 2   | 122.45  | 124.975 |
| 20. | 14 | 2   | 99.075  | 85.225  |
| 21. | 17 | 2   | 86.35   | 95.925  |
| 22. | 18 | 2   | 49.925  | 67.1    |
| 23. | 21 | 2   | 42.7    | 59.425  |
| 24. | 22 | 2   | 91.725  | 114.05  |

Because the outcome for one person is in two different variables, the treatment that was applied to an individual is a function of the period and the sequence. To analyze this treatment using anova, all the outcomes must be in one variable, and each covariate must be in its own variable. To reorganize these data, use `pkshape`:

```

. pkshape id seq period1 period2, order(RT TR)
. sort seq id period
. list, sep(8)

```

|     | id | sequence | outcome | treat | carry | period |
|-----|----|----------|---------|-------|-------|--------|
| 1.  | 1  | RT       | 74.675  | R     | 0     | 1      |
| 2.  | 1  | RT       | 73.675  | T     | R     | 2      |
| 3.  | 4  | RT       | 96.4    | R     | 0     | 1      |

| 35. | 10 | TR       | 66.125  | T     | 0     | 1      |
| 36. | 10 | TR       | 94.025  | R     | T     | 2      |
| 37. | 13 | TR       | 122.45  | T     | 0     | 1      |
| 38. | 13 | TR       | 124.975 | R     | T     | 2      |
| 39. | 14 | TR       | 99.075  | T     | 0     | 1      |
| 40. | 14 | TR       | 85.225  | R     | T     | 2      |
| 41. | 17 | TR       | 86.35   | T     | 0     | 1      |
| 42. | 17 | TR       | 95.925  | R     | T     | 2      |
| 43. | 18 | TR       | 49.925  | T     | 0     | 1      |
| 44. | 18 | TR       | 67.1    | R     | T     | 2      |
| 45. | 21 | TR       | 42.7    | T     | 0     | 1      |
| 46. | 21 | TR       | 59.425  | R     | T     | 2      |
| 47. | 22 | TR       | 91.725  | T     | 0     | 1      |
| 48. | 22 | TR       | 114.05  | R     | T     | 2      |

Now, the data are organized into separate variables that indicate each factor level for each of the covariates, so the data may be used with `anova` or `pkcross`; see [R] `anova` and [R] `pkcross`.

Initially, the output from `list` displayed sequence values 1 and 2, but now we see sequences RT and TR listed for the individuals. `pkshape` used the information we provided in the `order()` option to assign value labels to the numeric variables `sequence`, `treat`, and `carry`. Because we did not specify any new variable names, the default names were used.

◀

## ▶ Example 2

Consider the study of background music on bank teller productivity published in [Kutner et al. \(2005\)](#). The data are

| Week | Monday | Tuesday | Wednesday | Thursday | Friday |
|------|--------|---------|-----------|----------|--------|
| 1    | 18(D)  | 17(C)   | 14(A)     | 21(B)    | 17(E)  |
| 2    | 13(C)  | 34(B)   | 21(E)     | 16(A)    | 15(D)  |
| 3    | 7(A)   | 29(D)   | 32(B)     | 27(E)    | 13(C)  |
| 4    | 17(E)  | 13(A)   | 24(C)     | 31(D)    | 25(B)  |
| 5    | 21(B)  | 26(E)   | 26(D)     | 31(C)    | 7(A)   |

The numbers are the productivity scores, and the letters represent the treatment. We entered the data into Stata:

```
. use https://www.stata-press.com/data/r19/music, clear
(Background music and teller productivity)
. list
```

|    | id | seq   | day1 | day2 | day3 | day4 | day5 |
|----|----|-------|------|------|------|------|------|
| 1. | 1  | dcabe | 18   | 17   | 14   | 21   | 17   |
| 2. | 2  | cbead | 13   | 34   | 21   | 16   | 15   |
| 3. | 3  | adbec | 7    | 29   | 32   | 27   | 13   |
| 4. | 4  | eadcb | 17   | 13   | 24   | 31   | 25   |
| 5. | 5  | bedca | 21   | 26   | 26   | 31   | 7    |

We reshape these data with pkshape:

```
. pkshape id seq day1 day2 day3 day4 day5
. sort id period
. list, sep(0)
```

|     | id | sequence | outcome | treat | carry | period |
|-----|----|----------|---------|-------|-------|--------|
| 1.  | 1  | dcabe    | 18      | d     | 0     | 1      |
| 2.  | 1  | dcabe    | 17      | c     | d     | 2      |
| 3.  | 1  | dcabe    | 14      | a     | c     | 3      |
| 4.  | 1  | dcabe    | 21      | b     | a     | 4      |
| 5.  | 1  | dcabe    | 17      | e     | b     | 5      |
| 6.  | 2  | cbead    | 13      | c     | 0     | 1      |
| 7.  | 2  | cbead    | 34      | b     | c     | 2      |
| 8.  | 2  | cbead    | 21      | e     | b     | 3      |

Here the sequence variable is a string variable that specifies how the treatments were applied. The characters in this string variable are used to assign value labels to the newly created sequence, treat, and carry variables. We could now produce an ANOVA table:

```
. anova outcome sequence period treat
```

|          | Number of obs = | 25      | R-squared =     | 0.8666 |        |
|----------|-----------------|---------|-----------------|--------|--------|
|          | Root MSE =      | 3.96232 | Adj R-squared = | 0.7331 |        |
| Source   | Partial SS      | df      | MS              | F      | Prob>F |
| Model    | 1223.6          | 12      | 101.96667       | 6.49   | 0.0014 |
| sequence | 82              | 4       | 20.5            | 1.31   | 0.3226 |
| period   | 477.2           | 4       | 119.3           | 7.60   | 0.0027 |
| treat    | 664.4           | 4       | 166.1           | 10.58  | 0.0007 |
| Residual | 188.4           | 12      | 15.7            |        |        |
| Total    | 1412            | 24      | 58.833333       |        |        |

### ▶ Example 3

Consider the Latin-square crossover example published in [Kutner et al. \(2005\)](#). The example is about apple sales given different methods for displaying apples.

| Pattern | Store | Week 1 | Week 2 | Week 3 |
|---------|-------|--------|--------|--------|
| 1       | 1     | 9(B)   | 12(C)  | 15(A)  |
|         | 2     | 4(B)   | 12(C)  | 9(A)   |
| 2       | 1     | 12(A)  | 14(B)  | 3(C)   |
|         | 2     | 13(A)  | 14(B)  | 3(C)   |
| 3       | 1     | 7(C)   | 18(A)  | 6(B)   |
|         | 2     | 5(C)   | 20(A)  | 4(B)   |

We entered the data into Stata:

```
. use https://www.stata-press.com/data/r19/applesales, clear
(Display impact on apple sales)
. list, sep(2)
```

|    | id | seq | p1 | p2 | p3 | square |
|----|----|-----|----|----|----|--------|
| 1. | 1  | 1   | 9  | 12 | 15 | 1      |
| 2. | 2  | 1   | 4  | 12 | 9  | 2      |
| 3. | 3  | 2   | 12 | 14 | 3  | 1      |
| 4. | 4  | 2   | 13 | 14 | 3  | 2      |
| 5. | 5  | 3   | 7  | 18 | 6  | 1      |
| 6. | 6  | 3   | 5  | 20 | 4  | 2      |

Now, the data can be reorganized using descriptive names for the outcome variables.

```
. pkshape id seq p1 p2 p3, order(bca abc cab) seq(pattern) treat(displays)
. anova outcome pattern period displays id|pattern
```

|            | Number of obs = | 18      | R-squared =     | 0.9562 |        |
|------------|-----------------|---------|-----------------|--------|--------|
|            | Root MSE =      | 1.59426 | Adj R-squared = | 0.9069 |        |
| Source     | Partial SS      | df      | MS              | F      | Prob>F |
| Model      | 443.66667       | 9       | 49.296296       | 19.40  | 0.0002 |
| pattern    | .33333333       | 2       | .16666667       | 0.07   | 0.9370 |
| period     | 233.33333       | 2       | 116.66667       | 45.90  | 0.0000 |
| displays   | 189             | 2       | 94.5            | 37.18  | 0.0001 |
| id pattern | 21              | 3       | 7               | 2.75   | 0.1120 |
| Residual   | 20.333333       | 8       | 2.5416667       |        |        |
| Total      | 464             | 17      | 27.294118       |        |        |

These are the same results reported by [Kutner et al. \(2005\)](#).

## Description

`pksumm` obtains summary measures based on the first four moments from the empirical distribution of each pharmacokinetic measurement and tests the null hypothesis that the distribution of that measurement is normally distributed.

`pksumm` is one of the `pk` commands. Please read [R] [pk](#) before reading this entry.

## Quick start

Table of pharmacokinetic measures for concentrations `y` at times `tvar` for patients identified by `idvar`

```
pksumm idvar tvar y
```

Add a histogram of  $AUC_{0,t_{\max}}$  values

```
pksumm idvar tvar y, graph
```

Same as above

```
pksumm idvar tvar y, graph stat(auc)
```

Same as above, but plot AUC calculated from 0 to  $\infty$  using a linear extension

```
pksumm idvar tvar y, graph stat(aucline)
```

Same as above, but use 10 bins for the histogram

```
pksumm idvar tvar y, graph stat(aucline) bins(10)
```

## Menu

Statistics > Epidemiology and related > Other > Summarize pharmacokinetic data

## Syntax

```
pksumm id time concentration [if] [in] [, options]
```

## Options

### Main

`trapezoid` specifies that the trapezoidal rule be used to calculate the  $AUC_{0,t_{max}}$ . The default is cubic splines, which give better results for most situations. When the curve is irregular, the trapezoidal rule may give better results.

`fit (#)` specifies the number of points, counting back from the last time measurement, to use in fitting the extension to estimate the  $AUC_{0,\infty}$ . The default is `fit(3)`, the last three points. This default should be viewed as a minimum; the appropriate number of points will depend on the data.

`notimechk` suppresses the check that the follow-up time for all subjects is the same. By default, `pksumm` expects the maximum follow-up time to be equal for all subjects.

`nodots` suppresses the progress dots during calculation. By default, a dot (a period) is displayed for every call to calculate the pharmacokinetic measures.

`graph` requests a graph of the distribution of the statistic specified with `stat()`.

`stat (statistic)` specifies the statistic that `pksumm` should graph. The default is `stat(auc)`. If the `graph` option is not also specified, then this option is ignored.

Histogram, Density plots, Y axis, X axis, Titles, Legend, Overall

*histogram\_options* are any of the options documented in [R] [histogram](#), excluding `by()`. For `pksumm`, `fraction` is the default, not `density`.

## Remarks and examples

`pksumm` produces summary statistics for the distribution of nine common pharmacokinetic measurements. If there are more than eight subjects, `pksumm` also computes a test for normality on each measurement. The nine measurements summarized by `pksumm` are listed [above](#) and are described in [Methods and formulas](#) of [R] [pkexamine](#).

### ▷ Example 1

We demonstrate the use of `pksumm` on a variation of the data described in [R] [pk](#). We have drug concentration data on 15 subjects, each measured at 13 time points over a 32-hour period. A few of the records are as follows:

```
. use https://www.stata-press.com/data/r19/pksumm
. list, sep(0)
```

|                  | id | time | conc     |
|------------------|----|------|----------|
| 1.               | 1  | 0    | 0        |
| 2.               | 1  | .5   | 3.073403 |
| 3.               | 1  | 1    | 5.188444 |
| 4.               | 1  | 1.5  | 5.898577 |
| 5.               | 1  | 2    | 5.096378 |
| 6.               | 1  | 3    | 6.094085 |
| (output omitted) |    |      |          |
| 183.             | 15 | 0    | 0        |
| 184.             | 15 | .5   | 3.86493  |
| 185.             | 15 | 1    | 6.432444 |
| 186.             | 15 | 1.5  | 6.969195 |
| 187.             | 15 | 2    | 6.307024 |
| 188.             | 15 | 3    | 6.509584 |
| 189.             | 15 | 4    | 6.555091 |
| 190.             | 15 | 6    | 7.318319 |
| 191.             | 15 | 8    | 5.329813 |
| 192.             | 15 | 12   | 5.411624 |
| 193.             | 15 | 16   | 3.891397 |
| 194.             | 15 | 24   | 5.167516 |
| 195.             | 15 | 32   | 2.649686 |

We can use pksumm to view the summary statistics for all the pharmacokinetic parameters.

```
. pksumm id time conc
.....
Summary statistics for the pharmacokinetic measures
```

| Measure | Number of observations = 15 |        |           |          |          |         |

| tomc    | 3.47                        | 3.00   | 7.62      | 2.17     | 7.18     | 0.00    |
| tmax    | 32.00                       | 32.00  | 0.00      | .        | .        | .       |

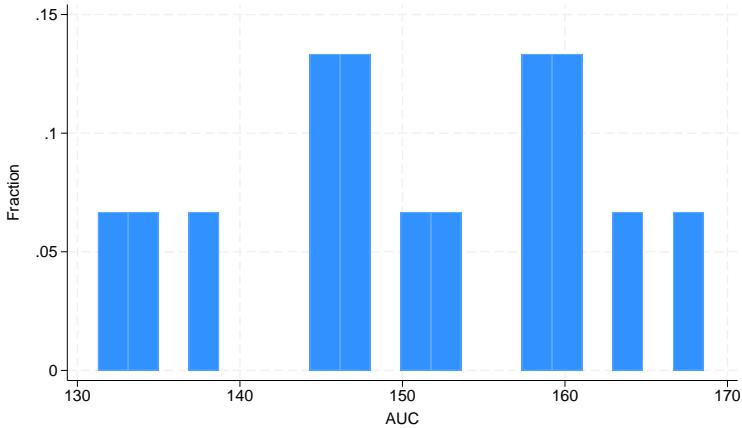

For the 15 subjects, the mean  $AUC_{0,t_{\max}}$  is 150.74, and  $\sigma^2 = 123.07$ . The skewness of  $-0.26$  indicates that the distribution is slightly skewed left. The  $p$ -value of 0.69 for the  $\chi^2$  test of normality indicates that we cannot reject the null hypothesis that the distribution is normal.

If we were to consider any of the three variants of the  $AUC_{0,\infty}$ , we would see that there is huge variability and that the distribution is heavily skewed. A skewness different from 0 and a kurtosis different from 3 are expected because the distribution of the  $AUC_{0,\infty}$  is not normal.

We now graph the distribution of  $AUC_{0,t_{\max}}$  by specifying the graph option.

```
. pksumm id time conc, graph bins(20)
.....
Summary statistics for the pharmacokinetic measures
```

| Measure | Number of observations = 15 |        |           |          |          |         |
|---------|-----------------------------|--------|-----------|----------|----------|---------|
|         | Mean                        | Median | Variance  | Skewness | Kurtosis | p-value |
| auc     | 150.74                      | 150.96 | 123.07    | -0.26    | 2.10     | 0.69    |

| ke      | 0.02                        | 0.02   | 0.00      | 0.89     | 3.70     | 0.09    |
| cmax    | 7.36                        | 7.42   | 0.42      | -0.60    | 2.56     | 0.44    |
| tomc    | 3.47                        | 3.00   | 7.62      | 2.17     | 7.18     | 0.00    |
| tmax    | 32.00                       | 32.00  | 0.00      | .        | .        | .       |

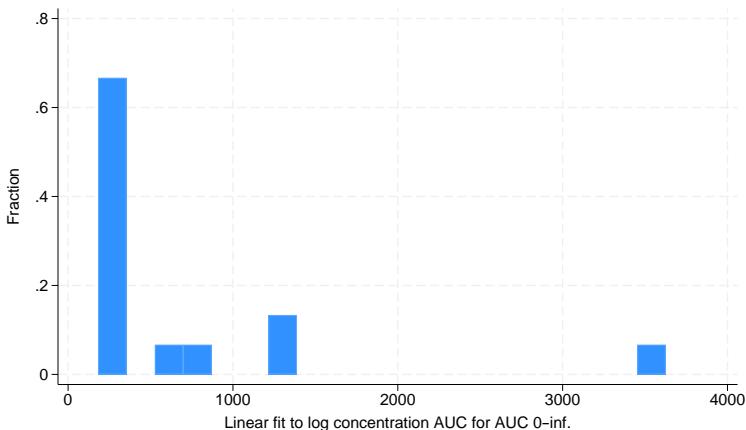

graph, by default, plots  $AUC_{0,t_{max}}$ . To plot a graph of one of the other pharmacokinetic measurements, we need to specify the `stat()` option. For example, we can ask Stata to produce a plot of the  $AUC_{0,\infty}$  using the log extension:

```
. pksumm id time conc, stat(auclog) graph bins(20)
.....
```

Summary statistics for the pharmacokinetic measures

## Methods and formulas

The  $\chi^2$  test for normality is conducted with `sktest`; see [\[R\] sktest](#) for more information on the test of normality.

The statistics reported by `pksumm` are identical to those reported by `summarize` and `sktest`; see [\[R\] summarize](#) and [\[R\] sktest](#).

## Description

`poisson` fits a Poisson regression of *depvar* on *indepvars*, where *depvar* is a nonnegative count variable.

If you have panel data, see [\[XT\] xtpoisson](#).

## Quick start

Poisson regression of *y* on *x*

```
poisson y x
```

Add categorical variable *a*

```
poisson y x i.a
```

Add exposure variable *v*

```
poisson y x i.a, exposure(v)
```

With robust standard errors

```
poisson y x i.a, vce(robust)
```

Report results as incidence-rate ratios

```
poisson y x i.a, irr
```

Replace data in memory with the results of running a Poisson regression model on each level of *catvar*

```
statsby, by(catvar) clear: poisson y x
```

## Menu

Statistics > Count outcomes > Poisson regression

## Syntax

```
poisson depvar [indepvars] [if] [in] [weight] [, options]
```

| <code>coeflegend</code>                           | display legend instead of statistics                                                                                                                                        |

*indepvars* may contain factor variables; see [U] 11.4.3 Factor variables.

*depvar*, *indepvars*, *varname<sub>e</sub>*, and *varname<sub>o</sub>* may contain time-series operators; see [U] 11.4.4 Time-series varlists.

`bayes`, `bayesboot`, `bootstrap`, `by`, `fmm`, `fp`, `jackknife`, `mfp`, `mi estimate`, `nestreg`, `rolling`, `statsby`, `stepwise`, and `svy` are allowed; see [U] 11.1.10 Prefix commands. For more details, see [BAYES] `bayes: poisson` and [FMM] `fmm: poisson`.

`vce(bootstrap)` and `vce(jackknife)` are not allowed with the `mi estimate` prefix; see [MI] `mi estimate`.

Weights are not allowed with the `bootstrap` prefix; see [R] `bootstrap`.

`vce()` and weights are not allowed with the `svy` prefix; see [SVY] `svy`.

`fweights`, `iweights`, and `pweights` are allowed; see [U] 11.1.6 `weight`.

`collinear` and `coeflegend` do not appear in the dialog box.

See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

## Options

### Model

`noconstant`, `exposure(varnamee)`, `offset(varnameo)`, `constraints(constraints)`; see [R] Estimation options.

### SE/Robust

`vce(vcetype)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory (`oim`, `opg`), that are robust to some kinds of misspecification (`robust`), that allow for intragroup correlation (`cluster clustvar`), and that use bootstrap or jackknife methods (`bootstrap`, `jackknife`); see [R] `vce_option`.

## Reporting

`level(#)`; see [R] [Estimation options](#).

`irr` reports estimated coefficients transformed to incidence-rate ratios, that is,  $e^{\beta_i}$  rather than  $\beta_i$ . Standard errors and confidence intervals are similarly transformed. This option affects how results are displayed, not how they are estimated or stored. `irr` may be specified at estimation or when replaying previously estimated results.

`nocnsreport`; see [R] [Estimation options](#).

`display_options`: `nocl`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `nolstretch`; see [R] [Estimation options](#).

## Maximization

`maximize_options`: `difficult`, `technique(algorithm_spec)`, `iterate(#)`, `[no]log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `ltolerance(#)`, `nrtolerance(#)`, `nonrtolerance`, and `from(init_specs)`; see [R] [Maximize](#). These options are seldom used.

Setting the optimization type to `technique(bhhh)` resets the default `vcetype` to `vce(opg)`.

The following options are available with `poisson` but are not shown in the dialog box:

`collinear`, `coeflegend`; see [R] [Estimation options](#).

## Remarks and examples

The basic idea of Poisson regression was outlined by [Coleman \(1964, 378–379\)](#). See [Cameron and Trivedi \(2013; 2022, chap. 20\)](#) and [Johnson, Kemp, and Kotz \(2005, chap. 4\)](#) for information about the Poisson distribution. See [Cameron and Trivedi \(2013\)](#), [Long \(1997, chap. 8\)](#), [Long and Freese \(2014, chap. 9\)](#), [McNeil \(1996, chap. 6\)](#), and [Selvin \(2011, chap. 6\)](#) for an introduction to Poisson regression. Also see [Selvin \(2004, chap. 5\)](#) for a discussion of the analysis of spatial distributions, which includes a discussion of the Poisson distribution. An early example of Poisson regression was [Cochran \(1940\)](#).

Poisson regression fits models of the number of occurrences (counts) of an event. The Poisson distribution has been applied to diverse events, such as the number of soldiers kicked to death by horses in the Prussian army ([von Bortkiewicz 1898](#)); the pattern of hits by buzz bombs launched against London during World War II ([Clarke 1946](#)); telephone connections to a wrong number ([Thorndike 1926](#)); and disease incidence, typically with respect to time, but occasionally with respect to space. The basic assumptions are as follows:

1. There is a quantity called the *incidence rate* that is the rate at which events occur. Examples are 5 per second, 20 per 1,000 person-years, 17 per square meter, and 38 per cubic centimeter.
2. The incidence rate can be multiplied by *exposure* to obtain the expected number of observed events. For example, a rate of 5 per second multiplied by 30 seconds means that 150 events are expected; a rate of 20 per 1,000 person-years multiplied by 2,000 person-years means that 40 events are expected; and so on.
3. Over very small exposures  $\epsilon$ , the probability of finding more than one event is small compared with  $\epsilon$ .
4. Nonoverlapping exposures are mutually independent.

With these assumptions, to find the probability of  $k$  events in an exposure of size  $E$ , you divide  $E$  into  $n$  subintervals  $E_1, E_2, \dots, E_n$ , and approximate the answer as the binomial probability of observing  $k$  successes in  $n$  trials. If you let  $n \rightarrow \infty$ , you obtain the Poisson distribution.

In the Poisson regression model, the incidence rate for the  $j$ th observation is assumed to be given by

$$r_j = e^{\beta_0 + \beta_1 x_{1,j} + \dots + \beta_k x_{k,j}}$$

If  $E_j$  is the exposure, the expected number of events,  $C_j$ , will be

$$\begin{aligned} C_j &= E_j e^{\beta_0 + \beta_1 x_{1,j} + \dots + \beta_k x_{k,j}} \\ &= e^{\ln(E_j) + \beta_0 + \beta_1 x_{1,j} + \dots + \beta_k x_{k,j}} \end{aligned}$$

This model is fit by `poisson`. Without the `exposure()` or `offset()` options,  $E_j$  is assumed to be 1 (equivalent to assuming that exposure is unknown), and controlling for exposure, if necessary, is your responsibility.

Comparing rates is most easily done by calculating *incidence-rate ratios* (IRRs). For instance, what is the relative incidence rate of chromosome interchanges in cells as the intensity of radiation increases; the relative incidence rate of telephone connections to a wrong number as load increases; or the relative incidence rate of deaths due to cancer for females relative to males? That is, you want to hold all the  $x$ 's in the model constant except one, say, the  $i$ th. The IRR for a one-unit change in  $x_i$  is

$$\frac{e^{\ln(E) + \beta_1 x_1 + \dots + \beta_i (x_i + 1) + \dots + \beta_k x_k}}{e^{\ln(E) + \beta_1 x_1 + \dots + \beta_i x_i + \dots + \beta_k x_k}} = e^{\beta_i}$$

More generally, the IRR for a  $\Delta x_i$  change in  $x_i$  is  $e^{\beta_i \Delta x_i}$ . The `lincom` command can be used after `poisson` to display incidence-rate ratios for any group relative to another; see [R] [lincom](#).

## ► Example 1

Chatterjee and Hadi (2012, 174) give the number of injury incidents and the proportion of flights for each airline out of the total number of flights from New York for nine major US airlines in one year:

```
. use https://www.stata-press.com/data/r19/airline
. list
```

|    | airline | injuries | n      | XYZowned |
|----|---------|----------|--------|----------|
| 1. | 1       | 11       | 0.0950 | 1        |
| 2. | 2       | 7        | 0.1920 | 0        |
| 3. | 3       | 7        | 0.0750 | 0        |
| 4. | 4       | 19       | 0.2078 | 0        |
| 5. | 5       | 9        | 0.1382 | 0        |
| 6. | 6       | 4        | 0.0540 | 1        |
| 7. | 7       | 3        | 0.1292 | 0        |
| 8. | 8       | 1        | 0.0503 | 0        |
| 9. | 9       | 3        | 0.0629 | 1        |

To their data, we have added a fictional variable, `XYZowned`. We will imagine that an accusation is made that the airlines owned by XYZ Company have a higher injury rate.

```
. poisson injuries XYZowned, exposure(n) irr
Iteration 0: Log likelihood = -23.027197
Iteration 1: Log likelihood = -23.027177
Iteration 2: Log likelihood = -23.027177

Poisson regression
Log likelihood = -23.027177
Number of obs = 9
LR chi2(1) = 1.77
Prob > chi2 = 0.1836
Pseudo R2 = 0.0370
```

| injuries | IRR      | Std. err.  | z     | P> z  | [95% conf. interval] |          |
|----------|----------|------------|-------|-------|----------------------|----------|
| XYZowned | 1.463467 | .406872    | 1.37  | 0.171 | .8486578             | 2.523675 |
| _cons    | 58.04416 | 8.558145   | 27.54 | 0.000 | 43.47662             | 77.49281 |
| ln(n)    | 1        | (exposure) |       |       |                      |          |

Note: `_cons` estimates baseline incidence rate.

We specified `irr` to see the IRRs rather than the underlying coefficients. We estimate that XYZ Airlines' injury rate is 1.46 times larger than that for other airlines, but the 95% confidence interval is 0.85 to 2.52; we cannot even reject the hypothesis that XYZ Airlines has a lower injury rate.

◀

## □ Technical note

In [example 1](#), we assumed that each airline's exposure was proportional to its fraction of flights out of New York. What if "large" airlines, however, also used larger planes, and so had even more passengers than would be expected, given this measure of exposure? A better measure would be each airline's fraction of passengers on flights out of New York, a number that we do not have. Even so, we suppose that `n` represents this number to some extent, so a better estimate of the effect might be

```
. generate lnN=ln(n)
. poisson injuries XYZowned lnN
Iteration 0: Log likelihood = -22.333875
Iteration 1: Log likelihood = -22.332276
Iteration 2: Log likelihood = -22.332276

Poisson regression
Log likelihood = -22.332276
Number of obs = 9
LR chi2(2) = 19.15
Prob > chi2 = 0.0001
Pseudo R2 = 0.3001
```

| injuries | Coefficient | Std. err. | z    | P> z  | [95% conf. interval] |          |
|----------|-------------|-----------|------|-------|----------------------|----------|
| XYZowned | .6840667    | .3895877  | 1.76 | 0.079 | -.0795111            | 1.447645 |
| lnN      | 1.424169    | .3725155  | 3.82 | 0.000 | .6940517             | 2.154285 |
| _cons    | 4.863891    | .7090501  | 6.86 | 0.000 | 3.474178             | 6.253603 |

Here rather than specifying the `exposure()` option, we explicitly included the variable that would normalize for exposure in the model. We did not specify the `irr` option, so we see coefficients rather than IRRs. We started with the model

$$\text{rate} = e^{\beta_0 + \beta_1 \text{XYZowned}}$$

The observed counts are therefore

$$\text{count} = ne^{\beta_0 + \beta_1 \text{XYZowned}} = e^{\ln(n) + \beta_0 + \beta_1 \text{XYZowned}}$$

which amounts to constraining the coefficient on  $\ln(n)$  to 1. This is what was estimated when we specified the `exposure(n)` option. In the above model, we included the normalizing exposure ourselves and, rather than constraining the coefficient to be 1, estimated the coefficient.

The estimated coefficient is 1.42, a respectable distance away from 1, and is consistent with our speculation that larger airlines also use larger airplanes. With this small amount of data, however, we also have a wide confidence interval that includes 1.

Our estimated *coefficient* on `XYZowned` is now 0.684, and the implied IRR is  $e^{0.684} \approx 1.98$  (which we could also see by typing `poisson, irr`). The 95% confidence interval for the coefficient still includes 0 (the interval for the IRR includes 1), so although the point estimate is now larger, we still cannot be certain of our results.

Our expert opinion would be that, although there is not enough evidence to support the charge, there is enough evidence to justify collecting more data. □

## ► Example 2

In a famous age-specific study of coronary disease deaths among male British doctors, [Doll and Hill \(1966\)](#) reported the following data (reprinted in [Lash et al. \[2021, 417\]](#)):

| Age   | Smokers |              | Nonsmokers |              |
|-------|---------|--------------|------------|--------------|
|       | Deaths  | Person-years | Deaths     | Person-years |
| 35–44 | 32      | 52,407       | 2          | 18,790       |
| 45–54 | 104     | 43,248       | 12         | 10,673       |
| 55–64 | 206     | 28,612       | 28         | 5,710        |
| 65–74 | 186     | 12,663       | 28         | 2,585        |
| 75–84 | 102     | 5,317        | 31         | 1,462        |

The first step is to enter these data into Stata, which we have done:

```
. use https://www.stata-press.com/data/r19/dollhill13, clear
(Doll and Hill (1966))
. list
```

|     | agecat | smokes | deaths | pyears |
|-----|--------|--------|--------|--------|
| 1.  | 35–44  | 1      | 32     | 52,407 |
| 2.  | 45–54  | 1      | 104    | 43,248 |
| 3.  | 55–64  | 1      | 206    | 28,612 |
| 4.  | 65–74  | 1      | 186    | 12,663 |
| 5.  | 75–84  | 1      | 102    | 5,317  |
| 6.  | 35–44  | 0      | 2      | 18,790 |
| 7.  | 45–54  | 0      | 12     | 10,673 |
| 8.  | 55–64  | 0      | 28     | 5,710  |
| 9.  | 65–74  | 0      | 28     | 2,585  |
| 10. | 75–84  | 0      | 31     | 1,462  |

The most “natural” analysis of these data would begin by introducing indicator variables for each age category and one indicator for smoking:

```
. poisson deaths smokes i.agecat, exposure(pyyears) irr
Iteration 0: Log likelihood = -33.823284
Iteration 1: Log likelihood = -33.600471
Iteration 2: Log likelihood = -33.600153
Iteration 3: Log likelihood = -33.600153

Poisson regression Number of obs = 10
LR chi2(5) = 922.93
Prob > chi2 = 0.0000
Pseudo R2 = 0.9321

Log likelihood = -33.600153
```

| deaths      | IRR      | Std. err.  | z      | P> z  | [95% conf. interval] |          |
|-------------|----------|------------|--------|-------|----------------------|----------|
| smokes      | 1.425519 | .1530638   | 3.30   | 0.001 | 1.154984             | 1.759421 |
| agecat      |          |            |        |       |                      |          |
| 45-54       | 4.410584 | .8605197   | 7.61   | 0.000 | 3.009011             | 6.464997 |
| 55-64       | 13.8392  | 2.542638   | 14.30  | 0.000 | 9.654328             | 19.83809 |
| 65-74       | 28.51678 | 5.269878   | 18.13  | 0.000 | 19.85177             | 40.96395 |
| 75-84       | 40.45121 | 7.775511   | 19.25  | 0.000 | 27.75326             | 58.95885 |
| _cons       | .0003636 | .0000697   | -41.30 | 0.000 | .0002497             | .0005296 |
| ln(pyyears) | 1        | (exposure) |        |       |                      |          |

Note: `_cons` estimates baseline incidence rate.

In the above, we specified `irr` to obtain IRRs. We estimate that smokers have 1.43 times the mortality rate of nonsmokers. See, however, [example 1](#) in [\[R\] poisson postestimation](#).

◀

## Stored results

`poisson` stores the following in `e()`:

### Scalars

|                            |                                           |
|----------------------------|-------------------------------------------|
| <code>e(N)</code>          | number of observations                    |
| <code>e(k)</code>          | number of parameters                      |
| <code>e(k_eq)</code>       | number of equations in <code>e(b)</code>  |
| <code>e(k_eq_model)</code> | number of equations in overall model test |
| <code>e(k_dv)</code>       | number of dependent variables             |

| <code>e(b)</code>            | coefficient vector                                                       |
| <code>e(Cns)</code>          | constraints matrix                                                       |
| <code>e(ilog)</code>         | iteration log (up to 20 iterations)                                      |
| <code>e(gradient)</code>     | gradient vector                                                          |
| <code>e(V)</code>            | variance–covariance matrix of the estimators                             |
| <code>e(V_modelbased)</code> | model-based variance                                                     |
| Functions                    |                                                                          |
| <code>e(sample)</code>       | marks estimation sample                                                  |

In addition to the above, the following is stored in `r()`:

|                       |                                                                                                                            |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------|
| Matrices              |                                                                                                                            |
| <code>r(table)</code> | matrix containing the coefficients with their standard errors, test statistics, <i>p</i> -values, and confidence intervals |

Note that results stored in `r()` are updated when the command is replayed and will be replaced when any *r*-class command is run after the estimation command.

## Methods and formulas

The log likelihood (with weights  $w_j$  and offsets) is given by

$$\Pr(Y = y) = \frac{e^{-\lambda} \lambda^y}{y!}$$

$$\xi_j = \mathbf{x}_j \boldsymbol{\beta} + \text{offset}_j$$

$$f(y_j) = \frac{e^{-\exp(\xi_j)} e^{\xi_j y_j}}{y_j!}$$

$$\ln L = \sum_{j=1}^n w_j \{-e^{\xi_j} + \xi_j y_j - \ln(y_j!)\}$$

This command supports the Huber/White/sandwich estimator of the variance and its clustered version using `vce(robust)` and `vce(cluster clustvar)`, respectively. See [P] [\\_robust](#), particularly *Maximum likelihood estimators* and *Methods and formulas*.

poisson also supports estimation with survey data. For details on VCEs with survey data, see [SVY] [Variance estimation](#).

[Siméon-Denis Poisson](#) (1781–1840) was a French mathematician and physicist who contributed to several fields: his name is perpetuated in Poisson brackets, Poisson’s constant, Poisson’s differential equation, Poisson’s integral, and Poisson’s ratio. Among many other results, he produced a version of the law of large numbers. His rather misleadingly titled *Recherches sur la probabilité des jugements* embraces a complete treatise on probability, as the subtitle indicates, including what is now known as the Poisson distribution. That, however, was discovered earlier by the Huguenot–British mathematician Abraham de Moivre (1667–1754).

## Postestimation commands

The following postestimation commands are of special interest after `poisson`:

| Command                | Description                           |
|------------------------|---------------------------------------|
| <code>estat gof</code> | goodness-of-fit test                  |
| <code>lassogof</code>  | calculate goodness-of-fit predictions |

`estat gof` is not appropriate with `svy` estimation results.

The following standard postestimation commands are also available:

| Command                      | Description                                                                                                                             |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <code>contrast</code>        | contrasts and ANOVA-style joint tests of parameters                                                                                     |
| <code>estat ic</code>        | Akaike's, consistent Akaike's, corrected Akaike's, and Schwarz's Bayesian information criteria (AIC, CAIC, AICc, and BIC, respectively) |
| <code>estat summarize</code> | summary statistics for the estimation sample                                                                                            |
| <code>estat vce</code>       | variance–covariance matrix of the estimators (VCE)                                                                                      |
| <code>estat (svy)</code>     | postestimation statistics for survey data                                                                                               |
| <code>estimates</code>       | cataloging estimation results                                                                                                           |
| <code>etable</code>          | table of estimation results                                                                                                             |
| * <code>forecast</code>      | dynamic forecasts and simulations                                                                                                       |
| * <code>hausman</code>       | Hausman's specification test                                                                                                            |
| <code>lincom</code>          | point estimates, standard errors, testing, and inference for linear combinations of parameters                                          |
| <code>linktest</code>        | link test for model specification                                                                                                       |
| * <code>lrtest</code>        | likelihood-ratio test                                                                                                                   |
| <code>margins</code>         | marginal means, predictive margins, marginal effects, and average marginal effects                                                      |
| <code>marginsplot</code>     | graph the results from <code>margins</code> (profile plots, interaction plots, etc.)                                                    |
| <code>nlcom</code>           | point estimates, standard errors, testing, and inference for nonlinear combinations of parameters                                       |
| <code>predict</code>         | number of events, incidence rates, probabilities, etc.                                                                                  |
| <code>predictnl</code>       | point estimates, standard errors, testing, and inference for generalized predictions                                                    |
| <code>pwcompare</code>       | pairwise comparisons of parameters                                                                                                      |
| <code>suest</code>           | seemingly unrelated estimation                                                                                                          |
| <code>test</code>            | Wald tests of simple and composite linear hypotheses                                                                                    |
| <code>testnl</code>          | Wald tests of nonlinear hypotheses                                                                                                      |

\*`forecast`, `hausman`, and `lrtest` are not appropriate with `svy` estimation results. `forecast` is also not appropriate with `mi` estimation results.

# predict

## Description for predict

`predict` creates a new variable containing predictions such as numbers of events, incidence rates, probabilities, linear predictions, standard errors, and the equation-level score.

## Menu for predict

Statistics > Postestimation

## Syntax for predict

```
predict [type] newvar [if] [in] [, statistic nooffset]
```

| <i>statistic</i>                    | Description                                                                |
|-------------------------------------|----------------------------------------------------------------------------|
| Main                                |                                                                            |
| <code>n</code>                      | number of events; the default                                              |
| <code>ir</code>                     | incidence rate                                                             |
| <code>pr(<i>n</i>)</code>           | probability $\Pr(y_j = n)$                                                 |
| <code>pr(<i>a</i>, <i>b</i>)</code> | probability $\Pr(a \leq y_j \leq b)$                                       |
| <code>xb</code>                     | linear prediction                                                          |
| <code>stdp</code>                   | standard error of the linear prediction                                    |
| <code>score</code>                  | first derivative of the log likelihood with respect to $\mathbf{x}_j\beta$ |

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

## Options for predict

Main

`n`, the default, calculates the predicted number of events, which is  $\exp(\mathbf{x}_j\beta)$  if neither `offset()` nor `exposure()` was specified when the model was fit;  $\exp(\mathbf{x}_j\beta + \text{offset}_j)$  if `offset()` was specified; or  $\exp(\mathbf{x}_j\beta) \times \text{exposure}_j$  if `exposure()` was specified.

`ir` calculates the incidence rate  $\exp(\mathbf{x}_j\beta)$ , which is the predicted number of events when exposure is 1. Specifying `ir` is equivalent to specifying `n` when neither `offset()` nor `exposure()` was specified when the model was fit.

`pr(n)` calculates the probability  $\Pr(y_j = n)$ , where *n* is a nonnegative integer that may be specified as a number or a variable.

`pr(a, b)` calculates the probability  $\Pr(a \leq y_j \leq b)$ , where *a* and *b* are nonnegative integers that may be specified as numbers or variables;

*b* missing (*b* ≥ .) means  $+\infty$ ;

`pr(20, .)` calculates  $\Pr(y_j \geq 20)$ ;

`pr(20, b)` calculates  $\Pr(y_j \geq 20)$  in observations for which *b* ≥ . and calculates  $\Pr(20 \leq y_j \leq b)$  elsewhere.

`pr(., b)` produces a syntax error. A missing value in an observation of the variable  $a$  causes a missing value in that observation for `pr(a, b)`.

`xb` calculates the linear prediction, which is  $\mathbf{x}_j\beta$  if neither `offset()` nor `exposure()` was specified;  $\mathbf{x}_j\beta + \text{offset}_j$  if `offset()` was specified; or  $\mathbf{x}_j\beta + \ln(\text{exposure}_j)$  if `exposure()` was specified; see `nooffset` below.

`stdp` calculates the standard error of the linear prediction.

`score` calculates the equation-level score,  $\partial \ln L / \partial (\mathbf{x}_j\beta)$ .

`nooffset` is relevant only if you specified `offset()` or `exposure()` when you fit the model. It modifies the calculations made by `predict` so that they ignore the offset or exposure variable; the linear prediction is treated as  $\mathbf{x}_j\beta$  rather than as  $\mathbf{x}_j\beta + \text{offset}_j$  or  $\mathbf{x}_j\beta + \ln(\text{exposure}_j)$ . Specifying `predict ..., nooffset` is equivalent to specifying `predict ..., ir`.

## margins

### Description for margins

`margins` estimates margins of response for numbers of events, incidence rates, probabilities, and linear predictions.

### Menu for margins

Statistics > Postestimation

### Syntax for margins

```
margins [marginlist] [, options]
```

```
margins [marginlist] , predict(statistic ...) [predict(statistic ...) ...] [options]
```

| <i>statistic</i>      | Description                           |
|-----------------------|---------------------------------------|
| <code>n</code>        | number of events; the default         |
| <code>ir</code>       | incidence rate                        |
| <code>pr(n)</code>    | probability $\Pr(y_j = n)$            |
| <code>pr(a, b)</code> | probability $\Pr(a \leq y_j \leq b)$  |
| <code>xb</code>       | linear prediction                     |
| <code>stdp</code>     | not allowed with <code>margins</code> |
| <code>score</code>    | not allowed with <code>margins</code> |

Statistics not allowed with `margins` are functions of stochastic quantities other than  $e(b)$ .

For the full syntax, see [R] [margins](#).

## estat

### Description for estat

`estat gof` performs a goodness-of-fit test of the model. Both the deviance statistic and the Pearson statistic are reported. If the tests are significant, the Poisson regression model is inappropriate.

### Menu for estat

Statistics > Postestimation

### Syntax for estat

```
estat gof
```

`collect` is allowed; see [U] 11.1.10 Prefix commands.

### Remarks and examples

#### ▷ Example 1

Continuing with [example 2](#) of [R] [poisson](#), we use `estat gof` to determine whether the model fits the data well.

```
. use https://www.stata-press.com/data/r19/dollhill13
(Doll and Hill (1966))
. poisson deaths smokes i.agecat, exp(pyears) irr
(output omitted)
. estat gof
 Deviance goodness-of-fit = 12.13237
 Prob > chi2(4) = 0.0164
 Pearson goodness-of-fit = 11.15533
 Prob > chi2(4) = 0.0249
```

The deviance goodness-of-fit test tells us that, given the model, we can reject the hypothesis that these data are Poisson distributed at the 1.64% significance level. The Pearson goodness-of-fit test tells us that we can reject the hypothesis at the 2.49% significance level.

So let us now back up and be more careful. We can most easily obtain the incidence-rate ratios within age categories by using `irr`; see [R] [Eptab](#):

```
. irr deaths smokes pyears, by(agecat) nohet
Stratified incidence-rate analysis
```

| Age category | IRR      | [95% conf. interval] |          | M-H weight       |
|--------------|----------|----------------------|----------|------------------|
| 35-44        | 5.736638 | 1.463557             | 49.40468 | 1.472169 (exact) |
| 45-54        | 2.138812 | 1.173714             | 4.272545 | 9.624747 (exact) |
| 55-64        | 1.46824  | .9863624             | 2.264107 | 23.34176 (exact) |
| 65-74        | 1.35606  | .9081925             | 2.096412 | 23.25315 (exact) |
| 75-84        | .9047304 | .6000757             | 1.399687 | 24.31435 (exact) |
| Crude        | 1.719823 | 1.391992             | 2.14353  | (exact)          |
| M-H combined | 1.424682 | 1.154703             | 1.757784 |                  |

We find that the mortality incidence ratios are greatly different within age category, being highest for the youngest categories and actually dropping below 1 for the oldest. (In the last case, we might argue that those who smoke and who have not died by age 75 are self-selected to be particularly robust.)

Seeing this, we will now parameterize the smoking effects separately for each category, although we will begin by constraining the smoking effects on third and fourth age categories to be equivalent:

```
. constraint 1 smokes#3.agecat = smokes#4.agecat
. poisson deaths c.smokes#agecat i.agecat, exposure(pyears) irr constraints(1)
Iteration 0: Log likelihood = -31.95424
Iteration 1: Log likelihood = -27.796801
Iteration 2: Log likelihood = -27.574177
Iteration 3: Log likelihood = -27.572645
Iteration 4: Log likelihood = -27.572645
Poisson regression
Log likelihood = -27.572645
(1) [deaths]3.agecat#c.smokes - [deaths]4.agecat#c.smokes = 0
Number of obs = 10
Wald chi2(8) = 632.14
Prob > chi2 = 0.0000
```

| deaths     | IRR      | Std. err.  | z      | P> z  | [95% conf. interval] |          |
|------------|----------|------------|--------|-------|----------------------|----------|
| agecat#    |          |            |        |       |                      |          |
| c.smokes   |          |            |        |       |                      |          |
| 35-44      | 5.736637 | 4.181256   | 2.40   | 0.017 | 1.374811             | 23.93711 |
| 45-54      | 2.138812 | .6520701   | 2.49   | 0.013 | 1.176691             | 3.887609 |
| 55-64      | 1.412229 | .2017485   | 2.42   | 0.016 | 1.067343             | 1.868557 |

Note: `_cons` estimates baseline incidence rate.

```
. estat gof
 Deviance goodness-of-fit = .0773491
 Prob > chi2(1) = 0.7809
 Pearson goodness-of-fit = .0773885
 Prob > chi2(1) = 0.7809
```

The goodness-of-fit is now small; we are no longer running roughshod over the data. Let us now consider simplifying the model. The point estimate of the incidence-rate ratio for smoking in age category 1 is much larger than that for smoking in age category 2, but the confidence interval for `smokes#1.agecat` is similarly wide. Is the difference real?

```
. test smokes#1.agecat = smokes#2.agecat
 (1) [deaths]1b.agecat#c.smokes - [deaths]2.agecat#c.smokes = 0
 chi2(1) = 1.56
 Prob > chi2 = 0.2117
```

The point estimates of the incidence-rate ratio for smoking in the 35–44 age category is much larger than that for smoking in the 45–54 age category, but there is insufficient data, and we may be observing random differences. With that success, might we also combine the smokers in the third and fourth categories with those in the first and second categories?

```
. test smokes#2.agecat = smokes#3.agecat, accum
 (1) [deaths]1b.agecat#c.smokes - [deaths]2.agecat#c.smokes = 0
 (2) [deaths]2.agecat#c.smokes - [deaths]3.agecat#c.smokes = 0
 chi2(2) = 4.73
 Prob > chi2 = 0.0938
```

Combining the first four categories may be overdoing it—the 9.38% significance level is enough to stop us, although others may disagree.

Thus, we now fit our final model:

```
. constraint 2 smokes#1.agecat = smokes#2.agecat
. poisson deaths c.smokes#agecat i.agecat, exposure(pyyears) irr constraints(1/2)
Iteration 0: Log likelihood = -31.550722
Iteration 1: Log likelihood = -28.525057
Iteration 2: Log likelihood = -28.514535
Iteration 3: Log likelihood = -28.514535

Poisson regression Number of obs = 10
 Wald chi2(7) = 642.25
Log likelihood = -28.514535 Prob > chi2 = 0.0000
(1) [deaths]3.agecat#c.smokes - [deaths]4.agecat#c.smokes = 0
(2) [deaths]1b.agecat#c.smokes - [deaths]2.agecat#c.smokes = 0
```

| deaths      | IRR      | Std. err.  | z      | P> z  | [95% conf. interval] |          |

| 45-54       | 4.294559 | .8385329   | 7.46   | 0.000 | 2.928987             | 6.296797 |
| 55-64       | 23.42263 | 7.787716   | 9.49   | 0.000 | 12.20738             | 44.94164 |
| 65-74       | 48.26309 | 16.06939   | 11.64  | 0.000 | 25.13068             | 92.68856 |
| 75-84       | 97.87965 | 34.30881   | 13.08  | 0.000 | 49.24123             | 194.561  |
| _cons       | .0002166 | .0000652   | -28.03 | 0.000 | .0001201             | .0003908 |
| ln(pyyears) | 1        | (exposure) |        |       |                      |          |

Note: **\_cons** estimates baseline incidence rate.

The above strikes us as a fair representation of the data. The probabilities of observing the deaths seen in these data are estimated using the following predict command:

```
. predict p, pr(0, deaths)
. list deaths p
```

|     | deaths | p        |
|-----|--------|----------|
| 1.  | 32     | .6891766 |
| 2.  | 104    | .4456625 |
| 3.  | 206    | .5455328 |
| 4.  | 186    | .4910622 |
| 5.  | 102    | .5263011 |
| 6.  | 2      | .227953  |
| 7.  | 12     | .7981917 |
| 8.  | 28     | .4772961 |
| 9.  | 28     | .6227565 |
| 10. | 31     | .5475718 |

The probability  $\Pr(y \leq \text{deaths})$  ranges from 0.23 to 0.80.

## Stored results

estat `gof` after `poisson` stores the following in `r()`:

Scalars

|                        |                                           |
|------------------------|-------------------------------------------|
| <code>r(df)</code>     | degrees of freedom (Pearson and deviance) |
| <code>r(chi2_p)</code> | $\chi^2$ (Pearson)                        |
| <code>r(chi2_d)</code> | $\chi^2$ (deviance)                       |
| <code>r(p_p)</code>    | $p$ -value for $\chi^2$ test (Pearson)    |
| <code>r(p_d)</code>    | $p$ -value for $\chi^2$ test (deviance)   |

## Methods and formulas

In the following, we use the [same notation](#) as in [\[R\] poisson](#).

The equation-level score is given by

$$\text{score}(\mathbf{x}\boldsymbol{\beta})_j = y_j - e^{\xi_j}$$

The deviance (D) and Pearson (P) goodness-of-fit statistics are given by

$$\begin{aligned}\ln L_{\max} &= \sum_{j=1}^n w_j [y_j \{ \ln(y_j) - 1 \} - \ln(y_j!)] \\ \chi_D^2 &= -2 \{ \ln L - \ln L_{\max} \} \\ \chi_P^2 &= \sum_{j=1}^n \frac{w_j (y_j - e^{\xi_j})^2}{e^{\xi_j}}\end{aligned}$$

postest
```

## Remarks and examples

Remarks are presented under the following headings:

[Overview](#)

[Video example](#)

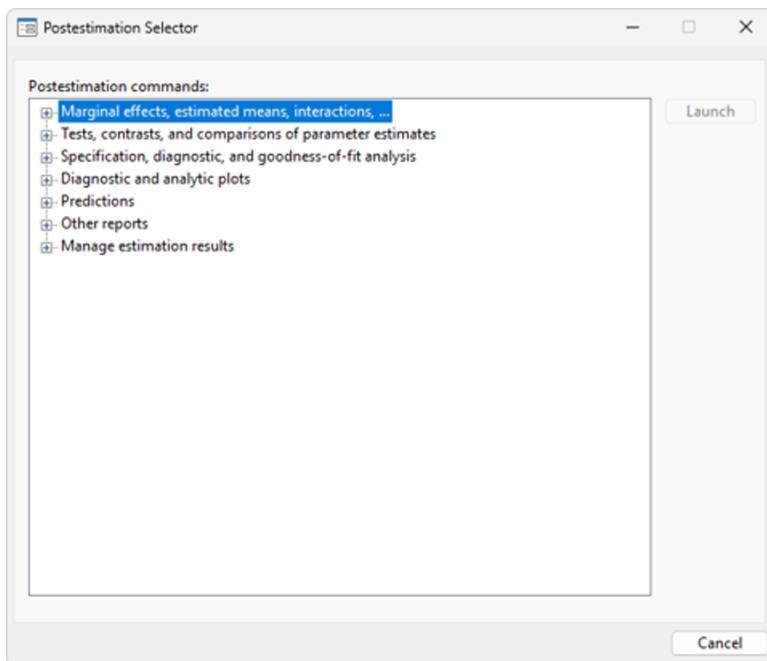

## Overview

Stata uses an estimation followed by postestimation analysis paradigm. You type `regress ...` to fit a regression model, then you type `test ...` to test linear relationships among the estimated parameters, or you type `contrast ...` to compare marginal means, or you type `rvfplot` to see a residual-versus-fitted plot, or you type one of a myriad of other postestimation commands. This is an extension of Stata's "type a little, get a little" concept. The Postestimation Selector exposes this type of postestimation analysis to those who prefer to use the dialog boxes to fit and analyze models, or at least they sometimes prefer the dialogs when exploring their data. We might call this "click a little, get a little".

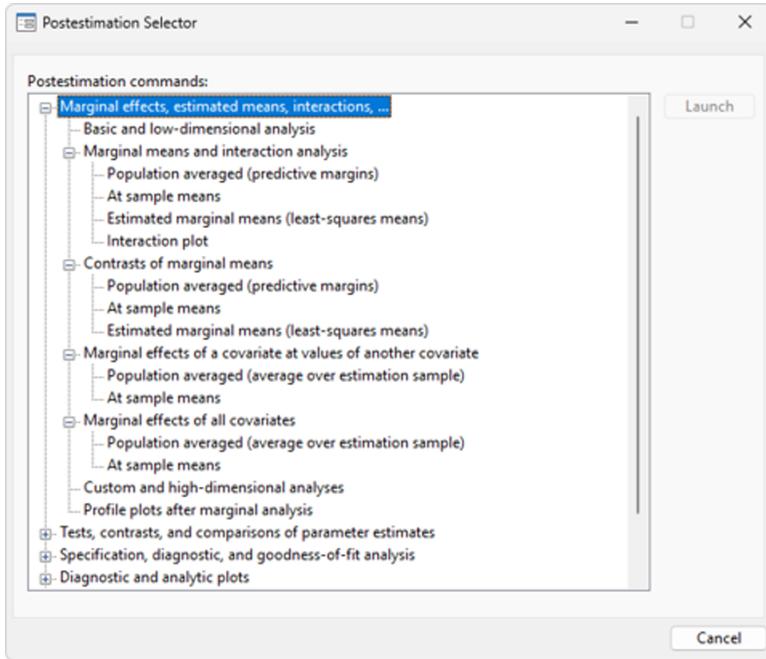

The Postestimation Selector knows what is available after any estimation command. It shows the full list of postestimation features that are available after any estimation, and it shows only those that are available. For example, if you fit a linear regression, you can choose from 59 postestimation analyses, including "Likelihood-ratio test comparing models". If, however, you fit that linear regression using survey estimation, the likelihood-ratio test is not available because that test has no meaning for survey estimation. You will, however, see 8 new postestimation features for survey-data analysis, including "Design and misspecification effects".

If you are using the menus and dialogs, we recommend you launch the Postestimation Selector and just leave it up—select **Statistics > Postestimation**, or type `postest` at the command line. All available postestimation features for whatever model you are analyzing will then be just a click away.

Here is what the Selector looks like after a linear regression,

And, here is what it looks like with all the groupings expanded.

## Description

`predict` calculates predictions, residuals, influence statistics, and the like after estimation. Exactly what `predict` can do is determined by the previous estimation command; command-specific options are documented with each estimation command. Regardless of command-specific options, the actions of `predict` share certain similarities across estimation commands:

1. `predict newvar` creates *newvar* containing “predicted values”—numbers related to the  $E(y_j|\mathbf{x}_j)$ . For instance, after linear regression, `predict newvar` creates  $\mathbf{x}_j\mathbf{b}$  and, after probit, creates the probability  $\Phi(\mathbf{x}_j\mathbf{b})$ .
2. `predict newvar, xb` creates *newvar* containing  $\mathbf{x}_j\mathbf{b}$ . This may be the same result as option 1 (for example, linear regression) or different (for example, probit), but regardless, option `xb` is allowed.
3. `predict newvar, stdp` creates *newvar* containing the standard error of the linear prediction  $\mathbf{x}_j\mathbf{b}$ .
4. `predict newvar, other_options` may create *newvar* containing other useful quantities; see `help` or the reference manual entry for the particular estimation command to find out about other available options.
5. `nooffset` added to any of the above commands requests that the calculation ignore any offset or exposure variable specified by including the `offset(varnameo)` or `exposure(varnamee)` option when you fit the model.

`predict` can be used to make in-sample or out-of-sample predictions:

6. `predict` calculates the requested statistic for all possible observations, whether they were used in fitting the model or not. `predict` does this for standard options 1 through 3 and generally does this for estimator-specific options 4.
7. `predict newvar if e(sample), ...` restricts the prediction to the estimation subsample.
8. Some statistics make sense only with respect to the estimation subsample. In such cases, the calculation is automatically restricted to the estimation subsample, and the documentation for the specific option states this. Even so, you can still specify `if e(sample)` if you are uncertain.
9. `predict` can make out-of-sample predictions even using other datasets. In particular, you can

```
. use ds1
. (fit a model)
. use two /* another dataset */
. predict yhat, ... /* fill in the predictions */
```

## Quick start

Create `newvar1` containing the default prediction for the previous estimation command

```
predict newvar1
```

Create `newvar2` containing the linear prediction

```
predict newvar2, xb
```

Same as above, but only for observations used in the previous estimation

```
predict newvar2 if e(sample), xb
```

Create `newvar3`, the default prediction for the first equation in a multiple-equation model

```
predict newvar3, equation(#1)
```

Same as above when `y1` is the name of the first equation

```
predict newvar3, equation(y1)
```

Note: For a complete list of options available with `predict` after an estimation command, see the corresponding `postestimation` entry.

## Menu for predict

## Options

Main

`xb` calculates the linear prediction from the fitted model. That is, all models can be thought of as estimating a set of parameters  $b_1, b_2, \dots, b_k$ , and the linear prediction is  $\hat{y}_j = b_1x_{1j} + b_2x_{2j} + \dots + b_kx_{kj}$ , often written in matrix notation as  $\hat{\mathbf{y}}_j = \mathbf{x}_j\mathbf{b}$ . For linear regression, the values  $\hat{y}_j$  are called the predicted values or, for out-of-sample predictions, the forecast. For logit and probit, for example,  $\hat{y}_j$  is called the logit or probit index.

$x_{1j}, x_{2j}, \dots, x_{kj}$  are obtained from the data currently in memory and do not necessarily correspond to the data on the independent variables used to fit the model (obtaining  $b_1, b_2, \dots, b_k$ ).

`stdp` calculates the standard error of the linear prediction. Here the prediction means the same thing as the “index”, namely,  $\mathbf{x}_j\mathbf{b}$ . The statistic produced by `stdp` can be thought of as the standard error of the predicted expected value, or mean index, for the observation’s covariate pattern. The standard error of the prediction is also commonly referred to as the standard error of the fitted value. The calculation can be made in or out of sample.

`stdp` is allowed only after you have previously fit a multiple-equation model. The standard error of the difference in linear predictions ( $\mathbf{x}_{1j}\mathbf{b} - \mathbf{x}_{2j}\mathbf{b}$ ) between equations 1 and 2 is calculated. This option requires that `equation(eqno1, eqno2)` be specified.

`score` calculates the equation-level score,  $\partial \ln L / \partial (\mathbf{x}_j \boldsymbol{\beta})$ . Here  $\ln L$  refers to the log-likelihood function.

`scores` is the ME model equivalent of the `score` option, resulting in multiple equation-level score variables. An equation-level score variable is created for each equation in the model; ancillary parameters—such as  $\ln \sigma$  and  $\text{atanh} \rho$ —make up separate equations.

`equation(eqno[ , eqno ])`—synonym `outcome()`—is relevant only when you have previously fit a multiple-equation model. It specifies the equation to which you are referring.

`equation()` is typically filled in with one `eqno`—it would be filled in that way with options `xb` and `stdp`, for instance. `equation(#1)` would mean the calculation is to be made for the first equation, `equation(#2)` would mean the second, and so on. You could also refer to the equations by their names. `equation(income)` would refer to the equation named `income` and `equation(hours)` to the equation named `hours`.

If you do not specify `equation()`, results are the same as if you specified `equation(#1)`.

Other statistics, such as `stdp`, refer to between-equation concepts. In those cases, you might specify `equation(#1, #2)` or `equation(income, hours)`. When two equations must be specified, `equation()` is required.

#### Options

`nooffset` may be combined with most statistics and specifies that the calculation should be made, ignoring any offset or exposure variable specified when the model was fit.

This option is available, even if it is not documented for `predict` after a specific command. If neither the `offset(varnameo)` option nor the `exposure(varnamee)` option was specified when the model was fit, specifying `nooffset` does nothing.

`other_options` refers to command-specific options that are documented with each command.

## Remarks and examples

Remarks are presented under the following headings:

- Estimation-sample predictions*
- Out-of-sample predictions*
- Residuals*
- Single-equation (SE) models*
- SE model scores*
- Multiple-equation (ME) models*
- ME model scores*

Most of the examples are presented using linear regression, but the general syntax is applicable to all estimators.

You can think of any estimation command as estimating a set of coefficients  $b_1, b_2, \dots, b_k$  corresponding to the variables  $x_1, x_2, \dots, x_k$ , along with a (possibly empty) set of ancillary statistics  $\gamma_1, \gamma_2, \dots, \gamma_m$ . All estimation commands store the  $b_i$ s and  $\gamma_i$ s. `predict` accesses that stored information and combines it with the data currently in memory to make various calculations. For instance, `predict` can calculate the linear prediction,  $\hat{y}_j = b_1x_{1j} + b_2x_{2j} + \dots + b_kx_{kj}$ . The data on which `predict` makes the calculation can be the same data used to fit the model or a different dataset—it does not matter. `predict` uses the stored parameter estimates from the model, obtains the corresponding values of  $x$  for each observation in the data, and then combines them to produce the desired result.

## Estimation-sample predictions

### ▷ Example 1

We have a 74-observation dataset on automobiles, including the mileage rating (`mpg`), the car's weight (`weight`), and whether the car is foreign (`foreign`). We fit the model

```
. use https://www.stata-press.com/data/r19/auto
(1978 automobile data)
. regress mpg weight if foreign
```

| Source   | SS         | df | MS         | Number of obs | = | 22     |
|----------|------------|----|------------|---------------|---|--------|

If we were to type `predict pmpg` now, we would obtain the linear predictions for all 74 observations. To obtain the predictions just for the sample on which we fit the model, we could type

```
. predict pmpg if e(sample)
(option xb assumed; fitted values)
(52 missing values generated)
```

Here `e(sample)` is true only for foreign cars because we typed `if foreign` when we fit the model and because there are no missing values among the relevant variables. If there had been missing values, `e(sample)` would also account for those.

By the way, the `if e(sample)` restriction can be used with any Stata command, so we could obtain summary statistics on the estimation sample by typing

```
. summarize if e(sample)
(output omitted)
```

## Out-of-sample predictions

By out-of-sample predictions, we mean predictions extending beyond the estimation sample. In the example above, typing `predict pmpg` would generate linear predictions using all 74 observations.

`predict` will work on other datasets, too. You can use a new dataset and type `predict` to obtain results for that sample.

### ► Example 2

Using the same auto dataset, assume that we wish to fit the model

$$\text{mpg} = \beta_1 \text{weight} + \beta_2 \ln(\text{weight}) + \beta_3 \text{foreign} + \beta_4$$

We first create the `ln(weight)` variable, and then type the `regress` command:

```
. use https://www.stata-press.com/data/r19/auto, clear
(1978 automobile data)
. generate lnweight = ln(weight)
. regress mpg weight lnweight foreign
```

| Source   | SS         | df | MS         | Number of obs | = | 74     |
|----------|------------|----|------------|---------------|---|--------|
| Model    | 1690.27997 | 3  | 563.426657 | F(3, 70)      | = | 52.36  |
| Residual | 753.179489 | 70 | 10.759707  | Prob > F      | = | 0.0000 |
|          |            |    |            | R-squared     | = | 0.6918 |
|          |            |    |            | Adj R-squared | = | 0.6785 |
| Total    | 2443.45946 | 73 | 33.4720474 | Root MSE      | = | 3.2802 |

| mpg      | Coefficient | Std. err. | t     | P> t  | [95% conf. interval] |
|----------|-------------|-----------|-------|-------|----------------------|
| weight   | .003304     | .0038995  | 0.85  | 0.400 | -0.0044734 .0110813  |
| lnweight | -29.59133   | 11.52018  | -2.57 | 0.012 | -52.5676 -6.615061   |
| foreign  | -2.125299   | 1.052324  | -2.02 | 0.047 | -4.224093 -.0265044  |
| _cons    | 248.0548    | 80.37079  | 3.09  | 0.003 | 87.76035 408.3493    |

If we typed `predict pmpg` now, we would obtain predictions for all 74 cars in the current data. Instead, we are going to use a new dataset.

`newautos.dta` contains the make, weight, and place of manufacture of two cars, the Pontiac Sunbird and the Volvo 260. Let's use the dataset and create the predictions:

```
. use https://www.stata-press.com/data/r19/newautos, clear
(New automobile models)
. list
```

|    | make          | weight | foreign  |
|----|---------------|--------|----------|
| 1. | Pont. Sunbird | 2690   | Domestic |
| 2. | Volvo 260     | 3170   | Foreign  |

```
. predict mpg
(option xb assumed; fitted values)
variable lnweight not found
r(111);
```

Things did not work. We typed `predict mpg`, and Stata responded with the message “variable `lnweight` not found”. `predict` can calculate predicted values on a different dataset only if that dataset contains the variables that went into the model. Here our dataset does not contain a variable called `lnweight`. `lnweight` is just the log of weight, so we can create it and try again:

```
. generate lnweight = ln(weight)
. predict mpg
(option xb assumed; fitted values)
. list
```

|    | make          | weight | foreign  | lnweight | mpg      |
|----|---------------|--------|----------|----------|----------|
| 1. | Pont. Sunbird | 2690   | Domestic | 7.897296 | 23.25097 |
| 2. | Volvo 260     | 3170   | Foreign  | 8.061487 | 17.85295 |

We obtained our predicted values. The Pontiac Sunbird has a predicted mileage rating of 23.3 mpg, whereas the Volvo 260 has a predicted rating of 17.9 mpg.

## Residuals

### ▷ Example 3

With many estimators, `predict` can calculate more than predicted values. With most regression-type estimators, we can, for instance, obtain residuals. Using our regression example, we return to our original data and obtain residuals by typing

```
. use https://www.stata-press.com/data/r19/auto, clear
(1978 automobile data)
. generate lnweight = ln(weight)
. regress mpg weight lnweight foreign
(output omitted)
. predict double resid, residuals
. summarize resid
```

| Variable | Obs | Mean      | Std. dev. | Min       | Max      |
|----------|-----|-----------|-----------|-----------|----------|
| resid    | 74  | -1.31e-14 | 3.212091  | -5.453078 | 13.83719 |

We could do this without refitting the model. Stata always remembers the last set of estimates, even as we use new datasets.

It was not necessary to type the `double` in `predict double resid, residuals`, but we wanted to remind you that you can specify the type of a variable in front of the variable’s name; see [U] 11.4.2 Lists of new variables. We made the new variable `resid` a `double` rather than the default `float`.

If we had not specified `%double`, the mean of `resid` would have been roughly  $9 \times 10^{-9}$  rather than  $1 \times 10^{-14}$ . Although  $1 \times 10^{-14}$  sounds more precise than  $9 \times 10^{-9}$ , the difference really does not matter.

For linear regression, `predict` can also calculate standardized residuals and Studentized residuals with the options `rstandard` and `rstudent`; for examples, see [R] regress postestimation.

## Single-equation (SE) models

If you have not read the discussion above on using `predict` after linear regression, please do so. And `predict`'s default calculation almost always produces a statistic in the same metric as the dependent variable of the fitted model—for example, predicted counts for Poisson regression. In any case, `xb` can always be specified to obtain the linear prediction.

`predict` can calculate the standard error of the prediction, which is obtained by using the covariance matrix of the estimators.

### ▷ Example 4

After most binary outcome models (for example, `logistic`, `logit`, `probit`, `cloglog`, `scobit`), `predict` calculates the probability of a positive outcome if we do not tell it otherwise. We can specify the `xb` option if we want the linear prediction (also known as the logit or probit index). The odd abbreviation `xb` is meant to suggest  $\mathbf{x}\beta$ . In logit and probit models, for example, the predicted probability is  $p = F(\mathbf{x}\beta)$ , where  $F()$  is the logistic or normal cumulative distribution function, respectively.

```
. logistic foreign mpg weight
 (output omitted)
. predict phat
(option pr assumed; Pr(foreign))
. predict idxhat, xb
. summarize foreign phat idxhat
```

| Variable | Obs | Mean      | Std. dev. | Min       | Max      |
|----------|-----|-----------|-----------|-----------|----------|
| foreign  | 74  | .2972973  | .4601885  | 0         | 1        |
| phat     | 74  | .2972973  | .3052979  | .000729   | .8980594 |
| idxhat   | 74  | -1.678202 | 2.321509  | -7.223107 | 2.175845 |

Because this is a logit model, we could obtain the predicted probabilities ourselves from the predicted index

```
. generate phat2 = exp(idxhat)/(1+exp(idxhat))
```

but using `predict` without options is easier.

### ▷ Example 5

For all models, `predict` attempts to produce a predicted value in the same metric as the dependent variable of the model. We have seen that for dichotomous outcome models, the default statistic produced by `predict` is the probability of a success. Similarly, for Poisson regression, the default statistic produced by `predict` is the predicted count for the dependent variable. You can always specify the `xb` option to obtain the linear combination of the coefficients with an observation's  $x$  values (the inner product of the coefficients and  $x$  values). For `poisson` (without an explicit exposure), this is the natural log of the count.

```
. use https://www.stata-press.com/data/r19/airline, clear
. poisson injuries XYZowned
 (output omitted)
```

```
. predict injhat
(option n assumed; predicted number of events)
. predict idx, xb
. generate exp_idx = exp(idx)
. summarize injuries injhat exp_idx idx
```

| Variable | Obs | Mean     | Std. dev. | Min      | Max      |
|----------|-----|----------|-----------|----------|----------|
| injuries | 9   | 7.111111 | 5.487359  | 1        | 19       |
| injhat   | 9   | 7.111111 | .8333333  | 6        | 7.666667 |
| exp_idx  | 9   | 7.111111 | .8333333  | 6        | 7.666667 |
| idx      | 9   | 1.955174 | .1225612  | 1.791759 | 2.036882 |

We note that our “hand-computed” prediction of the count (`exp_idx`) matches what was produced by the default operation of `predict`.

If our model has an exposure-time variable, we can use `predict` to obtain the linear prediction with or without the exposure. Let’s verify what we are getting by obtaining the linear prediction with and without exposure, transforming these predictions to count predictions and comparing them with the default count prediction from `predict`. We must remember to multiply by the exposure time when using `predict` . . . , `nooffset`.

```
. use https://www.stata-press.com/data/r19/airline, clear
. poisson injuries XYZowned, exposure(n)
(output omitted)
. predict double injhat
(option n assumed; predicted number of events)
. predict double idx, xb
. generate double exp_idx = exp(idx)
. predict double idxn, xb nooffset
. generate double exp_idxn = exp(idxn)*n
. summarize injuries injhat exp_idx exp_idxn idx idxn
```

| Variable | Obs | Mean     | Std. dev. | Min      | Max      |
|----------|-----|----------|-----------|----------|----------|
| injuries | 9   | 7.111111 | 5.487359  | 1        | 19       |
| injhat   | 9   | 7.111111 | 3.10936   | 2.919621 | 12.06158 |
| exp_idx  | 9   | 7.111111 | 3.10936   | 2.919621 | 12.06158 |
| exp_idxn | 9   | 7.111111 | 3.10936   | 2.919621 | 12.06158 |
| idx      | 9   | 1.869722 | .4671044  | 1.071454 | 2.490025 |
| idxn     | 9   | 4.18814  | .1904042  | 4.061204 | 4.442013 |

Looking at the identical means and standard deviations for `injhat`, `exp_idx`, and `exp_idxn`, we see that we can reproduce the default computations of `predict` for `poisson` estimations. We have also demonstrated the relationship between the count predictions and the linear predictions with and without exposure.

## SE model scores

### ▷ Example 6

With most maximum likelihood estimators, `predict` can calculate equation-level scores. The first derivative of the log likelihood with respect to  $\mathbf{x}_j\beta$  is the equation-level score.

```
. use https://www.stata-press.com/data/r19/auto, clear
(1978 automobile data)
. logistic foreign mpg weight
(output omitted)
. predict double sc, score
. summarize sc
```

| Variable | Obs | Mean      | Std. dev. | Min       | Max      |
|----------|-----|-----------|-----------|-----------|----------|
| sc       | 74  | -1.37e-12 | .3533133  | -.8760856 | .8821309 |

See [P] [\\_robust](#) and [SVY] [Variance estimation](#) for details regarding the role equation-level scores play in linearization-based variance estimators.

### □ Technical note

`predict` after some estimation commands, such as `regress` and `cnsreg`, allows the `score` option as a synonym for the `residuals` option.

## Multiple-equation (ME) models

If you have not read the above discussion on using `predict` after SE models, please do so. With the exception of the ability to select specific equations to predict from, the use of `predict` after ME models follows almost the same form that it does for SE models.

### ▷ Example 7

The details of prediction statistics that are specific to particular ME models are documented with the estimation command. If you are using ME commands that do not have separate discussions on obtaining predictions, read [Obtaining predicted values](#) in [R] [mlogit postestimation](#), even if your interest is not in multinomial logistic regression. As a general introduction to the ME models, we will demonstrate `predict` after `sureg`:

```
. use https://www.stata-press.com/data/r19/auto, clear
(1978 automobile data)
. sureg (price foreign displ) (weight foreign length)
Seemingly unrelated regression
```

| Equation | Obs | Params | RMSE     | "R-squared" | chi2   | P>chi2 |
|----------|-----|--------|----------|-------------|--------|--------|
| price    | 74  | 2      | 2202.447 | 0.4348      | 45.21  | 0.0000 |
| weight   | 74  | 2      | 245.5238 | 0.8988      | 658.85 | 0.0000 |

|              | Coefficient | Std. err. | z     | P> z  | [95% conf. interval] |
|--------------|-------------|-----------|-------|-------|----------------------|
| price        |             |           |       |       |                      |
| foreign      | 3137.894    | 697.3805  | 4.50  | 0.000 | 1771.054 4504.735    |
| displacement | 23.06938    | 3.443212  | 6.70  | 0.000 | 16.32081 29.81795    |
| _cons        | 680.8438    | 859.8142  | 0.79  | 0.428 | -1004.361 2366.049   |
| weight       |             |           |       |       |                      |
| foreign      | -154.883    | 75.3204   | -2.06 | 0.040 | -302.5082 -7.257674  |
| length       | 30.67594    | 1.531981  | 20.02 | 0.000 | 27.67331 33.67856    |
| _cons        | -2699.498   | 302.3912  | -8.93 | 0.000 | -3292.173 -2106.822  |

sureg estimated two equations, one called price and the other weight; see [R] sureg.

```
. predict pred_p, equation(price)
(option xb assumed; fitted values)
. predict pred_w, equation(weight)
(option xb assumed; fitted values)
. summarize price pred_p weight pred_w
```

| Variable | Obs | Mean     | Std. dev. | Min      | Max      |
|----------|-----|----------|-----------|----------|----------|
| price    | 74  | 6165.257 | 2949.496  | 3291     | 15906    |
| pred_p   | 74  | 6165.257 | 1678.805  | 2664.81  | 10485.33 |
| weight   | 74  | 3019.459 | 777.1936  | 1760     | 4840     |
| pred_w   | 74  | 3019.459 | 726.0468  | 1501.602 | 4447.996 |

You may specify the equation by name, as we did above, or by number: equation(#1) means the same thing as equation(price) in this case.

## ME model scores

### ▷ Example 8

For ME models, `predict` allows you to specify a stub when generating equation-level score variables. `predict` generates new variables using this stub by appending an equation index. Depending upon the command, the index will start with 0 or 1. Here is an example where `predict` starts indexing the score variables with 0.

```
. ologit rep78 mpg weight
(output omitted)
. predict double sc*, scores
. summarize sc*
```

| Variable | Obs | Mean      | Std. dev. | Min       | Max      |
|----------|-----|-----------|-----------|-----------|----------|
| sc0      | 69  | -1.33e-11 | .5337363  | -.9854088 | .921433  |
| sc1      | 69  | -7.69e-13 | .186919   | -.2738537 | .9854088 |
| sc2      | 69  | -2.87e-11 | .4061637  | -.5188487 | 1.130178 |
| sc3      | 69  | -1.04e-10 | .5315368  | -1.067351 | .8194842 |
| sc4      | 69  | 1.47e-10  | .360525   | -.921433  | .6140182 |

Although it involves much more typing, we could also specify the new variable names individually.

```
. predict double (sc_xb sc_1 sc_2 sc_3 sc_4), scores
. summarize sc_*
```

| Variable | Obs | Mean      | Std. dev. | Min       | Max      |
|----------|-----|-----------|-----------|-----------|----------|
| sc_xb    | 69  | -1.33e-11 | .5337363  | -.9854088 | .921433  |
| sc_1     | 69  | -7.69e-13 | .186919   | -.2738537 | .9854088 |
| sc_2     | 69  | -2.87e-11 | .4061637  | -.5188487 | 1.130178 |
| sc_3     | 69  | -1.04e-10 | .5315368  | -1.067351 | .8194842 |
| sc_4     | 69  | 1.47e-10  | .360525   | -.921433  | .6140182 |

◀

## Methods and formulas

Denote the previously estimated coefficient vector as  $\mathbf{b}$  and its estimated variance matrix as  $\mathbf{V}$ . `predict` works by recalling various aspects of the model, such as  $\mathbf{b}$ , and combining that information with the data currently in memory. Let's write  $\mathbf{x}_j$  for the  $j$ th observation currently in memory.

The *predicted value* (`xb` option) is defined as  $\hat{y}_j = \mathbf{x}_j \mathbf{b} + \text{offset}_j$

The *standard error of the prediction* (the `stdp` option) is defined as  $s_{pj} = \sqrt{\mathbf{x}_j \mathbf{V} \mathbf{x}_j'}$

The *standard error of the difference in linear predictions* between equations 1 and 2 is defined as

$$s_{dpj} = \{(\mathbf{x}_{1j}, -\mathbf{x}_{2j}, \mathbf{0}, \dots, \mathbf{0}) \mathbf{V} (\mathbf{x}_{1j}, -\mathbf{x}_{2j}, \mathbf{0}, \dots, \mathbf{0})'\}^{\frac{1}{2}}$$

See the individual estimation commands for information about calculating command-specific `predict` statistics.

## Description

`predictnl` calculates (possibly) nonlinear predictions after any Stata estimation command and optionally calculates the variances, standard errors, Wald test statistics,  $p$ -values, and confidence limits for these predictions. Unlike its companion nonlinear postestimation commands `testnl` and `nlcom`, `predictnl` generates functions of the data (that is, predictions), not scalars. The quantities generated by `predictnl` are thus vectorized over the observations in the data.

Consider some general prediction,  $g(\boldsymbol{\theta}, \mathbf{x}_i)$ , for  $i = 1, \dots, n$ , where  $\boldsymbol{\theta}$  are the model parameters and  $\mathbf{x}_i$  are some data for the  $i$ th observation;  $\mathbf{x}_i$  is assumed fixed. Typically,  $g(\boldsymbol{\theta}, \mathbf{x}_i)$  is estimated by  $g(\hat{\boldsymbol{\theta}}, \mathbf{x}_i)$ , where  $\hat{\boldsymbol{\theta}}$  are the estimated model parameters, which are stored in `e(b)` following any Stata estimation command.

In its most common use, `predictnl` generates two variables: one containing the estimated prediction,  $g(\hat{\boldsymbol{\theta}}, \mathbf{x}_i)$ , the other containing the estimated standard error of  $g(\hat{\boldsymbol{\theta}}, \mathbf{x}_i)$ . The calculation of standard errors (and other obtainable quantities that are based on the standard errors, such as test statistics) is based on the delta method, an approximation appropriate in large samples; see [Methods and formulas](#).

`predictnl` can be used with `svy` estimation results (assuming that `predict` is also allowed), see [\[SVY\] svy postestimation](#).

The specification of  $g(\hat{\boldsymbol{\theta}}, \mathbf{x}_i)$  is handled by specifying `pnl_exp`, and the values of  $g(\hat{\boldsymbol{\theta}}, \mathbf{x}_i)$  are stored in the new variable `newvar` of storage type `type`. `pnl_exp` is any valid Stata expression and may also contain calls to two special functions unique to `predictnl`:

1. `predict([predict_options])`: When you are evaluating `pnl_exp`, `predict()` is a convenience function that replicates the calculation performed by the command

```
predict ..., predict_options
```

As such, the `predict()` function may be used either as a shorthand for the formula used to make this prediction or when the formula is not readily available. When used without arguments, `predict()` replicates the default prediction for that particular estimation command.

2. `xb([eqno])`: The `xb()` function replicates the calculation of the linear predictor  $\mathbf{x}_i\mathbf{b}$  for equation `eqno`. If `xb()` is specified without `eqno`, the linear predictor for the first equation (or the only equation in single-equation estimation) is obtained.

For example, `xb(#1)` (or equivalently, `xb()` with no arguments) translates to the linear predictor for the first equation, `xb(#2)` for the second, and so on. You could also refer to the equations by their names, such as `xb(income)`.

When specifying `pnl_exp`, both of these functions may be used repeatedly, in combination, and in combination with other Stata functions and expressions. See [Remarks and examples](#) for examples that use both of these functions.

## Quick start

After `regress`, create `yhat` containing the default linear prediction

```
predictnl yhat = predict()
```

After `probit y x1 x2`, create `pr1` containing predicted probability that  $y = 1$

```
predictnl pr1 = predict(pr)
```

Same as above, and create `lb1` and `ub1` containing the upper and lower bounds of the 95% confidence interval for the prediction

```
predictnl pr1 = predict(pr), ci(lb1 ub1)
```

Same as above, specified as a function of the linear prediction

```
predictnl pr1 = normal(xb()), ci(lb1 ub1)
```

Same as above, specified as a function of the coefficients

```
predictnl pr1 = normal(_b[_cons]+_b[x1]*x1+_b[x2]*x2), ci(lb1 ub1)
```

Same as above, but create the prediction using `x1` equal to 0

```
predictnl pr1 = normal(_b[_cons]+_b[x1]*0+_b[x2]*x2), ci(lb1 ub1)
```

Same as above, but create variable `se1` containing the standard error of the prediction

```
predictnl pr1 = normal(_b[_cons]+_b[x1]*0+_b[x2]*x2), se(se1)
```

After a multiple-equation model, create `ratio` as the ratio of the linear predictions from the second and third equations

```
predictnl ratio = xb(#2)/xb(#3)
```

## Menu

Statistics > Postestimation

## Syntax

```
predictnl [type] newvar = pnl_exp [if] [in] [, options]
```

df(#) does not appear in the dialog box.

## Options

### Main

se(*newvar*) adds *newvar* of storage type *type*, where for each *i* in the prediction sample, *newvar*[*i*] contains the estimated standard error of  $g(\hat{\theta}, \mathbf{x}_i)$ .

variance(*newvar*) adds *newvar* of storage type *type*, where for each *i* in the prediction sample, *newvar*[*i*] contains the estimated variance of  $g(\hat{\theta}, \mathbf{x}_i)$ .

wald(*newvar*) adds *newvar* of storage type *type*, where for each *i* in the prediction sample, *newvar*[*i*] contains the Wald test statistic for the test of the hypothesis  $H_0: g(\theta, \mathbf{x}_i) = 0$ .

p(*newvar*) adds *newvar* of storage type *type*, where *newvar*[*i*] contains the *p*-value for the Wald test of  $H_0: g(\theta, \mathbf{x}_i) = 0$  versus the two-sided alternative.

ci(*newvars*) requires the specification of two *newvars*, such that the *i*th observation of each will contain the left and right endpoints (respectively) of a confidence interval for  $g(\theta, \mathbf{x}_i)$ . The level of the confidence intervals is determined by level(#).

level(#) specifies the confidence level, as a percentage, for confidence intervals. The default is level(95) or as set by set level; see [\[U\] 20.8 Specifying the width of confidence intervals](#).

g(*stub*) specifies that new variables, *stub1*, *stub2*, ..., *stubk* be created, where *k* is the dimension of  $\theta$ . *stub1* will contain the observation-specific derivatives of  $g(\theta, \mathbf{x}_i)$  with respect to the first element,  $\theta_1$ , of  $\theta$ ; *stub2* will contain the derivatives of  $g(\theta, \mathbf{x}_i)$  with respect to  $\theta_2$ , etc.; If the derivative of  $g(\theta, \mathbf{x}_i)$  with respect to a particular coefficient in  $\theta$  equals zero for all observations in the prediction sample, the *stub* variable for that coefficient is not created. The ordering of the parameters in  $\theta$  is precisely that of the stored vector of parameter estimates  $\mathbf{e}(b)$ .

Advanced

`iterate(#)` specifies the maximum number of iterations used to find the optimal step size in the calculation of numerical derivatives of  $g(\boldsymbol{\theta}, \mathbf{x}_i)$  with respect to  $\boldsymbol{\theta}$ . By default, the maximum number of iterations is 100, but convergence is usually achieved after only a few iterations. You should rarely have to use this option.

`force` forces the calculation of standard errors and other inference-related quantities in situations where `predictnl` would otherwise refuse to do so. The calculation of standard errors takes place by evaluating (at  $\hat{\boldsymbol{\theta}}$ ) the numerical derivative of  $g(\boldsymbol{\theta}, \mathbf{x}_i)$  with respect to  $\boldsymbol{\theta}$ . If `predictnl` detects that  $g(\cdot)$  is possibly a function of random quantities other than  $\hat{\boldsymbol{\theta}}$ , it will refuse to calculate standard errors or any other quantity derived from them. The `force` option forces the calculation to take place anyway. If you use the `force` option, there is no guarantee that any inference quantities (for example, standard errors) will be correct or that the values obtained can be interpreted.

The following option is available with `predictnl` but is not shown in the dialog box:

`df(#)` specifies that the  $F$  distribution with # denominator degrees of freedom be used for the reference distribution of the test statistic.

- [Confidence intervals](#)

## Introduction

`predictnl` and `nlcom` both use the delta method. They take a nonlinear transformation of the estimated parameter vector from some fitted model and apply the delta method to calculate the variance, standard error, Wald test statistic, etc., of this transformation. `nlcom` is designed for scalar functions of the parameters, and `predictnl` is designed for functions of the parameters and of the data, that is, for predictions.

## Nonlinear transformations and standard errors

We begin by fitting a probit model to the low-birthweight data of Hosmer, Lemeshow, and Sturdivant (2013, 24). The data are described in detail in [example 1](#) of [\[R\] logistic](#).

```
. use https://www.stata-press.com/data/r19/lbw
(Hosmer & Lemeshow data)
. probit low lwt smoke ptl ht
Iteration 0: Log likelihood = -117.336
Iteration 1: Log likelihood = -106.75886
Iteration 2: Log likelihood = -106.67852
Iteration 3: Log likelihood = -106.67851
Probit regression
Log likelihood = -106.67851
Number of obs = 189
LR chi2(4) = 21.31
Prob > chi2 = 0.0003
Pseudo R2 = 0.0908
```

|  | low   | Coefficient | Std. err. | z     | P> z  | [95% conf. interval] |           |
|--|-------|-------------|-----------|-------|-------|----------------------|-----------|
|  | lwt   | -.0095164   | .0036875  | -2.58 | 0.010 | -.0167438            | -.0022891 |
|  | smoke | .3487004    | .2041772  | 1.71  | 0.088 | -.0514794            | .7488803  |
|  | ptl   | .365667     | .1921201  | 1.90  | 0.057 | -.0108815            | .7422154  |
|  | ht    | 1.082355    | .410673   | 2.64  | 0.008 | .2774503             | 1.887259  |
|  | _cons | .4238985    | .4823224  | 0.88  | 0.379 | -.5214361            | 1.369233  |

After we fit such a model, we first would want to generate the predicted probabilities of a low birthweight, given the covariate values in the estimation sample. This is easily done using `predict` after `probit`, but it doesn't answer the question, "What are the standard errors of those predictions?"

For the time being, we will consider ourselves ignorant of any automated way to obtain the predicted probabilities after `probit`. The formula for the prediction is

$$\Pr(y \neq 0 | \mathbf{x}_i) = \Phi(\mathbf{x}_i \boldsymbol{\beta})$$

where  $\Phi$  is the standard cumulative normal. Thus for this example,  $g(\boldsymbol{\theta}, \mathbf{x}_i) = \Phi(\mathbf{x}_i \boldsymbol{\beta})$ . Armed with the formula, we can use `predictnl` to generate the predictions and their standard errors:

```
. predictnl phat = normal(_b[_cons] + _b[ht]*ht + _b[ptl]*ptl +
> _b[smoke]*smoke + _b[lwt]*lwt), se(phat_se)
. list phat phat_se lwt smoke ptl ht in -10/1
```

|      | phat     | phat_se  | lwt | smoke     | ptl | ht |
|------|----------|----------|-----|-----------|-----|----|
| 180. | .2363556 | .042707  | 120 | Nonsmoker | 0   | 0  |
| 181. | .6577712 | .1580714 | 154 | Nonsmoker | 1   | 1  |
| 182. | .2793261 | .0519958 | 106 | Nonsmoker | 0   | 0  |
| 183. | .1502118 | .0676339 | 190 | Smoker    | 0   | 0  |
| 184. | .5702871 | .0819911 | 101 | Smoker    | 1   | 0  |
| 185. | .4477045 | .079889  | 95  | Smoker    | 0   | 0  |
| 186. | .2988379 | .0576306 | 100 | Nonsmoker | 0   | 0  |
| 187. | .4514706 | .080815  | 94  | Smoker    | 0   | 0  |
| 188. | .5615571 | .1551051 | 142 | Nonsmoker | 0   | 1  |
| 189. | .7316517 | .1361469 | 130 | Smoker    | 0   | 1  |

Thus, subject 180 in our data has an estimated probability of low birthweight of 23.6% with standard error 4.3%.

Used without options, `predictnl` is not much different from `generate`. By specifying the `se(phat_se)` option, we were able to obtain a variable containing the standard errors of the predictions; therein lies the utility of `predictnl`.

## Using `xb()` and `predict()`

As was the case above, a prediction is often not a function of a few isolated parameters and their corresponding variables but instead is some (possibly elaborate) function of the entire linear predictor. For models with many predictors, the brute-force expression for the linear predictor can be cumbersome to type. An alternative is to use the inline function `xb()`. `xb()` is a shortcut for having to type `_b[_cons] + _b[ht]*ht + _b[ptl]*ptl + ...`,

```
. drop phat phat_se
. predictnl phat = norm(xb()), se(phat_se)
. list phat phat_se lwt smoke ptl ht in -10/1
```

|      | phat     | phat_se  | lwt | smoke     | ptl | ht |
|------|----------|----------|-----|-----------|-----|----|
| 180. | .2363556 | .042707  | 120 | Nonsmoker | 0   | 0  |
| 181. | .6577712 | .1580714 | 154 | Nonsmoker | 1   | 1  |
| 182. | .2793261 | .0519958 | 106 | Nonsmoker | 0   | 0  |
| 183. | .1502118 | .0676339 | 190 | Smoker    | 0   | 0  |
| 184. | .5702871 | .0819911 | 101 | Smoker    | 1   | 0  |
| 185. | .4477045 | .079889  | 95  | Smoker    | 0   | 0  |
| 186. | .2988379 | .0576306 | 100 | Nonsmoker | 0   | 0  |
| 187. | .4514706 | .080815  | 94  | Smoker    | 0   | 0  |
| 188. | .5615571 | .1551051 | 142 | Nonsmoker | 0   | 1  |
| 189. | .7316517 | .1361469 | 130 | Smoker    | 0   | 1  |

which yields the same results. This approach is easier, produces more readable code, and is less prone to error, such as forgetting to include a term in the sum.

Here we used `xb()` without arguments because we have only one equation in our model. In multiple-equation (ME) settings, `xb()` (or equivalently `xb(#1)`) yields the linear predictor from the first equation, `xb(#2)` from the second, etc. You can also refer to equations by their names, for example, `xb(income)`.

### □ Technical note

Most estimation commands in Stata allow the postestimation calculation of linear predictors and their standard errors via `predict`. For example, to obtain these for the first (or only) equation in the model, you could type

```
predict xbvar, xb
 predict stdpvar, stdp
```

Equivalently, you could type

```
predictnl xbvar = xb(), se(stdpvar)
```

but we recommend the first method, because it is faster. As we demonstrated above, however, `predictnl` is more general.

□

Returning to our probit example, we can further simplify the calculation by using the inline function `predict()`. `predict(pred_options)` works by substituting, within our `predictnl` expression, the calculation performed by

```
predict ..., pred_options
```

In our example, we are interested in the predicted probabilities after a probit regression, normally obtained via

```
predict ..., p
```

We can obtain these predictions (and standard errors) by using

```
. drop phat phat_se
. predictnl phat = predict(p), se(phat_se)
. list phat phat_se lwt smoke ptl ht in -10/1
```

|      | phat     | phat_se  | lwt | smoke     | ptl | ht |
|------|----------|----------|-----|-----------|-----|----|
| 180. | .2363556 | .042707  | 120 | Nonsmoker | 0   | 0  |
| 181. | .6577712 | .1580714 | 154 | Nonsmoker | 1   | 1  |
| 182. | .2793261 | .0519958 | 106 | Nonsmoker | 0   | 0  |
| 183. | .1502118 | .0676339 | 190 | Smoker    | 0   | 0  |
| 184. | .5702871 | .0819911 | 101 | Smoker    | 1   | 0  |
| 185. | .4477045 | .079889  | 95  | Smoker    | 0   | 0  |
| 186. | .2988379 | .0576306 | 100 | Nonsmoker | 0   | 0  |
| 187. | .4514706 | .080815  | 94  | Smoker    | 0   | 0  |
| 188. | .5615571 | .1551051 | 142 | Nonsmoker | 0   | 1  |
| 189. | .7316517 | .1361469 | 130 | Smoker    | 0   | 1  |

which again replicates what we have already done by other means. However, this version did not require knowledge of the formula for the predicted probabilities after a probit regression—`predict(p)` took care of that for us.

Because the predicted probability is the default prediction after `probit`, we could have just used `predict()` without arguments, namely,

```
. predictnl phat = predict(), se(phat_se)
```

Also, the expression `pnl_exp` can be inordinately complicated, with multiple calls to `predict()` and `xb()`. For example,

```
. predictnl phat = normal(invnormal(predict()) + predict(xb)/xb() - 1),
> se(phat_se)
```

is perfectly valid and will give the same result as before, albeit a bit inefficiently.

### □ Technical note

When using `predict()` and `xb()`, the *formula* for the calculation is substituted within `pnl_exp`, not the values that result from the application of that formula. To see this, note the subtle difference between

```
. predict xbeta, xb
. predictnl phat = normal(xbeta), se(phat_se)
```

and

```
. predictnl phat = normal(xb()), se(phat_se)
```

Both sequences will yield the same `phat`, yet for the first sequence, `phat_se` will equal zero for all observations. The reason is that, once evaluated, `xbeta` will contain the values of the linear predictor, yet these values are treated as fixed and nonstochastic as far as `predictnl` is concerned. By contrast, because `xb()` is shorthand for the formula used to calculate the linear predictor, it contains not values, but references to the estimated regression coefficients and corresponding variables. Thus, the second method produces the desired result. □

### Multiple-equation (ME) estimators

In [R] [mlogit](#), data on insurance choice (Tarlov et al. 1989; Wells et al. 1989) were examined, and a multinomial logit was used to assess the effects of age, gender, race, and site of study (one of three sites) on the type of insurance:

```
. use https://www.stata-press.com/data/r19/sysdsn1, clear
(Health insurance data)
. mlogit insure age male nonwhite i.site, nolog

Multinomial logistic regression Number of obs = 615
 LR chi2(10) = 42.99
 Prob > chi2 = 0.0000
 Pseudo R2 = 0.0387

Log likelihood = -534.36165
```

| insure    | Coefficient    | Std. err. | z     | P> z  | [95% conf. interval] |           |

Of particular interest is the estimation of the relative risk, which, for a given selection, is the ratio of the probability of making that selection to the probability of selecting the base category (Indemnity here), given a set of covariate values. In a multinomial logit model, the relative risk (when comparing to the base category) simplifies to the exponentiated linear predictor for that selection.

Using this example, we can estimate the observation-specific relative risks of selecting a prepaid plan over the base category (with standard errors) by either referring to the Prepaid equation by name or number,

```
. predictnl RRppaid = exp(xb(Prepaid)), se(SERRppaid)
```

or

```
. predictnl RRppaid = exp(xb(#1)), se(SERRppaid)
```

because Prepaid is the first equation in the model.

Those of us for whom the simplified formula for the relative risk does not immediately come to mind may prefer to calculate the relative risk directly from its definition, that is, as a ratio of two predicted probabilities. After `mlogit`, the predicted probability for a category may be obtained using `predict`, but we must specify the category as the outcome:

```
. predictnl RRppaid = predict(outcome(Prepaid))/predict(outcome(Indemnity)),
> se(SERRppaid)
(1 missing value generated)
. list RRppaid SERRppaid age male nonwhite site in 1/10
```

|     | RRppaid  | SERRpp-d | age       | male | nonwhite | site |
|-----|----------|----------|-----------|------|----------|------|
| 1.  | .6168578 | .1503759 | 73.722107 | 0    | 0        | 2    |

The “(1 missing value generated)” message is not an error; further examination of the data would reveal that `age` is missing in one observation and that the offending observation (among others) is not in the estimation sample. Just as with `predict`, `predictnl` can generate predictions in or out of the estimation sample.

Thus, we estimate (among other things) that a white, female, 73-year-old from site 2 is less likely to choose a prepaid plan over an indemnity plan—her relative risk is about 62% with standard error 15%.

### Test statistics and p-values

Often, a standard error calculation is just a means to an end, and what is really desired is a test of the hypothesis,

$$H_0 : g(\boldsymbol{\theta}, \mathbf{x}_i) = 0$$

versus the two-sided alternative.

We can use `predictnl` to obtain the Wald test statistics or *p*-values (or both) for the above tests, whether or not we want standard errors. To obtain the Wald test statistics, we use the `wald()` option; for *p*-values, we use `p()`.

Returning to our `mlogit` example, suppose that we wanted for each observation a test of whether the relative risk of choosing a prepaid plan over an indemnity plan is different from one. One way to do this would be to define  $g(\cdot)$  to be the relative risk minus one and then test whether  $g(\cdot)$  is different from zero.

```
. predictnl RRm1 = exp(xb(Prepaid)) - 1, wald(W_RRm1) p(sig_RRm1)
(1 missing value generated)
note: p-values are with respect to the chi-squared(1) distribution.
. list RRm1 W_RRm1 sig_RRm1 age male nonwhite in 1/10
```

|     | RRm1      | W_RRm1   | sig_RRm1 | age       | male | nonwhite |
|-----|-----------|----------|----------|-----------|------|----------|
| 1.  | -.3831422 | 6.491778 | .0108375 | 73.722107 | 0    | 0        |
| 2.  | .0566578  | .100109  | .7516989 | 27.89595  | 0    | 0        |
| 3.  | -.1573559 | 1.084116 | .2977787 | 37.541397 | 0    | 0        |
| 4.  | .4605812  | 1.573743 | .2096643 | 23.641327 | 0    | 1        |
| 5.  | -.0884253 | .4459299 | .5042742 | 40.470901 | 0    | 0        |
| 6.  | .0347015  | .0418188 | .8379655 | 29.683777 | 0    | 0        |
| 7.  | -.0776336 | .3331707 | .563798  | 39.468857 | 0    | 0        |
| 8.  | .6783119  | 2.587788 | .1076906 | 26.702255 | 1    | 0        |
| 9.  | -.0811482 | .1293816 | .719074  | 63.101974 | 0    | 1        |
| 10. | -.4233705 | 10.05909 | .001516  | 69.839828 | 0    | 0        |

The newly created variable `W_RRm1` contains the Wald test statistic for each observation, and `sig_RRm1` contains the  $p$ -value. Thus, our 73-year-old white female represented by the first observation would have a relative risk of choosing prepaid over indemnity that is significantly different from 1, at least at the 5% level. For this test, it was not necessary to generate a variable containing the standard error of the relative risk minus 1, but we could have done so had we wanted. We could have also omitted specifying `wald(W_RRm1)` if all we cared about were, say, the  $p$ -values for the tests.

In this regard, `predictnl` acts as an observation-specific version of `testnl`, with the test results vectorized over the observations in the data. The  $p$ -values are pointwise—they are not adjusted to reflect any simultaneous testing over the observations in the data.

## Manipulability

There are many ways to specify  $g(\boldsymbol{\theta}, \mathbf{x}_i)$  to yield tests such that, for multiple specifications of  $g(\cdot)$ , the theoretical conditions for which

$$H_0 : g(\boldsymbol{\theta}, \mathbf{x}_i) = 0$$

is true will be equivalent. However, this does not mean that the tests themselves will be equivalent. This is known as the manipulability of the Wald test for nonlinear hypotheses; also see [R] [boxcox](#).

As an example, consider the previous section where we defined  $g(\cdot)$  to be the relative risk between choosing a prepaid plan over an indemnity plan, minus 1. We could also have defined  $g(\cdot)$  to be the risk difference—the probability of choosing a prepaid plan minus the probability of choosing an indemnity plan. Either specification of  $g(\cdot)$  yields a mathematically equivalent specification of  $H_0 : g(\cdot) = 0$ ; that is, the risk difference will equal zero when the relative risk equals one. However, the tests themselves do not give the same results:

```
. predictnl RD = predict(outcome(Prepaid)) - predict(outcome(Indemnity)),
> wald(W_RD) p(sig_RD)
(1 missing value generated)
note: p-values are with respect to the chi-squared(1) distribution.
. list RD W_RD sig_RD RRm1 W_RRm1 sig_RRm1 in 1/10
```

|     | RD        | W_RD     | sig_RD   | RRm1      | W_RRm1   | sig_RRm1 |
|-----|-----------|----------|----------|-----------|----------|----------|
| 1.  | -.2303744 | 4.230243 | .0397097 | -.3831422 | 6.491778 | .0108375 |
| 2.  | .0266902  | .1058542 | .7449144 | .0566578  | .100109  | .7516989 |
| 3.  | -.0768078 | .9187646 | .3377995 | -.1573559 | 1.084116 | .2977787 |
| 4.  | .1710702  | 2.366535 | .1239619 | .4605812  | 1.573743 | .2096643 |
| 5.  | -.0448509 | .4072922 | .5233471 | -.0884253 | .4459299 | .5042742 |
| 6.  | .0165251  | .0432816 | .835196  | .0347015  | .0418188 | .8379655 |
| 7.  | -.0391535 | .3077611 | .5790573 | -.0776336 | .3331707 | .563798  |
| 8.  | .22382    | 4.539085 | .0331293 | .6783119  | 2.587788 | .1076906 |
| 9.  | -.0388409 | .1190183 | .7301016 | -.0811482 | .1293816 | .719074  |
| 10. | -.2437626 | 6.151558 | .0131296 | -.4233705 | 10.05909 | .001516  |

In certain cases (such as subject 8), the difference can be severe enough to potentially change the conclusion. The reason for this inconsistency is that the nonlinear Wald test is actually a standard Wald test of a first-order Taylor approximation of  $g(\cdot)$ , and this approximation can differ according to how  $g(\cdot)$  is specified.

As such, keep in mind the manipulability of nonlinear Wald tests when drawing scientific conclusions.

### Confidence intervals

We can also use `predictnl` to obtain confidence intervals for the observation-specific  $g(\theta, \mathbf{x}_i)$  by using the `ci()` option to specify two new variables to contain the left and right endpoints of the confidence interval, respectively. For example, we could generate confidence intervals for the risk differences calculated previously:

```
. drop RD
. predictnl RD = predict(outcome(Prepaid)) - predict(outcome(Indemnity)),
> ci(RD_lcl RD_rcl)
(1 missing value generated)
note: confidence intervals calculated using Z critical values.
. list RD RD_lcl RD_rcl age male nonwhite in 1/10
```

|     | RD        | RD_lcl    | RD_rcl    | age       | male | nonwhite |
|-----|-----------|-----------|-----------|-----------|------|----------|
| 1.  | -.2303744 | -.4499073 | -.0108415 | 73.722107 | 0    | 0        |
| 2.  | .0266902  | -.1340948 | .1874752  | 27.89595  | 0    | 0        |
| 3.  | -.0768078 | -.2338625 | .080247   | 37.541397 | 0    | 0        |
| 4.  | .1710702  | -.0468844 | .3890248  | 23.641327 | 0    | 1        |
| 5.  | -.0448509 | -.1825929 | .092891   | 40.470901 | 0    | 0        |
| 6.  | .0165251  | -.1391577 | .1722078  | 29.683777 | 0    | 0        |
| 7.  | -.0391535 | -.177482  | .099175   | 39.468857 | 0    | 0        |
| 8.  | .22382    | .0179169  | .4297231  | 26.702255 | 1    | 0        |
| 9.  | -.0388409 | -.2595044 | .1818226  | 63.101974 | 0    | 1        |
| 10. | -.2437626 | -.4363919 | -.0511332 | 69.839828 | 0    | 0        |

The confidence level, here, 95%, is either set using the `level()` option or obtained from the current default level, `c(level)`; see [U] 20.8 Specifying the width of confidence intervals.

From the above output, we can see that, for subjects 1, 8, and 10, a 95% confidence interval for the risk difference does not contain zero, meaning that, for these subjects, there is some evidence of a significant difference in risks.

The confidence intervals calculated by `predictnl` are pointwise; there is no adjustment (such as a Bonferroni correction) made so that these confidence intervals may be considered jointly at the specified level.

## Methods and formulas

For the  $i$ th observation, consider the transformation  $g(\boldsymbol{\theta}, \mathbf{x}_i)$ , estimated by  $g(\hat{\boldsymbol{\theta}}, \mathbf{x}_i)$ , for the  $1 \times k$  parameter vector  $\boldsymbol{\theta}$  and data  $\mathbf{x}_i$  ( $\mathbf{x}_i$  is assumed fixed). The variance of  $g(\hat{\boldsymbol{\theta}}, \mathbf{x}_i)$  is estimated by

$$\widehat{\text{Var}}\{g(\hat{\boldsymbol{\theta}}, \mathbf{x}_i)\} = \mathbf{G}\mathbf{V}\mathbf{G}'$$

where  $\mathbf{G}$  is the vector of derivatives

$$\mathbf{G} = \left\{ \left. \frac{\partial g(\boldsymbol{\theta}, \mathbf{x}_i)}{\partial \boldsymbol{\theta}} \right|_{\boldsymbol{\theta}=\hat{\boldsymbol{\theta}}} \right\}_{(1 \times k)}$$

and  $\mathbf{V}$  is the estimated variance–covariance matrix of  $\hat{\boldsymbol{\theta}}$ . Standard errors,  $\widehat{\text{se}}\{g(\hat{\boldsymbol{\theta}}, \mathbf{x}_i)\}$ , are obtained as the square roots of the variances.

The Wald test statistic for testing

$$H_0: g(\boldsymbol{\theta}, \mathbf{x}_i) = 0$$

versus the two-sided alternative is given by

$$W_i = \frac{\{g(\hat{\boldsymbol{\theta}}, \mathbf{x}_i)\}^2}{\widehat{\text{Var}}\{g(\hat{\boldsymbol{\theta}}, \mathbf{x}_i)\}}$$

When the variance–covariance matrix of  $\hat{\boldsymbol{\theta}}$  is an asymptotic covariance matrix,  $W_i$  is approximately distributed as  $\chi^2$  with 1 degree of freedom. For linear regression,  $W_i$  is taken to be approximately distributed as  $F_{1,r}$ , where  $r$  is the residual degrees of freedom from the original model fit. The  $p$ -values for the observation-by-observation tests of  $H_0$  versus the two-sided alternative are given by

$$p_i = \Pr(T > W_i)$$

where  $T$  is either a  $\chi^2$ - or  $F$ -distributed random variable, as described above.

A  $(1 - \alpha) \times 100\%$  confidence interval for  $g(\boldsymbol{\theta}, \mathbf{x}_i)$  is given by

$$g(\hat{\boldsymbol{\theta}}, \mathbf{x}_i) \pm z_{\alpha/2} \left[ \widehat{\text{se}} \left\{ g(\hat{\boldsymbol{\theta}}, \mathbf{x}_i) \right\} \right]$$

when  $W_i$  is  $\chi^2$ -distributed, and

$$g(\hat{\boldsymbol{\theta}}, \mathbf{x}_i) \pm t_{\alpha/2, r} \left[ \widehat{\text{se}} \left\{ g(\hat{\boldsymbol{\theta}}, \mathbf{x}_i) \right\} \right]$$

when  $W_i$  is  $F$ -distributed.  $z_p$  is the  $1 - p$  quantile of the standard normal distribution, and  $t_{p, r}$  is the  $1 - p$  quantile of the  $t$  distribution with  $r$  degrees of freedom.

## Description

`probit` fits a probit model for a binary dependent variable, assuming that the probability of a positive outcome is determined by the standard normal cumulative distribution function. `probit` can compute robust and cluster-robust standard errors and adjust results for complex survey designs.

## Quick start

Probit model of  $y$  on continuous variable  $x_1$

```
probit y x1
```

Add square of  $x_1$

```
probit y c.x1##c.x1
```

Same as above, but report bootstrap standard errors

```
probit y c.x1##c.x1, vce(bootstrap)
```

Bootstrap estimates of coefficients

```
bootstrap _b: probit y c.x1##c.x1
```

Adjust for complex survey design using `svyset` data and add  $x_2$

```
svy: probit y c.x1##c.x1 x2
```

## Menu

*indepvars* may contain factor variables; see [U] 11.4.3 **Factor variables**.

*depvar* and *indepvars* may contain time-series operators; see [U] 11.4.4 **Time-series varlists**.

`bayes`, `bayesboot`, `bootstrap`, `by`, `collect`, `fmm`, `fp`, `jackknife`, `mfp`, `mi estimate`, `nestreg`, `rolling`, `statsby`, `stepwise`, and `svy` are allowed; see [U] 11.1.10 **Prefix commands**. For more details, see [BAYES] **bayes: probit** and [FMM] **fmm: probit**.

`vce(bootstrap)` and `vce(jackknife)` are not allowed with the `mi estimate` prefix; see [MI] **mi estimate**.

Weights are not allowed with the `bootstrap` prefix; see [R] **bootstrap**.

`vce()`, `nocoef`, and `weights` are not allowed with the `svy` prefix; see [SVY] **svy**.

`fweights`, `iwweights`, and `pweights` are allowed; see [U] 11.1.6 **weight**.

`nocoef`, `collinear`, and `coeflegend` do not appear in the dialog box.

See [U] 20 **Estimation and postestimation commands** for more capabilities of estimation commands.

## Options

### Model

`noconstant`, `offset(varname)`, `constraints(constraints)`; see [R] [Estimation options](#).

`asis` specifies that all specified variables and observations be retained in the maximization process.

This option is typically not specified and may introduce numerical instability. Normally `probit` omits variables that perfectly predict success or failure in the dependent variable along with their associated observations. In those cases, the effective coefficient on the omitted variables is infinity (negative infinity) for variables that completely determine a success (failure). Dropping the variable and perfectly predicted observations has no effect on the likelihood or estimates of the remaining coefficients and increases the numerical stability of the optimization process. Specifying this option forces retention of perfect predictor variables and their associated observations.

### SE/Robust

`vce(vcetype)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory (`oim`, `opg`), that are robust to some kinds of misspecification (`robust`), that allow for intragroup correlation (`cluster clustvar`), and that use bootstrap or jackknife methods (`bootstrap`, `jackknife`); see [R] [vce\\_option](#).

### Reporting

`level(#)`; see [R] [Estimation options](#).

`nocnsreport`; see [R] [Estimation options](#).

`display_options`: `nocl`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `nolstretch`; see [R] [Estimation options](#).

### Maximization

`maximize_options`: `difficult`, `technique(algorithm_spec)`, `iterate(#)`, `[no]log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `ltolerance(#)`, `nrtolerance(#)`, `nonrtolerance`, and `from(init_specs)`; see [R] [Maximize](#). These options are seldom used.

The following options are available with `probit` but are not shown in the dialog box:

`nocoeff` specifies that the coefficient table not be displayed. This option is sometimes used by programmers but is of no use interactively.

`collinear`, `coeflegend`; see [R] [Estimation options](#).

## Remarks and examples

Remarks are presented under the following headings:

- [Robust standard errors](#)
- [Model identification](#)
- [Video examples](#)

probit fits maximum likelihood models with dichotomous dependent (left-hand-side) variables coded as 0/1 (more precisely, coded as 0 and not 0).

For grouped data or data in binomial form, a probit model can be fit using glm with the family(binomial) and link(probit) options.

### ▷ Example 1

We have data on the make, weight, and mileage rating of 22 foreign and 52 domestic automobiles. We wish to fit a probit model explaining whether a car is foreign based on its weight and mileage. Here is an overview of our data:

```
. use https://www.stata-press.com/data/r19/auto
(1978 automobile data)
. keep make mpg weight foreign
. describe
Contains data from https://www.stata-press.com/data/r19/auto.dta
Observations: 74 1978 automobile data
Variables: 4 13 Apr 2024 17:45
 (_dta has notes)
```

| Variable name | Storage type | Display format | Value label | Variable label |
|---------------|--------------|----------------|-------------|----------------|
| make          | str18        | %-18s          |             | Make and model |
| mpg           | int          | %8.0g          |             | Mileage (mpg)  |
| weight        | int          | %8.0gc         |             | Weight (lbs.)  |
| foreign       | byte         | %8.0g          | origin      | Car origin     |

Sorted by: foreign  
 Note: Dataset has changed since last saved.

```
. inspect foreign
foreign: Car origin
```

|     |          | Number of observations |          |             |
|-----|----------|------------------------|----------|-------------|
|     |          | Total                  | Integers | Nonintegers |
| #   | Negative | -                      | -        | -           |
| #   | Zero     | 52                     | 52       | -           |
| #   | Positive | 22                     | 22       | -           |
| #   |          |                        |          |             |
| # # | Total    | 74                     | 74       | -           |
| # # | Missing  | -                      |          |             |
|     |          |                        |          |             |
| 0   |          | 74                     |          |             |
|     | 1        |                        |          |             |

(2 unique values)

foreign is labeled and all values are documented in the label.

The foreign variable takes on two unique values, 0 and 1. The value 0 denotes a domestic car, and 1 denotes a foreign car.

The model that we wish to fit is

$$\Pr(\text{foreign} = 1) = \Phi(\beta_0 + \beta_1 \text{weight} + \beta_2 \text{mpg})$$

where  $\Phi$  is the cumulative normal distribution.

To fit this model, we type

```
. probit foreign weight mpg
Iteration 0: Log likelihood = -45.03321
Iteration 1: Log likelihood = -27.914626
 (output omitted)
Iteration 5: Log likelihood = -26.844189
Probit regression
Log likelihood = -26.844189
Number of obs = 74
LR chi2(2) = 36.38
Prob > chi2 = 0.0000
Pseudo R2 = 0.4039
```

| foreign | Coefficient | Std. err. | z     | P> z  | [95% conf. interval] |           |
|---------|-------------|-----------|-------|-------|----------------------|-----------|
| weight  | -.0023355   | .0005661  | -4.13 | 0.000 | -.003445             | -.0012261 |
| mpg     | -.1039503   | .0515689  | -2.02 | 0.044 | -.2050235            | -.0028772 |
| _cons   | 8.275464    | 2.554142  | 3.24  | 0.001 | 3.269437             | 13.28149  |

We find that heavier cars are less likely to be foreign and that cars yielding better gas mileage are also less likely to be foreign, at least holding the weight of the car constant.

See [R] [Maximize](#) for an explanation of the output.

### □ Technical note

Stata interprets a value of 0 as a negative outcome (failure) and treats all other values (except missing) as positive outcomes (successes). Thus if your dependent variable takes on the values 0 and 1, then 0 is interpreted as failure and 1 as success. If your dependent variable takes on the values 0, 1, and 2, then 0 is still interpreted as failure, but both 1 and 2 are treated as successes.

If you prefer a more formal mathematical statement, when you type `probit y x`, Stata fits the model

$$\Pr(y_j \neq 0 \mid \mathbf{x}_j) = \Phi(\mathbf{x}_j\boldsymbol{\beta})$$

where  $\Phi$  is the standard cumulative normal.

## Robust standard errors

If you specify the `vce(robust)` option, `probit` reports robust standard errors; see [U] 20.22 Obtaining robust variance estimates.

### ▷ Example 2

For the model from [example 1](#), the robust calculation increases the standard error of the coefficient on `mpg` by almost 15%:

```
. probit foreign weight mpg, vce(robust) nolog
Probit regression Number of obs = 74
 Wald chi2(2) = 30.26
 Prob > chi2 = 0.0000
Log pseudolikelihood = -26.844189 Pseudo R2 = 0.4039
```

| foreign | Coefficient | Robust<br>std. err. | z     | P> z  | [95% conf. interval] |           |
|---------|-------------|---------------------|-------|-------|----------------------|-----------|
| weight  | -.0023355   | .0004934            | -4.73 | 0.000 | -.0033025            | -.0013686 |
| mpg     | -.1039503   | .0593548            | -1.75 | 0.080 | -.2202836            | .0123829  |
| _cons   | 8.275464    | 2.539177            | 3.26  | 0.001 | 3.298769             | 13.25216  |

Without `vce(robust)`, the standard error for the coefficient on `mpg` was reported to be 0.052 with a resulting confidence interval of  $[-0.21, -0.00]$ .

► Example 3

The `vce(cluster clustvar)` option can relax the independence assumption required by the probit estimator to independence between clusters. To demonstrate, we will switch to a different dataset.

We are studying unionization of women in the United States and have a dataset with 26,200 observations on 4,434 women between 1970 and 1988. We will use the variables `age` (the women were 14–26 in 1968, and our data span the age range of 16–46), `grade` (years of schooling completed, ranging from 0 to 18), `not_smsa` (28% of the person-time was spent living outside an SMSA—standard metropolitan statistical area), `south` (41% of the person-time was in the South), and `year`. Each of these variables is included in the regression as a covariate along with the interaction between `south` and `year`. This interaction, along with the `south` and `year` variables, is specified in the probit command using factor-variables notation, `south##c.year`. We also have variable `union`, indicating union membership. Overall, 22% of the person-time is marked as time under union membership, and 44% of these women have belonged to a union.

We fit the following model, ignoring that women are observed an average of 5.9 times each in these data:

```
. use https://www.stata-press.com/data/r19/union, clear
(NLS Women 14-24 in 1968)

. probit union age grade not_smsa south##c.year

Iteration 0: Log likelihood = -13864.23
Iteration 1: Log likelihood = -13545.541
Iteration 2: Log likelihood = -13544.385
Iteration 3: Log likelihood = -13544.385

Probit regression Number of obs = 26,200
 LR chi2(6) = 639.69
 Prob > chi2 = 0.0000
 Pseudo R2 = 0.0231

Log likelihood = -13544.385
```

|                           | Coefficient | Std. err. | z     | P> z  | [95% conf. interval] |           |
|---------------------------|-------------|-----------|-------|-------|----------------------|-----------|
| <code>union</code>        |             |           |       |       |                      |           |
| <code>age</code>          | .0118481    | .0029072  | 4.08  | 0.000 | .0061502             | .017546   |
| <code>grade</code>        | .0267365    | .0036689  | 7.29  | 0.000 | .0195457             | .0339273  |
| <code>not_smsa</code>     | -.1293525   | .0202595  | -6.38 | 0.000 | -.1690604            | -.0896445 |
| <code>1.south</code>      | -.8281077   | .2472219  | -3.35 | 0.001 | -1.312654            | -.3435618 |
| <code>year</code>         | -.0080931   | .0033469  | -2.42 | 0.016 | -.0146529            | -.0015333 |
| <code>south#c.year</code> |             |           |       |       |                      |           |
| <code>1</code>            | .0057369    | .0030917  | 1.86  | 0.064 | -.0003226            | .0117965  |
| <code>_cons</code>        | -.6542487   | .2007777  | -3.26 | 0.001 | -1.047766            | -.2607316 |

The reported standard errors in this model are probably meaningless. Women are observed repeatedly, and so the observations are not independent. Looking at the coefficients, we find a large southern effect against unionization and a time trend for the south that is almost significantly different from the overall downward trend. The `vce(cluster clustvar)` option provides a way to fit this model and obtains correct standard errors:

```
. probit union age grade not_smsa south##c.year, vce(cluster id)
Iteration 0: Log pseudolikelihood = -13864.23
Iteration 1: Log pseudolikelihood = -13545.541
Iteration 2: Log pseudolikelihood = -13544.385
Iteration 3: Log pseudolikelihood = -13544.385
Probit regression
Number of obs = 26,200
Wald chi2(6) = 166.53
Prob > chi2 = 0.0000
Pseudo R2 = 0.0231
Log pseudolikelihood = -13544.385
(Std. err. adjusted for 4,434 clusters in idcode)
```

| union        | Coefficient | Robust<br>std. err. | z     | P> z  | [95% conf. interval] |           |
|--------------|-------------|---------------------|-------|-------|----------------------|-----------|
| age          | .0118481    | .0056625            | 2.09  | 0.036 | .0007499             | .0229463  |
| grade        | .0267365    | .0078124            | 3.42  | 0.001 | .0114244             | .0420486  |
| not_smsa     | -.1293525   | .0403885            | -3.20 | 0.001 | -.2085125            | -.0501925 |
| 1.south      | -.8281077   | .3201584            | -2.59 | 0.010 | -1.455607            | -.2006089 |
| year         | -.0080931   | .0060829            | -1.33 | 0.183 | -.0200153            | .0038292  |
| south#c.year |             |                     |       |       |                      |           |
| 1            | .0057369    | .0040133            | 1.43  | 0.153 | -.002129             | .0136029  |
| _cons        | -.6542487   | .3485976            | -1.88 | 0.061 | -1.337487            | .02899    |

These standard errors are larger than those reported by the inappropriate conventional calculation. By comparison, another model we could fit is an equal-correlation population-averaged probit model:

```
. xtprobit union age grade not_smsa south##c.year, pa
Iteration 1: Tolerance = .12544249
Iteration 2: Tolerance = .0034686
Iteration 3: Tolerance = .00017448
Iteration 4: Tolerance = 8.382e-06

The coefficient estimates are similar, but these standard errors are smaller than those produced by `probit`, `vce(cluster clustvar)`, as we would expect. If the equal-correlation assumption is valid, the population-averaged probit estimator above should be more efficient.

Is the assumption valid? That is a difficult question to answer. The default population-averaged estimates correspond to an assumption of exchangeable correlation within person. It would not be unreasonable to assume an AR(1) correlation within person or to assume that the observations are correlated but that we do not wish to impose any structure. See [XT] `xtprobit` and [XT] `xtgee` for full details. ◀

`probit, vce(cluster clustvar)` is robust to assumptions about within-cluster correlation. That is, it inefficiently sums within cluster for the standard error calculation rather than attempting to exploit what might be assumed about the within-cluster correlation.

## Model identification

The `probit` command has one more feature that is probably the most useful. It will automatically check the model for identification and, if the model is underidentified, omit whatever variables and observations are necessary for estimation to proceed.

### ▶ Example 4

Have you ever fit a probit model where one or more of your independent variables perfectly predicted one or the other outcome?

For instance, consider the following data:

| Outcome $y$ | Independent variable $x$ |
|-------------|--------------------------|
| 0           | 1                        |
| 0           | 1                        |
| 0           | 0                        |
| 1           | 0                        |

Say that we wish to predict the outcome on the basis of the independent variable. The outcome is always zero when the independent variable is one. In our data,  $\Pr(y = 0 \mid x = 1) = 1$ , which means that the probit coefficient on  $x$  must be minus infinity with a corresponding infinite standard error. At this point, you may suspect that we have a problem.

Unfortunately, not all such problems are so easily detected, especially if you have many independent variables in your model. If you have ever had such difficulties, then you have experienced one of the more unpleasant aspects of computer optimization. The computer has no idea that it is trying to solve for an infinite coefficient as it begins its iterative process. All it knows is that, at each step, making the coefficient a little bigger, or a little smaller, works wonders. It continues on its merry way until either 1) the whole thing comes crashing to the ground when a numerical overflow error occurs or 2) it reaches some predetermined cutoff that stops the process. Meanwhile, you have been waiting. And the estimates that you finally receive, if any, may be nothing more than numerical roundoff.

Stata watches for these sorts of problems, alerts you, fixes them, and then properly fits the model.

Let's return to our automobile data. Among the variables we have in the data is one called `repair` that takes on three values. A value of 1 indicates that the car has a poor repair record, 2 indicates an average record, and 3 indicates a better-than-average record. Here is a tabulation of our data:

```
. use https://www.stata-press.com/data/r19/repair
(1978 automobile data)
. tabulate foreign repair
```

| Car origin | Repair |    |    | Total |
|------------|--------|----|----|-------|
|            | 1      | 2  | 3  |       |
| Domestic   | 10     | 27 | 9  | 46    |
| Foreign    | 0      | 3  | 9  | 12    |
| Total      | 10     | 30 | 18 | 58    |

All the cars with poor repair records (`repair = 1`) are domestic. If we were to attempt to predict `foreign` on the basis of the repair records, the predicted probability for the `repair = 1` category would have to be zero. This in turn means that the probit coefficient must be minus infinity, and that would set most computer programs buzzing.

Let's try using Stata on this problem.

```
. probit foreign b3.repair
note: 1.repair != 0 predicts failure perfectly;
 1.repair omitted and 10 obs not used.
Iteration 0: Log likelihood = -26.992087
Iteration 1: Log likelihood = -22.276479
Iteration 2: Log likelihood = -22.229184
Iteration 3: Log likelihood = -22.229138
Iteration 4: Log likelihood = -22.229138
Probit regression Number of obs = 48
 LR chi2(1) = 9.53
 Prob > chi2 = 0.0020
 Pseudo R2 = 0.1765
Log likelihood = -22.229138
```

| foreign | Coefficient | Std. err. | z     | P> z  | [95% conf. interval] |           |
|---------|-------------|-----------|-------|-------|----------------------|-----------|
| repair  |             |           |       |       |                      |           |
| 1       | 0           | (empty)   |       |       |                      |           |
| 2       | -1.281552   | .4297326  | -2.98 | 0.003 | -2.123812            | -.4392911 |
| _cons   | 1.16e-16    | .295409   | 0.00  | 1.000 | -.578991             | .578991   |

Remember that all the cars with poor repair records (`repair = 1`) are domestic, so the model cannot be fit, or at least it cannot be fit if we restrict ourselves to finite coefficients. Stata noted that fact “note: 1.repair != 0 predicts failure perfectly”. This is Stata’s mathematically precise way of saying what we said in English. When `repair` is 1, the car is domestic.

Stata then went on to say, “1.repair omitted and 10 obs not used”. This is Stata eliminating the problem. First, `1.repair` had to be removed from the model because it would have an infinite coefficient. Then, the 10 observations that led to the problem had to be eliminated, as well, so as not to bias the remaining coefficients in the model. The 10 observations that are not used are the 10 domestic cars that have poor repair records.

Stata then fit what was left of the model, using the remaining observations. Because no observations remained for cars with poor repair records, Stata reports “(empty)” in the row for `repair = 1`.

## □ Technical note

Stata is pretty smart about catching these problems. It will catch “one-way causation by a dummy variable”, as we demonstrated above.

Stata also watches for “two-way causation”, that is, a variable that perfectly determines the outcome, both successes and failures. Here Stata says that the variable “predicts outcome perfectly” and stops. Statistics dictate that no model can be fit.

Stata also checks your data for collinear variables; it will say “so-and-so omitted because of collinearity”. No observations need to be eliminated here and model fitting will proceed without the offending variable.

It will also catch a subtle problem that can arise with continuous data. For instance, if we were estimating the chances of surviving the first year after an operation, and if we included in our model age, and if all the persons over 65 died within the year, Stata will say, “age > 65 predicts failure perfectly”. It will then inform us about how it resolves the issue and fit what can be fit of our model.

`probit` (and `logit`, `logistic`, and `ivprobit`) will also occasionally fail to converge and then display messages such as

```
Note: 4 failures and 0 successes completely determined.
```

The cause of this message and what to do if you see it are described in [\[R\] logit](#).

## Matrices

|                              |                                              |
|------------------------------|----------------------------------------------|
| <code>e(b)</code>            | coefficient vector                           |
| <code>e(Cns)</code>          | constraints matrix                           |
| <code>e(ilog)</code>         | iteration log (up to 20 iterations)          |
| <code>e(gradient)</code>     | gradient vector                              |
| <code>e(mns)</code>          | vector of means of the independent variables |
| <code>e(rules)</code>        | information about perfect predictors         |
| <code>e(V)</code>            | variance–covariance matrix of the estimators |
| <code>e(V_modelbased)</code> | model-based variance                         |

## Functions

|                        |                         |
|------------------------|-------------------------|
| <code>e(sample)</code> | marks estimation sample |
|------------------------|-------------------------|

In addition to the above, the following is stored in `r()`:

## Matrices

|                       |                                                                                                                            |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------|
| <code>r(table)</code> | matrix containing the coefficients with their standard errors, test statistics, <i>p</i> -values, and confidence intervals |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------|

Note that results stored in `r()` are updated when the command is replayed and will be replaced when any *r*-class command is run after the estimation command.

## Methods and formulas

Probit analysis originated in connection with bioassay, and the word *probit*, a contraction of “probability unit”, was suggested by Bliss (1934a, 1934b). For an introduction to probit and logit, see, for example, Aldrich and Nelson (1984), Cameron and Trivedi (2022), Long (1997), Pampel (2021), or Powers and Xie (2008). Long and Freese (2014, chap. 5 and 6) and Jones (2007, chap. 3) provide introductions to probit and logit, along with Stata examples.

The log-likelihood function for probit is

$$\ln L = \sum_{j \in S} w_j \ln \Phi(\mathbf{x}_j \boldsymbol{\beta}) + \sum_{j \notin S} w_j \ln \{1 - \Phi(\mathbf{x}_j \boldsymbol{\beta})\}$$

where  $\Phi$  is the cumulative normal and  $w_j$  denotes the optional weights.  $\ln L$  is maximized, as described in [R] **Maximize**.

This command supports the Huber/White/sandwich estimator of the variance and its clustered version using `vce(robust)` and `vce(cluster clustvar)`, respectively. See [P] **\_robust**, particularly *Maximum likelihood estimators* and *Methods and formulas*. The scores are calculated as  $\mathbf{u}_j = \{\phi(\mathbf{x}_j \mathbf{b}) / \Phi(\mathbf{x}_j \mathbf{b})\} \mathbf{x}_j$  for the positive outcomes and  $-\{\phi(\mathbf{x}_j \mathbf{b}) / \{1 - \Phi(\mathbf{x}_j \mathbf{b})\}\} \mathbf{x}_j$  for the negative outcomes, where  $\phi$  is the normal density.

`probit` also supports estimation with survey data. For details on VCEs with survey data, see [SVY] **Variance estimation**.

Chester Ittner Bliss (1899–1979) was born in Ohio. He was educated as an entomologist, earning degrees from Ohio State and Columbia, and was employed by the United States Department of Agriculture until 1933. When he lost his job because of the Depression, Bliss then worked with R. A. Fisher in London and at the Institute of Plant Protection in Leningrad before returning to a post at the Connecticut Agricultural Experiment Station in 1938. He was also a lecturer at Yale for 25 years. Among many contributions to biostatistics, his development and application of probit methods to biological problems are outstanding.

## Postestimation commands

The following postestimation commands are of special interest after `probit`:

| Command                           | Description                                                           |
|-----------------------------------|-----------------------------------------------------------------------|
| <code>estat classification</code> | report various summary statistics, including the classification table |
| <code>estat gof</code>            | Pearson or Hosmer–Lemeshow goodness-of-fit test                       |
| <code>lroc</code>                 | compute area under ROC curve and graph the curve                      |
| <code>lsens</code>                | graph sensitivity and specificity versus probability cutoff           |
| <code>lassogof</code>             | calculate goodness-of-fit predictions                                 |

These commands are not appropriate with `svy` estimation results.

The following standard postestimation commands are also available:

| Command                      | Description                                                                                                                             |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <code>contrast</code>        | contrasts and ANOVA-style joint tests of parameters                                                                                     |
| <code>estat ic</code>        | Akaike’s, consistent Akaike’s, corrected Akaike’s, and Schwarz’s Bayesian information criteria (AIC, CAIC, AICc, and BIC, respectively) |
| <code>estat summarize</code> | summary statistics for the estimation sample                                                                                            |
| <code>estat vce</code>       | variance–covariance matrix of the estimators (VCE)                                                                                      |
| <code>estat (svy)</code>     | postestimation statistics for survey data                                                                                               |
| <code>estimates</code>       | cataloging estimation results                                                                                                           |
| <code>etable</code>          | table of estimation results                                                                                                             |
| * <code>forecast</code>      | dynamic forecasts and simulations                                                                                                       |
| * <code>hausman</code>       | Hausman’s specification test                                                                                                            |
| <code>lincom</code>          | point estimates, standard errors, testing, and inference for linear combinations of parameters                                          |
| <code>linktest</code>        | link test for model specification                                                                                                       |
| * <code>lrtest</code>        | likelihood-ratio test                                                                                                                   |
| <code>margins</code>         | marginal means, predictive margins, marginal effects, and average marginal effects                                                      |
| <code>marginsplot</code>     | graph the results from <code>margins</code> (profile plots, interaction plots, etc.)                                                    |
| <code>nlcom</code>           | point estimates, standard errors, testing, and inference for nonlinear combinations of parameters                                       |
| <code>predict</code>         | probabilities, linear predictions and their SEs, etc.                                                                                   |
| <code>predictnl</code>       | point estimates, standard errors, testing, and inference for generalized predictions                                                    |
| <code>pwcompare</code>       | pairwise comparisons of parameters                                                                                                      |
| <code>suest</code>           | seemingly unrelated estimation                                                                                                          |
| <code>test</code>            | Wald tests of simple and composite linear hypotheses                                                                                    |
| <code>testnl</code>          | Wald tests of nonlinear hypotheses                                                                                                      |

\* `forecast`, `hausman`, and `lrtest` are not appropriate with `svy` estimation results. `forecast` is also not appropriate with `mi` estimation results.

# predict

## Description for predict

`predict` creates a new variable containing predictions such as probabilities, linear predictions, standard errors, deviance residuals, and the equation-level score.

## Menu for predict

Statistics > Postestimation

## Syntax for predict

```
predict [type] newvar [if] [in] [, statistic nooffset rules asif]
```

| <i>statistic</i> | Description |
|------------------|-------------|
|------------------|-------------|

Main

|                         |                                                                                         |
|-------------------------|-----------------------------------------------------------------------------------------|
| <code>pr</code>         | probability of a positive outcome; the default                                          |
| <code>xb</code>         | linear prediction                                                                       |
| <code>stdp</code>       | standard error of the linear prediction                                                 |
| * <code>deviance</code> | deviance residual                                                                       |
| <code>score</code>      | first derivative of the log likelihood with respect to $\mathbf{x}_j\boldsymbol{\beta}$ |

Unstarred statistics are available both in and out of sample; type `predict ... if e(sample) ... if` wanted only for the estimation sample. Starred statistics are calculated only for the estimation sample, even when `if e(sample)` is not specified.

## Options for predict

Main

`pr`, the default, calculates the probability of a positive outcome.

`xb` calculates the linear prediction.

`stdp` calculates the standard error of the linear prediction.

`deviance` calculates the deviance residual.

`score` calculates the equation-level score,  $\partial \ln L / \partial (\mathbf{x}_j\boldsymbol{\beta})$ .

`nooffset` is relevant only if you specified `offset(varname)` for `probit`. It modifies the calculations made by `predict` so that they ignore the offset variable; the linear prediction is treated as  $\mathbf{x}_j\mathbf{b}$  rather than as  $\mathbf{x}_j\mathbf{b} + \text{offset}_j$ .

`rules` requests that Stata use any rules that were used to identify the model when making the prediction. By default, Stata calculates missing for excluded observations.

`asif` requests that Stata ignore the rules and exclusion criteria and calculate predictions for all observations possible using the estimated parameter from the model.

## margins

### Description for margins

`margins` estimates margins of response for probabilities and linear predictions.

### Menu for margins

Statistics > Postestimation

### Syntax for margins

```
margins [marginlist] [, options]
margins [marginlist] , predict(statistic ...) [predict(statistic ...) ...] [options]
```

| <i>statistic</i>      | Description                                    |
|-----------------------|------------------------------------------------|
| <code>pr</code>       | probability of a positive outcome; the default |
| <code>xb</code>       | linear prediction                              |
| <code>stdp</code>     | not allowed with <code>margins</code>          |
| <code>deviance</code> | not allowed with <code>margins</code>          |
| <code>score</code>    | not allowed with <code>margins</code>          |

Statistics not allowed with `margins` are functions of stochastic quantities other than  $e(b)$ .

For the full syntax, see [R] [margins](#).

## Remarks and examples

Remarks are presented under the following headings:

*Obtaining predicted values*  
*Performing hypothesis tests*

### Obtaining predicted values

Once you have fit a probit model, you can obtain the predicted probabilities by using the `predict` command for both the estimation sample and other samples; see [U] [20 Estimation and postestimation commands](#) and [R] [predict](#). Here we will make only a few additional comments.

`predict` without arguments calculates the predicted probability of a positive outcome. With the `xb` option, `predict` calculates the linear combination  $\mathbf{x}_j\mathbf{b}$ , where  $\mathbf{x}_j$  are the independent variables in the  $j$ th observation and  $\mathbf{b}$  is the estimated parameter vector. This is known as the index function because the cumulative density indexed at this value is the probability of a positive outcome.

In both cases, Stata remembers any rules used to identify the model and calculates missing for excluded observations unless `rules` or `asif` is specified. This is covered in the following example.

With the `stdp` option, `predict` calculates the standard error of the prediction, which is *not* adjusted for replicated covariate patterns in the data.

You can calculate the unadjusted-for-replicated-covariate-patterns diagonal elements of the hat matrix, or leverage, by typing

```
. predict pred
. predict stdp, stdp
. generate hat = stdp^2*pred*(1-pred)
```

### ▷ Example 1

In [example 4](#) of [R] [probit](#), we fit the probit model `probit foreign b3.repair`. To obtain predicted probabilities, we type

```
. predict p
(option pr assumed; Pr(foreign))
(10 missing values generated)
. summarize foreign p
```

| Variable | Obs | Mean     | Std. dev. | Min | Max |
|----------|-----|----------|-----------|-----|-----|
| foreign  | 58  | .2068966 | .4086186  | 0   | 1   |
| p        | 48  | .25      | .1956984  | .1  | .5  |

Stata remembers any rules used to identify the model and sets predictions to missing for any excluded observations. In [example 4](#) of [R] [probit](#), `probit` omitted the variable `1.repair` from our model and excluded 10 observations. When we typed `predict p`, those same 10 observations were again excluded and their predictions set to missing.

`predict`'s `rules` option uses the rules in the prediction. During estimation, we were told, “`1.repair != 0` predicts failure perfectly”, so the rule is that when `1.repair` is not zero, we should predict 0 probability of success or a positive outcome:

```
. predict p2, rules
(option pr assumed; Pr(foreign))
. summarize foreign p p2
```

| Variable | Obs | Mean     | Std. dev. | Min | Max |
|----------|-----|----------|-----------|-----|-----|
| foreign  | 58  | .2068966 | .4086186  | 0   | 1   |
| p        | 48  | .25      | .1956984  | .1  | .5  |
| p2       | 58  | .2068966 | .2016268  | 0   | .5  |

`predict`'s `asif` option ignores the rules and the exclusion criteria and calculates predictions for all observations possible using the estimated parameters from the model:

```
. predict p3, asif
(option pr assumed; Pr(foreign))
. summarize for p p2 p3
```

| Variable | Obs | Mean     | Std. dev. | Min | Max |
|----------|-----|----------|-----------|-----|-----|
| foreign  | 58  | .2068966 | .4086186  | 0   | 1   |
| p        | 48  | .25      | .1956984  | .1  | .5  |
| p2       | 58  | .2068966 | .2016268  | 0   | .5  |
| p3       | 58  | .2931034 | .2016268  | .1  | .5  |

Which is right? By default, `predict` uses the most conservative approach. If many observations had been excluded due to a simple rule, we could be reasonably certain that the `rules` prediction is correct. The `asif` prediction is correct only if the exclusion is a fluke and we would be willing to exclude the variable from the analysis, anyway. Then, however, we should refit the model to include the excluded observations.

◀

## Performing hypothesis tests

After estimation with `probit`, you can perform hypothesis tests by using the `test` or `testnl` command; see [U] 20 Estimation and postestimation commands.

## Methods and formulas

Let index  $j$  be used to index observations. Define  $M_j$  for each observation as the total number of observations sharing  $j$ 's covariate pattern. Define  $Y_j$  as the total number of positive responses among observations sharing  $j$ 's covariate pattern. Define  $p_j$  as the predicted probability of a positive outcome for observation  $j$ .

For  $M_j > 1$ , the deviance residual  $d_j$  is defined as

$$d_j = \pm \left( 2 \left[ Y_j \ln \left( \frac{Y_j}{M_j p_j} \right) + (M_j - Y_j) \ln \left\{ \frac{M_j - Y_j}{M_j (1 - p_j)} \right\} \right] \right)^{1/2}$$

where the sign is the same as the sign of  $(Y_j - M_j p_j)$ . In the limiting cases, the deviance residual is given by

$$d_j = \begin{cases} -\sqrt{2M_j |\ln(1 - p_j)|} & \text{if } Y_j = 0 \\ \sqrt{2M_j |\ln p_j|} & \text{if } Y_j = M_j \end{cases}$$

## Description

`proportion` produces estimates of proportions, along with standard errors, for the categories identified by the values in each variable of *varlist*.

## Quick start

Proportions, standard errors, and 95% CIs for each level of *v1*

```
proportion v1
```

Also compute statistics for *v2*

```
proportion v1 v2
```

Same as above, for each subpopulation defined by the levels of *catvar*

```
proportion v1 v2, over(catvar)
```

Standardizing across strata defined by *svar* with stratum weight *wvar1*

```
proportion v1, stdize(svar) stdweight(wvar1)
```

Weighting by sampling weight *wvar2*

```
proportion v1 [pweight=wvar2]
```

## Menu

Statistics > Summaries, tables, and tests > Summary and descriptive statistics > Proportions

## Syntax

```
proportion varlist [if] [in] [weight] [, options]
```

| <i>options</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | Description                                                                                                                          |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------|

| <code>normal</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | calculate normal (Wald) confidence intervals                                                                                         |
| <code>wald</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | synonym for <code>normal</code>                                                                                                      |
| <code>wilson</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | calculate Wilson confidence intervals                                                                                                |

## Options

### Model

`stdize(varname)` specifies that the point estimates be adjusted by direct standardization across the strata identified by *varname*. This option requires the `stdweight()` option.

`stdweight(varname)` specifies the weight variable associated with the standard strata identified in the `stdize()` option. The standardization weights must be constant within the standard strata.

`nostdrescale` prevents the standardization weights from being rescaled within the `over()` groups. This option requires `stdize()` but is ignored if the `over()` option is not specified.

### if/in/over

`over(varlisto)` specifies that estimates be computed for multiple subpopulations, which are identified by the different values of the variables in *varlist<sub>o</sub>*. Only numeric, nonnegative, integer-valued variables are allowed in `over(varlisto)`.

### SE/Cluster

`vce(vcetype)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory (`analytic`), that allow for intragroup correlation (`cluster clustvar`), and that use bootstrap or jackknife methods (`bootstrap`, `jackknife`); see [R] [vce\\_option](#).

`vce(analytic)`, the default, uses the analytically derived variance estimator associated with the sample proportion.

### Reporting

`level(#)`; see [R] [Estimation options](#).

`citype(citype)` specifies how to compute the limits of confidence intervals. *citype* may be one of `logit` (default), `agresti`, `exact`, `jeffreys`, `normal`, `wald`, or `wilson`.

`percent` specifies that the proportions be reported as percentages.

`noheader` prevents the table header from being displayed.

*display\_options*: `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, and `no!stretch`; see [R] [Estimation options](#).

The following option is available with `proportion` but is not shown in the dialog box:

`coeflegend`; see [R] [Estimation options](#).

## Remarks and examples

### ▷ Example 1

We can estimate the proportion of each repair rating in `auto2.dta`:

```
. use https://www.stata-press.com/data/r19/auto2
(1978 automobile data)
. proportion rep78
```

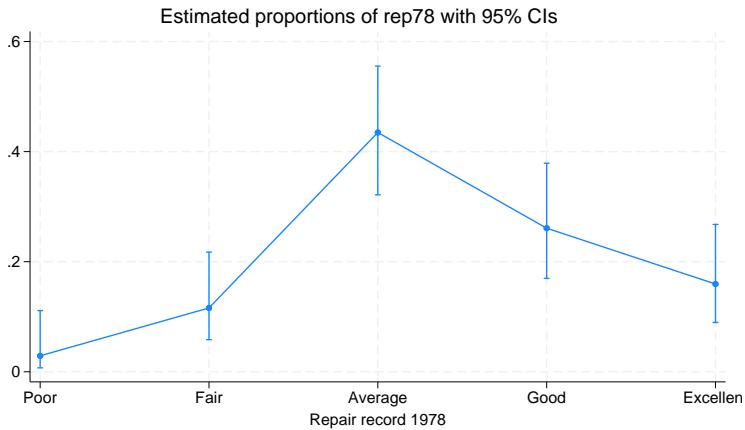

Proportion estimation Number of obs = 69

|           | Proportion | Std. err. | Logit<br>[95% conf. interval] |          |
|-----------|------------|-----------|-------------------------------|----------|
| rep78     |            |           |                               |          |
| Poor      | .0289855   | .0201966  | .0070794                      | .1110924 |
| Fair      | .115942    | .0385422  | .058317                       | .2173648 |
| Average   | .4347826   | .0596787  | .3214848                      | .5553295 |
| Good      | .2608696   | .0528625  | .1695907                      | .3788629 |
| Excellent | .1594203   | .0440694  | .0895793                      | .267702  |

`marginsplot` will produce a graph of the results from `proportion`:

```
. marginsplot
```

Variables that uniquely identify proportions: **rep78**

▷ Example 2

We can also estimate proportions over groups:

```
. proportion rep78, over(foreign)
```

Proportion estimation Number of obs = 69

|                    | Proportion | Std. err.         | Logit<br>[95% conf. interval] |          |
|--------------------|------------|-------------------|-------------------------------|----------|
| rep78@foreign      |            |                   |                               |          |
| Poor Domestic      | .0416667   | .0288424          | .0101825                      | .1552326 |
| Poor Foreign       | 0          | (no observations) |                               |          |
| Fair Domestic      | .1666667   | .0537914          | .084534                       | .3022522 |
| Fair Foreign       | 0          | (no observations) |                               |          |
| Average Domestic   | .5625      | .0716027          | .4184154                      | .6967587 |
| Average Foreign    | .1428571   | .0763604          | .0458191                      | .3664757 |
| Good Domestic      | .1875      | .0563367          | .0993684                      | .3255432 |
| Good Foreign       | .4285714   | .1079898          | .2372889                      | .6438783 |
| Excellent Domestic | .0416667   | .0288424          | .0101825                      | .1552326 |
| Excellent Foreign  | .4285714   | .1079898          | .2372889                      | .6438783 |

To see the results as percentages instead of proportions, we add the percent option:

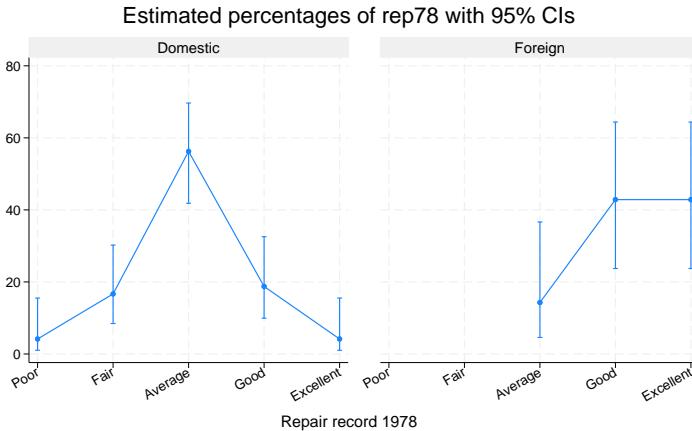

```
. proportion rep78, over(foreign) percent
```

Percent estimation Number of obs = 69

|                    | Percent | Std. err.         | Logit<br>[95% conf. interval] |       |
|--------------------|---------|-------------------|-------------------------------|-------|
| rep78@foreign      |         |                   |                               |       |
| Poor Domestic      | 4.17    | 2.88              | 1.02                          | 15.52 |
| Poor Foreign       | 0.00    | (no observations) |                               |       |
| Fair Domestic      | 16.67   | 5.38              | 8.45                          | 30.23 |
| Fair Foreign       | 0.00    | (no observations) |                               |       |
| Average Domestic   | 56.25   | 7.16              | 41.84                         | 69.68 |
| Average Foreign    | 14.29   | 7.64              | 4.58                          | 36.65 |
| Good Domestic      | 18.75   | 5.63              | 9.94                          | 32.55 |
| Good Foreign       | 42.86   | 10.80             | 23.73                         | 64.39 |
| Excellent Domestic | 4.17    | 2.88              | 1.02                          | 15.52 |
| Excellent Foreign  | 42.86   | 10.80             | 23.73                         | 64.39 |

We can now use `marginsplot` to graph the percentages for each group. We add the `bydimension(foreign)` option to plot the groups in separate graph panels. The `xlabel(, angle(30))` option prevents the *x*-axis labels from running into each other.

```
. marginsplot, bydimension(foreign) xlabel(, angle(30))
Variables that uniquely identify proportions: rep78 foreign
```

We estimate that only 19% of domestic cars have good repair records and only 4% have excellent repair records. For foreign cars, however, we find that 43% have good repair records and 43% have excellent repair records.

### ► Example 3

Instead of estimating percentages within the foreign and domestic groupings, we might want to know overall percentages. For instance, what percentage of all cars are foreign and have excellent repair records? What percentage are domestic and have average records? We can obtain all such percentages by specifying an interaction between rep78 and foreign.

```
. proportion rep78#foreign, percent
Percent estimation Number of obs = 69
```

|                    | Percent estimation |                   | Logit [95% conf. interval] |       |
|--------------------|--------------------|-------------------|----------------------------|-------|
|                    | Percent            | Std. err.         |                            |       |
| rep78#foreign      |                    |                   |                            |       |
| Poor#Domestic      | 2.90               | 2.02              | 0.71                       | 11.11 |
| Poor#Foreign       | 0.00               | (no observations) |                            |       |
| Fair#Domestic      | 11.59              | 3.85              | 5.83                       | 21.74 |
| Fair#Foreign       | 0.00               | (no observations) |                            |       |
| Average#Domestic   | 39.13              | 5.88              | 28.21                      | 51.26 |
| Average#Foreign    | 4.35               | 2.46              | 1.38                       | 12.86 |
| Good#Domestic      | 13.04              | 4.05              | 6.85                       | 23.44 |
| Good#Foreign       | 13.04              | 4.05              | 6.85                       | 23.44 |
| Excellent#Domestic | 2.90               | 2.02              | 0.71                       | 11.11 |
| Excellent#Foreign  | 13.04              | 4.05              | 6.85                       | 23.44 |

Looking at the last line of this output, we estimate that 13% of all cars are foreign with excellent repair records.

## Stored results

`proportion` stores the following in `e()`:

### Scalars

|                          |                                          |
|--------------------------|------------------------------------------|
| <code>e(N)</code>        | number of observations                   |
| <code>e(N_over)</code>   | number of subpopulations                 |
| <code>e(N_stdize)</code> | number of standard strata                |
| <code>e(N_clust)</code>  | number of clusters                       |

### Matrices

|                           |                                                              |
|---------------------------|--------------------------------------------------------------|
| <code>e(b)</code>         | vector of proportion estimates                               |
| <code>e(V)</code>         | (co)variance estimates                                       |
| <code>e(_N)</code>        | vector of numbers of nonmissing observations                 |
| <code>e(_N_stdsum)</code> | number of nonmissing observations within the standard strata |
| <code>e(_p_stdize)</code> | standardizing proportions                                    |
| <code>e(freq)</code>      | vector of frequency estimates                                |
| <code>e(error)</code>     | error code corresponding to <code>e(b)</code>                |

### Functions

|                        |                         |
|------------------------|-------------------------|
| <code>e(sample)</code> | marks estimation sample |
|------------------------|-------------------------|

In addition to the above, the following is stored in `r()`:

### Matrices

|                       |                                                                                                                            |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------|
| <code>r(table)</code> | matrix containing the coefficients with their standard errors, test statistics, <i>p</i> -values, and confidence intervals |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------|

Note that results stored in `r()` are updated when the command is replayed and will be replaced when any `r-class` command is run after the estimation command.

## Methods and formulas

The point estimate of a proportion,  $\hat{p}$ , is computed as the mean of an indicator variable; see [\[R\] mean](#).

Methods and formulas are presented under the following headings:

*Confidence intervals*  
*Survey data and sampling weights*

## Confidence intervals

For an overview of confidence interval methods for binomial proportions, see [Dean and Pagano \(2015\)](#).

Given  $k$  successes of  $n$  trials, the estimated proportion (probability of a success) is  $\hat{p} = k/n$  with estimated standard error  $\hat{s} = \sqrt{\hat{p}(1-\hat{p})/n}$ .

For weighted data,  $k = \sum_{i=1}^N w_i \mathbf{1}(\text{obs } i \text{ is a success})$  and  $n = \sum_{i=1}^N w_i$ , where  $N$  is the total number of observations,  $w_i$  is the weight for the  $i$ th observation, and  $\mathbf{1}(\cdot)$  denotes the indicator function that evaluates to 1 if observation  $i$  is a success and 0 otherwise.

The logit-transformed confidence interval is given by

$$\log\left(\frac{\hat{p}}{1-\hat{p}}\right) \pm t_{1-\alpha/2, \nu} \frac{\hat{s}}{\hat{p}(1-\hat{p})}$$

where  $t_{p, \nu}$  is the  $p$ th quantile of Student's  $t$  distribution with  $\nu$  degrees of freedom.

The endpoints of this confidence interval are transformed back to the proportion metric by using the inverse of the logit transform

$$f^{-1}(y) = \frac{e^y}{1 + e^y}$$

Hence, the displayed confidence intervals for proportions are

$$f^{-1}\left\{\ln\left(\frac{\hat{p}}{1-\hat{p}}\right) \pm t_{1-\alpha/2, \nu} \frac{\hat{s}}{\hat{p}(1-\hat{p})}\right\}$$

The Wald-type  $100(1-\alpha)\%$  confidence interval is given by

$$\hat{p} \pm t_{1-\alpha/2, \nu} \hat{s}$$

The formulas below (for the Wilson, exact, Jeffreys, and Agresti–Coull intervals) are slightly different when using the `svy` prefix, `pweights`, or the `vce(cluster clustvar)` option; see [Survey data and sampling weights](#) below.

The Wilson interval is given by

$$\frac{\hat{p} + z_{1-\alpha/2}^2/2n \pm z_{1-\alpha/2} \sqrt{\hat{p}(1-\hat{p})/n + z_{1-\alpha/2}^2/4n^2}}{1 + z_{1-\alpha/2}^2/n}$$

where  $z_p$  is the  $p$ th quantile of the standard normal distribution.

The exact (Clopper–Pearson) interval is given by

$$\left\{ \frac{\nu_1 F_{\alpha/2, \nu_1, \nu_2}}{\nu_2 + \nu_1 F_{\alpha/2, \nu_1, \nu_2}}; \frac{\nu_3 F_{1-\alpha/2, \nu_3, \nu_4}}{\nu_4 + \nu_3 F_{\alpha/2, \nu_3, \nu_4}} \right\}$$

where  $\nu_1 = 2k$ ,  $\nu_2 = 2(n-k+1)$ ,  $\nu_3 = 2(k+1)$ ,  $\nu_4 = 2(n-k)$ , and  $F_{p, \nu_1, \nu_2}$  is the  $p$ th quantile of an  $F$  distribution with  $\nu_1$  and  $\nu_2$  degrees of freedom.

The Jeffreys interval is given by

$$\{\text{Beta}_{\alpha/2, \alpha_1, \beta_1}; \text{Beta}_{1-\alpha/2, \alpha_1, \beta_1}\}$$

where  $\alpha_1 = k + 0.5$ ,  $\beta_1 = n - k + 0.5$ , and  $\text{Beta}_{p, \alpha_1, \beta_1}$  is the  $p$ th quantile of a Beta distribution with  $\alpha_1$  and  $\beta_1$  degrees of freedom.

The Agresti–Coull interval is given by

$$\tilde{p} \pm z_{1-\alpha/2} \sqrt{\tilde{p}(1-\tilde{p})/\tilde{n}}$$

where  $\tilde{k} = k + z_{1-\alpha/2}^2/2$ ,  $\tilde{n} = n + z_{1-\alpha/2}^2$ , and  $\tilde{p} = \tilde{k}/\tilde{n}$ .

## Survey data and sampling weights

With the `svy` prefix, `pweights`, or the `vce(cluster clustvar)` option, the Wilson, exact, Jeffreys, and Agresti–Coull intervals use  $k^*$  in place of  $k$  and  $n^*$  in place of  $n$ , where  $k^* = n^*\hat{p}$ ,

$$n^* = \frac{\hat{p}(1-\hat{p})}{\hat{s}^2} \left\{ \frac{z_{1-\alpha/2}}{t_{1-\alpha/2, \nu}} \right\}^2$$

and  $\hat{s}$  is the linearized standard error estimate. For more details about the linearized standard error estimate, see *Ratios and other functions of survey data* in [SVY] **Variance estimation**.

## Postestimation commands

The following postestimation commands are available after `proportion`:

| Command                  | Description                                                                                       |
|--------------------------|---------------------------------------------------------------------------------------------------|
| <code>contrast</code>    | contrasts and ANOVA-style joint tests of parameters                                               |
| <code>estat vce</code>   | variance–covariance matrix of the estimators (VCE)                                                |
| <code>estat (svy)</code> | postestimation statistics for survey data                                                         |
| <code>estimates</code>   | cataloging estimation results                                                                     |
| <code>etable</code>      | table of estimation results                                                                       |
| <code>lincom</code>      | point estimates, standard errors, testing, and inference for linear combinations of parameters    |
| <code>marginsplot</code> | graph the results from <code>proportion</code>                                                    |
| <code>nlcom</code>       | point estimates, standard errors, testing, and inference for nonlinear combinations of parameters |
| <code>pwcompare</code>   | pairwise comparisons of parameters                                                                |
| <code>test</code>        | Wald tests of simple and composite linear hypotheses                                              |
| <code>testnl</code>      | Wald tests of nonlinear hypotheses                                                                |

## Remarks and examples

### ▷ Example 1

In [example 2](#) of [\[R\] proportion](#), we computed the proportions of cars with different repair records for each group, foreign or domestic. We use `test` to test whether the proportion of cars with repair record equal to 4 is the same for domestic and foreign cars.

```
. use https://www.stata-press.com/data/r19/auto
(1978 automobile data)
. proportion rep78, over(foreign)
(output omitted)
. test 4.rep78@0.foreign=4.rep78@1.foreign
(1) 4.rep78@0bn.foreign - 4.rep78@1.foreign = 0
 F(1, 68) = 3.92
 Prob > F = 0.0518
```

There is not a significant difference between those proportions at the 5% level.

▷ Example 2

Continuing with `auto.dta` from [example 1](#), we generate a new variable, `highprice`, that indicates if the price is larger than \$5,000 and then use `proportion` to see the proportion of cars with high price among domestic and foreign cars separately.

```
. generate highprice = price>5000
. proportion highprice, over(foreign)
Proportion estimation Number of obs = 74
```

|                   | Proportion | Std. err. | Logit<br>[95% conf. interval] |          |
|-------------------|------------|-----------|-------------------------------|----------|
| highprice@foreign |            |           |                               |          |
| 0 Domestic        | .5576923   | .0688744  | .4195373                      | .6874611 |
| 0 Foreign         | .3636364   | .1025593  | .191094                       | .5802222 |
| 1 Domestic        | .4423077   | .0688744  | .3125389                      | .5804627 |
| 1 Foreign         | .6363636   | .1025593  | .4197778                      | .808906  |

We will compute the odds ratio of having a high price in group `Foreign` to having a high price in group `Domestic`. Usually, odds ratios are computed by using the `logistic` command, but here we will perform the computation by using `nlcom` after `proportion`.

```
. nlcom OR: (_b[1.highprice@1.foreign]/_b[0.highprice@1.foreign])/(_b[1.highpri
> ce@0.foreign]/_b[0.highprice@0.foreign])
 OR: (_b[1.highprice@1.foreign]/_b[0.highprice@1.foreign])/(_b[1.high
> price@0.foreign]/_b[0.highprice@0.foreign])
```

| Proportion | Coefficient | Std. err. | z    | P> z  | [95% conf. interval] |          |
|------------|-------------|-----------|------|-------|----------------------|----------|
| OR         | 2.206522    | 1.155825  | 1.91 | 0.056 | -.0588533            | 4.471897 |

This is the same odds ratio that we would obtain from

```
. logistic highprice foreign
```

The odds ratio is slightly larger than 2, which means that the odds of having a high price among foreign cars are more than twice that of having a high price among domestic cars.

[Description](#)[Options for prtest](#)[Methods and formulas](#)[Quick start](#)[Options for prtesti](#)[References](#)[Menu](#)[Remarks and examples](#)[Also see](#)[Syntax](#)[Stored results](#)

## Description

`prtest` performs tests on the equality of proportions using large-sample statistics. The test can be performed for one sample against a hypothesized population value or for no difference in population proportions estimated from two samples. Clustered data are supported.

`prtesti` is the immediate form of `prtest`; see [\[U\] 19 Immediate commands](#).

## Quick start

One-sample test that the proportion of 1s in `v` is equal to 0.1

```
prtest v == 0.1
```

Same as above, but using the 90% confidence level and adjusting for clustering with clusters defined by `cvar` and an intraclass correlation of 0.5

```
prtest v == 0.1, level(90) cluster(cvar) rho(0.5)
```

Test that the proportion of 1s in `v` is equal between two groups defined by `catvar`

```
prtest v, by(catvar)
```

Same as above, and adjust for clustering with clusters defined by `cvar` and an intraclass correlation of 0.5 in the two groups

```
prtest v, by(catvar) cluster(cvar) rho(0.5)
```

Test equality of proportions between `v1` and `v2`

```
prtest v1 == v2
```

Test  $p_1 = p_2$  if  $\hat{p}_1 = 0.10$ ,  $\hat{p}_2 = 0.17$ ,  $n_1 = 29$ , and  $n_2 = 36$

```
prtesti 29 0.10 36 0.17
```

## Menu

### **prtest**

Statistics > Summaries, tables, and tests > Classical tests of hypotheses > Proportion test

### **prtesti**

Statistics > Summaries, tables, and tests > Classical tests of hypotheses > Proportion test calculator

## Syntax

One-sample test of proportion

```
prtest varname == #p [if] [in] [, onesampleopts]
```

Two-sample test of proportions using groups

```
prtest varname [if] [in] , by(groupvar) [twosamplegopts]
```

Two-sample test of proportions using variables

```
prtest varname1 == varname2 [if] [in] [, level(#)]
```

Immediate form of one-sample test of proportion

```
prtesti #obs1 #p1 #p2 [, level(#) count]
```

Immediate form of two-sample test of proportions

```
prtesti #obs1 #p1 #obs2 #p2 [, level(#) count]
```

| <i>onesampleopts</i>              | Description                                    |

| <i>rho2</i> (#)                   | intraclass correlation for group 2             |

\**by*(*groupvar*) is required.

*by* is allowed with *prtest*, and *collect* is allowed with *prtest* and *prtesti*; see [\[U\] 11.1.10 Prefix commands](#).

## Options for prtest

Main

*by*(*groupvar*) specifies a numeric variable that contains the group information for a given observation. This variable must have only two values. Do not confuse the *by*() option with the *by* prefix; both may be specified.

*level*(#) specifies the confidence level, as a percentage, for confidence intervals. The default is *level*(95) or as set by *set level*; see [\[U\] 20.8 Specifying the width of confidence intervals](#).

- `cluster(varname)` specifies the variable that identifies clusters. The `cluster()` option is required to adjust the computation for clustering.
- `rho(#)` specifies the intraclass correlation for a one-sample test or the common intraclass correlation for a two-sample test. The `rho()` option is required to adjust the computation for clustering for a one-sample test.
- `rho1(#)` specifies the intraclass correlation of the first group for a two-sample test using groups. The `rho()` option or both `rho1()` and `rho2()` options are required to adjust the computation for clustering.
- `rho2(#)` specifies the intraclass correlation of the second group for a two-sample test using groups. The `rho()` option or both `rho1()` and `rho2()` options are required to adjust the computation for clustering.

## Options for prtesti

- `level(#)` specifies the confidence level, as a percentage, for confidence intervals. The default is `level(95)` or as set by `set level`; see [U] 20.8 Specifying the width of confidence intervals.
- `count` specifies that integer counts instead of proportions be used in the immediate forms of `prtest`. In the first syntax, `prtesti` expects that  $\#_{\text{obs1}}$  and  $\#_{p1}$  are counts— $\#_{p1} \leq \#_{\text{obs1}}$ —and  $\#_{p2}$  is a proportion. In the second syntax, `prtesti` expects that all four numbers are integer counts, that  $\#_{\text{obs1}} \geq \#_{p1}$ , and that  $\#_{\text{obs2}} \geq \#_{p2}$ .

## Remarks and examples

Remarks are presented under the following headings:

*Tests of proportions*  
*Adjust for clustering*  
*Immediate form*

## Tests of proportions

The `prtest` output follows the output of `tttest` in providing a lot of information. Each proportion is presented along with a confidence interval. The appropriate one- or two-sample test is performed, and the two-sided and both one-sided results are included at the bottom of the output. For a two-sample test, the calculated difference is also presented with its confidence interval. This command may be used for both large-sample testing and large-sample interval estimation. For one-sample tests of proportions with small-sample sizes and to obtain exact  $p$ -values, researchers should use `bitest`; see [R] [bitest](#).

### ▷ Example 1: One-sample test of proportion

In the first form, `prtest` tests whether the mean of the sample is equal to a known constant. Assume that we have a sample of 74 automobiles. We wish to test whether the proportion of automobiles that are foreign is different from 40%.

```
. use https://www.stata-press.com/data/r19/auto
(1978 automobile data)
. prtest foreign == 0.4
```

One-sample test of proportion

| Variable | Mean     | Std. err. | [95% conf. interval] |          |
|----------|----------|-----------|----------------------|----------|
| foreign  | .2972973 | .0531331  | .1931583             | .4014363 |

```

p = proportion(foreign) z = -1.8034
HO: p = 0.4
 Ha: p < 0.4 Ha: p != 0.4 Ha: p > 0.4
Pr(Z < z) = 0.0357 Pr(|Z| > |z|) = 0.0713 Pr(Z > z) = 0.9643

```

The test indicates that we cannot reject the hypothesis that the proportion of foreign automobiles is 0.40 at the 5% significance level.

◀

### ▷ Example 2: Two-sample test of proportions

We have two headache remedies that we give to patients. Each remedy's effect is recorded as 0 for failing to relieve the headache and 1 for relieving the headache. We wish to test the equality of the proportion of people relieved by the two treatments.

```
. use https://www.stata-press.com/data/r19/cure
. prtest cure1 == cure2
```

Two-sample test of proportions

| Variable | Mean      | Std. err. | z     | P> z  | [95% conf. interval] |           |
|----------|-----------|-----------|-------|-------|----------------------|-----------|
| cure1    | .52       | .0706541  |       |       | .3815205             | .6584795  |
| cure2    | .7118644  | .0589618  |       |       | .5963013             | .8274275  |
| diff     | -.1918644 | .0920245  |       |       | -.372229             | -.0114998 |
|          | under HO: | .0931155  | -2.06 | 0.039 |                      |           |

```

diff = prop(cure1) - prop(cure2) z = -2.0605
HO: diff = 0
 Ha: diff < 0 Ha: diff != 0 Ha: diff > 0
Pr(Z < z) = 0.0197 Pr(|Z| > |z|) = 0.0394 Pr(Z > z) = 0.9803

```

We find that the proportions are statistically different from each other at any level greater than 3.9%.

◀

## Adjust for clustering

When observations are not independent and can be grouped into clusters, we need to adjust for clustering in a proportion test. For example, in a cluster randomized design, groups of individuals are randomized instead of individuals. To adjust for clustering, we need to specify the cluster identifier variable in the `cluster()` option. In the case of a one-sample proportion test, we need to also specify the intraclass correlation in the `rho()` option. In the case of a two sample proportions test, we need to also specify the common population intraclass correlation in the `rho()` option or group-specific population intraclass correlations in the `rho1()` and `rho2()` options.

### ► Example 3: One-sample test of proportion, adjusting for clusters

Consider data from [Hujoel, Moulton, and Loesche \(1990\)](#) on the accuracy of an enzymatic diagnostic test (EDT) of bacterial infections for 29 patients with multiple sites. The EDT was conducted on each site, a specific area in a patient's mouth, to determine infection by two strings of bacteria. A separate reference test was also conducted on each site with an antibody assay against the two strings of bacteria. The data record whether there was a positive EDT result at each infected site, a true positive result.

We want to test whether the proportion of infected sites that were correctly diagnosed by the EDT is different from 0.6. Because we have multiple infections per patient, we cluster by the patient-identifier subject and use a value of 0.2 from [Ahn, Heo, and Zhang \(2015, 33\)](#) for the inpatient correlation.

To perform the test, we specify the `cluster(subject)` and `rho(0.2)` options:

```
. use https://www.stata-press.com/data/r19/infection
(Target infections detected by EDT (Hujoel, Moulton, and Loesche 1990))
. prtest infect == 0.6, cluster(subject) rho(0.2)

One-sample test of proportion Number of obs = 142
Cluster variable: subject Number of clusters = 29
 Avg. cluster size = 4.90
 CV cluster size = 0.2419
 Intraclass corr. = 0.2000
```

| Variable  | Mean     | Std. err. | [95% conf. interval] |          |
|-----------|----------|-----------|----------------------|----------|
| infection | .6619718 | .0537974  | .5565308             | .7674129 |

```
 p = proportion(infection) z = 1.1123
HO: p = 0.6
 Ha: p < 0.6 Ha: p != 0.6 Ha: p > 0.6
Pr(Z < z) = 0.8670 Pr(|Z| > |z|) = 0.2660 Pr(Z > z) = 0.1330
```

We do not find statistical evidence to reject the null hypothesis of  $H_0: P_{\text{infection}} = 0.6$  versus the two-sided alternative  $H_a: P_{\text{infection}} \neq 0.6$  at the 5% significance level; the  $p$ -value = 0.2660 > 0.05.

▷ Example 4: Two-sample test of proportions using groups, adjusting for clusters

Consider a dataset provided by Hayes and Moulton (2009), which contains a random subsample of the original participants in a cluster randomized trial of a pneumococcal conjugate vaccine in American Indian populations in the southwestern United States. There are two groups of infants with 18 clusters in each group. The control group received a meningococcal C conjugate vaccine (MnCC), and the experimental group received the seven-valent pneumococcal conjugate vaccine (PnCRM7). The two groups are identified by the vaccine variable, and the pneumonia variable records 1 if an infant had at least one bacterial pneumonia episode and 0 otherwise. These data are originally from O'Brien et al. (2003).

We want to test the equality of the proportion of cases of pneumonia in the two vaccine groups. We assume a common known intraclass correlation of 0.02. To perform the test, we type

```
. use https://www.stata-press.com/data/r19/pneumoniacr
(Bacterial pneumonia episodes data from CRT (Hayes and Moulton 2009))
. prtest pneumonia, by(vaccine) cluster(cluster) rho(0.02)
Two-sample test of proportions
Cluster variable: cluster
Group: MnCC
Number of obs = 238
Number of clusters = 18
Avg. cluster size = 13.22
CV cluster size = 0.9605
Intraclass corr. = 0.0200
Group: PnCRM7
Number of obs = 211
Number of clusters = 18
Avg. cluster size = 11.72
CV cluster size = 0.7976
Intraclass corr. = 0.0200
```

| Group  | Mean      | Std. err. | z    | P> z  | [95% conf. interval] |
|--------|-----------|-----------|------|-------|----------------------|
| MnCC   | .2226891  | .0329017  |      |       | .1582029 .2871753    |
| PnCRM7 | .1658768  | .0299027  |      |       | .1072686 .224485     |
| diff   | .0568123  | .04446    |      |       | -.0303278 .1439524   |
|        | under H0: | .0447641  | 1.27 | 0.204 |                      |

```
diff = prop(MnCC) - prop(PnCRM7)
H0: diff = 0
Ha: diff < 0
Pr(Z < z) = 0.8978
diff = prop(MnCC) - prop(PnCRM7)
H0: diff = 0
Ha: diff != 0
Pr(|Z| > |z|) = 0.2044
diff = prop(MnCC) - prop(PnCRM7)
H0: diff = 0
Ha: diff > 0
Pr(Z > z) = 0.1022
z = 1.2691
```

We do not find statistical evidence to reject the null hypothesis of  $H_0: P_{\text{diff}} = 0$  versus the two-sided alternative  $H_a: P_{\text{diff}} \neq 0$  at the 5% significance level; the  $p$ -value = 0.2044 > 0.05.

◁

## Immediate form

### ▷ Example 5: Immediate form of one-sample test of proportion

`prtesti` is like `prtest`, except that you specify summary statistics rather than variables as arguments. For instance, we are reading an article that reports the proportion of registered voters among 50 randomly selected eligible voters as 0.52. We wish to test whether the proportion is 0.7:

```
. prtesti 50 0.52 0.70
One-sample test of proportion x: Number of obs = 50
```

|   | Mean | Std. err. | [95% conf. interval] |          |
|---|------|-----------|----------------------|----------|
| x | .52  | .0706541  | .3815205             | .6584795 |

```

p = proportion(x) z = -2.7775
HO: p = 0.7
Ha: p < 0.7 Ha: p != 0.7 Ha: p > 0.7
Pr(Z < z) = 0.0027 Pr(|Z| > |z|) = 0.0055 Pr(Z > z) = 0.9973

```

◀

### ▷ Example 6: Immediate form of two-sample test of proportions

To judge teacher effectiveness, we wish to test whether the same proportion of people from two classes will answer an advanced question correctly. In the first classroom of 30 students, 40% answered the question correctly, whereas in the second classroom of 45 students, 67% answered the question correctly.

```
. prtesti 30 0.4 45 0.67
Two-sample test of proportions x: Number of obs = 30
 y: Number of obs = 45
```

|      | Mean      | Std. err. | z     | P> z  | [95% conf. interval] |           |
|------|-----------|-----------|-------|-------|----------------------|-----------|
| x    | .4        | .0894427  |       |       | .2246955             | .5753045  |
| y    | .67       | .0700952  |       |       | .532616              | .807384   |
| diff | -.27      | .1136368  |       |       | -.4927241            | -.0472759 |
|      | under HO: | .1169416  | -2.31 | 0.021 |                      |           |

```

diff = prop(x) - prop(y) z = -2.3088
HO: diff = 0
Ha: diff < 0 Ha: diff != 0 Ha: diff > 0
Pr(Z < z) = 0.0105 Pr(|Z| > |z|) = 0.0210 Pr(Z > z) = 0.9895

```

◀

## Stored results

One-sample `prtest` and `prtesti` store the following in `r()`:

### Scalars

|                       |                                             |
|-----------------------|---------------------------------------------|
| <code>r(N)</code>     | sample size                                 |
| <code>r(P)</code>     | sample proportion                           |
| <code>r(se)</code>    | standard error of sample proportion         |
| <code>r(lb)</code>    | lower confidence bound of sample proportion |
| <code>r(ub)</code>    | upper confidence bound of sample proportion |
| <code>r(z)</code>     | $z$ statistic                               |
| <code>r(p_l)</code>   | lower one-sided $p$ -value                  |
| <code>r(p)</code>     | two-sided $p$ -value                        |
| <code>r(p_u)</code>   | upper one-sided $p$ -value                  |
| <code>r(level)</code> | confidence level                            |

Cluster-adjusted one-sample `prtest` also stores the following in `r()`:

### Scalars

|                            |                                            |
|----------------------------|--------------------------------------------|
| <code>r(K)</code>          | number of clusters $K$                     |
| <code>r(M)</code>          | cluster size $M$                           |
| <code>r(rho)</code>        | intraclass correlation                     |
| <code>r(CV_cluster)</code> | coefficient of variation for cluster sizes |

Two-sample `prtest` and two-sample `prtesti` store the following in `r()`:

### Scalars

|                          |                                                             |
|--------------------------|-------------------------------------------------------------|
| <code>r(N1)</code>       | sample size of population one                               |
| <code>r(N2)</code>       | sample size of population two                               |
| <code>r(P1)</code>       | sample proportion for population one                        |
| <code>r(P2)</code>       | sample proportion for population two                        |
| <code>r(P_diff)</code>   | difference of proportions                                   |
| <code>r(se1)</code>      | standard error of population-one sample proportion          |
| <code>r(se2)</code>      | standard error of population-two sample proportion          |
| <code>r(se_diff)</code>  | standard error of the difference of proportions             |
| <code>r(se_diff0)</code> | standard error of the difference of proportions under $H_0$ |
| <code>r(lb1)</code>      | lower confidence bound of population-one sample proportion  |
| <code>r(ub1)</code>      | upper confidence bound of population-one sample proportion  |
| <code>r(lb2)</code>      | lower confidence bound of population-two sample proportion  |
| <code>r(ub2)</code>      | upper confidence bound of population-two sample proportion  |
| <code>r(lb_diff)</code>  | lower confidence bound of the difference of proportions     |
| <code>r(ub_diff)</code>  | upper confidence bound of the difference of proportions     |
| <code>r(z)</code>        | $z$ statistic                                               |
| <code>r(p_l)</code>      | lower one-sided $p$ -value                                  |
| <code>r(p)</code>        | two-sided $p$ -value                                        |
| <code>r(p_u)</code>      | upper one-sided $p$ -value                                  |
| <code>r(level)</code>    | confidence level                                            |

Cluster-adjusted two-sample `prtest` using the `by()` option also stores the following in `r()`:

### Scalars

|                             |                                                           |
|-----------------------------|-----------------------------------------------------------|
| <code>r(K1)</code>          | population-one number of clusters $K_1$                   |
| <code>r(K2)</code>          | population-two number of clusters $K_2$                   |
| <code>r(M1)</code>          | population-one cluster size $M_1$                         |
| <code>r(M2)</code>          | population-two cluster size $M_2$                         |
| <code>r(rho)</code>         | common intraclass correlation                             |
| <code>r(rho1)</code>        | population-one intraclass correlation                     |
| <code>r(rho2)</code>        | population-two intraclass correlation                     |
| <code>r(CV_cluster1)</code> | population-one coefficient of variation for cluster sizes |
| <code>r(CV_cluster2)</code> | population-two coefficient of variation for cluster sizes |

## Methods and formulas

Remarks are presented under the following headings:

*One-sample test*

*Two-sample test*

For all the tests below, the test statistic  $z$  has an asymptotic standard normal distribution, and the  $p$ -value is computed as

$$p = \begin{cases} 1 - \Phi(z) & \text{for an upper one-sided test} \\ \Phi(z) & \text{for a lower one-sided test} \\ 2\{1 - \Phi(|z|)\} & \text{for a two-sided test} \end{cases}$$

where  $\Phi(\cdot)$  is the cdf of a standard normal distribution and  $|z|$  is an absolute value of  $z$ .

See [Acock \(2023, 158–164\)](#) for additional examples of tests of proportions using Stata.

## One-sample test

Let  $n$  be the number of observations,  $\hat{p}$  be the observed proportion, and  $\hat{q} = 1 - \hat{p}$ .

The one-tailed and two-tailed tests of a population proportion use an asymptotically normally distributed test statistic calculated as

$$z = \frac{\hat{p} - p_0}{s_0}$$

where  $p_0$  is the hypothesized proportion,  $q_0 = 1 - p_0$ , and  $s_0 = \sqrt{p_0 q_0 / n}$  is the standard error of  $\hat{p}$  under the null hypothesis of  $p = p_0$ .

A large-sample  $100(1 - \alpha)\%$  confidence interval for a proportion  $p$  is

$$\hat{p} \pm z_{1-\alpha/2} s$$

where  $s = \sqrt{\hat{p}\hat{q}/n}$  and  $z_{1-\alpha/2}$  is the  $(1 - \alpha/2)$ th quantile of the standard normal distribution.

With clustered data, suppose that there are  $K$  clusters, each of size  $M_i$  such that  $n = \sum_{i=1}^K M_i$ . Let  $\rho$  be the intraclass correlation. Following [Ahn, Heo, and Zhang \(2015\)](#), we assume that the cluster sizes  $M_i$  are independent and identically distributed. Let  $C_{\text{adj}}$  be the adjustment to the standard error for clustered data,

$$C_{\text{adj}} = \sqrt{\sum_{i=1}^K M_i \{1 + \rho(M_i - 1)\} / n}$$

such that  $s_{0,\text{cl}} = C_{\text{adj}} s_0$  and  $s_{\text{cl}} = C_{\text{adj}} s$ .

$C_{\text{adj}}$  can be equivalently written as

$$C_{\text{adj}} = \sqrt{1 + \rho(\bar{M} - 1) + \rho\bar{M}CV_{\text{cl}}^2}$$

where  $\bar{M} = \sum_{i=1}^K M_i/K$  is the average cluster size and  $CV_{\text{cl}}$  is the coefficient of variation for cluster sizes:

$$CV_{\text{cl}} = \frac{\sqrt{\sum_{i=1}^K (M_i - \bar{M})^2 / K}}{\bar{M}}$$

To adjust the test statistic  $z$  and the confidence interval for clustering, replace  $s_0$  with  $s_{0,\text{cl}}$  and  $s$  with  $s_{\text{cl}}$  in the corresponding formulas. In the presence of clustering, the test statistic  $z$  is asymptotically normally distributed conditional on the empirical distribution of  $M_i$ 's.

## Two-sample test

Let  $n_1$  be the number of observations in population one and  $n_2$  be the number of observations in population two,  $\hat{p}_1$  be the observed proportion in population one and  $\hat{p}_2$  be the observed proportion in population two, and  $\hat{q}_1 = 1 - \hat{p}_1$  and  $\hat{q}_2 = 1 - \hat{p}_2$ . Let  $x_1$  and  $x_2$  be the total number of successes in the two populations.

A test of the difference of two proportions uses an asymptotically normally distributed test statistic calculated as

$$z = \frac{\hat{p}_1 - \hat{p}_2}{s_{d0}}$$

where  $s_{d0} = \sqrt{\hat{p}_p \hat{q}_p (1/n_1 + 1/n_2)}$  is the standard error of  $\hat{p}_1 - \hat{p}_2$  under the null hypothesis of  $p_1 = p_2$ , with  $\hat{p}_p = (x_1 + x_2)/(n_1 + n_2)$  and  $\hat{q}_p = 1 - \hat{p}_p$ .

The  $100(1 - \alpha)\%$  confidence interval for the difference of two proportions is given by

$$(\hat{p}_1 - \hat{p}_2) \pm z_{1-\alpha/2} \sqrt{s_1^2 + s_2^2}$$

where  $s_1 = \sqrt{\hat{p}_1 \hat{q}_1 / n_1}$  and  $s_2 = \sqrt{\hat{p}_2 \hat{q}_2 / n_2}$  are the standard errors of the two sample proportions and  $z_{1-\alpha/2}$  is the  $(1 - \alpha/2)$ th quantile of the standard normal distribution.

With clustered data, suppose that there are  $K_1$  and  $K_2$  clusters in population one and population two with the corresponding average cluster sizes of  $\bar{M}_1$  and  $\bar{M}_2$ . Let  $\rho_1$  and  $\rho_2$  be the intraclass correlations and  $CV_{\text{cl},1}$  and  $CV_{\text{cl},2}$  be the coefficients of variation for cluster sizes for population one and population two. Let  $C_{\text{adj},1}$  and  $C_{\text{adj},2}$  be the adjustments to standard errors of the two sample proportions for clustered data, defined analogously to  $C_{\text{adj}}$  in *One-sample test* for each population.

Let  $s_{d0,cl} = \sqrt{\hat{p}_p \hat{q}_p (C_{adj,1}^2/n_1 + C_{adj,2}^2/n_2)}$  be the standard error of  $\hat{p}_1 - \hat{p}_2$  under the null hypothesis of  $p_1 = p_2$  adjusted for clustered data. Also, let  $s_{1,cl} = C_{adj,1}s_1$  and  $s_{2,cl} = C_{adj,2}s_2$  be the standard errors of  $\hat{p}_1$  and  $\hat{p}_2$  adjusted for clustered data. To adjust the two-sample test statistic and the confidence interval for clustering, replace  $s_{d0}$  with  $s_{d0,cl}$ ,  $s_1$  with  $s_{1,cl}$ , and  $s_2$  with  $s_{2,cl}$  in the corresponding formulas.

## Description

`pwcompare` performs pairwise comparisons across the levels of factor variables from the most recently fit model. `pwcompare` can compare estimated cell means, marginal means, intercepts, marginal intercepts, slopes, or marginal slopes—collectively called margins. `pwcompare` reports the comparisons as contrasts (differences) of margins along with significance tests or confidence intervals for the contrasts. The tests and confidence intervals can be adjusted for multiple comparisons.

`pwcompare` can be used with `svy` estimation results; see [\[SVY\] svy postestimation](#).

See [\[R\] margins, pwcompare](#) for performing pairwise comparisons of margins of linear and nonlinear predictions.

## Quick start

All pairwise comparisons of the means of `y` across levels of `a` after `regress y i . a`

```
pwcompare a
```

Same as above, and report test statistics and *p*-values for tests of differences in means

```
pwcompare a, effects
```

Adjust *p*-values and confidence intervals for multiple comparisons using Tukey's method

```
pwcompare a, effects mcompare(tukey)
```

Same as above, but adjust for multiple comparisons using Bonferroni's method

```
pwcompare a, effects mcompare(bonferroni)
```

Report means for the levels of `a`, and group those that are not significantly different

```
pwcompare a, groups
```

Pairwise comparisons of cell means after `regress y1 a##b`

```
pwcompare a#b
```

Pairwise comparisons of the marginal means of `a`

```
pwcompare a
```

Pairwise comparisons of slopes for continuous `x` after `regress y1 a##c.x`

```
pwcompare a#c.x
```

Pairwise comparisons of log odds after `logit y2 i . a`

```
pwcompare a
```

Pairwise comparisons of the means of `y2` across levels of `a` after `mvreg y1 y2 y3 = i . a`

```
pwcompare a, equation(y2)
```

Same as above, but report pairwise comparisons of `a` for each equation

```
pwcompare a, atequations
```

Pairwise comparisons of overall margins of  $y_1$ ,  $y_2$ , and  $y_3$

```
pwcompare _eqns
```

## Menu

Statistics > Postestimation

## Syntax

```
pwcompare marginlist [, options]
```

where *marginlist* is a list of factor variables or interactions that appear in the current estimation results or *\_eqns* to reference equations. The variables may be typed with or without the *i.* prefix, and you may use any factor-variable syntax:

```
. pwcompare i.sex i.group i.sex#i.group
. pwcompare sex group sex#group
. pwcompare sex##group
```

| <u>s</u> ort                         | sort the margins or contrasts within each term                                                              |
| <u>p</u> ost                         | post margins and their VCEs as estimation results                                                           |
| <u>d</u> isplay_options              | control column formats, row spacing, line width, and factor-variable labeling                               |
| <u>e</u> form_option                 | report exponentiated contrasts                                                                              |
| <u>d</u> f (#)                       | use <i>t</i> distribution with # degrees of freedom for computing <i>p</i> -values and confidence intervals |

`df (#)` does not appear in the dialog box.

| <i>method</i>                                      | Description                                         |
|----------------------------------------------------|-----------------------------------------------------|
| <code>noadjust</code>                              | do not adjust for multiple comparisons; the default |
| <code>bonferroni</code> [ <code>adjustall</code> ] | Bonferroni's method; adjust across all terms        |
| <code>sidak</code> [ <code>adjustall</code> ]      | Šidák's method; adjust across all terms             |
| <code>scheffe</code>                               | Scheffé's method                                    |
| * <code>tukey</code>                               | Tukey's method                                      |
| * <code>snk</code>                                 | Student–Newman–Keuls's method                       |
| * <code>duncan</code>                              | Duncan's method                                     |
| * <code>dunnett</code>                             | Dunnett's method                                    |

\*`tukey`, `snk`, `duncan`, and `dunnett` are only allowed with results from `anova`, `manova`, `regress`, and `mvreg`.  
`tukey`, `snk`, `duncan`, and `dunnett` are not allowed with results from `svy`.

Time-series operators are allowed if they were used in the estimation.

`collect` is allowed; see [U] 11.1.10 Prefix commands.

## Options

Main

`mcompare`(*method*) specifies the method for computing  $p$ -values and confidence intervals that account for multiple comparisons within a factor-variable term.

Most methods adjust the comparisonwise error rate,  $\alpha_c$ , to achieve a prespecified experimentwise error rate,  $\alpha_e$ .

`mcompare`(`noadjust`) is the default; it specifies no adjustment.

$$\alpha_c = \alpha_e$$

`mcompare`(`bonferroni`) adjusts the comparisonwise error rate based on the upper limit of the Bonferroni inequality:

$$\alpha_e \leq m\alpha_c$$

where  $m$  is the number of comparisons within the term.

The adjusted comparisonwise error rate is

$$\alpha_c = \alpha_e/m$$

`mcompare`(`sidak`) adjusts the comparisonwise error rate based on the upper limit of the probability inequality

$$\alpha_e \leq 1 - (1 - \alpha_c)^m$$

where  $m$  is the number of comparisons within the term.

The adjusted comparisonwise error rate is

$$\alpha_c = 1 - (1 - \alpha_e)^{1/m}$$

This adjustment is exact when the  $m$  comparisons are independent.

`mcompare`(`scheffe`) controls the experimentwise error rate using the  $F$  (or  $\chi^2$ ) distribution with degrees of freedom equal to the rank of the term.

For results from `anova`, `regress`, `manova`, and `mvreg` (see [R] `anova`, [R] `regress`, [MV] `manova`, and [MV] `mvreg`), `pwcompare` allows the following additional methods. These methods are not allowed with results that used `vce(robust)` or `vce(cluster clustvar)`.

`mcompare(tukey)` uses what is commonly referred to as Tukey’s honestly significant difference.

This method uses the Studentized range distribution instead of the  $t$  distribution.

`mcompare(snk)` is a variation on `mcompare(tukey)` that counts only the number of margins in the range for a given comparison instead of the full number of margins.

`mcompare(duncan)` is a variation on `mcompare(snk)` with additional adjustment to the significance probabilities.

`mcompare(dunnett)` uses Dunnett’s method for making comparisons with a reference category.

`mcompare(method adjustall)` specifies that the multiple-comparison adjustments count all comparisons across all terms rather than performing multiple comparisons term by term. This leads to more conservative adjustments when multiple variables or terms are specified in *marginlist*. This option is compatible only with the *bonferroni* and *sidak* methods.

`asobserved` specifies that factor covariates be evaluated using the cell frequencies observed when the model was fit. The default is to treat all factor covariates as though there were an equal number of observations at each level.

#### Equations

`equation(egspec)` specifies the equation from which margins are to be computed. The default is to compute margins from the first equation.

`atequations` specifies that the margins be computed within each equation.

#### Advanced

`emptycells(emptspec)` specifies how empty cells are handled in interactions involving factor variables that are being treated as balanced.

`emptycells(strict)` is the default; it specifies that margins involving empty cells be treated as not estimable.

`emptycells(reweight)` specifies that the effects of the observed cells be increased to accommodate any missing cells. This makes the margins estimable but changes their interpretation.

`noestimcheck` specifies that `pwcompare` not check for estimability. By default, the requested margins are checked and those found not estimable are reported as such. Nonestimability is usually caused by empty cells. If `noestimcheck` is specified, estimates are computed in the usual way and reported even though the resulting estimates are manipulable, which is to say they can differ across equivalent models having different parameterizations.

#### Reporting

`level(#)` specifies the confidence level, as a percentage, for confidence intervals. The default is `level(95)` or as set by `set level`; see [U] 20.8 Specifying the width of confidence intervals. The significance level used by the `groups` option is  $100 - \#$ , expressed as a percentage.

`cieffects` specifies that a table of the pairwise comparisons with their standard errors and confidence intervals be reported. This is the default.

`pveffects` specifies that a table of the pairwise comparisons with their standard errors, test statistics, and  $p$ -values be reported.

`effects` specifies that a table of the pairwise comparisons with their standard errors, test statistics,  $p$ -values, and confidence intervals be reported.

`cimargins` specifies that a table of the margins with their standard errors and confidence intervals be reported.

`groups` specifies that a table of the margins with their standard errors and group codes be reported. Margins with the same letter in the group code are not significantly different at the specified significance level.

`sort` specifies that the reported tables be sorted on the margins or differences in each term.

`post` causes `pwcompare` to behave like a Stata estimation (`e-class`) command. `pwcompare` posts the vector of estimated margins along with the estimated variance–covariance matrix to `e()`, so you can treat the estimated margins just as you would results from any other estimation command. For example, you could use `test` to perform simultaneous tests of hypotheses on the margins, or you could use `lincom` to create linear combinations.

*display\_options*: `vsquish`, `nofvlabel`, `fvwrap(#)`, `fvwraon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `nolstretch`.

`vsquish` specifies that the blank space separating factor-variable terms or time-series–operated variables from other variables in the model be suppressed.

`nofvlabel` displays factor-variable level values rather than attached value labels. This option overrides the `fvlabel` setting; see [R] [set showbaselevels](#).

`fvwrap(#)` specifies how many lines to allow when long value labels must be wrapped. Labels requiring more than `#` lines are truncated. This option overrides the `fvwrap` setting; see [R] [set showbaselevels](#).

`fvwraon(style)` specifies whether value labels that wrap will break at word boundaries or break based on available space.

`fvwraon(word)`, the default, specifies that value labels break at word boundaries.

`fvwraon(width)` specifies that value labels break based on available space.

This option overrides the `fvwraon` setting; see [R] [set showbaselevels](#).

`cformat(%fmt)` specifies how to format contrasts or margins, standard errors, and confidence limits in the table of pairwise comparisons.

`pformat(%fmt)` specifies how to format *p*-values in the table of pairwise comparisons.

`sformat(%fmt)` specifies how to format test statistics in the table of pairwise comparisons.

`nolstretch` specifies that the width of the table of pairwise comparisons not be automatically widened to accommodate longer variable names. The default, `lstretch`, is to automatically widen the table of pairwise comparisons up to the width of the Results window. Specifying `lstretch` or `nolstretch` overrides the setting given by `set lstretch`. If `set lstretch` has not been set, the default is `lstretch`. `nolstretch` is not shown in the dialog box.

*eform\_option* specifies that the contrasts table be displayed in exponentiated form.  $e^{\text{contrast}}$  is displayed rather than `contrast`. Standard errors and confidence intervals are also transformed. See [R] [eform\\_option](#) for the list of available options.

The following option is available with `pwcompare` but is not shown in the dialog box:

`df(#)` specifies that the  $t$  distribution with  $\#$  degrees of freedom be used for computing  $p$ -values and confidence intervals. The default is to use `e(df_r)` degrees of freedom or the standard normal distribution if `e(df_r)` is missing.

## Remarks and examples

`pwcompare` performs pairwise comparisons of margins across the levels of factor variables from the most recently fit model. The margins can be estimated cell means, marginal means, intercepts, marginal intercepts, slopes, or marginal slopes. With the exception of slopes, we can also consider these margins to be marginal linear predictions.

The margins are calculated as linear combinations of the coefficients. Let  $k$  be the number of levels for a factor term in our model; then there are  $k$  margins for that term, and

$$m = \binom{k}{2} = \frac{k(k-1)}{2}$$

unique pairwise comparisons of those margins.

The confidence intervals and  $p$ -values for these pairwise comparisons can be adjusted to account for multiple comparisons. Bonferroni's, Šidák's, and Scheffé's adjustments can be made for multiple comparisons after fitting any type of model. In addition, Tukey's, Student–Newman–Keuls's, Duncan's, and Dunnett's adjustments are available when fitting ANOVA, linear regression, MANOVA, or multivariate regression models.

## Pairwise comparisons of means

Suppose we are interested in the effects of five different fertilizers on wheat yield. We could estimate the following linear regression model to determine the effect of each type of fertilizer on the yield.

```
. use https://www.stata-press.com/data/r19/yield
(Artificial wheat yield dataset)
. regress yield i.fertilizer
```

| Source   | SS         | df  | MS         | Number of obs | = | 200    |
|----------|------------|-----|------------|---------------|---|--------|
| Model    | 1078.84207 | 4   | 269.710517 | F(4, 195)     | = | 5.33   |
| Residual | 9859.55334 | 195 | 50.561812  | Prob > F      | = | 0.0004 |
| Total    | 10938.3954 | 199 | 54.9668111 | R-squared     | = | 0.0986 |
|          |            |     |            | Adj R-squared | = | 0.0801 |
|          |            |     |            | Root MSE      | = | 7.1107 |

| yield      | Coefficient | Std. err. | t     | P> t  | [95% conf. interval] |          |
|------------|-------------|-----------|-------|-------|----------------------|----------|
| fertilizer |             |           |       |       |                      |          |
| 10-08-22   | 3.62272     | 1.589997  | 2.28  | 0.024 | .4869212             | 6.758518 |
| 16-04-08   | .4906299    | 1.589997  | 0.31  | 0.758 | -2.645169            | 3.626428 |
| 18-24-06   | 4.922803    | 1.589997  | 3.10  | 0.002 | 1.787005             | 8.058602 |
| 29-03-04   | -1.238328   | 1.589997  | -0.78 | 0.437 | -4.374127            | 1.89747  |
| _cons      | 41.36243    | 1.124298  | 36.79 | 0.000 | 39.14509             | 43.57977 |

In this simple case, the coefficients for fertilizers 10-08-22, 16-04-08, 18-24-06, and 29-03-04 indicate the difference in the mean yield for that fertilizer versus the mean yield for fertilizer 10-10-10. That the standard errors of all four coefficients are identical results from having perfectly balanced data.

## Marginal means

We can use `pwcompare` with the `cimargins` option to compute the mean yield for each of the fertilizers.

```
. pwcompare fertilizer, cimargins
Pairwise comparisons of marginal linear predictions
Margins: asbalanced
```

|            | Margin   | Std. err. | Unadjusted<br>[95% conf. interval] |          |
|------------|----------|-----------|------------------------------------|----------|
| fertilizer |          |           |                                    |          |
| 10-10-10   | 41.36243 | 1.124298  | 39.14509                           | 43.57977 |
| 10-08-22   | 44.98515 | 1.124298  | 42.7678                            | 47.20249 |
| 16-04-08   | 41.85306 | 1.124298  | 39.63571                           | 44.0704  |
| 18-24-06   | 46.28523 | 1.124298  | 44.06789                           | 48.50258 |
| 29-03-04   | 40.1241  | 1.124298  | 37.90676                           | 42.34145 |

Looking at the confidence intervals for fertilizers 10-10-10 and 10-08-22 in the table above, we might be tempted to conclude that these means are not significantly different because the intervals overlap. However, as discussed in *Interaction plots* of [R] `marginplot`, we cannot draw conclusions about the differences in means by looking at confidence intervals for the means themselves. Instead, we would need to look at confidence intervals for the difference in means.

## All pairwise comparisons

By default, pwcompare calculates all pairwise differences of the margins, in this case pairwise differences of the mean yields.

```
. pwcompare fertilizer
Pairwise comparisons of marginal linear predictions
Margins: asbalanced
```

If a confidence interval does not include zero, the means for the compared fertilizers are significantly different. Therefore, at the 5% significance level, we would reject the hypothesis that the means for fertilizers 10-10-10 and 10-08-22 are equivalent—as we would do for 18-24-06 vs 10-10-10, 29-03-04 vs 10-08-22, 18-24-06 vs 16-04-08, and 29-03-04 vs 18-24-06.

We may prefer to see the  $p$ -values instead of looking at confidence intervals to determine whether the pairwise differences are significantly different from zero. We could use the `pveffects` option to see the differences with standard errors and  $p$ -values, or we could use the `effects` option to see both  $p$ -values and confidence intervals in the same table. Here we specify `effects` as well as the `sort` option so that the differences are sorted from smallest to largest.

```

| 16-04-08   | 4.432173  | 1.589997  | 2.79       | 0.006 | 1.296375             | 7.567972  |
| 18-24-06   |           |           |            |       |                      |           |
| vs         |           |           |            |       |                      |           |
| 10-10-10   | 4.922803  | 1.589997  | 3.10       | 0.002 | 1.787005             | 8.058602  |

We find that 5 of the 10 pairs of means are significantly different at the 5% significance level.

We can use the `groups` option to obtain a table that identifies groups whose means are not significantly different by assigning them the same letter.

```
. pwcompare fertilizer, groups sort
Pairwise comparisons of marginal linear predictions
Margins: asbalanced
```

|            | Margin   | Std. err. | Unadjusted groups |
|------------|----------|-----------|-------------------|
| fertilizer |          |           |                   |
| 29-03-04   | 40.1241  | 1.124298  | A                 |
| 10-10-10   | 41.36243 | 1.124298  | A                 |
| 16-04-08   | 41.85306 | 1.124298  | AB                |
| 10-08-22   | 44.98515 | 1.124298  | BC                |
| 18-24-06   | 46.28523 | 1.124298  | C                 |

Note: Margins sharing a letter in the group label are not significantly different at the 5% level.

The letter A that is assigned to fertilizers 29-03-04, 10-10-10, and 16-04-08 designates that the mean yields for these fertilizers are not different at the 5% level.

## Overview of multiple-comparison methods

For a single test, if we choose a 5% significance level, we would have a 5% chance of concluding that two margins are different when the population values are actually equal. This is known as making a type I error. When we perform  $m = k(k - 1)/2$  pairwise comparisons of the  $k$  margins, we have  $m$  opportunities to make a type I error.

`pwcompare` with the `mcompare()` option allows us to adjust the confidence intervals and  $p$ -values for each comparison to account for the increased probability of making a type I error when making multiple comparisons. Bonferroni's adjustment, Šidák's adjustment, and Scheffé's adjustment can be used when making pairwise comparisons of the margins after any estimation command. Tukey's honestly significant difference, Student–Newman–Keuls's method, Duncan's method, and Dunnett's method are only available when fitting linear models after `anova`, `manova`, `regress`, or `mvreg`.

## Fisher's protected least-significant difference (LSD)

`pwcompare` does not offer an `mcompare()` option specifically for Fisher's protected least-significant difference (LSD). In this methodology, no adjustment is made to the confidence intervals or  $p$ -values. However, it is protected in the sense that no pairwise comparisons are tested unless the joint test for the corresponding term in the model is significant. Therefore, the default `mcompare(noadjust)` corresponds to Fisher's protected LSD assuming that the corresponding joint test was performed before using `pwcompare`.

Milliken and Johnson (2009) recommend using this methodology for planned comparisons, assuming the corresponding joint test is significant.

## Bonferroni's adjustment

`mcompare(bonferroni)` adjusts significance levels based on the Bonferroni inequality, which, in the case of multiple testing, tells us that the maximum error rate for all comparisons is the sum of the error rates for the individual comparisons. Assuming that we are using the same significance level for all tests, the experimentwise error rate is the error rate for a single test multiplied by the number of comparisons. Therefore, a  $p$ -value for each comparison can be computed by multiplying the unadjusted  $p$ -value by the total number of comparisons. If the adjusted  $p$ -value is greater than 1, then `pwcompare` will report a  $p$ -value of 1.

Bonferroni's adjustment is popular because it is easy to compute manually and because it can be applied to any set of tests, not only the pairwise comparisons available in `pwcompare`. In addition, this method does not require equal sample sizes.

Because Bonferroni's adjustment is so general, it is more conservative than many of the other adjustments. It is especially conservative when a large number of tests is being performed.

## Šidák's adjustment

`mcompare(sidak)` performs an adjustment using Šidák's method. This adjustment, like Bonferroni's adjustment, is derived from an inequality. However, in this case, the inequality is based on the probability of not making a type I error. For a single test, the probability that we do not make a type I error is  $1 - \alpha$ . For two independent tests, both using  $\alpha$  as a significance level, the probability is  $(1 - \alpha)(1 - \alpha)$ . Likewise, for  $m$  independent tests, the probability of not making a type I error is  $(1 - \alpha)^m$ . Therefore, the probability of making one or more type I errors is  $1 - (1 - \alpha)^m$ . When tests are not independent, the probability of making at least one error is less than  $1 - (1 - \alpha)^m$ . Therefore, we can compute an adjusted  $p$ -value as  $1 - (1 - {}_u p)^m$ , where  ${}_u p$  is the unadjusted  $p$ -value for a single comparison.

Šidák's method is also conservative although slightly less so than Bonferroni's method. Like Bonferroni's method, this method does not require equal sample sizes.

## Scheffé's adjustment

Scheffé's adjustment is used when `mcompare(scheffe)` is specified. This adjustment is derived from the joint  $F$  test and its correspondence to the maximum normalized comparison. To adjust for multiple comparisons, the absolute value of the  $t$  statistic for a particular comparison can be compared with a critical value of  $\sqrt{(k-1)F_{k-1,\nu}}$ , where  $\nu$  is the residual degrees of freedom.  $F_{k-1,\nu}$  is the distribution of the joint  $F$  test for the corresponding term in a one-way ANOVA model. [Winer, Brown, and Michels \(1991, 191–195\)](#) discuss this in detail. For estimation commands that report  $z$  statistics instead of  $t$  statistics for the tests on coefficients, a  $\chi^2$  distribution is used instead of an  $F$  distribution.

Scheffé's method allows for making all possible comparisons of the  $k$  margins, not just the pairwise comparisons. Unlike the methods described above, it does not take into account the number of comparisons that are currently being made. Therefore, this method is even more conservative than the others. Because this method adjusts for all possible comparisons of the levels of the term, [Milliken and Johnson \(2009\)](#) recommend using this procedure when making unplanned contrasts that are suggested by the data. As [Winer, Brown, and Michels \(1991, 191\)](#) put it, this method is often used to adjust for “unfettered data snooping”. When using this adjustment, a contrast will never be significant if the joint  $F$  or  $\chi^2$  test for the term is not also significant.

This is another method that does not require equal sample sizes.

## Tukey's HSD adjustment

Tukey's adjustment is also referred to as Tukey's honestly significant difference (HSD) and is used when `mcompare(tukey)` is specified. It is often applied to all pairwise comparisons of means. Tukey's HSD is commonly used as a post hoc test although this is not a requirement.

To adjust for multiple comparisons, Tukey's method compares the absolute value of the  $t$  statistic from the individual comparison with a critical value based on a Studentized range distribution with parameter equal to the number of levels in the term. When applied to pairwise comparisons of means,

$$q = \frac{\text{mean}_{\max} - \text{mean}_{\min}}{s}$$

follows a Studentized range distribution with parameter  $k$  and  $\nu$  degrees of freedom. Here  $\text{mean}_{\max}$  and  $\text{mean}_{\min}$  are the largest and smallest marginal means, and  $s$  is an estimate of the standard error of the means.

Now for the comparison of the smallest and largest means, we can say that the probability of not making a type I error is

$$\Pr\left(\frac{\text{mean}_{\max} - \text{mean}_{\min}}{s} \leq q_{k,\nu}\right) = 1 - \alpha$$

Then, the following inequality holds for all pairs of means simultaneously:

$$\Pr\left(\frac{|\text{mean}_i - \text{mean}_j|}{s} \leq q_{k,\nu}\right) \geq 1 - \alpha$$

Based on this procedure, Tukey's HSD computes the  $p$ -value for each of the individual comparisons using the Studentized range distribution. However, because the equality holds only for the difference in the largest and smallest means, this procedure produces conservative tests for the remaining comparisons. [Winer, Brown, and Michels \(1991, 172–182\)](#) discuss this in further detail.

With unequal sample sizes, `mcompare(tukey)` produces the Tukey–Kramer adjustment ([Tukey 1953](#); [Kramer 1956](#)).

## Student–Newman–Keuls's adjustment

The Student–Newman–Keuls (SNK) method is used when `mcompare(snk)` is specified. It is a modification to Tukey's method and is less conservative. In this procedure, we first order the means. We then test the difference in the smallest and largest means using a critical value from the Studentized range distribution with parameter  $k$ , where  $k$  is the number of levels in the term. This step uses the same methodology as in Tukey's procedure. However, in the next step, we will then test for differences in the two sets of means that are the endpoints of the two ranges including  $k - 1$  means. Specifically, we test the difference in the smallest mean and the second-largest mean using a critical value from the Studentized range distribution with parameter  $k - 1$ . We would also test the difference in the second-smallest mean and the largest mean using this critical value. Likewise, the means that are the endpoints of ranges including  $k - 2$  means when ordered are tested using the Studentized range distribution with parameter  $k - 2$ , and so on.

Equal sample sizes are required for this method.

## Duncan's adjustment

When `mcompare(duncan)` is specified, tests are adjusted for multiple comparisons using Duncan's method, which is sometimes referred to as Duncan's new multiple range method. This adjustment produces tests that are less conservative than both Tukey's HSD and SNK. This procedure is performed in the same manner as SNK except that the  $p$ -values for the individual comparisons are adjusted as  $1 - (1 - \text{snk}p_i)^{1/(r+1)}$ , where  $\text{snk}p_i$  is the  $p$ -value computed using the SNK method and  $r$  represents the number of means that, when ordered, fall between the two that are being compared.

Again, equal sample sizes are required for this adjustment.

## Dunnett's adjustment

Dunnett's adjustment is obtained by specifying `mcompare(dunnett)`. It is used when one of the levels of a factor can be considered a control or reference level with which each of the other levels is being compared. When Dunnett's adjustment is requested,  $k - 1$  instead of  $k(k - 1)/2$  pairwise comparisons are made. [Dunnett \(1955, 1964\)](#) developed tables of critical values for what [Miller \(1981, 76\)](#) refers to as the "many-one  $t$  statistic". The  $t$  statistics for individual comparisons are compared with these critical values when making many comparisons to a single reference level.

This method also requires equal sample sizes.

## Example adjustments using one-way models

### Fisher's protected LSD

Fisher's protected LSD requires that we first verify that the joint test for a term in our model is significant before proceeding with pairwise comparisons. Using our [previous example](#), we could have first used the `contrast` command to obtain a joint test for the effects of fertilizer.

```
. contrast fertilizer
Contrasts of marginal linear predictions
Margins: asbalanced
```

|             | df  | F    | P>F    |
|-------------|-----|------|--------|
| fertilizer  | 4   | 5.33 | 0.0004 |
| Denominator | 195 |      |        |

This test for the effects of fertilizer is highly significant. Now we can say we are using Fisher's protected LSD when looking at the unadjusted  $p$ -values that were obtained from our previous command,

```
. pwcompare fertilizer, effects sort
```

## Tukey's HSD

Because we fit a linear regression model and are interested in all pairwise comparisons of the marginal means, we may instead choose to use Tukey's HSD.

```
. pwcompare fertilizer, effects sort mcompare(tukey)
Pairwise comparisons of marginal linear predictions
Margins: asbalanced
```

|            | Number of comparisons |
|------------|-----------------------|
| fertilizer | 10                    |

|            | Contrast  | Std. err. | Tukey<br>t | P> t  | Tukey<br>[95% conf. interval] |           |
|------------|-----------|-----------|------------|-------|-------------------------------|-----------|
| fertilizer |           |           |            |       |                               |           |
| 29-03-04   |           |           |            |       |                               |           |

This time, our *p*-values have been modified, and we find that only four of the pairwise differences are considered significantly different from zero at the 5% level.

If we are interested only in performing pairwise comparisons of a subset of our means, we can use factor-variable operators to select the levels of the factor that we want to compare. Here we exclude all comparisons involving fertilizer 10-10-10.

```
. pwcompare i(2/5).fertilizer, effects sort mcompare(tukey)
```

Pairwise comparisons of marginal linear predictions

The adjusted *p*-values and confidence intervals differ from those in the previous output because Tukey's adjustment takes into account the total number of comparisons being made when determining the appropriate degrees of freedom to use for the Studentized range distribution.

### Dunnett's method for comparisons to a control

If one of our five fertilizer groups represents fields where no fertilizer was applied, we may want to use Dunnett's method to compare each of the four fertilizers with the control group. In this case, we make only  $k - 1$  comparisons for  $k$  groups.

```
. pwcompare fertilizer, effects mcompare(dunnett)
Pairwise comparisons of marginal linear predictions
Margins: asbalanced
```

|            | Number of comparisons |
|------------|-----------------------|
| fertilizer | 4                     |

|            | Contrast  | Std. err. | Dunnett |       | Dunnett              |          |
|------------|-----------|-----------|---------|-------|----------------------|----------|

| 10-10-10   | -1.238328 | 1.589997  | -0.78   | 0.852 | -5.152881            | 2.676225 |

In our previous `regress` command, fertilizer 10-10-10 was treated as the base. Therefore, by default, it was treated as the control when using Dunnett's adjustment, and the pairwise comparisons are equivalent to the coefficients reported by `regress`. Based on our `regress` output, we would conclude that fertilizers 10-08-22 and 18-24-06 are different from fertilizer 10-10-10 at the 5% level. However, using Dunnett's adjustment, we find only fertilizer 18-24-06 to be different from fertilizer 10-10-10 at this same significance level.

If the model is fit without a base level for a factor variable, then `pwcompare` will choose the first level as the reference level. If we want to make comparisons with a different level than the one `mcompare(dunnett)` chooses by default, we can use the `b.` operator to override the default. Here we use fertilizer 5 (29-03-04) as the reference level.

```
. pwcompare b5.fertilizer, effects sort mcompare(dunnett)
```

Pairwise comparisons of marginal linear predictions

| 10-08-22#1            | 51.17547 | 1.116571  | F            |

Note: Margins sharing a letter in the group label are not significantly different at the 5% level.

Based on Tukey's HSD and a 5% significance level, we would conclude that the mean yield for fertilizer 29-03-04 without irrigation is not significantly different from the mean yields for fertilizers 10-10-10, 10-08-22, and 16-04-08 when used without irrigation but is significantly different from the remaining means.

Up to this point, most of the pairwise comparisons that we have performed could have also been obtained with `pwmean` (see [R] [pwmean](#)) if we had not been interested in examining the results from the estimation command before making pairwise comparisons of the means. For instance, we could reproduce the results from the above `pwcompare` command by typing

```
. pwmean yield, over(fertilizer irrigation) sort group mcompare(tukey)
```

However, `pwcompare` extends the capabilities of `pwmean` in many ways. For instance, `pwmean` only allows for pairwise comparisons of the cell means determined by the highest-level interaction of the variables specified in the `over()` option. However, `pwcompare` allows us to fit a single model, such as the two-way model that we fit above,

```
. regress yield fertilizer##irrigation
```

and compute pairwise comparisons of the marginal means for only one of the variables in the model:

```
. pwcompare fertilizer, sort effects mcompare(tukey)
Pairwise comparisons of marginal linear predictions
Margins: asbalanced
```

|            | Number of comparisons |
|------------|-----------------------|
| fertilizer | 10                    |

Here the standard errors for the differences in marginal means and the residual degrees of freedom are based on the full model. Therefore, the results will differ from those obtained from pwcompare after fitting the one-way model with only fertilizer (or equivalently using pwmean).

## Pairwise comparisons of slopes

If we fit a model with a factor variable that is interacted with a continuous variable, pwcompare will even allow us to make pairwise comparisons of the slopes of the continuous variable for the levels of the factor variable.

In this case, we have a continuous variable, N03\_N, indicating the amount of nitrate nitrogen already existing in the soil, based on a sample taken from each field.

```
. regress yield fertilizer##c.N03_N
```

| 29-03-04           | -3.275947   | .8247385  | -3.97 | 0.000 | -4.902767            | -1.649127 |
| _cons              | -5.459168   | 7.638241  | -0.71 | 0.476 | -20.52581            | 9.607477  |

These are the pairwise differences of the slopes of N03\_N for each pair of fertilizers:

```
. pwcompare fertilizer#c.N03_N, pveffects sort mcompare(scheffe)
```

Pairwise comparisons of marginal linear predictions

Margins: asbalanced

|                    | Number of comparisons |
|--------------------|-----------------------|
| fertilizer#c.N03_N | 10                    |

| fertilizer#c.N03_N   | Contrast  | Std. err. | Scheffe |       |
|----------------------|-----------|-----------|---------|-------|
|                      |           |           | t       | P> t  |
| 29-03-04 vs 10-10-10 | -3.275947 | .8247385  | -3.97   | 0.004 |
| 18-24-06 vs 10-10-10 | -2.97627  | .9136338  | -3.26   | 0.034 |
| 29-03-04 vs 16-04-08 | -2.270237 | .4691771  | -4.84   | 0.000 |
| 29-03-04 vs 10-08-22 | -1.993909 | .4550851  | -4.38   | 0.001 |
| 18-24-06 vs 16-04-08 | -1.97056  | .612095   | -3.22   | 0.038 |
| 18-24-06 vs 10-08-22 | -1.694232 | .6013615  | -2.82   | 0.099 |
| 10-08-22 vs 10-10-10 | -1.282039 | .8953419  | -1.43   | 0.727 |
| 16-04-08 vs 10-10-10 | -1.00571  | .9025862  | -1.11   | 0.871 |
| 29-03-04 vs 18-24-06 | -.2996772 | .4900939  | -0.61   | 0.984 |
| 16-04-08 vs 10-08-22 | .276328   | .5844405  | 0.47    | 0.994 |

Using Scheffé’s adjustment, we find that five of the pairs have significantly different slopes at the 5% level.

## Nonlinear models

pwcompare can also perform pairwise comparisons of the marginal linear predictions after fitting a nonlinear model. For instance, we can use the dataset from *Beyond linear models* in [R] **contrast** and fit the following logistic regression model of patient satisfaction on hospital:

```
. use https://www.stata-press.com/data/r19/hospital
```

(Artificial hospital satisfaction data)

```
. logit satisfied i.hospital
```

Iteration 0: Log likelihood = -393.72216

Iteration 1: Log likelihood = -387.55736

Iteration 2: Log likelihood = -387.4768

Iteration 3: Log likelihood = -387.47679

Logistic regression

Number of obs = 802

LR chi2(2) = 12.49

Prob > chi2 = 0.0019

Pseudo R2 = 0.0159

Log likelihood = -387.47679

| satisfied | Coefficient | Std. err. | z    | P> z  | [95% conf. interval] |          |
|-----------|-------------|-----------|------|-------|----------------------|----------|
| hospital  |             |           |      |       |                      |          |
| 2         | .5348129    | .2136021  | 2.50 | 0.012 | .1161604             | .9534654 |
| 3         | .7354519    | .2221929  | 3.31 | 0.001 | .2999618             | 1.170942 |
| _cons     | 1.034708    | .1391469  | 7.44 | 0.000 | .7619855             | 1.307431 |

For this model, the marginal linear predictions are the predicted log odds for each hospital and can be obtained with the `cimargins` option:

```
. pwcompare hospital, cimargins
Pairwise comparisons of marginal linear predictions
Margins: asbalanced
```

|          | Margin   | Std. err. | Unadjusted<br>[95% conf. interval] |          |
|----------|----------|-----------|------------------------------------|----------|
| hospital |          |           |                                    |          |
| 1        | 1.034708 | .1391469  | .7619855                           | 1.307431 |
| 2        | 1.569521 | .1620618  | 1.251886                           | 1.887157 |
| 3        | 1.77016  | .1732277  | 1.43064                            | 2.10968  |

The pairwise comparisons are, therefore, differences in the log odds. We can specify `mcompare(bonferroni)` and `effects` to request Bonferroni-adjusted *p*-values and confidence intervals.

```
. pwcompare hospital, effects mcompare(bonferroni)
Pairwise comparisons of marginal linear predictions
Margins: asbalanced
```

|                       | Number of<br>comparisons |
|-----------------------|--------------------------|
| satisfied<br>hospital | 3                        |

|                       | Contrast | Std. err. | Bonferroni |       | Bonferroni<br>[95% conf. interval] |          |
|-----------------------|----------|-----------|------------|-------|------------------------------------|----------|
| satisfied<br>hospital |          |           |            |       |                                    |          |
| 2 vs 1                | .5348129 | .2136021  | 2.50       | 0.037 | .0234537                           | 1.046172 |
| 3 vs 1                | .7354519 | .2221929  | 3.31       | 0.003 | .2035265                           | 1.267377 |
| 3 vs 2                | .200639  | .2372169  | 0.85       | 1.000 | -.3672535                          | .7685314 |

For nonlinear models, only Bonferroni's adjustment, Šidák's adjustment, and Scheffé's adjustment are available.

If we want pairwise comparisons reported as odds ratios, we can specify the `or` option.

```
. pwcompare hospital, effects mcompare(bonferroni) or
Pairwise comparisons of marginal linear predictions
Margins: asbalanced
```

|                       | Number of<br>comparisons |
|-----------------------|--------------------------|
| satisfied<br>hospital | 3                        |

|                       | Odds ratio | Std. err. | Bonferroni |       | Bonferroni           |          |
|-----------------------|------------|-----------|------------|-------|----------------------|----------|
|                       |            |           | z          | P> z  | [95% conf. interval] |          |
| satisfied<br>hospital |            |           |            |       |                      |          |
| 2 vs 1                | 1.707129   | .3646464  | 2.50       | 0.037 | 1.023731             | 2.846733 |
| 3 vs 1                | 2.086425   | .4635888  | 3.31       | 0.003 | 1.225718             | 3.551525 |
| 3 vs 2                | 1.222183   | .2899226  | 0.85       | 1.000 | .6926341             | 2.156597 |

Notice that these tests are still performed on the marginal linear predictions. The odds ratios reported here are the exponentiated versions of the pairwise differences of log odds in the previous output. For further discussion, see [\[R\] contrast](#).

## Multiple-equation models

`pwcompare` works with models containing multiple equations. Commands such as `intreg` and `gnbreg` allow their ancillary parameters to be modeled as a function of independent variables, and `pwcompare` can compare the margins within these equations. The `equation()` option can be used to specify the equation for which pairwise comparisons of the margins should be made. The `atequations` option specifies that pairwise comparisons be computed for each equation. In addition, `pwcompare` allows a special pseudofactor for equation—called `_eqns`—when working with results from `manova`, `mvreg`, `mlogit`, and `mprobit`.

Here we use the jaw fracture dataset described in [example 4](#) of [\[MV\] manova](#). We fit a multivariate regression model including one independent factor variable, fracture.

```
. use https://www.stata-press.com/data/r19/jaw
(Table 4.6. Two-way unbalanced data for fractures of the jaw, Rencher (1998))
```

```
. mvreg y1 y2 y3 = i.fracture
```

| Equation | Obs | Parms | RMSE     | "R-sq" | F        | P>F    |
|----------|-----|-------|----------|--------|----------|--------|
| y1       | 27  | 3     | 10.42366 | 0.2966 | 5.060804 | 0.0147 |
| y2       | 27  | 3     | 6.325398 | 0.1341 | 1.858342 | 0.1777 |

pwcompare performs pairwise comparisons of the margins using the coefficients from the first equation by default:

```
. pwcompare fracture, mcompare(bonferroni)
Pairwise comparisons of marginal linear predictions
Margins: asbalanced
```

|                | Number of comparisons |
|----------------|-----------------------|
| y1<br>fracture | 3                     |

|                                                                              | Contrast  | Std. err. | Bonferroni<br>[95% conf. interval] |          |
|------------------------------------------------------------------------------|-----------|-----------|------------------------------------|----------|
| y1<br>fracture                                                               |           |           |                                    |          |
| Two compound fractures<br>vs<br>One compound fracture<br>One simple fracture | -8.833333 | 4.957441  | -21.59201                          | 3.925341 |
| One compound fracture<br>vs<br>One simple fracture                           | 6         | 5.394759  | -7.884173                          | 19.88417 |
| Two compound fractures                                                       | 14.83333  | 4.75773   | 2.588644                           | 27.07802 |

We can use the equation() option to get pwcompare to perform comparisons in the y2 equation:

```
. pwcompare fracture, equation(y2) mcompare(bonferroni)
Pairwise comparisons of marginal linear predictions
Margins: asbalanced
```

|                | Number of comparisons |
|----------------|-----------------------|
| y2<br>fracture | 3                     |

|                                                                              | Contrast  | Std. err. | Bonferroni<br>[95% conf. interval] |          |
|------------------------------------------------------------------------------|-----------|-----------|------------------------------------|----------|
| y2<br>fracture                                                               |           |           |                                    |          |
| Two compound fractures<br>vs<br>One compound fracture<br>One simple fracture | -5.761905 | 3.008327  | -13.50426                          | 1.980449 |
| One compound fracture<br>vs<br>One simple fracture                           | -3.053571 | 3.273705  | -11.47891                          | 5.371769 |
| Two compound fractures                                                       | 2.708333  | 2.887136  | -4.722119                          | 10.13879 |

Because we are working with mvreg results, we can use the `_eqns` pseudofactor to compare the margins between the three dependent variables. The levels of `_eqns` index the equations: 1 for the first equation, 2 for the second, and 3 for the third.

```
. pwcompare _eqns, mcompare(bonferroni)
Pairwise comparisons of marginal linear predictions
Margins: asbalanced
```

|                    | Number of comparisons |
|--------------------|-----------------------|
| <code>_eqns</code> | 3                     |

|                    | Contrast  | Std. err. | Bonferroni<br>[95% conf. interval] |          |
|--------------------|-----------|-----------|------------------------------------|----------|
| <code>_eqns</code> |           |           |                                    |          |
| 2 vs 1             | -.5654762 | 2.545923  | -7.117768                          | 5.986815 |
| 3 vs 1             | 24.24603  | 2.320677  | 18.27344                           | 30.21862 |
| 3 vs 2             | 24.81151  | 2.368188  | 18.71664                           | 30.90637 |

For the previous command, the only methods available are `mcompare(bonferroni)`, `mcompare(sidak)`, or `mcompare(scheffe)`. Methods that use the Studentized range are not appropriate for making comparisons across equations.

## Unbalanced data

`pwcompare` treats all factors as balanced when it computes the marginal means. By “balanced”, we mean that the number of observations in each combination of factor levels (in each cell mean) is equal. We can alternatively specify the `asobserved` option when we have unbalanced data to obtain marginal means that are based on the observed cell frequencies from the model fit. For more details on the difference in these two types of marginal means and a discussion of when each may be appropriate, see [\[R\] margins](#) and [\[R\] contrast](#).

In addition, when our data are not balanced, some of the multiple-comparison adjustments are no longer appropriate. Student–Newman–Keuls’s method, Duncan’s method, and Dunnett’s method assume equal numbers of observations per group.

Here we use an unbalanced dataset and fit a two-way ANOVA model for cholesterol levels on race and age group. Then we perform pairwise comparisons of the mean cholesterol levels for each race, requesting Šidák’s adjustment as well as marginal means that are computed using the observed cell frequencies.

```
. use https://www.stata-press.com/data/r19/cholesterol3
(Artificial cholesterol data, unbalanced)
. anova chol race##agegrp

 Number of obs = 67 R-squared = 0.8179

## Empty cells

An empty cell is a combination of the levels of factor variables that is not observed in the estimation sample. When we have empty cells in our data, the marginal means involving those empty cells are not estimable as described in [R] margins. In addition, all pairwise comparisons involving a marginal mean that is not estimable are themselves not estimable. Here we use a dataset where we do not have any observations for white individuals in the 20–29 age group. We can use the emptycells(reweight) option to reweight the nonempty cells so that we can estimate the marginal mean for whites and compute pairwise comparisons involving that marginal mean.

```
. use https://www.stata-press.com/data/r19/cholesterol2
(Artificial cholesterol data, empty cells)
. tabulate race agegrp
```

| Race  | Age group |       |       |       |       | Total |
|-------|-----------|-------|-------|-------|-------|-------|

## Methods and formulas

Methods and formulas are presented under the following headings:

*Notation*  
*Unadjusted comparisons*  
*Bonferroni’s method*  
*Šidák’s method*  
*Scheffé’s method*  
*Tukey’s method*  
*Student–Newman–Keuls’s method*  
*Duncan’s method*  
*Dunnnett’s method*

## Notation

pwcompare performs comparisons of margins; see *Methods and formulas* in [R] **contrast**.

If there are  $k$  margins for a given factor term, then there are

$$m = \binom{k}{2} = \frac{k(k-1)}{2}$$

unique pairwise comparisons. Let the  $i$ th pairwise comparison be denoted by

$$\hat{\delta}_i = l'_i \mathbf{b}$$

where  $\mathbf{b}$  is a column vector of coefficients from the fitted model and  $l_i$  is a column vector that forms the corresponding linear combination. If  $\hat{\mathbf{V}}$  denotes the estimated variance matrix for  $\mathbf{b}$ , then the standard error for  $\hat{\delta}_i$  is given by

$$\widehat{\text{se}}(\hat{\delta}_i) = \sqrt{l'_i \hat{\mathbf{V}} l_i}$$

The corresponding test statistic is then

$$t_i = \frac{\hat{\delta}_i}{\widehat{\text{se}}(\hat{\delta}_i)}$$

and the limits for a  $100(1 - \alpha)\%$  confidence interval for the expected value of  $\hat{\delta}_i$  are

$$\hat{\delta}_i \pm c_i(\alpha) \widehat{\text{se}}(\hat{\delta}_i)$$

where  $c_i(\alpha)$  is the critical value corresponding to the chosen multiple-comparison method.

## Unadjusted comparisons

pwcompare computes unadjusted  $p$ -values and confidence intervals by default. pwcompare uses the  $t$  distribution with  $\nu = e(\text{df\_r})$  degrees of freedom when  $e(\text{df\_r})$  is posted by the estimation command. The unadjusted two-sided  $p$ -value is

$${}_u p_i = 2 \Pr(t_\nu > |t_i|)$$

and the unadjusted critical value  ${}_u c_i(\alpha)$  satisfies the following probability statement:

$$\alpha = 2 \Pr\{t_\nu > {}_u c_i(\alpha)\}$$

pwcompare uses the standard normal distribution when  $e(\text{df\_r})$  is not posted.

## Bonferroni's method

For `mcompare(bonferroni)`, the adjusted  $p$ -value is

$${}_b p_i = \min(1, m {}_u p_i)$$

and the adjusted critical value is

$${}_b c_i(\alpha) = {}_u c_i(\alpha/m)$$

## Šidák's method

For `mcompare(sidak)`, the adjusted  $p$ -value is

$${}_{\text{si}} p_i = 1 - (1 - {}_u p_i)^m$$

and the adjusted critical value is

$${}_{\text{si}} c_i(\alpha) = {}_u c_i \{1 - (1 - \alpha)^{1/m}\}$$

## Scheffé's method

For `mcompare(scheffe)`, the adjusted  $p$ -value is

$${}_{\text{sc}} p_i = \Pr(F_{d,\nu} > t_i^2/d)$$

where  $F_{d,\nu}$  is distributed as an  $F$  with  $d$  numerator and  $\nu$  denominator degrees of freedom and  $d$  is the rank of the VCE for the term. The adjusted critical value satisfies the following probability statement:

$$\alpha = \Pr[F_{d,\nu} > \{ {}_{\text{sc}} c_i(\alpha) \}^2/d]$$

`pwcompare` uses the  $\chi^2$  distribution when `e(df_r)` is not posted.

## Tukey's method

For `mcompare(tukey)`, the adjusted  $p$ -value is

$${}_t p_i = \Pr(q_{k,\nu} > |t_i| \sqrt{2})$$

where  $q_{k,\nu}$  is distributed as the Studentized range statistic for  $k$  means and  $\nu$  residual degrees of freedom (Miller 1981). The adjusted critical value satisfies the following probability statement:

$$\alpha = \Pr\{q_{k,\nu} > {}_t c_i(\alpha) \sqrt{2}\}$$

## Student–Newman–Keuls’s method

For `mcompare(snk)`, suppose  $t_i$  is comparing two margins that have  $r$  other margins between them. Then the adjusted  $p$ -value is

$${}_{\text{snk}}p_i = \Pr(q_{r+2,\nu} > |t_i|\sqrt{2})$$

where  $r$  ranges from 0 to  $k - 2$ . The adjusted critical value  ${}_{\text{snk}}c_i(\alpha)$  satisfies the following probability statement:

$$\alpha = \Pr\{q_{r+2,\nu} > {}_{\text{snk}}c_i(\alpha)\sqrt{2}\}$$

## Duncan’s method

For `mcompare(duncan)`, the adjusted  $p$ -value is

$${}_{\text{dunc}}p_i = 1 - (1 - {}_{\text{snk}}p_i)^{1/(r+1)}$$

and the adjusted critical value is

$${}_{\text{dunc}}c_i(\alpha) = {}_{\text{snk}}c_i\{1 - (1 - \alpha)^{r+1}\}$$

## Dunnett’s method

For `mcompare(dunnett)`, the margins are compared with a reference category, resulting in only  $k - 1$  pairwise comparisons. The adjusted  $p$ -value is

$${}_{\text{dunn}}p_i = \Pr(d_{k-1,\nu} > |t_i|)$$

where  $d_{k-1,\nu}$  is distributed as the many-one  $t$  statistic (Miller 1981, 76). The adjusted critical value  ${}_{\text{dunn}}c_i(\alpha)$  satisfies the following probability statement:

$$\alpha = \Pr\{d_{k-1,\nu} > {}_{\text{dunn}}c_i(\alpha)\}$$

The multiple-comparison methods for `mcompare(tukey)`, `mcompare(snk)`, `mcompare(duncan)`, and `mcompare(dunnett)` assume the normal distribution with equal variance; thus, these methods are allowed only with results from `anova`, `regress`, `manova`, and `mvreg`. `mcompare(snk)`, `mcompare(duncan)`, and `mcompare(dunnett)` assume equal sample size for each marginal mean. These options will cause `pwcompare` to report a footnote if unbalanced factors are detected.

## Postestimation commands

The following postestimation commands are available after `pwcompare`, `post`:

| Command                  | Description                                                                                       |
|--------------------------|---------------------------------------------------------------------------------------------------|
| <code>estat vce</code>   | variance–covariance matrix of the estimators (VCE)                                                |
| <code>estat (svy)</code> | postestimation statistics for survey data                                                         |
| <code>estimates</code>   | cataloging estimation results                                                                     |
| <code>etable</code>      | table of estimation results                                                                       |
| <code>lincom</code>      | point estimates, standard errors, testing, and inference for linear combinations of parameters    |
| <code>nlcom</code>       | point estimates, standard errors, testing, and inference for nonlinear combinations of parameters |
| <code>test</code>        | Wald tests of simple and composite linear hypotheses                                              |
| <code>testnl</code>      | Wald tests of nonlinear hypotheses                                                                |

## Remarks and examples

When we use the `post` option with `pwcompare`, the marginal linear predictions are posted as estimation results, and we can use postestimation commands to perform further analysis on them.

In *Pairwise comparisons of means* of [R] `pwcompare`, we fit a regression of wheat yield on types of fertilizers.

```
. use https://www.stata-press.com/data/r19/yield
(Artificial wheat yield dataset)
. regress yield i.fertilizer
(output omitted)
```

We also used `pwcompare` with the `cimargins` option to obtain the marginal mean yield for each fertilizer. We can add the `post` option to this command to post these marginal means and their VCEs as estimation results.

```
. pwcompare fertilizer, cimargins post
Pairwise comparisons of marginal linear predictions
Margins: asbalanced
```

|            | Margin   | Std. err. | Unadjusted<br>[95% conf. interval] |          |
|------------|----------|-----------|------------------------------------|----------|
| fertilizer |          |           |                                    |          |
| 10-10-10   | 41.36243 | 1.124298  | 39.14509                           | 43.57977 |
| 10-08-22   | 44.98515 | 1.124298  | 42.7678                            | 47.20249 |
| 16-04-08   | 41.85306 | 1.124298  | 39.63571                           | 44.0704  |
| 18-24-06   | 46.28523 | 1.124298  | 44.06789                           | 48.50258 |
| 29-03-04   | 40.1241  | 1.124298  | 37.90676                           | 42.34145 |

Now, we can use `nlcom` to compute a percentage improvement in the mean yield for fertilizer 2 when compared with fertilizer 1.

```
. nlcom (pct_chg: 100*(_b[2.fertilizer] - _b[1.fertilizer])/_b[1.fertilizer])
 pct_chg: 100*(_b[2.fertilizer] - _b[1.fertilizer])/_b[1.fertilizer]
```

|         | Coefficient | Std. err. | z    | P> z  | [95% conf. interval] |          |
|---------|-------------|-----------|------|-------|----------------------|----------|
| pct_chg | 8.758479    | 4.015932  | 2.18 | 0.029 | .8873982             | 16.62956 |

The mean yield for fertilizer 2 is about 9% higher than that of fertilizer 1, with a standard error of 4%.

## Description

`pwmean` performs pairwise comparisons of means. It computes all pairwise differences of the means of *varname* over the combination of the levels of the variables in *varlist*. The tests and confidence intervals for the pairwise comparisons assume equal variances across groups. `pwmean` also allows for adjusting the confidence intervals and *p*-values to account for multiple comparisons using Bonferroni's method, Scheffé's method, Tukey's method, Dunnett's method, and others.

See [R] [pwcompare](#) for performing pairwise comparisons of means, estimated marginal means, and other types of marginal linear predictions after [anova](#), [regress](#), and most other estimation commands.

## Quick start

All pairwise differences in the means of *y* over levels of categorical variable *catvar*

```
pwmean y, over(catvar)
```

Same as above, and report test statistics and *p*-values for tests that differences equal zero

```
pwmean y, over(catvar) effects
```

Adjust *p*-values and confidence intervals for multiple comparisons using Tukey's method

```
pwmean y, over(catvar) effects mcompare(tukey)
```

Same as above, but adjust for multiple comparisons using Bonferroni's method

```
pwmean y, over(catvar) effects mcompare(bonferroni)
```

Report mean of *y* for each level of *catvar*, grouping means that are not significantly different

```
pwmean y, over(catvar) groups
```

## Menu

Statistics > Summaries, tables, and tests > Summary and descriptive statistics > Pairwise comparisons of means

## Syntax

pwmean *varname* [*if*] [*in*], over(*varlist*) [*options*]

| <i>options</i>                    | Description                                                                                               |
|-----------------------------------|-----------------------------------------------------------------------------------------------------------|
| Main                              |                                                                                                           |
| * <i>over</i> ( <i>varlist</i> )  | compare means across each combination of the levels in <i>varlist</i>                                     |
| <i>mcompare</i> ( <i>method</i> ) | adjust for multiple comparisons; default is <i>mcompare</i> ( <i>noadjust</i> )                           |
| Reporting                         |                                                                                                           |
| <i>level</i> (#)                  | confidence level; default is <i>level</i> (95)                                                            |
| <i>ci</i> effects                 | display a table of mean differences and confidence intervals; the default                                 |
| <i>p</i> effects                  | display a table of mean differences and <i>p</i> -values                                                  |
| <i>effects</i>                    | display a table of mean differences with <i>p</i> -values and confidence intervals                        |
| <i>ci</i> means                   | display a table of means and confidence intervals                                                         |
| <i>groups</i>                     | display a table of means with codes that group them with other means that are not significantly different |
| <i>sort</i>                       | sort results tables by displayed mean or difference                                                       |
| <i>display_options</i>            | control column formats, line width, and factor-variable labeling                                          |

\**over* (*varlist*) is required.

*collect* is allowed; see [U] 11.1.10 Prefix commands.

See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

| <i>method</i>     | Description                                         |
|-------------------|-----------------------------------------------------|
| <i>noadjust</i>   | do not adjust for multiple comparisons; the default |
| <i>bonferroni</i> | Bonferroni's method                                 |
| <i>sidak</i>      | Šidák's method                                      |
| <i>scheffe</i>    | Scheffé's method                                    |
| <i>tukey</i>      | Tukey's method                                      |
| <i>snk</i>        | Student–Newman–Keuls's method                       |
| <i>duncan</i>     | Duncan's method                                     |
| <i>dunnett</i>    | Dunnett's method                                    |

## Options

Main

*over* (*varlist*) is required and specifies that means are computed for each combination of the levels of the variables in *varlist*.

*mcompare* (*method*) specifies the method for computing *p*-values and confidence intervals that account for multiple comparisons.

Most methods adjust the comparisonwise error rate,  $\alpha_c$ , to achieve a prespecified experimentwise error rate,  $\alpha_e$ .

*mcompare*(*noadjust*) is the default; it specifies no adjustment.

$$\alpha_c = \alpha_e$$

`mcompare(bonferroni)` adjusts the comparisonwise error rate based on the upper limit of the Bonferroni inequality:

$$\alpha_e \leq m\alpha_c$$

where  $m$  is the number of comparisons within the term.

The adjusted comparisonwise error rate is

$$\alpha_c = \alpha_e/m$$

`mcompare(sidak)` adjusts the comparisonwise error rate based on the upper limit of the probability inequality

$$\alpha_e \leq 1 - (1 - \alpha_c)^m$$

where  $m$  is the number of comparisons within the term.

The adjusted comparisonwise error rate is

$$\alpha_c = 1 - (1 - \alpha_e)^{1/m}$$

This adjustment is exact when the  $m$  comparisons are independent.

`mcompare(scheffe)` controls the experimentwise error rate using the  $F$  (or  $\chi^2$ ) distribution with degrees of freedom equal to  $k - 1$  where  $k$  is the number of means being compared.

`mcompare(tukey)` uses what is commonly referred to as Tukey's honestly significant difference. This method uses the Studentized range distribution instead of the  $t$  distribution.

`mcompare(snk)` is a variation on `mcompare(tukey)` that counts only the number of means participating in the range for a given comparison instead of the full number of means.

`mcompare(duncan)` is a variation on `mcompare(snk)` with additional adjustment to the significance probabilities.

`mcompare(dunnett)` uses Dunnett's method for making comparisons with a reference category.

---

Reporting

`level(#)` specifies the confidence level, as a percentage, for confidence intervals. The default is `level(95)` or as set by `set level`; see [U] 20.8 Specifying the width of confidence intervals. The significance level used by the `groups` option is `100 - #`, expressed as a percentage.

`cieffects` specifies that a table of the pairwise comparisons of means with their standard errors and confidence intervals be reported. This is the default.

`pveffects` specifies that a table of the pairwise comparisons of means with their standard errors, test statistics, and  $p$ -values be reported.

`effects` specifies that a table of the pairwise comparisons of means with their standard errors, test statistics,  $p$ -values, and confidence intervals be reported.

`cimeans` specifies that a table of the means with their standard errors and confidence intervals be reported.

`groups` specifies that a table of the means with their standard errors and group codes be reported. Means with the same letter in the group code are not significantly different at the specified significance level.

`sort` specifies that the reported tables be sorted by the mean or difference that is displayed in the table.

`display_options`: `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `no1stretch`.

- `nofvlabel` displays factor-variable level values rather than attached value labels. This option overrides the `fvlabel` setting; see [R] [set showbaselevels](#).
- `fvwrap(#)` specifies how many lines to allow when long value labels must be wrapped. Labels requiring more than `#` lines are truncated. This option overrides the `fvwrap` setting; see [R] [set showbaselevels](#).
- `fvwrapon(style)` specifies whether value labels that wrap will break at word boundaries or break based on available space.
- `fvwrapon(word)`, the default, specifies that value labels break at word boundaries.
  - `fvwrapon(width)` specifies that value labels break based on available space.
- This option overrides the `fvwrapon` setting; see [R] [set showbaselevels](#).
- `cformat(%fmt)` specifies how to format means, standard errors, and confidence limits in the table of pairwise comparison of means.
- `pformat(%fmt)` specifies how to format  $p$ -values in the table of pairwise comparison of means.
- `sformat(%fmt)` specifies how to format test statistics in the table of pairwise comparison of means.
- `no1stretch` specifies that the width of the table of pairwise comparisons not be automatically widened to accommodate longer variable names. The default, `1stretch`, is to automatically widen the table of pairwise comparisons up to the width of the Results window. Specifying `1stretch` or `no1stretch` overrides the setting given by [set 1stretch](#). If `set 1stretch` has not been set, the default is `1stretch`. `no1stretch` is not shown in the dialog box.

## Remarks and examples

`pwmean` performs pairwise comparisons (differences) of means, assuming a common variance among groups. It can easily adjust the  $p$ -values and confidence intervals for the differences to account for the elevated type I error rate due to multiple comparisons. Adjustments for multiple comparisons can be made using Bonferroni's method, Scheffé's method, Tukey's method, Dunnett's method, and others.

See [R] [margins](#), [pwcompare](#) for performing pairwise comparisons of marginal probabilities and other linear and nonlinear predictions after estimation commands.

Remarks are presented under the following headings:

- Group means*
- Pairwise differences of means*
- Group output*
- Adjusting for multiple comparisons*
  - Tukey's method*
  - Dunnett's method*
- Multiple over() variables*
- Equal variance assumption*

## Group means

Suppose we have data on the wheat yield of fields that were each randomly assigned an application of one of five types of fertilizers. Let's first look at the mean yield for each type of fertilizer.

```
. use https://www.stata-press.com/data/r19/yield
(Artificial wheat yield dataset)
```

```
. pwmean yield, over(fertilizer) cimeans
Pairwise comparisons of means with equal variances
Over: fertilizer
```

| yield      | Mean     | Std. err. | Unadjusted<br>[95% conf. interval] |          |
|------------|----------|-----------|------------------------------------|----------|
| fertilizer |          |           |                                    |          |
| 10-10-10   | 41.36243 | 1.124298  | 39.14509                           | 43.57977 |
| 10-08-22   | 44.98515 | 1.124298  | 42.7678                            | 47.20249 |
| 16-04-08   | 41.85306 | 1.124298  | 39.63571                           | 44.0704  |
| 18-24-06   | 46.28523 | 1.124298  | 44.06789                           | 48.50258 |
| 29-03-04   | 40.1241  | 1.124298  | 37.90676                           | 42.34145 |

### Pairwise differences of means

We can compute all pairwise differences in mean wheat yields for the types of fertilizers.

```
. pwmean yield, over(fertilizer) effects
Pairwise comparisons of means with equal variances
Over: fertilizer
```

| yield                      | Contrast  | Std. err. | Unadjusted<br>t P> t |       | Unadjusted<br>[95% conf. interval] |           |
|----------------------------|-----------|-----------|----------------------|-------|------------------------------------|-----------|
| fertilizer                 |           |           |                      |       |                                    |           |

| 29-03-04<br>vs<br>10-08-22 | -4.861048 | 1.589997  | -3.06                | 0.003 | -7.996847                          | -1.725249 |
| 18-24-06<br>vs<br>16-04-08 | 4.432173  | 1.589997  | 2.79                 | 0.006 | 1.296375                           | 7.567972  |
| 29-03-04<br>vs<br>16-04-08 | -1.728958 | 1.589997  | -1.09                | 0.278 | -4.864757                          | 1.406841  |
| 29-03-04<br>vs<br>18-24-06 | -6.161132 | 1.589997  | -3.87                | 0.000 | -9.29693                           | -3.025333 |

The contrast in the row labeled (10-08-22 vs 10-10-10) is the difference in the mean wheat yield for fertilizer 10-08-22 and fertilizer 10-10-10. At a 5% significance level, we conclude that there is a difference in the means for these two fertilizers. Likewise, the rows labeled (18-24-06 vs 10-10-10), (29-03-04 vs 10-08-22), (18-24-06 vs 16-04-08) and (29-03-04 vs 18-24-06) show differences in these pairs of means. In all, we find that 5 of the 10 mean differences are significantly different from zero at a 5% significance level.

We can specify the sort option to order the differences from smallest to largest in the table.

```
. pwmean yield, over(fertilizer) effects sort
Pairwise comparisons of means with equal variances
Over: fertilizer
```

| yield      | Contrast  | Std. err. | Unadjusted<br>t | P> t  | Unadjusted<br>[95% conf. interval] |           |

Ordering the pairwise differences is particularly convenient when we are comparing means for a large number of groups.

## Group output

We can use the `group` option to see the mean of each group and a visual representation of the tests for differences.

```
. pwmean yield, over(fertilizer) group sort
Pairwise comparisons of means with equal variances
Over: fertilizer
```

| yield      | Mean     | Std. err. | Unadjusted groups |
|------------|----------|-----------|-------------------|
| fertilizer |          |           |                   |
| 29-03-04   | 40.1241  | 1.124298  | A                 |
| 10-10-10   | 41.36243 | 1.124298  | A                 |
| 16-04-08   | 41.85306 | 1.124298  | AB                |
| 10-08-22   | 44.98515 | 1.124298  | BC                |
| 18-24-06   | 46.28523 | 1.124298  | C                 |

Note: Means sharing a letter in the group label are not significantly different at the 5% level.

Fertilizers 29-03-04, 10-10-10, and 16-04-08 are all in group A. This means that at our 5% level of significance, we have insufficient information to distinguish their means. Likewise, fertilizers 16-04-08 and 10-08-22 are in group B and cannot be distinguished at the 5% level. The same is true for fertilizers 10-08-22 and 18-24-06 in group C.

Fertilizer 29-03-04 and fertilizer 10-08-22 have no letters in common, indicating that the mean yields of these two groups are significantly different at the 5% level. We can conclude that any other fertilizers without a letter in common have significantly different means as well.

## Adjusting for multiple comparisons

The statistics in the examples above take no account that we are performing 10 comparisons. With our 5% significance level and assuming the comparisons are independent, we expect 1 in 20 tests of comparisons to be significant, even if all the population means are truly the same. If we are performing many comparisons, then we should account for the fact that some tests will be found significant by chance alone. More formally, the test for each pairwise comparison is made without adjusting for the elevated type I experimentwise error rate that is introduced when performing multiple tests. We can use the `mcompare()` option to adjust the confidence intervals and  $p$ -values for multiple comparisons.

## Tukey's method

Of the available adjustments for multiple comparisons, Tukey's honestly significant difference, Student–Newman–Keuls's method, and Duncan's method are most often used when performing all pairwise comparisons of means. Of these, Tukey's method is the most conservative and Duncan's method is the least conservative. For further discussion of each of the multiple-comparison adjustments, see [R] [pwcompare](#).

Here we use Tukey’s adjustment to compute  $p$ -values and confidence intervals for the pairwise differences.

```
. pwmean yield, over(fertilizer) effects sort mcompare(tukey)
Pairwise comparisons of means with equal variances
Over: fertilizer
```

|            | Number of comparisons |
|------------|-----------------------|
| fertilizer | 10                    |

| 18-24-06   |           |           |            |       |                               |
| vs         |           |           |            |       |                               |
| 10-10-10   | 4.922803  | 1.589997  | 3.10       | 0.019 | .5447922 9.300815             |

When using a 5% significance level, Tukey’s adjustment indicates that four pairs of means are different. With the adjustment, we no longer conclude that the difference in the mean yields for fertilizers 10-08-22 and 10-10-10 is significantly different from zero.

### Dunnett's method

Now, let's suppose that fertilizer 10-10-10 actually represents fields on which no fertilizer was applied. In this case, we can use Dunnett's method for comparing each of the fertilizers with the control.

```
. pwmean yield, over(fertilizer) effects mcompare(dunnett)
Pairwise comparisons of means with equal variances
Over: fertilizer
```

|            | Number of comparisons |
|------------|-----------------------|
| fertilizer | 4                     |

| yield                                                | Contrast  | Std. err. | Dunnett |       | Dunnett              |          |
|------------------------------------------------------|-----------|-----------|---------|-------|----------------------|----------|
|                                                      |           |           | t       | P> t  | [95% conf. interval] |          |
| fertilizer<br>10-08-22<br>vs<br>10-10-10<br>16-04-08 | 3.62272   | 1.589997  | 2.28    | 0.079 | -.2918331            | 7.537273 |
| vs<br>10-10-10<br>18-24-06                           | .4906299  | 1.589997  | 0.31    | 0.994 | -3.423923            | 4.405183 |
| vs<br>10-10-10<br>29-03-04                           | 4.922803  | 1.589997  | 3.10    | 0.008 | 1.00825              | 8.837356 |
| vs<br>10-10-10                                       | -1.238328 | 1.589997  | -0.78   | 0.852 | -5.152881            | 2.676225 |

Using Dunnett's adjustment, we conclude that only fertilizer 4 (18-24-06) produces a mean yield that is significantly different from the mean yield of the field with no fertilizer applied.

By default, pwmean treats the lowest level of the group variable as the control. If, for instance, fertilizer 3 (16-04-08) was our control group, we could type

```
. pwmean yield, over(b3.fertilizer) effects mcompare(dunnett)
```

using the b3. factor-variable operator to specify this level as the reference level.

## Multiple over() variables

When we specify more than one variable in the `over()` option, pairwise comparisons are performed for the means defined by each combination of levels of these variables.

```
. pwmean yield, over(fertilizer irrigation) group
Pairwise comparisons of means with equal variances
Over: fertilizer irrigation
```

| yield                 | Mean     | Std. err. | Unadjusted groups |
|-----------------------|----------|-----------|-------------------|
| fertilizer#irrigation |          |           |                   |
| 10-10-10#0            | 36.91257 | 1.116571  | A                 |
| 10-10-10#1            | 45.81229 | 1.116571  | B                 |
| 10-08-22#0            | 38.79482 | 1.116571  | A C               |
| 10-08-22#1            | 51.17547 | 1.116571  | E                 |
| 16-04-08#0            | 36.34383 | 1.116571  | A                 |
| 16-04-08#1            | 47.36229 | 1.116571  | B                 |
| 18-24-06#0            | 41.81757 | 1.116571  | CD                |
| 18-24-06#1            | 50.7529  | 1.116571  | E                 |
| 29-03-04#0            | 35.69507 | 1.116571  | A                 |
| 29-03-04#1            | 44.55313 | 1.116571  | B D               |

Note: Means sharing a letter in the group label are not significantly different at the 5% level.

Here the row labeled 10-10-10#0 is the mean for the fields treated with fertilizer 10-10-10 and without irrigation. This mean is significantly different from the mean of all fertilizer/irrigation pairings that do not have an A in the “Unadjusted groups” column. These include all pairings where the fields were irrigated as well as the fields treated with fertilizer 18-24-06 but without irrigation.

## Equal variance assumption

`pwmean` performs multiple comparisons assuming that there is a common variance for all groups. In the case of two groups, this is equivalent to performing the familiar two-sample *t* test when equal variances are assumed.

```
. ttest yield, by(irrigation)
Two-sample t test with equal variances
```

| Group    | Obs | Mean      | Std. err. | Std. dev. | [95% conf. interval] |           |
|----------|-----|-----------|-----------|-----------|----------------------|-----------|
| 0        | 100 | 37.91277  | .5300607  | 5.300607  | 36.86102             | 38.96453  |
| 1        | 100 | 47.93122  | .5630353  | 5.630353  | 46.81403             | 49.0484   |
| Combined | 200 | 42.92199  | .5242462  | 7.413961  | 41.8882              | 43.95579  |
| diff     |     | -10.01844 | .7732872  |           | -11.54338            | -8.493509 |

```
diff = mean(0) - mean(1) t = -12.9557
HO: diff = 0 Degrees of freedom = 198
Ha: diff < 0 Ha: diff != 0
Pr(T < t) = 0.0000 Pr(|T| > |t|) = 0.0000 Ha: diff > 0
Pr(T > t) = 1.0000
```

```
. pwmean yield, over(irrigation) effects
Pairwise comparisons of means with equal variances
Over: irrigation
```

| yield                | Contrast | Std. err. | Unadjusted<br>t | P> t  | Unadjusted<br>[95% conf. interval] |          |
|----------------------|----------|-----------|-----------------|-------|------------------------------------|----------|
| irrigation<br>1 vs 0 | 10.01844 | .7732872  | 12.96           | 0.000 | 8.493509                           | 11.54338 |

The signs for the difference, the test statistic, and the confidence intervals are reversed because the difference is taken in the opposite direction. The  $p$ -value from `pwmean` is equivalent to the one for the two-sided test in the `ttest` output.

`pwmean` extends the capabilities of `ttest` to allow for simultaneously comparing all pairs of means and to allow for using one common variance estimate for all the tests instead of computing a separate pooled variance for each pair of means when using multiple `ttest` commands. In addition, `pwmean` allows adjustments for multiple comparisons, many of which rely on an assumption of equal variances among groups.

## Stored results

`pwmean` stores the following in `e()`:

### Scalars

`e(df_r)` variance degrees of freedom  
`e(balanced)` 1 if fully balanced data, 0 otherwise

### Macros

`e(cmd)` `pwmean`  
`e(cmdline)` command as typed  
`e(title)` title in output  
`e(depvar)` name of variable from which the means are computed  
`e(over)` *varlist* from `over()`  
`e(properties)` `b V`

### Matrices

`e(b)` mean estimates  
`e(V)` variance–covariance matrix of the mean estimates  
`e(error)` mean estimability codes;  
     0 means estimable,  
     8 means not estimable  
`e(b_vs)` mean difference estimates  
`e(V_vs)` variance–covariance matrix of the mean difference estimates  
`e(error_vs)` mean difference estimability codes;  
     0 means estimable,  
     8 means not estimable

In addition to the above, the following is stored in `r()`:

#### Scalars

`r(level)` confidence level of confidence intervals

#### Macros

`r(groups#)` group codes for the #th margin in `r(b)`

`r(mcmethod_vs)` *method* from `mcompare()`

`r(mctitle_vs)` title for *method* from `mcompare()`

#### Matrices

`r(table)` matrix containing the coefficients with their standard errors, test statistics, *p*-values, and confidence intervals

`r(table_vs)` matrix containing the margin differences with their standard errors, test statistics, *p*-values, and confidence intervals

`r(k_groups)` number of significance groups for each term

Note that results stored in `r()` are updated when the command is replayed and will be replaced when any `r-class` command is run after the estimation command.

## Methods and formulas

`pwmean` is a convenience command that uses `pwcompare` after fitting a fully factorial linear model. See [Methods and formulas](#) described in [\[R\] pwcompare](#).

## Postestimation commands

The following postestimation commands are available after pwmean:

| Command                | Description                                                                                       |
|------------------------|---------------------------------------------------------------------------------------------------|
| <code>estat vce</code> | variance–covariance matrix of the estimators (VCE)                                                |
| <code>estimates</code> | cataloging estimation results                                                                     |
| <code>etable</code>    | table of estimation results                                                                       |
| <code>lincom</code>    | point estimates, standard errors, testing, and inference for linear combinations of parameters    |
| <code>nlcom</code>     | point estimates, standard errors, testing, and inference for nonlinear combinations of parameters |
| <code>test</code>      | Wald tests of simple and composite linear hypotheses                                              |
| <code>testnl</code>    | Wald tests of nonlinear hypotheses                                                                |

## Remarks and examples

In *Pairwise differences of means* of [R] **pwmean**, we computed all pairwise differences in mean wheat yields for five fertilizers.

```
. use https://www.stata-press.com/data/r19/yield
(Artificial wheat yield dataset)
. pwmean yield, over(fertilizer)
Pairwise comparisons of means with equal variances
Over: fertilizer
```

| yield                | Contrast  | Std. err. | Unadjusted<br>[95% conf. interval] |           |
|----------------------|-----------|-----------|------------------------------------|-----------|
| fertilizer           |           |           |                                    |           |
| 10-08-22 vs 10-10-10 | 3.62272   | 1.589997  | .4869212                           | 6.758518  |
| 16-04-08 vs 10-10-10 | .4906299  | 1.589997  | -2.645169                          | 3.626428  |
| 18-24-06 vs 10-10-10 | 4.922803  | 1.589997  | 1.787005                           | 8.058602  |
| 29-03-04 vs 10-10-10 | -1.238328 | 1.589997  | -4.374127                          | 1.89747   |
| 16-04-08 vs 10-08-22 | -3.13209  | 1.589997  | -6.267889                          | .0037086  |
| 18-24-06 vs 10-08-22 | 1.300083  | 1.589997  | -1.835715                          | 4.435882  |
| 29-03-04 vs 10-08-22 | -4.861048 | 1.589997  | -7.996847                          | -1.725249 |
| 18-24-06 vs 16-04-08 | 4.432173  | 1.589997  | 1.296375                           | 7.567972  |
| 29-03-04 vs 16-04-08 | -1.728958 | 1.589997  | -4.864757                          | 1.406841  |
| 29-03-04 vs 18-24-06 | -6.161132 | 1.589997  | -9.29693                           | -3.025333 |

After `pwmean`, we can use `testnl` to test whether the improvement in mean wheat yield when using fertilizer 18-24-06 instead of fertilizer 29-03-04 is significantly different from 10%.

```
. testnl (_b[4.fertilizer] - _b[5.fertilizer])/_b[5.fertilizer] = 0.1
(1) (_b[4.fertilizer] - _b[5.fertilizer])/_b[5.fertilizer] = 0.1
 chi2(1) = 1.57
 Prob > chi2 = 0.2106
```

The improvement is not significantly different from 10%.

[Description](#)[Remarks and examples](#)[Quick start](#)[Stored results](#)[Menu](#)[Methods and formulas](#)[Syntax](#)[References](#)[Options](#)[Also see](#)

## Description

These commands provide standard quality-control charts. `cchart` draws a  $c$  chart; `pchart`, a  $p$  (fraction-defective) chart; `rchart`, an  $R$  (range or dispersion) chart; `xchart`, an  $\bar{X}$  (control line) chart; and `shewhart`, vertically aligned  $\bar{X}$  and  $R$  charts.

## Quick start

$c$  chart for `dvar` defects per unit identified by `uvar`

```
cchart dvar uvar
```

$p$  chart for `dvar` defective items out of `nvar` items inspected from each unit identified by `uvar`

```
pchart dvar uvar nvar
```

Same as above, but stabilize the  $p$  chart for unequal numbers of items inspected per unit

```
pchart dvar uvar nvar, stabilized
```

$R$  chart for the range of measurements `m1`, `m2`, `m3`, and `m4`

```
rchart m1 m2 m3 m4, connect(1)
```

Same as above, but use known process standard deviation of 0.5 for control limits

```
rchart m1 m2 m3 m4, connect(1) std(.5)
```

$\bar{X}$  chart for measurements `m1`, `m2`, `m3`, and `m4`

```
xchart m1 m2 m3 m4, connect(1)
```

Same as above, but use known process standard deviation of 0.5 and grand mean of 10 for control limits

```
xchart m1 m2 m3 m4, connect(1) std(.5) mean(10)
```

Shewhart chart with vertically aligned  $R$  and  $\bar{X}$  charts

```
shewhart m1 m2 m3 m4, connect(1) std(.5) mean(10)
```

## Menu

### cchart

Statistics > Other > Quality control > C chart

### pchart

Statistics > Other > Quality control > P chart

### rchart

Statistics > Other > Quality control > R chart

### xchart

Statistics > Other > Quality control > X-bar chart

### shewhart

Statistics > Other > Quality control > Vertically aligned X-bar and R chart

## Syntax

Draw a *c* chart

```
cchart defect_var unit_var [, cchart_options]
```

Draw a *p* (fraction-defective) chart

```
pchart reject_var unit_var ssize_var [, pchart_options]
```

Draw an *R* (range or dispersion) chart

```
rchart varlist [if] [in] [, rchart_options]
```

Draw an  $\bar{X}$  (control line) chart

```
xchart varlist [if] [in] [, xchart_options]
```

Draw vertically aligned  $\bar{X}$  and *R* charts

```
shewhart varlist [if] [in] [, shewhart_options]
```

| <i>cchart_options</i>                                                                                 | Description                                                                      |

| <b>Y axis, X axis, Titles, Legend, Overall</b> |                                                      |
| <i>combine_options</i>                         | any options documented in [G-2] <b>graph combine</b> |

collect is allowed with all QC commands; see [U] **11.1.10 Prefix commands**.

## Options

### Main

**stabilized** stabilizes the p chart when sample sizes are unequal.

**std**(#) specifies the standard deviation of the process. The R chart is calculated (based on the range) if this option is not specified.

**mean**(#) specifies the grand mean, which is calculated if not specified.

**lower**(#) and **upper**(#) must be specified together or not at all. They specify the lower and upper limits of the  $\bar{X}$  chart. Calculations based on the mean and standard deviation (whether specified by option or calculated) are used otherwise.

**nograph** suppresses the graph.

**generate**(*newvar<sub>f</sub>* *newvar<sub>lcl</sub>* *newvar<sub>ucl</sub>*) stores the plotted values in the p chart. *newvar<sub>f</sub>* will contain the fractions of defective elements; *newvar<sub>lcl</sub>* and *newvar<sub>ucl</sub>* will contain the lower and upper control limits, respectively.

### Plot

*connect\_options* affect whether lines connect the plotted points and the rendition of those lines; see [G-3] **connect\_options**.

*marker\_options* affect the rendition of markers drawn at the plotted points, including their shape, size, color, and outline; see [G-3] **marker\_options**.

*marker\_label\_options* specify if and how the markers are to be labeled; see [G-3] **marker\_label\_options**.

### Control limits

clopts(*cline\_options*) affects the rendition of the control limits; see [G-3] **cline\_options**.

Add plots

`addplot` (*plot*) provides a way to add other plots to the generated graph. See [G-3] [addplot\\_option](#).

Y axis, X axis, Titles, Legend, Overall

`twoway_options` are any of the options documented in [G-3] [twoway\\_options](#), excluding `by()`. These include options for titling the graph (see [G-3] [title\\_options](#)) and for saving the graph to disk (see [G-3] [saving\\_option](#)).

`combine_options` (`shewhart` only) are any of the options documented in [G-2] [graph\\_combine](#). These include options for titling the graph (see [G-3] [title\\_options](#)) and for saving the graph to disk (see [G-3] [saving\\_option](#)).

## Remarks and examples

Control charts may be used to define the goal of a repetitive process, to control that process, and to determine if the goal has been achieved. Walter A. Shewhart of Bell Telephone Laboratories devised the first control chart in 1924. In 1931, Shewhart published *Economic Control of Quality of Manufactured Product*. According to Burr, “Few fields of knowledge have ever been so completely explored and charted in the first exposition” (1976, 29). Shewhart states that “a phenomenon will be said to be controlled when, through the use of past experience, we can predict, at least within limits, how the phenomenon may be expected to vary in the future. Here it is understood that prediction within limits means that we can state, at least approximately, the probability that the observed phenomenon will fall within given limits” (1931, 6).

For more information on quality-control charts, see Burr (1976), Duncan (1986), Harris (1999), or Ryan (2011).

### ▷ Example 1: `cchart`

`cchart` graphs a `c` chart showing the number of nonconformities in a unit, where `defect_var` records the number of defects in each inspection unit and `unit_var` records the unit number. The unit numbers need not be in order. For instance, consider the following example dataset from Ryan (2011, 186):

```
. use https://www.stata-press.com/data/r19/ncu
. describe
```

```
Contains data from https://www.stata-press.com/data/r19/ncu.dta
Observations: 30
Variables: 2 2 Dec 2024 15:15
```

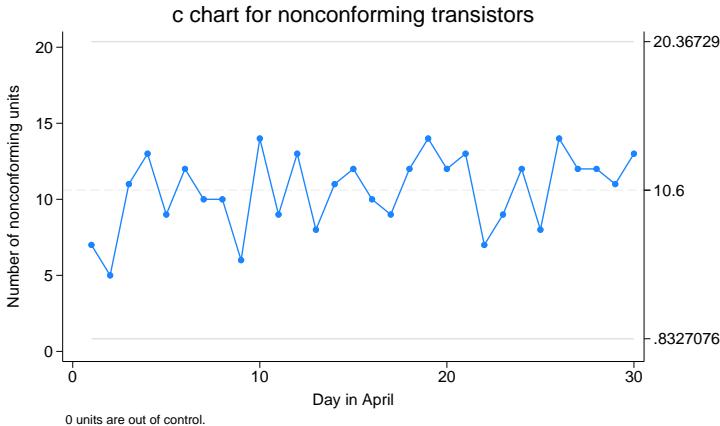

| Variable name | Storage type | Display format | Value label | Variable label                |
|---------------|--------------|----------------|-------------|-------------------------------|
| day           | byte         | %9.0g          |             | Day in April                  |
| defects       | byte         | %9.0g          |             | Number of nonconforming units |

Sorted by:

```
. list in 1/5
```

|    | day | defects |
|----|-----|---------|
| 1. | 1   | 7       |
| 2. | 2   | 5       |
| 3. | 3   | 11      |
| 4. | 4   | 13      |
| 5. | 5   | 9       |

```
. cchart defects day, title(c chart for nonconforming transistors)
```

The expected number of defects is 10.6, with lower and upper control limits of 0.8327 and 20.37, respectively. No units are out of control.

## ▷ Example 2: pchart

pchart graphs a p chart, which shows the fraction of nonconforming items in a subgroup, where *reject\_var* records the number rejected in each inspection unit, *unit\_var* records the inspection unit number, and *ssize\_var* records the number inspected in each unit.

Consider the example dataset from [Ryan \(2011, 186\)](#) of the number of nonconforming transistors out of 1,000 inspected each day during the month of April:

```
. use https://www.stata-press.com/data/r19/ncu2
. describe
```

Contains data from <https://www.stata-press.com/data/r19/ncu2.dta>

```
Observations: 30
Variables: 3 2 Dec 2024 15:16
```

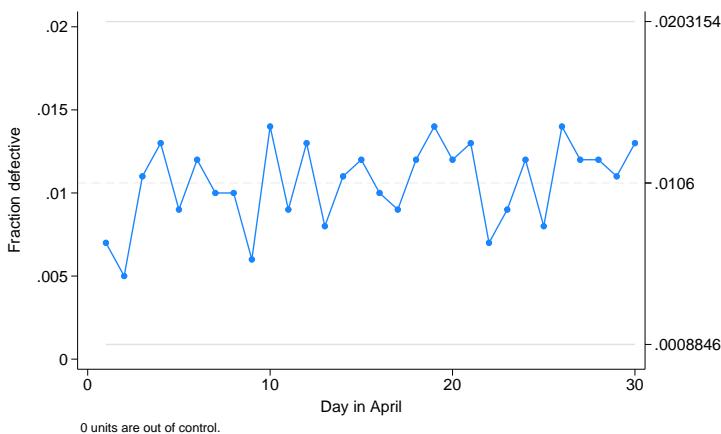

| Variable name | Storage type | Display format | Value label | Variable label                |
|---------------|--------------|----------------|-------------|-------------------------------|
| day           | byte         | %9.0g          |             | Day in April                  |
| rejects       | byte         | %9.0g          |             | Number of nonconforming units |
| ssize         | int          | %9.0g          |             | Sample size                   |

Sorted by:

```
. list in 1/5
```

|    | day | rejects | ssize |
|----|-----|---------|-------|
| 1. | 1   | 7       | 1000  |
| 2. | 2   | 5       | 1000  |
| 3. | 3   | 11      | 1000  |
| 4. | 4   | 13      | 1000  |
| 5. | 5   | 9       | 1000  |

```
. pchart rejects day ssize
```

All the points are within the control limits, which are 0.0009 for the lower limit and 0.0203 for the upper limit.

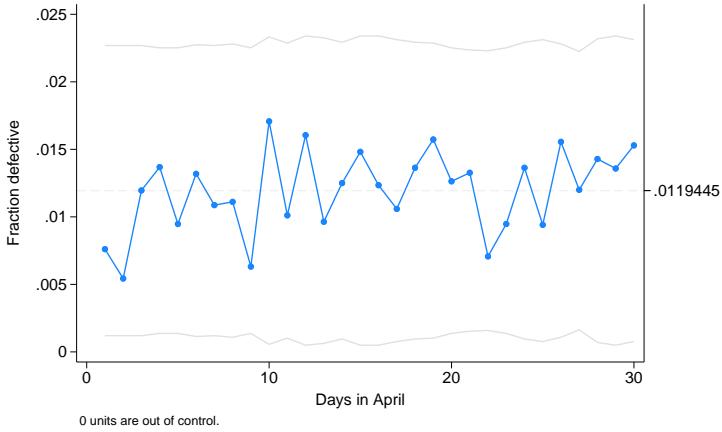

Here the sample sizes are fixed at 1,000, so the `ssize` variable contains 1,000 for each observation. Sample sizes need not be fixed, however. Say that our data were slightly different:

```
. use https://www.stata-press.com/data/r19/ncu3
```

```
. list in 1/5
```

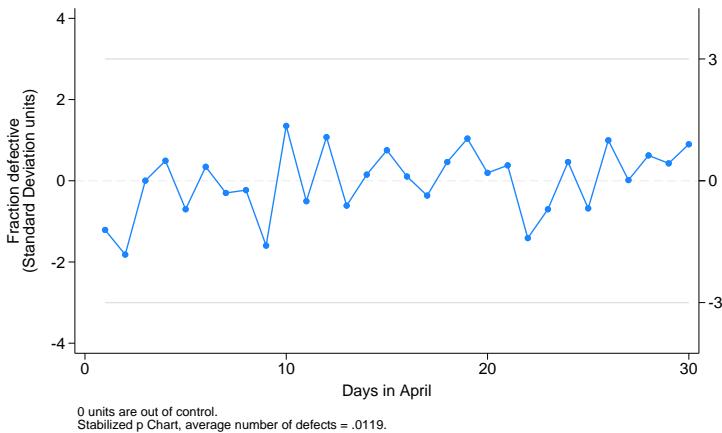

|    | day | rejects | ssize |
|----|-----|---------|-------|
| 1. | 1   | 7       | 920   |
| 2. | 2   | 5       | 920   |
| 3. | 3   | 11      | 920   |
| 4. | 4   | 13      | 950   |
| 5. | 5   | 9       | 950   |

```
. pchart rejects day ssize
```

Here the control limits are, like the sample size, no longer constant. The stabilize option will stabilize the control chart:

```
. pchart rejects day ssize, stabilize
```

### ► Example 3: rchart

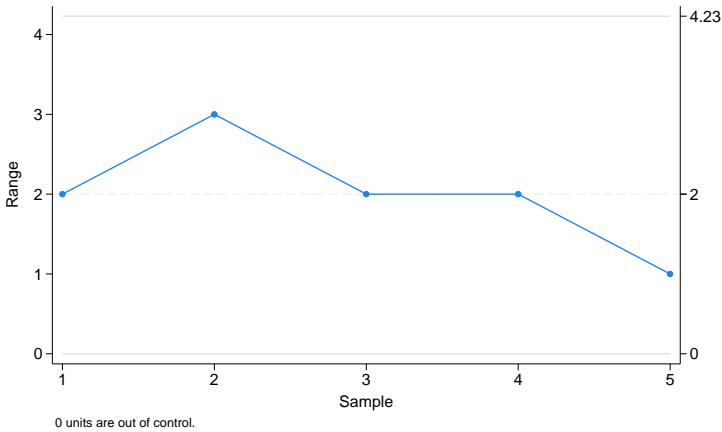

rchart displays an R chart showing the range for repeated measurements at various times. Variables within observations record measurements. Observations represent different samples.

For instance, say that we take five samples of 5 observations each. In our first sample, our measurements are 10, 11, 10, 11, and 12. The data are

```
. list
```

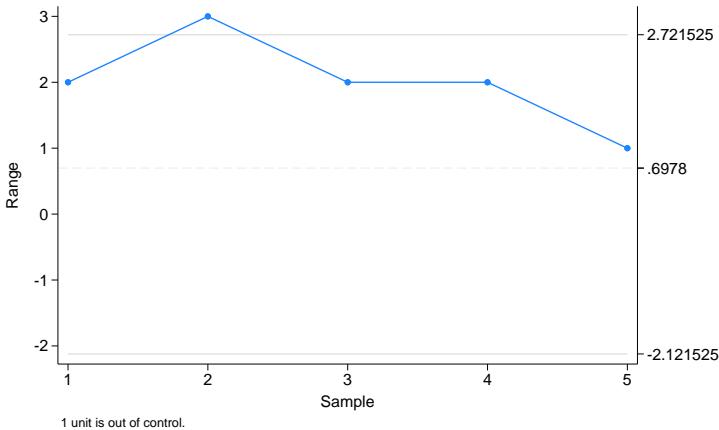

|    | m1 | m2 | m3 | m4 | m5 |
|----|----|----|----|----|----|
| 1. | 10 | 11 | 10 | 11 | 12 |
| 2. | 12 | 10 | 9  | 10 | 9  |
| 3. | 10 | 11 | 10 | 12 | 10 |
| 4. | 9  | 9  | 9  | 10 | 11 |
| 5. | 12 | 12 | 12 | 12 | 13 |

```
. rchart m1-m5, connect(1)
```

The expected range in each sample is 2 with lower and upper control limits of 0 and 4.23, respectively. If we know that the process standard deviation is 0.3, we could specify

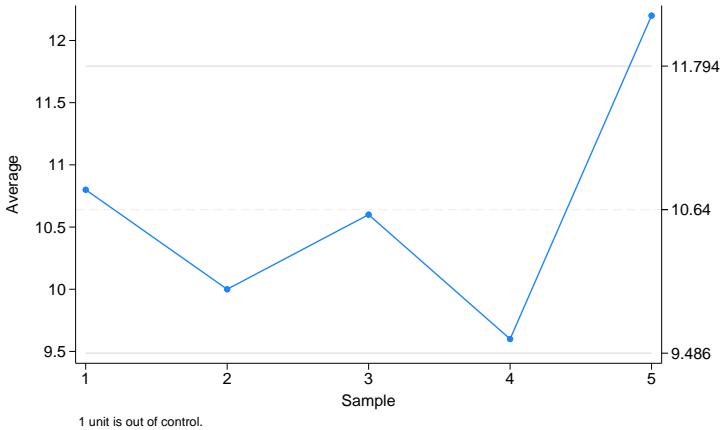

```
. rchart m1-m5, connect(1) std(.3)
```

### ► Example 4: xchart

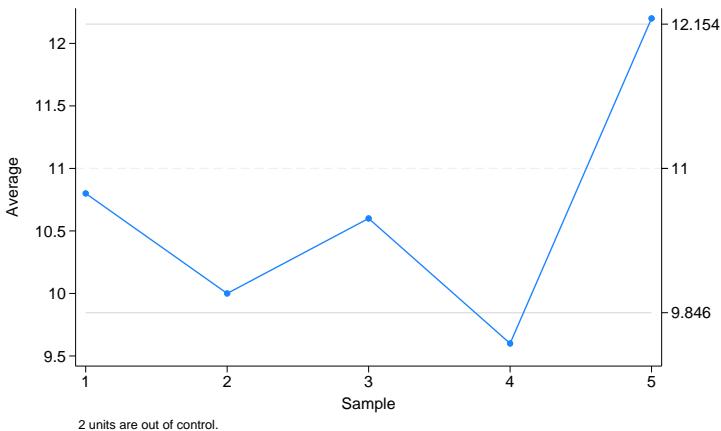

xchart graphs an  $\bar{X}$  chart for repeated measurements at various times. Variables within observations record measurements, and observations represent different samples. Using the same data as in the previous example, we type

```
. xchart m1-m5, connect(1)
```

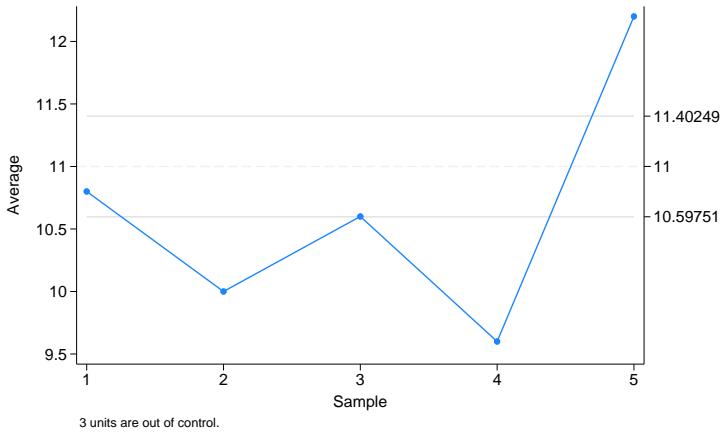

The average measurement in the sample is 10.64, and the lower and upper control limits are 9.486 and 11.794, respectively. Suppose that we knew from prior information that the mean of the process is 11. Then, we would type

```
. xchart m1-m5, connect(1) mean(11)
```

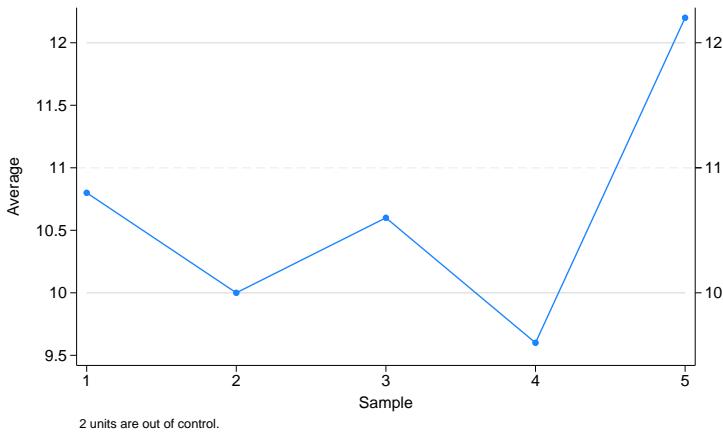

If we also know that the standard deviation of the process is 0.3, we could type

```
. xchart m1-m5, connect(1) mean(11) std(.3)
```

Finally, `xchart` allows us to specify our own control limits:

```
. xchart m1-m5, connect(1) mean(11) lower(10) upper(12)
```

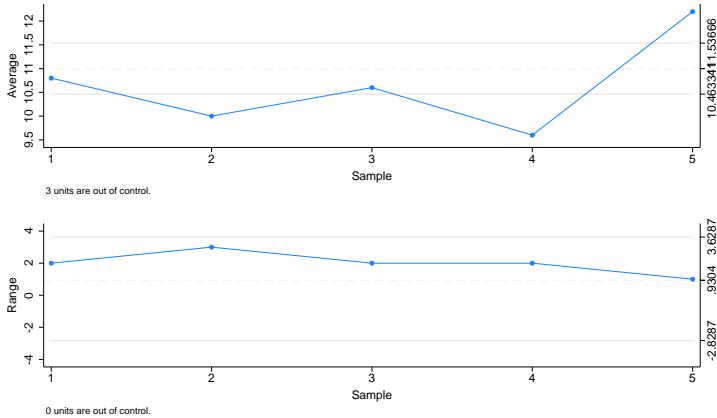

### ► Example 5: shewhart

`shewhart` displays a vertically aligned  $\bar{X}$  and R chart in the same image. To produce the best-looking combined image possible, you will want to use the `xchart` and `rchart` commands separately and then combine the graphs. `shewhart`, however, is more convenient.

Using the same data as previously, but realizing that the standard deviation should have been 0.4, we type

```
. shewhart m1-m5, connect(1) mean(11) std(.4)
```

Walter Andrew Shewhart (1891–1967) was born in Illinois and educated as a physicist, with degrees from the Universities of Illinois and California. After a brief period teaching physics, he worked for the Western Electric Company and (from 1925) the Bell Telephone Laboratories. His name is most associated with control charts used in quality controls, but his many other interests ranged generally from quality assurance to the philosophy of science.

## Stored results

`cchart` stores the following in `r()`:

Scalars

|                         |                                       |
|-------------------------|---------------------------------------|
| <code>r(cbar)</code>    | expected number of nonconformities    |
| <code>r(lcl_c)</code>   | lower control limit                   |
| <code>r(uc1_c)</code>   | upper control limit                   |
| <code>r(N)</code>       | number of observations                |
| <code>r(out_c)</code>   | number of units out of control        |
| <code>r(below_c)</code> | number of units below the lower limit |
| <code>r(above_c)</code> | number of units above the upper limit |

`pchart` stores the following in `r()`:

Scalars

|                         |                                       |
|-------------------------|---------------------------------------|
| <code>r(pbar)</code>    | average fraction of nonconformities   |
| <code>r(lcl_p)</code>   | lower control limit                   |
| <code>r(uc1_p)</code>   | upper control limit                   |
| <code>r(N)</code>       | number of observations                |
| <code>r(out_p)</code>   | number of units out of control        |
| <code>r(below_p)</code> | number of units below the lower limit |
| <code>r(above_p)</code> | number of units above the upper limit |

rchart stores the following in r():

Scalars

|                 |                                       |
|-----------------|---------------------------------------|
| r(central_line) | ordinate of the central line          |
| r(lcl_r)        | lower control limit                   |
| r(ucl_r)        | upper control limit                   |
| r(N)            | number of observations                |
| r(out_r)        | number of units out of control        |
| r(below_r)      | number of units below the lower limit |
| r(above_r)      | number of units above the upper limit |

xchart stores the following in r():

Scalars

|            |                                       |
|------------|---------------------------------------|
| r(xbar)    | grand mean                            |
| r(lcl_x)   | lower control limit                   |
| r(ucl_x)   | upper control limit                   |
| r(N)       | number of observations                |
| r(out_x)   | number of units out of control        |
| r(below_x) | number of units below the lower limit |
| r(above_x) | number of units above the upper limit |

shewhart stores in r() the combination of stored results from xchart and rchart.

## Methods and formulas

For the c chart, the number of defects per unit,  $C$ , is taken to be a value of a random variable having a Poisson distribution. If  $k$  is the number of units available for estimating  $\lambda$ , the parameter of the Poisson distribution, and if  $C_i$  is the number of defects in the  $i$ th unit, then  $\lambda$  is estimated by  $\bar{C} = \sum_i C_i/k$ . Then

$$\begin{aligned}\text{central line} &= \bar{C} \\ \text{UCL} &= \bar{C} + 3\sqrt{\bar{C}} \\ \text{LCL} &= \bar{C} - 3\sqrt{\bar{C}}\end{aligned}$$

Control limits for the p chart are based on the sampling theory for proportions, using the normal approximation to the binomial. If  $k$  samples are taken, the estimator of  $p$  is given by  $\bar{p} = \sum_i \hat{p}_i/k$ , where  $\hat{p}_i = x_i/n_i$ , and  $x_i$  is the number of defects in the  $i$ th sample of size  $n_i$ . The central line and the control limits are given by

$$\begin{aligned}\text{central line} &= \bar{p} \\ \text{UCL} &= \bar{p} + 3\sqrt{\bar{p}(1-\bar{p})/n_i} \\ \text{LCL} &= \bar{p} - 3\sqrt{\bar{p}(1-\bar{p})/n_i}\end{aligned}$$

Control limits for the R chart are based on the distribution of the range of samples of size  $n$  from a normal population. If the standard deviation of the process,  $\sigma$ , is known,

$$\begin{aligned}\text{central line} &= d_2\sigma \\ \text{UCL} &= D_2\sigma \\ \text{LCL} &= D_1\sigma\end{aligned}$$

where  $d_2$ ,  $D_1$ , and  $D_2$  are functions of the number of observations in the sample and are obtained from the table published in Beyer (1976).

When  $\sigma$  is unknown,

$$\begin{aligned}\text{central line} &= \bar{R} \\ \text{UCL} &= (D_2/d_2)\bar{R} \\ \text{LCL} &= (D_1/d_2)\bar{R}\end{aligned}$$

where  $\bar{R} = \sum_i R_i/k$  is the range of the  $k$  sample ranges  $R_i$ .

Control limits for the  $\bar{X}$  chart are given by

$$\begin{aligned}\text{central line} &= \bar{x} \\ \text{UCL} &= \bar{x} + (3/\sqrt{n})\sigma \\ \text{LCL} &= \bar{x} - (3/\sqrt{n})\sigma\end{aligned}$$

if  $\sigma$  is known. If  $\sigma$  is unknown,

$$\begin{aligned}\text{central line} &= \bar{x} \\ \text{UCL} &= \bar{x} + A_2\bar{R} \\ \text{LCL} &= \bar{x} - A_2\bar{R}\end{aligned}$$

where  $\bar{R}$  is the average range as defined above and  $A_2$  is a function (op. cit.) of the number of observations in the sample.

Isobel Loutit (1909–2009) is known for her work during World War II to improve the accuracy of targeting for anti-aircraft guns and as a contributor to the field of quality control. Loutit was born in Selkirk Manitoba, Canada. She graduated from the University of Manitoba in 1929 with a degree in mathematics and was one of the first women to work as a professional statistician in Canada. After graduation, she obtained a job teaching French. However, because of her training, she served as a substitute math teacher when needed.

When World War II started, Loutit took a job as a quality control statistician at Northern Electric. Shortly after that, the Canadian government advertised for women with technical training to fill jobs that had been vacated by men who had gone to war. She took a position testing equipment for the military. This job eventually returned her to Northern Electric, this time as a government employee verifying the accuracy of Northern Electric's Vickers anti-aircraft gun predictor, which was used to aim artillery at incoming planes. Recognizing the quality of her work, the CEO of Northern Electric rehired Loutit as an engineer, the only position for which her pay would not be capped as a woman. She later became the first female manager at Northern Electric and the first woman to chair the Montreal Section of the American Society for Quality Control.

## Description

`qreg` fits quantile (including median) regression models, also known as least absolute value, minimum absolute deviation, or minimum L1-norm value. The quantile regression models fit by `qreg` express the quantiles of the conditional distribution as linear functions of the independent variables.

`iqreg` estimates interquantile range regressions, regressions of the difference in quantiles. The estimated variance–covariance matrix of the estimators (VCE) is obtained via bootstrapping.

`sqreg` estimates simultaneous-quantile regression. It produces the same coefficients as `qreg` for each quantile. Reported standard errors will be similar, but `sqreg` obtains an estimate of the VCE via bootstrapping, and the VCE includes between-quantile blocks. Thus, you can test and construct confidence intervals comparing coefficients describing different quantiles.

`bsqreg` is equivalent to `sqreg` with one quantile.

## Quick start

*Quantile regression*

Median regression of  $y$  on  $x_1$  and  $x_2$

```
qreg y x1 x2
```

Add categorical covariate  $a$  using factor-variable syntax

```
qreg y x1 x2 i.a
```

Same as above, but with standard errors using a biweight kernel for the nonparametric density estimator

```
qreg y x1 x2 i.a, vce(, kernel(biweight))
```

Quantile regression of the 75th percentile of  $y$  on  $x_1$ ,  $x_2$ , and  $a$

```
qreg y x1 x2 i.a, quantile(.75)
```

*Interquantile range regression*

Difference between the 90th and 10th quantiles of  $y$  on  $x_1$ ,  $x_2$ , and  $a$  with bootstrap standard errors

```
iqreg y x1 x2 i.a, quantiles(.1 .9)
```

### *Simultaneous-quantile regression*

Simultaneous estimation of quantile regressions for the 10th and 90th quantiles of  $y$  with bootstrap standard errors

```
sqreg y x1 x2 i.a, quantiles(.1 .9)
```

Same as above, but for the 25th, 50th, and 75th quantiles of  $y$

```
sqreg y x1 x2 i.a, quantiles(.25 .5 .75)
```

Same as above, but increase the number of bootstrap replications to 500

```
sqreg y x1 x2 i.a, quantiles(.25 .5 .75) reps(500)
```

### *Bootstrapped quantile regression*

Single quantile regression for the 25th quantile with bootstrap standard errors

```
bsqreg y x1 x2 i.a, quantile(.25)
```

## Menu

### **qreg**

Statistics > Nonparametric analysis > Quantile regression

### **iqreg**

Statistics > Nonparametric analysis > Interquantile regression

### **sqreg**

Statistics > Nonparametric analysis > Simultaneous-quantile regression

### **bsqreg**

Statistics > Nonparametric analysis > Bootstrapped quantile regression

## Syntax

### Quantile regression

```
qreg depvar [indepvars] [if] [in] [weight] [, qreg_options]
```

### Interquantile range regression

```
iqreg depvar [indepvars] [if] [in] [, iqreg_options]
```

### Simultaneous-quantile regression

```
sqreg depvar [indepvars] [if] [in] [, sqreg_options]
```

### Bootstrapped quantile regression

```
bsqreg depvar [indepvars] [if] [in] [, bsqreg_options]
```

| <i>display_options</i>   | control columns and column formats, row spacing, line width, display of omitted variables and base and empty cells, and factor-variable labeling |

*indepvars* may contain factor variables; see [U] 11.4.3 **Factor variables**.

`by`, `collect`, `mi estimate`, `rolling`, and `statsby`, are allowed by `qreg`, `iqreg`, `sqreg`, and `bsqreg`; `bayes`, `bayesboot`, `mfp`, `nestreg`, and `stepwise` are allowed only with `qreg`; see [U] 11.1.10 **Prefix commands**. For more details, see [BAYES] **bayes: qreg**.

`qreg` allows `fweights`, `iweights`, and `pweights`; see [U] 11.1.6 **weight**.

See [U] 20 **Estimation and postestimation commands** for more capabilities of estimation commands.

## Options for qreg

### Model

`quantile(#)` specifies the quantile to be estimated and should be a number between 0 and 1, exclusive. Numbers larger than 1 are interpreted as percentages. The default value of 0.5 corresponds to the median.

### SE/Robust

`vce([vcetype], [vceopts])` specifies the type of VCE to compute and the density estimation method to use in computing the VCE.

*vcetype* specifies the type of VCE to compute. Available types are `iid` and `robust`.

`vce(iid)`, the default, computes the VCE under the assumption that the residuals are independent and identically distributed (i.i.d.).

`vce(robust)` computes the robust VCE under the assumption that the residual density is continuous and bounded away from 0 and infinity at the specified `quantile()`; see [Koenker \(2005, sec. 4.2\)](#).

*vceopts* consists of available *denmethod* and *bwidth* options.

*denmethod* specifies the method to use for the nonparametric density estimator. Available methods are `fitted`, `residual`, or `kernel` [*kernel*], where the optional *kernel* must be one of the kernel choices listed below.

`fitted` and `residual` specify that the nonparametric density estimator use some of the structure imposed by quantile regression. The default `fitted` uses a function of the fitted values and `residual` uses a function of the residuals. `vce(robust, residual)` is not allowed.

`kernel()` specifies that the nonparametric density estimator use a kernel method. The available kernel functions are `epanechnikov`, `epan2`, `biweight`, `cosine`, `gaussian`, `parzen`, `rectangle`, and `triangle`. The default is `epanechnikov`. See [R] **kdensity** for the kernel function forms.

*bw* specifies the bandwidth method to use by the nonparametric density estimator. Available methods are *hsheather* for the Hall–Sheather bandwidth, *bofinger* for the Bofinger bandwidth, and *chamberlain* for the Chamberlain bandwidth.

See [Koenker \(2005, sec. 3.4 and 4.10\)](#) for a description of the sparsity estimation techniques and the Hall–Sheather and Bofinger bandwidth formulas. See [Chamberlain \(1994, eq. 2.2\)](#) for the Chamberlain bandwidth.

#### Reporting

`level(#)`; see [\[R\] Estimation options](#).

*display\_options*: `nocl`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `no1stretch`; see [\[R\] Estimation options](#).

#### Optimization

*optimization\_options*: `iterate(#)`, `[no]log`, `trace`. `iterate()` specifies the maximum number of iterations; `log/nolog` specifies whether to show the iteration log (see `set iterlog` in [\[R\] set iter](#)); and `trace` specifies that the iteration log should include the current parameter vector. These options are seldom used.

`wlsiter(#)` specifies the number of weighted least-squares iterations that will be attempted before the linear programming iterations are started. The default is `wlsiter(1)`. If there are convergence problems, increasing this number should help.

## Options for iqreg

#### Model

`quantiles(# #)` specifies the quantiles to be compared. The first number must be less than the second, and both should be between 0 and 1, exclusive. Numbers larger than 1 are interpreted as percentages. Not specifying this option is equivalent to specifying `quantiles(.25 .75)`, meaning the interquartile range.

`reps(#)` specifies the number of bootstrap replications to be used to obtain an estimate of the variance–covariance matrix of the estimators (standard errors). `reps(20)` is the default and is arguably too small. `reps(100)` would perform 100 bootstrap replications. `reps(1000)` would perform 1,000 replications.

#### Reporting

`level(#)`; see [\[R\] Estimation options](#).

`nodots` suppresses display of the replication dots.

*display\_options*: `nocl`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `no1stretch`; see [\[R\] Estimation options](#).

## Options for sqreg

### Model

`quantiles(# [# [# . . . ]])` specifies the quantiles to be estimated and should contain numbers between 0 and 1, exclusive. Numbers larger than 1 are interpreted as percentages. The default value of 0.5 corresponds to the median.

`reps(#)` specifies the number of bootstrap replications to be used to obtain an estimate of the variance–covariance matrix of the estimators (standard errors). `reps(20)` is the default and is arguably too small. `reps(100)` would perform 100 bootstrap replications. `reps(1000)` would perform 1,000 replications.

### Reporting

`level(#)`; see [R] [Estimation options](#).

`nodots` suppresses display of the replication dots.

*display\_options*: `nocl`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `no1stretch`; see [R] [Estimation options](#).

## Options for bsqreg

### Model

`quantile(#)` specifies the quantile to be estimated and should be a number between 0 and 1, exclusive. Numbers larger than 1 are interpreted as percentages. The default value of 0.5 corresponds to the median.

`reps(#)` specifies the number of bootstrap replications to be used to obtain an estimate of the variance–covariance matrix of the estimators (standard errors). `reps(20)` is the default and is arguably too small. `reps(100)` would perform 100 bootstrap replications. `reps(1000)` would perform 1,000 replications.

### Reporting

`level(#)`; see [R] [Estimation options](#).

*display\_options*: `nocl`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `no1stretch`; see [R] [Estimation options](#).

## Remarks and examples

Remarks are presented under the following headings:

*Median regression*  
*Quantile regression*  
*Estimated standard errors*  
*Interquantile and simultaneous-quantile regression*  
*What are the parameters?*

### Median regression

qreg fits quantile regression models. The default form is median regression, where the objective is to estimate the median of the dependent variable, conditional on the values of the independent variables. This method is similar to ordinary regression, where the objective is to estimate the conditional mean of the dependent variable. Simply put, median regression finds a line through the data that minimizes the sum of the *absolute* residuals rather than the sum of the *squares* of the residuals, as in ordinary regression. Equivalently, median regression expresses the median of the conditional distribution of the dependent variable as a linear function of the conditioning (independent) variables. Cameron and Trivedi (2022, chap. 15) provide a nice introduction to quantile regression using Stata.

#### ► Example 1: Estimating the conditional median

Consider a two-group experimental design with 5 observations per group:

```
. use https://www.stata-press.com/data/r19/twogrp
. list
```

|     | x | y  |
|-----|---|----|
| 1.  | 0 | 0  |
| 2.  | 0 | 1  |
| 3.  | 0 | 3  |
| 4.  | 0 | 4  |
| 5.  | 0 | 95 |
| 6.  | 1 | 14 |
| 7.  | 1 | 19 |
| 8.  | 1 | 20 |
| 9.  | 1 | 22 |
| 10. | 1 | 23 |

```
. qreg y x
```

```
Iteration 1: WLS sum of weighted deviations = 60.941342
Iteration 1: Sum of abs. weighted deviations = 55.5
Iteration 2: Sum of abs. weighted deviations = 55

Median regression
Raw sum of deviations 78.5 (about 14) Number of obs = 10
Min sum of deviations 55 Pseudo R2 = 0.2994
```

|  | y     | Coefficient | Std. err. | t    | P> t  | [95% conf. interval] |          |
|--|-------|-------------|-----------|------|-------|----------------------|----------|
|  | x     | 17          | 18.23213  | 0.93 | 0.378 | -25.04338            | 59.04338 |
|  | _cons | 3           | 12.89207  | 0.23 | 0.822 | -26.72916            | 32.72916 |

We have estimated the equation

$$y_{\text{median}} = 3 + 17x$$

We look back at our data.  $x$  takes on the values 0 and 1, so the median for the  $x = 0$  group is 3, whereas for  $x = 1$  it is  $3 + 17 = 20$ . The output reports that the raw sum of absolute deviations about 14 is 78.5; that is, the sum of  $|y - 14|$  is 78.5. Fourteen is the unconditional median of  $y$ , although in these data, any value between 14 and 19 could also be considered an unconditional median (we have an even number of observations, so the median is bracketed by those two values). In any case, the raw sum of deviations of  $y$  about the median would be the same no matter what number we choose between 14 and 19. (With a “median” of 14, the raw sum of deviations is 78.5. Now think of choosing a slightly larger number for the median and recalculating the sum. Half the observations will have larger negative residuals, but the other half will have smaller positive residuals, resulting in no net change.)

We turn now to the actual estimated equation. The sum of the absolute deviations about the solution  $y_{\text{median}} = 3 + 17x$  is 55. The pseudo- $R^2$  is calculated as  $1 - 55/78.5 \approx 0.2994$ . This result is based on the idea that the median regression is the maximum likelihood estimate for the double-exponential distribution.

◀

## □ Technical note

`qreg` is an alternative to regular regression or robust regression—see [R] [regress](#) and [R] [rreg](#). Let’s compare the results:

```
. regress y x
```

| Source   | SS     | df | MS         | Number of obs | = | 10      |
|----------|--------|----|------------|---------------|---|---------|
| Model    | 2.5    | 1  | 2.5        | F(1, 8)       | = | 0.00    |
| Residual | 6978.4 | 8  | 872.3      | Prob > F      | = | 0.9586  |
|          |        |    |            | R-squared     | = | 0.0004  |
|          |        |    |            | Adj R-squared | = | -0.1246 |
| Total    | 6980.9 | 9  | 775.655556 | Root MSE      | = | 29.535  |

| y     | Coefficient | Std. err. | t     | P> t  | [95% conf. interval] |          |
|-------|-------------|-----------|-------|-------|----------------------|----------|
| x     | -1          | 18.6794   | -0.05 | 0.959 | -44.07477            | 42.07477 |
| _cons | 20.6        | 13.20833  | 1.56  | 0.157 | -9.858465            | 51.05847 |

Unlike `qreg`, `regress` fits ordinary linear regression and is concerned with predicting the mean rather than the median, so both results are, in a technical sense, correct. Putting aside those technicalities, however, we tend to use either regression to describe the central tendency of the data, of which the mean is one measure and the median another. Thus, we can ask, “which method better describes the central tendency of these data?”

Means—and therefore ordinary linear regression—are sensitive to outliers, and our data were purposely designed to contain two such outliers: 95 for  $x = 0$  and 14 for  $x = 1$ . These two outliers dominated the ordinary regression and produced results that do not reflect the central tendency well—you are invited to enter the data and graph  $y$  against  $x$ .

Robust regression attempts to correct the outlier-sensitivity deficiency in ordinary regression:

```
. rreg y x, genwt(wt)
 Huber iteration 1: Maximum difference in weights = .7311828
 Huber iteration 2: Maximum difference in weights = .17695779
 Huber iteration 3: Maximum difference in weights = .03149585
 Biweight iteration 4: Maximum difference in weights = .1979335
 Biweight iteration 5: Maximum difference in weights = .23332905
 Biweight iteration 6: Maximum difference in weights = .09960067
 Biweight iteration 7: Maximum difference in weights = .02691458
 Biweight iteration 8: Maximum difference in weights = .0009113
 Robust regression
 Number of obs = 10
 F(1, 8) = 80.63
 Prob > F = 0.0000
```

|  | y     | Coefficient | Std. err. | t    | P> t  | [95% conf. interval] |          |
|--|-------|-------------|-----------|------|-------|----------------------|----------|
|  | x     | 18.16597    | 2.023114  | 8.98 | 0.000 | 13.50066             | 22.83128 |
|  | _cons | 2.000003    | 1.430558  | 1.40 | 0.200 | -1.298869            | 5.298875 |

Here `rreg` discarded the first outlier completely. (We know this because we included the `genwt()` option on `rreg` and, after fitting the robust regression, examined the weights.) For the other “outlier”, `rreg` produced a weight of 0.47.

In any case, the answers produced by `qreg` and `rreg` to describe the central tendency are similar, but the standard errors are different. In general, robust regression will have smaller standard errors because it is not as sensitive to the exact placement of observations near the median. You are welcome to try removing the first outlier in the `qreg` estimation to observe an improvement in the standard errors by typing

```
. qreg y x if _n!=5
```

Also, some authors ([Rousseeuw and Leroy 1987](#), 11) have noted that quantile regression, unlike the unconditional median, may be sensitive to even one outlier if its leverage is high enough. [Rousseeuw and Leroy \(1987\)](#) discuss estimators that are more robust to perturbations to the data than either mean regression or quantile regression.

In the end, quantile regression may be more useful for the interpretation of the parameters that it estimates than for its robustness to perturbations to the data.

□

## ► Example 2: Median regression

Let's now consider a less artificial example using the automobile data described in [\[U\] 1.2.2 Example datasets](#). Using median regression, we will regress each car's price on its weight and length and whether it is of foreign manufacture:

```
. use https://www.stata-press.com/data/r19/auto, clear
(1978 automobile data)

. qreg price weight length foreign

Iteration 1: WLS sum of weighted deviations = 56397.829
Iteration 1: Sum of abs. weighted deviations = 55950.5
Iteration 2: Sum of abs. weighted deviations = 55264.718
Iteration 3: Sum of abs. weighted deviations = 54762.283
Iteration 4: Sum of abs. weighted deviations = 54734.152
Iteration 5: Sum of abs. weighted deviations = 54552.638
note: alternate solutions exist.
Iteration 6: Sum of abs. weighted deviations = 54465.511
Iteration 7: Sum of abs. weighted deviations = 54443.699
Iteration 8: Sum of abs. weighted deviations = 54411.294

Median regression Number of obs = 74
Raw sum of deviations 71102.5 (about 4934)
Min sum of deviations 54411.29 Pseudo R2 = 0.2347
```

| price   | Coefficient | Std. err. | t     | P> t  | [95% conf. interval] |          |
|---------|-------------|-----------|-------|-------|----------------------|----------|
| weight  | 3.933588    | 1.328718  | 2.96  | 0.004 | 1.283543             | 6.583632 |
| length  | -41.25191   | 45.46469  | -0.91 | 0.367 | -131.9284            | 49.42456 |
| foreign | 3377.771    | 885.4198  | 3.81  | 0.000 | 1611.857             | 5143.685 |
| _cons   | 344.6489    | 5182.394  | 0.07  | 0.947 | -9991.31             | 10680.61 |

The estimated equation is

$$\text{price}_{\text{median}} = 3.93 \text{ weight} - 41.25 \text{ length} + 3377.8 \text{ foreign} + 344.65$$

The output may be interpreted in the same way as linear regression output; see [\[R\] regress](#). The variables `weight` and `foreign` are significant, but `length` is not significant. The median price of the cars in these data is \$4,934. This value is a median (one of the two center observations), not *the* median, which would typically be defined as the midpoint of the two center observations.

◀

## Quantile regression

Quantile regression is similar to median regression in that it estimates an equation expressing a quantile of the conditional distribution, albeit one that generally differs from the 0.5 quantile that is the median. For example, specifying `quantile(.25)` estimates the parameters that describe the 25th percentile (first quartile) of the conditional distribution.

Quantile regression allows for effects of the independent variables to differ over the quantiles. For example, [Chamberlain \(1994\)](#) finds that union membership has a larger effect on the lower quantiles than on the higher quantiles of the conditional distribution of US wages. That the effects of the independent variables may vary over quantiles of the conditional distribution is an important advantage of quantile regression over mean regression.

## ► Example 3: Estimating quantiles other than the median

Returning to real data, the equation for the 25th percentile of price conditional on weight, length, and foreign in our automobile data is

```
. use https://www.stata-press.com/data/r19/auto
(1978 automobile data)

. qreg price weight length foreign, quantile(.25)

Iteration 1: WLS sum of weighted deviations = 49469.235
Iteration 1: Sum of abs. weighted deviations = 49728.883
Iteration 2: Sum of abs. weighted deviations = 45669.89
Iteration 3: Sum of abs. weighted deviations = 43416.646
Iteration 4: Sum of abs. weighted deviations = 41947.221
Iteration 5: Sum of abs. weighted deviations = 41093.025
Iteration 6: Sum of abs. weighted deviations = 37623.424
Iteration 7: Sum of abs. weighted deviations = 35721.453
Iteration 8: Sum of abs. weighted deviations = 35226.308
Iteration 9: Sum of abs. weighted deviations = 34823.319
Iteration 10: Sum of abs. weighted deviations = 34801.777

.25 Quantile regression Number of obs = 74
Raw sum of deviations 41912.75 (about 4187)
Min sum of deviations 34801.78 Pseudo R2 = 0.1697
```

| price   | Coefficient | Std. err. | t     | P> t  | [95% conf. interval] |          |
|---------|-------------|-----------|-------|-------|----------------------|----------|
| weight  | 1.831789    | .6328903  | 2.89  | 0.005 | .5695289             | 3.094049 |
| length  | 2.84556     | 21.65558  | 0.13  | 0.896 | -40.34514            | 46.03626 |
| foreign | 2209.925    | 421.7401  | 5.24  | 0.000 | 1368.791             | 3051.059 |
| _cons   | -1879.775   | 2468.46   | -0.76 | 0.449 | -6802.963            | 3043.413 |

Compared with our previous median regression, the coefficient on length now has a positive sign, and the coefficients on foreign and weight are reduced. The actual lower quartile is \$4,187, substantially less than the median \$4,934.

We can also estimate the upper quartile as a function of the same three variables:

```
. qreg price weight length foreign, quantile(.75)

Iteration 1: WLS sum of weighted deviations = 55465.741
Iteration 1: Sum of abs. weighted deviations = 55652.957
Iteration 2: Sum of abs. weighted deviations = 52994.785
Iteration 3: Sum of abs. weighted deviations = 50189.446
Iteration 4: Sum of abs. weighted deviations = 49898.245
Iteration 5: Sum of abs. weighted deviations = 49398.106
Iteration 6: Sum of abs. weighted deviations = 49241.835
Iteration 7: Sum of abs. weighted deviations = 49197.967

.75 Quantile regression Number of obs = 74
Raw sum of deviations 79860.75 (about 6342)
Min sum of deviations 49197.97 Pseudo R2 = 0.3840
```

| price   | Coefficient | Std. err. | t     | P> t  | [95% conf. interval] |           |
|---------|-------------|-----------|-------|-------|----------------------|-----------|
| weight  | 9.22291     | 1.785767  | 5.16  | 0.000 | 5.66131              | 12.78451  |
| length  | -220.7833   | 61.10352  | -3.61 | 0.001 | -342.6504            | -98.91616 |
| foreign | 3595.133    | 1189.984  | 3.02  | 0.004 | 1221.785             | 5968.482  |
| _cons   | 20242.9     | 6965.02   | 2.91  | 0.005 | 6351.61              | 34134.2   |

This result tells a different story: `weight` is much more important, and `length` is now significant—with a negative coefficient! The prices of high-priced cars seem to be determined by factors different from those affecting the prices of low-priced cars.

◀

## □ Technical note

One explanation for having substantially different regression functions for different quantiles is that the data are heteroskedastic, as we will demonstrate below. The following statements create a sharply heteroskedastic set of data:

```
. drop _all
. set obs 10000
Number of observations (_N) was 0, now 10,000.
. set seed 50550
. generate x = .1 + .9 * runiform()
. generate y = x * runiform()^2
```

Let's now fit the regressions for the 5th and 95th quantiles:

```
. qreg y x, quantile(.05)
Iteration 1: WLS sum of weighted deviations = 555.44181
Iteration 1: Sum of abs. weighted deviations = 555.25622
Iteration 2: Sum of abs. weighted deviations = 115.02628
Iteration 3: Sum of abs. weighted deviations = 89.617883
Iteration 4: Sum of abs. weighted deviations = 89.61679

.05 Quantile regression Number of obs = 10,000
Raw sum of deviations 89.68001 (about .00105493)
Min sum of deviations 89.61679 Pseudo R2 = 0.0007
```

|  | y     | Coefficient | Std. err. | t     | P> t  | [95% conf. interval] |
|--|-------|-------------|-----------|-------|-------|----------------------|
|  | x     | .0028667    | .0004395  | 6.52  | 0.000 | .0020052 .0037283    |
|  | _cons | -.0001135   | .0002661  | -0.43 | 0.670 | -.0006352 .0004081   |

```
. qreg y x, quantile(.95)
Iteration 1: WLS sum of weighted deviations = 624.91903
Iteration 1: Sum of abs. weighted deviations = 621.88928
Iteration 2: Sum of abs. weighted deviations = 182.03243
Iteration 3: Sum of abs. weighted deviations = 170.42588
Iteration 4: Sum of abs. weighted deviations = 169.05915
Iteration 5: Sum of abs. weighted deviations = 169.05911

.95 Quantile regression Number of obs = 10,000
Raw sum of deviations 275.9779 (about .60579139)
Min sum of deviations 169.0591 Pseudo R2 = 0.3874
```

|  | y     | Coefficient | Std. err. | t      | P> t  | [95% conf. interval] |
|--|-------|-------------|-----------|--------|-------|----------------------|
|  | x     | .9010814    | .008758   | 102.89 | 0.000 | .883914 .9182488     |
|  | _cons | -.0004053   | .0053028  | -0.08  | 0.939 | -.0107999 .0099893   |

The coefficient on `x`, in particular, differs markedly between the two estimates. For the mathematically inclined, it is not too difficult to show that the theoretical lines are  $y = 0.0025x$  for the 5th percentile and  $y = 0.9025x$  for the 95th, numbers in close agreement with our numerical results.

The estimator for the standard errors computed by `qreg` assumes that the sample is independent and identically distributed (i.i.d.); see *Estimated standard errors* and *Methods and formulas* for details. Because the data are conditionally heteroskedastic, we should have used `bsqreg` to consistently estimate the standard errors using a bootstrap method. □

## Estimated standard errors

The variance–covariance matrix of the estimator (VCE) depends on the reciprocal of the density of the dependent variable evaluated at the quantile of interest. This function, known as the “sparsity function”, is hard to estimate.

The default method, which uses the fitted values for the predicted quantiles, generally performs well, but other methods may be preferred in larger samples. The `vce()` suboptions *denmethod* and *bwidth* provide other estimators of the sparsity function, the details of which are described in *Methods and formulas*.

For models with heteroskedastic errors, option `vce(robust)` computes a [Huber \(1967\)](#) form of sandwich estimate ([Koenker 2005](#)). Alternatively, [Gould \(1992, 1997b\)](#) introduced generalized versions of `qreg` that obtain estimates of the standard errors by using bootstrap resampling (see [Efron and Tibshirani \[1993\]](#) or [Wu \[1986\]](#) for an introduction to bootstrap standard errors). The `iqreg`, `sqreg`, and `bsqreg` commands provide a bootstrapped estimate of the entire variance–covariance matrix of the estimators.

### ▷ Example 4: Obtaining robust standard errors

[Example 2](#) of `qreg` on real data above was a median regression of price on weight, length, and foreign using `auto.dta`. Suppose, after investigation, we are convinced that car price observations are not independent. We decide that standard errors robust to non-i.i.d. errors would be appropriate and use the option `vce(robust)`.

```
. use https://www.stata-press.com/data/r19/auto, clear
(1978 automobile data)

. qreg price weight length foreign, vce(robust)
Iteration 1: WLS sum of weighted deviations = 56397.829
Iteration 1: Sum of abs. weighted deviations = 55950.5
Iteration 2: Sum of abs. weighted deviations = 55264.718
Iteration 3: Sum of abs. weighted deviations = 54762.283
Iteration 4: Sum of abs. weighted deviations = 54734.152
Iteration 5: Sum of abs. weighted deviations = 54552.638
note: alternate solutions exist.
Iteration 6: Sum of abs. weighted deviations = 54465.511
Iteration 7: Sum of abs. weighted deviations = 54443.699
Iteration 8: Sum of abs. weighted deviations = 54411.294

Median regression Number of obs = 74
 Raw sum of deviations 71102.5 (about 4934)
 Min sum of deviations 54411.29 Pseudo R2 = 0.2347
```

| price   | Robust      |           | t     | P> t  | [95% conf. interval] |          |
|---------|-------------|-----------|-------|-------|----------------------|----------|
|         | Coefficient | std. err. |       |       |                      |          |
| weight  | 3.933588    | 1.694477  | 2.32  | 0.023 | .55406               | 7.313116 |
| length  | -41.25191   | 51.73571  | -0.80 | 0.428 | -144.4355            | 61.93171 |
| foreign | 3377.771    | 728.5115  | 4.64  | 0.000 | 1924.801             | 4830.741 |
| _cons   | 344.6489    | 5096.528  | 0.07  | 0.946 | -9820.055            | 10509.35 |

We see that the robust standard error for `weight` increases, making it less significant in modifying the median automobile price. The standard error for `length` also increases, but the standard error for the `foreign` indicator decreases.

For comparison, we repeat the estimation using bootstrap standard errors:

```
. use https://www.stata-press.com/data/r19/auto, clear
(1978 automobile data)
. set seed 1001
. bsqreg price weight length foreign
(fitting base model)
Bootstrap replications (20):10.....20 done
Median regression, bootstrap(20) SEs Number of obs = 74
Raw sum of deviations 71102.5 (about 4934)
Min sum of deviations 54411.29 Pseudo R2 = 0.2347
```

| price   | Coefficient | Std. err. | t     | P> t  | [95% conf. interval] |          |
|---------|-------------|-----------|-------|-------|----------------------|----------|
| weight  | 3.933588    | 2.941839  | 1.34  | 0.186 | -1.933726            | 9.800901 |
| length  | -41.25191   | 73.47105  | -0.56 | 0.576 | -187.7853            | 105.2815 |
| foreign | 3377.771    | 1352.518  | 2.50  | 0.015 | 680.2582             | 6075.284 |
| _cons   | 344.6489    | 5927.045  | 0.06  | 0.954 | -11476.47            | 12165.77 |

The coefficient estimates are the same—indeed, they are obtained using the same technique. Only the standard errors differ. Therefore, the  $t$  statistics, significance levels, and confidence intervals also differ.

Because `bsqreg` (as well as `sqreg` and `iqreg`) obtains standard errors by randomly resampling the data, the standard errors it produces will not be the same from run to run unless we first set the random-number seed to the same number; see [R] [set seed](#).

By default, `bsqreg`, `sqreg`, and `iqreg` use 20 replications. We can control the number of replications by specifying the `reps()` option:

```
. bsqreg price weight length i.foreign, reps(1000)
(fitting base model)

Bootstrap replications (1,000):10.....20.....30.....40...
>50.....60.....70.....80.....90.....100.....110...
>120.....130.....140.....150.....160.....170.....
> ...180.....190.....200.....210.....220.....230.....24
> 0.....250.....260.....270.....280.....290.....300.....
>310.....320.....330.....340.....350.....360.....
> 370.....380.....390.....400.....410.....420.....430...
>440.....450.....460.....470.....480.....490.....
> ..500.....510.....520.....530.....540.....550.....560
>570.....580.....590.....600.....610.....620.....
> ...630.....640.....650.....660.....670.....680.....6
> 90.....700.....710.....720.....730.....740.....750...
>760.....770.....780.....790.....800.....810.....
> .820.....830.....840.....850.....860.....870.....880...
>890.....900.....910.....920.....930.....940.....
> ...950.....960.....970.....980.....990.....1,000 done

Median regression, bootstrap(1000) SEs Number of obs = 74
Raw sum of deviations 71102.5 (about 4934)
Min sum of deviations 54411.29 Pseudo R2 = 0.2347
```

| price   | Coefficient | Std. err. | t     | P> t  | [95% conf. interval] |          |
|---------|-------------|-----------|-------|-------|----------------------|----------|
| weight  | 3.933588    | 2.58771   | 1.52  | 0.133 | -1.227437            | 9.094613 |
| length  | -41.25191   | 68.02626  | -0.61 | 0.546 | -176.926             | 94.42219 |
| foreign |             |           |       |       |                      |          |
| Foreign | 3377.771    | 1070.777  | 3.15  | 0.002 | 1242.174             | 5513.368 |
| _cons   | 344.6489    | 5862.991  | 0.06  | 0.953 | -11348.72            | 12038.02 |

A comparison of the standard errors is informative.

| Variable  | qreg  | qreg<br>vce(robust) | bsqreg<br>reps(20) | bsqreg<br>reps(1000) |
|-----------|-------|---------------------|--------------------|----------------------|
| weight    | 1.329 | 1.694               | 2.942              | 2.588                |
| length    | 45.46 | 51.74               | 73.47              | 68.03                |
| 1.foreign | 885.4 | 728.5               | 1353.              | 1071.                |
| _cons     | 5182. | 5097.               | 5927.              | 5863.                |

The results shown above are typical for models with heteroskedastic errors. (Our dependent variable is `price`; if our model had been in terms of `ln(price)`, the standard errors estimated by `qreg` and `bsqreg` would have been nearly identical.) Also, even for heteroskedastic errors, 20 replications is generally sufficient for hypothesis tests against 0.

## Interquantile and simultaneous-quantile regression

Consider a quantile regression model where the  $q$ th quantile is given by

$$Q_q(y) = a_q + b_{q,1}x_1 + b_{q,2}x_2$$

For instance, the 75th and 25th quantiles are given by

$$Q_{0.75}(y) = a_{0.75} + b_{0.75,1}x_1 + b_{0.75,2}x_2$$

$$Q_{0.25}(y) = a_{0.25} + b_{0.25,1}x_1 + b_{0.25,2}x_2$$

The difference in the quantiles is then

$$Q_{0.75}(y) - Q_{0.25}(y) = (a_{0.75} - a_{0.25}) + (b_{0.75,1} - b_{0.25,1})x_1 + (b_{0.75,2} - b_{0.25,2})x_2$$

`qreg` fits models such as  $Q_{0.75}(y)$  and  $Q_{0.25}(y)$ . `iqreg` fits interquantile models, such as  $Q_{0.75}(y) - Q_{0.25}(y)$ . The relationships of the coefficients estimated by `qreg` and `iqreg` are exactly as shown: `iqreg` reports coefficients that are the difference in coefficients of two `qreg` models, and, of course, `iqreg` reports the appropriate standard errors, which it obtains by bootstrapping.

`sqreg` is like `qreg` in that it estimates the equations for the quantiles

$$Q_{0.75}(y) = a_{0.75} + b_{0.75,1}x_1 + b_{0.75,2}x_2$$

$$Q_{0.25}(y) = a_{0.25} + b_{0.25,1}x_1 + b_{0.25,2}x_2$$

The coefficients it obtains are the same that would be obtained by estimating each equation separately using `qreg`. `sqreg` differs from `qreg` in that it estimates the equations simultaneously and obtains an estimate of the entire variance–covariance matrix of the estimators by bootstrapping. Thus, you can perform hypothesis tests concerning coefficients both within and across equations.

For example, to fit the above model, you could type

```
. qreg y x1 x2, quantile(.25)
. qreg y x1 x2, quantile(.75)
```

By doing this, you would obtain estimates of the parameters, but you could not test whether  $b_{0.25,1} = b_{0.75,1}$  or, equivalently,  $b_{0.75,1} - b_{0.25,1} = 0$ . If your interest really is in the difference of coefficients, you could type

```
. iqreg y x1 x2, quantiles(.25 .75)
```

The “coefficients” reported would be the difference in quantile coefficients. You could also estimate both quantiles simultaneously and then test the equality of the coefficients:

```
. sqreg y x1 x2, quantiles(.25 .75)
. test [q25]x1 = [q75]x1
```

Whether you use `iqreg` or `sqreg` makes no difference for this test. `sqreg`, however, because it estimates the quantiles simultaneously, allows you to test other hypotheses. `iqreg`, by focusing on quantile differences, presents results in a way that is easier to read.

Finally, `sqreg` can estimate quantiles singly,

```
. sqreg y x1 x2, quantiles(.5)
```

and can thereby be used as a substitute for the slower `bsqreg`. (Gould [1997b] presents timings demonstrating that `sqreg` is faster than `bsqreg`.) `sqreg` can also estimate more than two quantiles simultaneously:

```
. sqreg y x1 x2, quantiles(.25 .5 .75)
```

### ► Example 5: Simultaneous quantile estimation

In demonstrating `qreg`, we performed quantile regressions using `auto.dta`. We discovered that the regression of `price` on `weight`, `length`, and `foreign` produced vastly different coefficients for the 0.25, 0.5, and 0.75 quantile regressions. Here are the coefficients that we obtained:

| Variable             | 25th percentile | 50th percentile | 75th percentile |
|----------------------|-----------------|-----------------|-----------------|
| <code>weight</code>  | 1.83            | 3.93            | 9.22            |
| <code>length</code>  | 2.85            | -41.25          | -220.8          |
| <code>foreign</code> | 2209.9          | 3377.8          | 3595.1          |
| <code>_cons</code>   | -1879.8         | 344.6           | 20242.9         |

All we can say, having estimated these equations separately, is that `price` seems to depend differently on the `weight`, `length`, and `foreign` variables depending on the portion of the `price` distribution we examine. We cannot be more precise because the estimates have been made separately. With `sqreg`, however, we can estimate all the effects simultaneously:

```
. use https://www.stata-press.com/data/r19/auto, clear
(1978 automobile data)
. set seed 1001
. sqreg price weight length foreign, q(.25 .5 .75) reps(100)
(fitting base model)
Bootstrap replications (100):10.....20.....30.....40.....
>50.....60.....70.....80.....90.....100 done
Simultaneous quantile regression Number of obs = 74
 bootstrap(100) SEs .25 Pseudo R2 = 0.1697
 .50 Pseudo R2 = 0.2347
 .75 Pseudo R2 = 0.3840
```

|     | price                | Coefficient | Bootstrap<br>std. err. | t     | P> t  | [95% conf. interval] |           |
|-----|----------------------|-------------|------------------------|-------|-------|----------------------|-----------|
| q25 | <code>weight</code>  | 1.831789    | 1.206151               | 1.52  | 0.133 | - .573803            | 4.237381  |
|     | <code>length</code>  | 2.84556     | 26.775                 | 0.11  | 0.916 | -50.55549            | 56.24661  |
|     | <code>foreign</code> | 2209.925    | 946.9585               | 2.33  | 0.022 | 321.2762             | 4098.575  |
|     | <code>_cons</code>   | -1879.775   | 3243.182               | -0.58 | 0.564 | -8348.097            | 4588.548  |
| q50 | <code>weight</code>  | 3.933588    | 2.34028                | 1.68  | 0.097 | - .7339531           | 8.601129  |
|     | <code>length</code>  | -41.25191   | 59.58361               | -0.69 | 0.491 | -160.0877            | 77.58386  |
|     | <code>foreign</code> | 3377.771    | 1081.475               | 3.12  | 0.003 | 1220.836             | 5534.706  |
|     | <code>_cons</code>   | 344.6489    | 5062.804               | 0.07  | 0.946 | -9752.795            | 10442.09  |
| q75 | <code>weight</code>  | 9.22291     | 2.631084               | 3.51  | 0.001 | 3.975378             | 14.47044  |
|     | <code>length</code>  | -220.7833   | 89.54754               | -2.47 | 0.016 | -399.3802            | -42.18635 |
|     | <code>foreign</code> | 3595.133    | 1208.769               | 2.97  | 0.004 | 1184.319             | 6005.947  |
|     | <code>_cons</code>   | 20242.9     | 9682.24                | 2.09  | 0.040 | 932.2846             | 39553.52  |

The coefficient estimates above are the same as those previously estimated, although the standard error estimates are a little different. `sqreg` obtains estimates of variance by bootstrapping. The important thing here, however, is that the full covariance matrix of the estimators has been estimated and stored, and thus it is now possible to perform hypothesis tests. Are the effects of `weight` the same at the 25th and 75th percentiles?

```
. test [q25]weight = [q75]weight
(1) [q25]weight - [q75]weight = 0
 F(1, 70) = 8.57
 Prob > F = 0.0046
```

It appears that they are not. We can obtain a confidence interval for the difference by using `lincom`:

```
. lincom [q75]weight-[q25]weight
(1) - [q25]weight + [q75]weight = 0
```

| price | Coefficient | Std. err. | t    | P> t  | [95% conf. interval] |          |
|-------|-------------|-----------|------|-------|----------------------|----------|
| (1)   | 7.391121    | 2.524626  | 2.93 | 0.005 | 2.355914             | 12.42633 |

Indeed, we could test whether the weight and length sets of coefficients are equal at the three quantiles estimated:

```
. quietly test [q25]weight = [q50]weight
. quietly test [q25]weight = [q75]weight, accumulate
. quietly test [q25]length = [q50]length, accumulate
. test [q25]length = [q75]length, accumulate
(1) [q25]weight - [q50]weight = 0
(2) [q25]weight - [q75]weight = 0
(3) [q25]length - [q50]length = 0
(4) [q25]length - [q75]length = 0
 F(4, 70) = 2.25
 Prob > F = 0.0727
```

`iqreg` focuses on one quantile comparison but presents results that are more easily interpreted:

```
. set seed 1001
. iqreg price weight length foreign, q(.25 .75) reps(100) nolog
.75-.25 Interquantile regression Number of obs = 74
bootstrap(100) SEs .75 Pseudo R2 = 0.3840
 .25 Pseudo R2 = 0.1697
```

| price   | Coefficient | Bootstrap |  | t     | P> t  | [95% conf. interval] |           |
|---------|-------------|-----------|--|-------|-------|----------------------|-----------|
|         |             | std. err. |  |       |       |                      |           |
| weight  | 7.391121    | 2.524626  |  | 2.93  | 0.005 | 2.355914             | 12.42633  |
| length  | -223.6288   | 84.21504  |  | -2.66 | 0.010 | -391.5904            | -55.66724 |
| foreign | 1385.208    | 1321.832  |  | 1.05  | 0.298 | -1251.103            | 4021.519  |
| _cons   | 22122.68    | 9329.178  |  | 2.37  | 0.020 | 3516.219             | 40729.14  |

Looking only at the 0.25 and 0.75 quantiles (the interquartile range), the `iqreg` command output is easily interpreted. Increases in `weight` correspond significantly to increases in price dispersion. Increases in `length` correspond to decreases in price dispersion. The `foreign` variable does not significantly change price dispersion.

Do not make too much of these results; the purpose of this example is simply to illustrate the `sqreg` and `iqreg` commands and to do so in a context that suggests why analyzing dispersion might be of interest.

lincom after sqreg produced the same  $t$  statistic for the interquartile range of weight, as did the iqreg command above. In general, they will not agree exactly because of the randomness of bootstrapping, unless the random-number seed is set to the same value before estimation (as was done here).

◀

Gould (1997a) presents simulation results showing that the coverage—the actual percentage of confidence intervals containing the true value—for iqreg is appropriate.

## What are the parameters?

In this section, we use a specific data-generating process (DGP) to illustrate the interpretation of the parameters estimated by qreg. If simulation experiments are not intuitive to you, skip this section.

In general, quantile regression parameterizes the quantiles of the distribution of  $y$  conditional on the independent variables  $\mathbf{x}$  as  $\mathbf{x}\beta$ , where  $\beta$  is a vector of estimated parameters. In our example, we include a constant term and a single independent variable, and we express quantiles of the distribution of  $y$  conditional on  $x$  as  $\beta_0 + \beta_1 x$ .

We use simulated data to illustrate what we mean by a conditional distribution and how to interpret the parameters  $\beta$  estimated by qreg. We also note how we could change our example to illustrate a DGP for which the estimator in qreg would be misspecified.

We suppose that the distribution of  $y$  conditional on  $x$  has a Weibull form. If  $y$  has a Weibull distribution, the distribution function is  $F(y) = 1 - \exp\{-(y/\lambda)^k\}$ , where the scale parameter  $\lambda > 0$  and the shape parameter  $k > 0$ . We can make  $y$  have a Weibull distribution function conditional on  $x$  by making the scale parameter or the shape parameter functions of  $x$ . In our example, we specify a particular DGP by supposing that  $\lambda = (1 + \alpha x)$ ,  $\alpha = 1.5$ ,  $x = 1 + \sqrt{\nu}$ , and that  $\nu$  has a  $\chi^2(1)$  distribution. For the moment, we leave the parameter  $k$  as is so that we can discuss how this decision relates to model specification.

Plugging in for  $\lambda$  yields the functional form for the distribution of  $y$  conditional on  $x$ , which is known as the conditional distribution function and is denoted  $F(y|x)$ .  $F(y|x)$  is the distribution for  $y$  for each given value of  $x$ .

Some algebra yields that  $F(y|x) = 1 - \exp[-\{y/(1 + \alpha x)\}^k]$ . Letting  $\tau = F(y|x)$  implies that  $0 \leq \tau \leq 1$ , because probabilities must be between 0 and 1.

To obtain the  $\tau$  quantile of the distribution of  $y$  conditional on  $x$ , we solve

$$\tau = 1 - \exp[-\{y/(1 + \alpha x)\}^k]$$

for  $y$  as a function of  $\tau$ ,  $x$ ,  $\alpha$ , and  $k$ . The solution is

$$y = (1 + \alpha x)\{-\ln(1 - \tau)\}^{(1/k)} \quad (1)$$

For any value of  $\tau \in (0, 1)$ , expression (1) gives the  $\tau$  quantile of the distribution of  $y$  conditional on  $x$ . To use qreg, we must rewrite (1) as a function of  $x$ ,  $\beta_0$ , and  $\beta_1$ . Some algebra yields that (1) can be rewritten as

$$y = \beta_0 + \beta_1 * x$$

where  $\beta_0 = \{-\ln(1 - \tau)\}^{(1/k)}$  and  $\beta_1 = \alpha\{-\ln(1 - \tau)\}^{(1/k)}$ . We can express the conditional quantiles as linear combinations of  $x$ , which is a property of the estimator implemented in qreg.

If we parameterize  $k$  as a nontrivial function of  $x$ , the conditional quantiles will not be linear in  $x$ . If the conditional quantiles cannot be represented as linear functions of  $x$ , we cannot estimate the true parameters of the DGP. This restriction illustrates the limits of the estimator implemented in qreg.

We set  $k = 2$  for our example.

Conditional quantile regression allows the coefficients to change with the specified quantile. For our DGP, the coefficients  $\beta_0$  and  $\beta_1$  increase as  $\tau$  gets larger. Substituting in for  $\alpha$  and  $k$  yields that  $\beta_0 = \sqrt{-\ln(1-\tau)}$  and  $\beta_1 = 1.5\sqrt{-\ln(1-\tau)}$ . Table 1 presents the true values for  $\beta_0$  and  $\beta_1$  implied by our DGP when  $\tau \in \{0.25, 0.5, 0.8\}$ .

Table 1: True values for  $\beta_0$  and  $\beta_1$

| $\tau$ | $\beta_0$ | $\beta_1$ |
|--------|-----------|-----------|
| 0.25   | 0.53636   | 0.80454   |
| 0.5    | 0.8325546 | 1.248832  |
| 0.8    | 1.268636  | 1.902954  |

We can also use (1) to generate data from the specified distribution of  $y$  conditional on  $x$  by plugging in random uniform numbers for  $\tau$ . Each random uniform number substituted in for  $\tau$  in (1) yields a draw from the conditional distribution of  $y$  given  $x$ .

## ▷ Example 6

In this example, we generate 100,000 observations from our specified DGP by substituting random uniform numbers for  $\tau$  in (1), with  $\alpha = 1.5$ ,  $k = 2$ ,  $x = 1 + \sqrt{\nu}$ , and  $\nu$  coming from a  $\chi^2(1)$  distribution.

We begin by executing the code that implements this method; below, we discuss each line of the output produced.

```
. clear // drop existing variables
. set seed 1234571 // set random-number seed
. set obs 100000 // set number of observations
Number of observations (_N) was 0, now 100,000.
. generate double tau = runiform() // generate uniform variate
. generate double x = 1 + sqrt(rchi2(1)) // generate values for x
. generate double lambda = 1 + 1.5*x // lambda is 1 + alpha*x
. generate double k = 2 // fix value of k
. // generate random values for y
. // given x
. generate double y = lambda*((-ln(1-tau))^(1/k))
```

Although the comments at the end of each line briefly describe what each line is doing, we provide a more careful description. The first line drops any variables in memory. The second sets the seed of the random-number generator so that we will always get the same sequence of random uniform numbers. The third line sets the sample size to 100,000 observations, and the fourth line reports the change in sample size.

The fifth line substitutes random uniform numbers for  $\tau$ . This line is the key to the algorithm. This standard method, known as inverse-probability transforms, for computing random numbers is discussed by [Cameron and Trivedi \(2022, 220–221\)](#), among others.

Lines 6–8 generate  $x$ ,  $\lambda$ , and  $k$  per our specified DGP. Lines 9–11 implement (1) using the previously generated  $\lambda$ ,  $x$ , and  $k$ .

At the end, we have 100,000 observations on  $y$  and  $x$ , with  $y$  coming from the conditional distribution that we specified above.

## ▷ Example 7

In the example below, we use `qreg` to estimate  $\beta_1$  and  $\beta_0$ , the parameters from the conditional quantile function, for the 0.5 quantile from our simulated data.

```
. qreg y x, quantile(.5)
Iteration 1: WLS sum of weighted deviations = 68573.243
Iteration 1: Sum of abs. weighted deviations = 68571.918
Iteration 2: Sum of abs. weighted deviations = 68308.342
Iteration 3: Sum of abs. weighted deviations = 68241.17
Iteration 4: Sum of abs. weighted deviations = 68232.043
Iteration 5: Sum of abs. weighted deviations = 68230.304
Iteration 6: Sum of abs. weighted deviations = 68229.643
